1 Introduction

MapForce Server is an enterprise software solution that runs data mapping transformations on Windows, Linux, and macOS operating systems. The data mappings themselves (or Mapping Design Files, *.mfd) are visually designed with Altova MapForce (https://www.altova.com/mapforce), where you define the inputs, outputs, and any intermediary processing steps that must be applied to your data. The role of MapForce Server is to run MapForce Server Execution (.mfx) files compiled with MapForce, and to produce the output files or data, or even update databases or call Web services, according to the design of the underlying mapping.

MapForce Server can run standalone as well as under the management of Altova FlowForce Server (https://www.altova.com/flowforceserver). When installed on the same machine as MapForce Server, FlowForce Server automates execution of mappings through scheduled or trigger-based jobs, which can also be exposed as Web services. In addition to this, FlowForce Server includes a built-in library of functions that enable you to take additional automated actions before or after mapping execution, such as sending email, copying files and directories, uploading files to FTP, running shell commands, and others.

Features

- Server-level performance when executing data mappings
- Cross-platform: MapForce Server runs on Windows, Linux, or macOS operating systems
- Command line interface
- An API that you can call from C++, C#, Java, VB.NET, VBScript, or VBA code
- Native integration with FlowForce Server
- Support for Altova Global Resources—a way of making file, folder, or database references configurable and portable across multiple environments and across multiple Altova applications, see Altova Global Resources
- Runs mappings that read data from and write data to Protocol Buffers binary format
- Runs mappings that perform bulk database inserts

Limitations

- XML digital signatures are not supported
- ADO, ADO.NET, and ODBC database connections are supported only on Windows. On Linux and macOS, native database connectivity is available for SQLite and PostgreSQL databases. For other databases running on Linux or macOS, JDBC should be used.

Last updated: 11 November 2019
2 Installation

2.1 System Requirements

- **Windows**
  - Windows 7 SP1 with Platform Update, Windows 8, Windows 10

- **Windows Server**
  - Windows Server 2008 R2 SP1 with Platform Update or newer

On Windows, MapForce Server is available both as a 32-bit and 64-bit package.

- **Linux**
  - CentOS 6 or newer
  - RedHat 6 or newer
  - Debian 8 or newer
  - Ubuntu 14.04 or newer

The following libraries are required as a prerequisite to install and run the application. If the packages below are not already available on your Linux machine, run the command `yum` (or `apt-get` if applicable) to install them.

<table>
<thead>
<tr>
<th>Required by</th>
<th>CentOS, RedHat</th>
<th>Debian</th>
<th>Ubuntu</th>
</tr>
</thead>
<tbody>
<tr>
<td>LicenseServer</td>
<td>krb5-libs</td>
<td>libgssapi-krb5-2</td>
<td>libgssapi-krb5-2</td>
</tr>
<tr>
<td>MapForce Server</td>
<td>libidn, krb5-libs</td>
<td>libidn11, libgssapi-krb5-2</td>
<td>libidn11, libgssapi-krb5-2</td>
</tr>
</tbody>
</table>

- **macOS**
  - macOS 10.12 or newer

**Note:** On Windows and macOS, it is possible to install multiple versions of MapForce Server on the same machine. In such cases, be aware that only one version can be registered to the same Altova LicenseServer at a time. Hence, two different versions of MapForce Server cannot run concurrently on the same machine. Multiple instances of the same product version can run in parallel, however. For more information, see the Altova License Server documentation (https://www.altova.com/documentation#licenseserver).
2.2 Processor Cores and Licenses

The licensing of Altova server products is based on the number of physical processor cores available on the product machine (as opposed to the number of logical cores). For example, a dual-core processor has two cores, a quad-core processor four cores, a hexa-core processor six cores, and so on. The number of cores licensed for a product must be greater than or equal to the number of cores available on that server machine, whether the server is a physical or virtual machine. For example, if a server has eight cores, you must purchase an 8-core license. You can also combine licenses to achieve the core count. So, two 4-core licenses can be used for an eight-core server instead of one 8-core license.

If you are using a computer server with a large number of CPU cores but only have a low volume to process, you may also create a virtual machine that is allocated a smaller number of cores, and purchase a license for that number. Such a deployment, of course, will have less processing speed than if all available cores of the computer were utilized.

**Note**: Each Altova server product license can be used for only one client machine at a time—the machine on which the Altova server product is installed—even if the license has unused licensing capacity. For example, if a 10-core license is used for a client machine that has 6 CPU cores, then the remaining 4 cores of licensing capacity cannot be used simultaneously for another client machine.

**Single-thread execution**

If an Altova server-product license for only one core is available in the license pool, a machine with multiple cores can be assigned this one-core license. In such a case, the machine will run that product on a single core. Processing will therefore be slower, because multi-threading (which is possible on multiple cores) will not be available. The product will be executed in single thread mode on that machine.

To assign a single-core license to a multiple-core machine, in LicenseServer, select the *Limit to single thread execution* check box for that product.

**Estimate of core requirements**

There are various external factors that influence the data volumes and processing times your server can handle (for example: the hardware, the current load on the CPU, and memory allocation of other applications running on the server). In order to measure performance as accurately as possible, test the applications in your environment with data volumes and in conditions that approximate as closely as possible to real business situations.
2.3 Important Paths

Installation directory
The application is installed in the following directory:

Linux  /opt/Altova/MapForceServer2020/bin
Mac    /usr/local/Altova/MapForceServer2020/bin
Windows <ProgramFilesFolder>\Altova\MapForceServer2020\bin

Executable
After installation, the MapForce Server executable can be found at the following path:

Linux  /opt/Altova/MapForceServer2020/bin/mapforceserver
Mac    /usr/local/Altova/MapForceServer2020/bin/mapforceserver
Windows <ProgramFilesFolder>\Altova\MapForceServer2020\bin\MapForceServer.exe

Application Configuration Data
The application's configuration data is stored in the following directory:

Linux  /var/opt/Altova/MapForceServer
Mac    /var/Altova/MapForceServer
Windows C:\ProgramData\Altova\MapForceServer
2.4 Linux

2.4.1 Installing MapForce Server

System requirements

- **Linux**
  - CentOS 6 or newer
  - RedHat 6 or newer
  - Debian 8 or newer
  - Ubuntu 14.04 or newer

The following libraries are required as a prerequisite to install and run the application. If the packages below are not already available on your Linux machine, run the command `yum` (or `apt-get` if applicable) to install them.

<table>
<thead>
<tr>
<th>Required by</th>
<th>CentOS, RedHat</th>
<th>Debian</th>
<th>Ubuntu</th>
</tr>
</thead>
<tbody>
<tr>
<td>LicenseServer</td>
<td>krb5-libs</td>
<td>libgssapi-krb5-2</td>
<td>libgssapi-krb5-2</td>
</tr>
<tr>
<td>MapForce Server</td>
<td>libidn, krb5-libs</td>
<td>libidn11, libgssapi-krb5-2</td>
<td>libidn11, libgssapi-krb5-2</td>
</tr>
</tbody>
</table>

**Prerequisites**

- Perform installation either as **root** user or as a user with **sudo** privileges.
- The previous version of MapForce Server must be uninstalled before a new one is installed.
- If you are installing FlowForce Server with other Altova server products, it is recommended to install FlowForce Server first.

**Installing MapForce Server**

1. Download the installation package from [https://www.altova.com/download#server](https://www.altova.com/download#server) to a local directory.
2. Change to the directory where you downloaded the installation package, for example:

```
cd /home/User/Downloads
```
3. Install the MapForce Server package.

```
[Debian, Ubuntu] sudo dpkg --install mapforceserver-2020-debian.deb
[CentOS, RedHat] sudo rpm -ivh mapforceserver-2020-1.x86_64.rpm
```

**Note:** You may need to adjust the name of the package above to match the current release or service pack version.
Licensing MapForce Server

1. Ensure that the latest version of Altova LicenseServer (https://www.altova.com/licenseserver) is installed and running either on the local machine or network.
2. Register MapForce Server with Altova LicenseServer. For this, you need to know either the host name or the IP address of the computer where LicenseServer runs. For example, if LicenseServer runs on 127.0.0.1, you can register it as follows:

   ```bash
   sudo mapforceserver licenseserver 127.0.0.1
   ```

   **Note:** The command above assumes you are calling the executable from the program installation directory. On CentOS and macOS, make sure to prepend "/." in front of the executable.

3. Log on to LicenseServer administration interface and assign the license to the machine where MapForce Server runs.

For more information about licensing, refer to Altova LicenseServer documentation (https://www.altova.com/documentation).

### 2.4.2 Viewing Currently Installed Products

To check if an Altova server product is installed:

- Run the following command:

  ```bash
  [Debian, Ubuntu] dpkg --list | grep Altova
  [CentOS, RedHat] rpm -qa | grep server
  ```

### 2.4.3 Uninstalling MapForce Server

To uninstall MapForce Server:

- Run the following command:

  ```bash
  [Debian, Ubuntu] sudo dpkg --remove mapforceserver
  [CentOS, RedHat] sudo rpm -e mapforceserver
  ```

If you need to uninstall other packages, use the same command as above and supply the package you want to remove as argument. For example:

```bash
[Debian, Ubuntu] sudo dpkg --remove licenseserver
[CentOS, RedHat] sudo rpm -e licenseserver
```
2.5 **macOS**

### 2.5.1 Installing MapForce Server

**System requirements**

- **macOS**
  - macOS 10.12 or newer

**Prerequisites**

- Perform installation as a user with administrative (root) privileges.

**FlowForce Server Integration**

If you install MapForce Server together with FlowForce Server, it is recommended that you install FlowForce Server first. Otherwise, see the "Post-installation tasks" below.

**Installing MapForce Server**

1. Download the disk image (.dmg) file from the Altova Download Center (https://www.altova.com/download) and click to open it. Once you do this, the installer appears as a new drive on your computer.
2. Double-click the package (.pkg) file, and go through the successive steps of the installation wizard. These are self-explanatory and include one step in which you have to agree to the license agreement before being able to proceed. When you complete the wizard, the MapForce Server icon becomes available in Applications. The package is installed in the directory `/usr/local/Altova/MapForceServer2020/`.
3. If you have not installed Altova License Server already, or if you want to upgrade to the latest version, double-click the corresponding package (.pkg) file and follow the on-screen instructions.

**Licensing MapForce Server**

1. Ensure that the latest version of Altova LicenseServer (https://www.altova.com/licenseserver) is installed and running either on the local machine or network.
2. Register MapForce Server with Altova LicenseServer. For this, you need to know either the host name or the IP address of the computer where LicenseServer runs. For example, if LicenseServer runs on 127.0.0.1, you can register it as follows:

```
sudo mapforceserver licenseserver 127.0.0.1
```
3. Log on to LicenseServer administration interface and assign the license to the machine where MapForce Server runs.

For more information, refer to Altova LicenseServer documentation (https://www.altova.com/documentation).

**Post-installation tasks**

If you installed MapForce Server before FlowForce Server, then, after having installed both MapForce Server and FlowForce Server, run the following command:

```
cp /usr/local/Altova/MapForceServer2019/etc/*.tool /usr/local/Altova/FlowForceServer2019/tools
```

The command above copies the `.tool` file from `/etc` directory of MapForce Server to the FlowForce Server `/tools` directory. The `.tool` file is required by FlowForce Server; it contains the path to the MapForce Server executable. You do not need to run this command if you install FlowForce Server before installing MapForce Server.

### 2.5.2 Uninstalling MapForce Server

**To uninstall MapForce Server:**

1. In **Applications**, right-click the MapForce Server icon and select **Move to Trash**. Note that your MapForce Server installation directory and configuration data are not removed by this step.
2. Optionally, if you want to remove the MapForce Server installation directory as well, run the following command:

```
sudo rm -rf /usr/local/Altova/MapForceServer2020/
```

**Note:** The steps above do not remove the configuration data from `/var/Altova/MapForceServer2020`. Be aware that once the configuration data is removed, it cannot be recovered later.
2.6 Windows

2.6.1 Installing MapForce Server

System requirements

- Windows 7 SP1 with Platform Update, Windows 8, Windows 10
- Windows Server 2008 R2 SP1 with Platform Update or newer

Prerequisites

- Perform installation as a user with administrative privileges.

Installing MapForce Server

To install MapForce Server standalone:

1. Download the installation file from the Altova Download Center (https://www.altova.com/download) and run it.
2. Optionally, select the installation language from the box in the lower left area of the wizard, and click Next. You can change the language later from the command line.
3. Do one of the following:
   a. If you haven't installed Altova LicenseServer yet, leave the default settings as is. The wizard will install the latest version of Altova LicenseServer on the computer where you are running the wizard.
   b. If you haven't installed Altova LicenseServer yet and want to install Altova LicenseServer on another computer, clear the Install Altova LicenseServer on this machine check box, and then choose Register Later. In this case, you will need to install Altova LicenseServer and register MapForce Server separately.
   c. If Altova LicenseServer has already been installed on your computer but it has a lower version than the one indicated by the installation wizard, leave the default settings as is. In this case, the installation wizard will automatically upgrade your LicenseServer version with the one indicated on the dialog box. Note that the existing registration and licensing information will be preserved after the upgrade.
   d. If Altova LicenseServer has already been installed on your computer or network, and if it has the same version as the one indicated by the wizard, do the following:
      i. Clear the Install Altova LicenseServer on this machine check box.
      ii. Under Register this product with, choose the Altova LicenseServer instance on which you want to register MapForce Server, or choose Register later. Note that you can always select Register Later if you want to ignore the LicenseServer associations and carry on with the installation of MapForce Server.
4. Click Next.
5. Follow the wizard instructions to complete the installation.
Licensing MapForce Server

1. Ensure that the latest version of Altova LicenseServer (https://www.altova.com/licenseserver) is installed and running either on the local machine or network.
2. If you haven't done so already during installation, register MapForce Server with Altova LicenseServer. For this, you need to know either the host name or the IP address of the computer where LicenseServer runs. For example, if LicenseServer runs on 127.0.0.1, you can register it as follows:

```
MapForceServer.exe licenseserver 127.0.0.1
```

3. Log on to LicenseServer administration interface and assign the license to the machine where MapForce Server runs.

For more information, refer to Altova LicenseServer documentation (https://www.altova.com/documentation).

2.6.2 Uninstalling MapForce Server

Uninstalling MapForce Server

1. Right-click the Windows "Start" button and select Settings.
2. Open the Control Panel (start typing "Control Panel" and click the suggested entry).
3. Under Programs, click Uninstall a program.
4. In Control Panel, select "Altova MapForce Server" and then click Uninstall.
3 Running Mappings

The role of MapForce Server is to execute data mappings created with Altova MapForce (https://www.altova.com/mapforce.html).

First, you design the data mappings (or Mapping Design Files, *.mfd) visually in MapForce, where you define the inputs, outputs, and any intermediary processing steps that must be applied to your data (including sorting, filtering, custom functions, and others). Once your mapping is ready, you can execute it with MapForce Server in one of the following ways:

- On the Windows machine where MapForce runs, compile the mapping to a MapForce Server Execution File (.mfx). The .mfx files are in fact data mappings packaged for execution in a server environment. You can copy such files to any of the supported operating systems where MapForce Server runs (including across different platforms, see System Requirements). On the server machine, you can execute the .mfx file using the command line interface of MapForce Server, or using the MapForce Server API.

- On the Windows machine where MapForce runs, deploy the mapping to a server machine where both MapForce Server and FlowForce Server are installed. The server machine can be a different operating system (see System Requirements). Mappings deployed in this way become FlowForce Server functions and you can create scheduled or trigger-based jobs from them. When mappings run as FlowForce Server jobs, they can also be exposed as Web services, chained as sub-steps of other jobs, or made part of workflows which include sending emails, verifying exit codes, running shell commands, and others.
For more information about this scenario, see the FlowForce Server documentation (https://www.altova.com/documentation).

How to execute mappings compiled as MapForce Server Execution files
1. Run MapForce Enterprise or Professional Edition.
2. Open the mapping to be compiled.
3. On the File menu, click Compile to MapForce Server Execution file, and select a destination directory.
4. Copy the .mfx file to the destination directory or server, along with any input files or dependencies. For further information, see Preparing Mappings for Server Execution.
5. Call the "run" command of the command line interface, or the equivalent method of the MapForce Server API.

How to execute mappings deployed to FlowForce Server
1. Open in MapForce Enterprise or Professional the mapping to be deployed.
2. Make sure that the transformation language (execution engine) of the mapping is set to Built-in. To change the execution engine to Built-in, select the menu command Output | Built-In Execution Engine, or click the Select Built-In Execution Engine toolbar button.
4. Enter the server connection details (host, port), the FlowForce credentials, and the destination FlowForce container. To proceed to creating the FlowForce job immediately in the browser, select the option Open web browser to create new job. You can also create the FlowForce job later (see next step).
5. Open a browser, log on to the FlowForce Server Web administration interface, and navigate to the container where you deployed the mapping (see previous step). This step is not required if you selected the option Open web browser to create new job in the previous step.
6. Define the FlowForce Server job, including its triggers, parameters, or additional execution steps (for examples, refer to the FlowForce Server documentation https://www.altova.com/documentation). Whenever the job is configured to run, the underlying mapping transformation will be executed, and the mapping output will be produced.

Note: If MapForce Server runs on a machine other than the one where the mapping was designed, make sure to adjust paths to input files or database connection details in such a way that they are meaningful in the new target execution environment. For example, if a mapping calls a database and requires a database driver, the driver must also be installed in the target environment in order for the mapping to
be executed successfully. To view or adjust the database connection details, right-click the database component in MapForce and select **Properties**. After making any changes to the mapping design in MapForce, remember to recompile it to a MapForce Server execution file (.mfx) or, depending on the case, redeploy it to FlowForce Server. For more information, see [Preparing Mappings for Server Execution](#).
### 3.1 Preparing Mappings for Server Execution

A mapping designed and previewed with MapForce may refer to resources which are outside of the current machine and operating system (such as databases). In addition to this, in MapForce, all mapping paths follow Windows-style conventions by default. Thirdly, the machine where MapForce Server runs might not support the same database connections as the machine where the mapping was designed. For this reason, running mappings in a server environment typically requires some preparation, especially if the target machine is not the same as the source machine.

**Note:** The term "source machine" refers to the computer where the MapForce is installed and the term "target machine" refers to the computer where MapForce Server or FlowForce Server is installed. In the most simple scenario, this is the same computer. In a more advanced scenario, MapForce runs on a Windows machine whereas MapForce Server or FlowForce Server runs on a Linux or macOS machine.

As best practice, always make sure that the mapping validates successfully in MapForce before deploying it to FlowForce Server or compiling it to a MapForce Server execution file.

If MapForce Server runs standalone (without FlowForce Server), the required licenses are as follows:

- On the source machine, MapForce Enterprise or Professional edition is required to design the mapping and compile it to a server execution file (.mfx).
- On the target machine, MapForce Server or MapForce Server Advanced Edition is required to run the mapping.

If MapForce Server runs under FlowForce Server management, the following requirements apply:

- On the source machine, MapForce Enterprise or Professional edition is required to design the mapping and deploy it to a target machine.
- Both MapForce Server and FlowForce Server must be licensed on the target machine. The role of MapForce Server is to run the mapping; the role of FlowForce is to make the mapping available as a job which benefits from features such as scheduled or on demand execution, execution as a Web service, error handling, conditional processing, email notifications, and others.
- FlowForce Server must be up and running at the configured network address and port. Namely, the "FlowForce Web Server" service must be started and configured to accept connections from HTTP clients (or HTTPS if configured) and must not be blocked by the firewall. The "FlowForce Server" service must also be started and running at the designated address and port.
- You have a FlowForce Server user account with permissions to one of the containers (by default, the /public container is accessible to any authenticated user).

**General considerations**

- If you intend to run the mapping on a target machine with standalone MapForce Server, all input files referenced by the mapping must be copied to the target machine as well. If MapForce Server runs under FlowForce Server management, there is no need to copy files manually. In this case, the instance and schema files are included in the package deployed to the target machine.
- If the mapping includes database components which require specific database drivers, such drivers must be installed on the target machine as well. For example, if your mapping reads data from a Microsoft Access database, then Microsoft Access or Microsoft Access Runtime ([https://www.microsoft.com/en-us/download/details.aspx?id=50040](https://www.microsoft.com/en-us/download/details.aspx?id=50040)) must be installed on the target machine as well.
When you deploy a mapping to non-Windows platforms, ADO, ADO.NET and ODBC database connections are automatically changed to JDBC. Native SQLite and native PostgreSQL connections are preserved as such and require no additional configuration. See also "Database connections" below.

If the mapping contains custom function calls (for example, to .dll or .class files), such dependencies are not deployed together with the mapping, since they are not known before runtime. In this case, copy them manually to the target machine. The path of the .dll or .class file on the server must be the same as on the "Options" dialog box in MapForce, for example:

Some mappings read multiple input files using a wildcard path. In this case, the input file names are not known before runtime and so they are not deployed. For the mapping to execute successfully, the input files must exist on the target machine.

If the mapping output path includes directories, those directories must exist on the target machine. Otherwise, an error will be generated when you execute the mapping. This behavior is unlike MapForce, where non-existing directories are generated automatically if the option Generate output to temporary files is enabled.

If the mapping calls a Web service that requires HTTPS authentication with a client certificate, the certificate must be transferred to the target machine as well, see Digital Certificate Management.

If the mapping connects to file-based databases such as Microsoft Access and SQLite, the database file must be manually transferred to the target machine or saved to a shared directory which is accessible to both the source and the target machine and referenced from there, see "File-based databases" below.

Making paths portable
If you intend to run the mapping on a server, ensure that the mapping follows the applicable path conventions and uses a supported database connection.
To make paths portable to non-Windows operating systems, use relative instead of absolute paths when designing the mapping in MapForce. For example, you can copy all input or output files required by the mapping into the same directory as the mapping, and then reference them just by file name. Importantly, both MapForce Server and FlowForce Server support a so-called “working directory” against which all relative paths will be resolved. The working directory is specified at mapping runtime, as follows:

- In FlowForce Server, by editing the “Working-directory” parameter of any job.
- In MapForce Server API, through the `WorkingDirectory` property of the COM and .NET API, or through the `setWorkingDirectory` method of the Java API.
- In MapForce Server command line, the working directory is the current directory of the command shell.

Database connections

Be aware that ADO, ADO.NET, and ODBC connections are not supported on Linux and macOS machines. Therefore, if the target machine is Linux or macOS, such connections are converted to JDBC when you deploy the mapping to FlowForce or when you compile the mapping to a MapForce Server execution file. In this case, you have the following options before deploying the mapping or compiling it to a server execution file:

- In MapForce, create a JDBC connection to the database
- In MapForce, fill the JDBC database connection details in the “JDBC-specific Settings” section of the database component.

If the mapping uses a native connection to a PostgreSQL or SQLite database, the native connection is preserved and no JDBC conversion takes place. If the mapping connects to a file-based database, such as Microsoft Access and SQLite, additional configuration is required, see "File-based databases" below.

Running mappings with JDBC connections requires that the Java Runtime Environment or Java Development Kit be installed on the server machine. This may be either Oracle JDK or an open source build such as Oracle OpenJDK.

- The `JAVA_HOME` environment variable must point to the JDK installation directory.
- On Windows, a Java Virtual Machine path found in the Windows registry will take priority over the `JAVA_HOME` variable.
- The JDK platform (64-bit, 32-bit) must be the same as that of MapForce Server. Otherwise, you may get an error with the reason: "JVM is inaccessible".

### To set up a JDBC connection on Linux or macOS:

1. Download the JDBC driver supplied by the database vendor and install it on the operating system. Make sure to select the 32-bit version if your operating system runs on 32-bit, and the 64-bit version if your operating system runs on 64-bit.
2. Set the environment variables to the location where the JDBC driver is installed. Typically, you will need to set the `CLASSPATH` variable, and possibly a few others. To find out which specific environment variables must be configured, check the documentation supplied with the JDBC driver.

**Note:** On macOS, the system expects any installed JDBC libraries to be in the `/Library/Java/Extensions` directory. Therefore, it is recommended that you unpack the JDBC driver to this location; otherwise, you will need to configure the system to look for the JDBC library at the path where you installed the JDBC driver.
**Oracle Instant Client connections on macOS**

These instructions are applicable if you connect to an Oracle database through the Oracle Database Instant Client, on macOS. Prerequisites:

- Java 8.0 or later must be installed. If the Mac machine runs a Java version prior to Java 8, you can also connect through the JDBC Thin for All Platforms library, and disregard the instructions below.
- Oracle Instant Client must be installed. You can download the Oracle Instant Client from the Oracle official download page. Note that there are several Instant Client packages available on the Oracle download page. Make sure to select a package with Oracle Call Interface (OCI) support, (for example, Instant Client Basic). Also, make sure to select the 32-bit version if your operating system runs on 32-bit, and the 64-bit version if your operating system runs on 64-bit.

Once you have downloaded and unpacked the Oracle Instant Client, edit the property list (.plist) file shipped with the installer so that the following environment variables point to the location of the corresponding driver paths, for example:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASSPATH</td>
<td><code>/opt/oracle/instantclient_11_2/ojdbc6.jar:/opt/oracle/instantclient_11_2/ojdbc5.jar</code></td>
</tr>
<tr>
<td>TNS_ADMIN</td>
<td><code>/opt/oracle/NETWORK_ADMIN</code></td>
</tr>
<tr>
<td>ORACLE_HOME</td>
<td><code>/opt/oracle/instantclient_11_2</code></td>
</tr>
<tr>
<td>DYLD_LIBRARY_PATH</td>
<td><code>/opt/oracle/instantclient_11_2</code></td>
</tr>
<tr>
<td>PATH</td>
<td><code>${PATH}:/opt/oracle/instantclient_11_2</code></td>
</tr>
</tbody>
</table>

Note: Edit the sample values above to fit the paths where Oracle Instant Client files are installed on your operating system.

**File-based databases**

File-based databases such as Microsoft Access and SQLite are not included in the package deployed to FlowForce Server or in the compiled MapForce Server execution file. Therefore, if the source and target machine are not the same, take the following steps:

1. In MapForce, right-click the mapping and clear the check box **Make paths absolute in generated code**.
2. Right-click the database component on the mapping and add a connection to the database file using a relative path. A simple way to avoid path-related issues is to save the mapping design (.mfd file) in the same directory as the database file and to refer to the latter from the mapping just by file name (thus using a relative path).
3. Copy the database file to a directory on the target machine (let's call it "working directory"). Keep this directory in mind since it will be required to run the mapping on the server, as shown below.

To run such mappings on the server, do one of the following:

- If the mapping will be run by MapForce Server under FlowForce Server control, configure the FlowForce Server job to point to the working directory created previously. The database file must reside in the

- If the mapping will be run by standalone MapForce Server at the command line, change the current directory to the working directory (for example, cd path\to\working\directory) before calling the run command of MapForce Server.

- If the mapping will be run by the MapForce Server API, set the working directory programmatically before running the mapping. To facilitate this, the property WorkingDirectory is available for the MapForce Server object in the COM and .NET API. In the Java API, the method setWorkingDirectory is available.

If both the source and the target machines are Windows machines running on the local network, an alternative approach is to configure the mapping to read the database file from a common shared directory, as follows:

1. Store the database file in a common shared directory which is accessible by both the source and the target machine.
2. Right-click the database component on the mapping and add a connection to the database file using an absolute path.

**Global Resources**

If a mapping includes references to Global Resources instead of direct paths or database connections, you will be able to use Global Resources on the server side as well. When you compile a mapping to a MapForce Server execution file (.mfx), the references to Global Resources will be kept intact, so that you can provide these on the server side, at mapping runtime. When deploying a mapping to FlowForce Server, you can optionally choose whether it should use resources on the server.

For mappings (or mapping functions, in case of FlowForce Server) to run successfully, the actual file, folder, or database connection details that you supply as Global Resources must be compatible with the server environment. For example, files and folders paths must use the Linux convention for paths if the mapping will run on a Linux server. Likewise, Global Resources defined as database connections must be possible on the server machine.

For further information, see Global Resources.

**XBRL Taxonomy Packages**

When you deploy a mapping that references XBRL Taxonomy Packages to FlowForce Server, MapForce collects all external references from the mapping and then resolves them using the current configuration and currently installed taxonomy packages. If there are resolved external references that point to a taxonomy package, then the taxonomy package is deployed together with the mapping. FlowForce Server will use that package—as it was during deployment—to execute the mapping. To refresh the taxonomy package used by FlowForce Server, you will need to change it in MapForce and redeploy the mapping.

Note that the root catalog of MapForce Server influences the way taxonomies are resolved on the target machine. The root catalog is found at the following path relative to the MapForce Server installation directory: etc/RootCatalog.xml.

Taxonomy packages that were deployed with a mapping will be used if the root catalog of MapForce Server does not already contain such package or does not contain a package that is defined for the same URL prefix. The root catalog of MapForce Server has priority over the deployed taxonomy.

If MapForce Server runs standalone (without FlowForce Server), it is possible to specify the root catalog that
Preparing Mappings for Server Execution

Running Mappings

Altova MapForce Server 2020 should be used by the mapping as follows:

- At the command line, this is possible by adding the option `-catalog` to the `run` command.
- In the MapForce Server API, call the method `SetOption`, and supply the string "catalog" as first argument, and the path to the root catalog as second argument.

If a mapping uses XBRL components with table linkbases, the taxonomy package or the taxonomy package configuration file must be supplied to the mapping at runtime, as follows:

- At the MapForce Server command line, add the option `--taxonomy-package` or `--taxonomy-packages-config-file` to the `run` command.
- In the MapForce Server API, call the method `SetOption`. The first argument must be either "taxonomy-package" or "taxonomy-packages-config-file". The second argument must be the actual path to the taxonomy package (or taxonomy package configuration) file.
3.2 Global Resources

Altova Global Resources are portable references to files, folders, or databases. When stored as Global Resources, paths and database connection details become reusable and available across multiple Altova applications. For example, if you frequently need to open the same file in multiple Altova desktop applications, you may find it convenient to define it as a Global Resource. This way, you don't even need to remember the file path because you can select the respective Global Resource from the "Open File" dialog box instead. This also has the advantage that, if the file path ever changes, you will change it in one place only.

A typical usage of Global Resources is to define a database connection once and reuse it across all Altova applications that support Global Resources. For example, you can create a database connection on the machine where a MapForce mapping was designed and then reuse the same connection on the machine where MapForce Server runs the mapping (this may require, in some cases, that both machines have the same database client software installed).

Optionally, you can create multiple variations of the same Global Resource (known as "configurations"). This lets you easily switch file or folder paths (or even databases) depending on your needs. For example, you could create a "database" resource with two configurations: "development" and "production". Taking MapForce Server as example, you could then easily retrieve data from either the development or production database, by indicating the desired configuration as command line parameter at mapping runtime.

You can create Global Resources from the following Altova desktop applications: Altova Authentic, DatabaseSpy, MobileTogether Designer, MapForce, StyleVision, and XMLSpy. On the server side, Global Resources can be consumed by the following Altova server applications: FlowForce Server, MapForce Server, RaptorXML Server, RaptorXML+XBRL Server.

For more information about creating Global Resources, refer to the "Altova Global Resources" chapter of MapForce documentation.

Resources in MapForce Server

When you compile a mapping to a MapForce Server execution file (.mfx), any Global Resource references used by the mapping are preserved, not resolved. This means that you will need to provide these references on the server side in order to run the mapping successfully. More specifically, in MapForce Server, the following is required to run an .mfx file which uses Global Resources:

1. The Global Resource XML file. On the machine where MapForce is installed, the file is called GlobalResources.xml, and you can find it in the Documents\Altova folder. You can copy this file to the machine where MapForce Server runs, and you can also create multiple such files if necessary.
2. The Global Resource configuration name. Each Global Resource has a default configuration called "Default", but you can create additional configurations if so required. If you created additional configurations, then you must specify the desired configuration name instead of "Default".

In MapForce, the Global Resource file path and the Global Resource configuration name are set or changed from the graphical user interface. In MapForce Server, these are specified at mapping runtime.

- If you run the mapping through the command line interface, set the options --globalresourceconfig and --globalresourcefile after the run command, for example:

```bash
C:\Program Files (x86)\Altova\MapForceServer2020\bin\MapForceServer.exe run
```
If you run the mapping through the MapForce Server API, call the method `SetOptions` two times before calling the `Run` method. The first call is required to supply the Global Resource XML file path as option, and the second one is required to supply the Global Resource configuration name. For further information, see the MapForce Server API.
3.3 Credentials

Credential objects provide a way to make authentication data (such as usernames and passwords) portable across various mapping execution environments, in a secure way. Credentials are useful in mappings that require basic HTTP authentication. You can define credentials in MapForce and also in FlowForce Server. If credentials were defined in MapForce, you can optionally deploy them to FlowForce Server, similar to how mappings are deployed.

After you compile the mapping to a MapForce Server execution file (.mfx), MapForce Server will run the .mfx file depending on your choices at mapping design time.

If you selected the Include in MapForce Server Execution File and Mapping Deployment check box when creating the credential in MapForce, MapForce Server will use at mapping runtime any credentials that were stored in the .mfx file. This means that you can run the mapping with a command such as:

```
<exec> run mapping.mfx
```

Where `<exec>` is the path to the MapForce Server executable. This path can be either absolute or, if the current directory is the same as the executable, you can enter just the executable name.

If you entered only the credential name (without username and password) in MapForce, then you must explicitly provide these details at mapping runtime, with the help of the `--credential` command line option available for the `run` command. This way, you can use, for example, a different set of credentials in production, as opposed to those used when you designed the mapping. The `--credential` option has the form `--credential=KEY:VALUE`, where

- **KEY** is the name of the credential as it was defined in MapForce.
- **VALUE** is a credential property, or a list of properties separated by ampersand (&). For credentials of type "password", the possible properties are `username` and `password`. For credentials of type OAuth 2.0, the only supported property is `oauth:token`.
- The actual property values are supplied just like query parameters in a URL, using the "=" sign.

For example:

```
<exec> run mapping.mfx --credential="mycredential:username=admin&password=4xJ38dnx7"
```

In the code listing above, the value of the `--credential` option was enclosed within quotes in order to treat the value literally, since the username and password are separated by an ampersand character.

If your mapping needs multiple sets of named credentials to run, you can specify the `--credential` option multiple times.

The credentials supplied as command line options take precedence over stored credentials.

If you did not select the Include in MapForce Server Execution File and Mapping Deployment check box, the sensitive fields are missing. This means that you must supply the password at the command line while still referring the credential by its name, for example:
MapForce Server API

The MapForce Server API provides methods to create credentials, add properties to credentials, and close credentials after you finished declaring them. The following code listing illustrates the typical way of declaring password credentials in a C# program that runs a mapping:

```csharp
//Create a MapForce Server object
// Set the credential name as it was defined in MapForce
objMFS.BeginCredential("mycredential");
// Add the credential properties
objMFS.AddCredentialProperty("username", "altova");
objMFS.AddCredentialProperty("password", "b45ax78!");
// Close the credential
objMFS.EndCredential();
```

If the mapping needs multiple credential sets, use the methods above to add as many sets of credentials as required. Once you have declared all the required credentials, you can run the mapping execution file in a standard way, by calling the Run() method. For more information, see the API Reference.
3.4 Dynamic Authentication

In MapForce, it is possible to configure mappings that call Web services for basic HTTP authentication. Dynamic authentication is one of the ways to achieve this; it is an alternative to using credentials. Dynamic authentication means designing the mapping so that it accepts the username and password as input parameters. For details about configuring dynamic authentication, refer to MapForce documentation (https://www.altova.com/documentation).

If you configured the mapping for dynamic authentication, then the respective username and password must be supplied as parameters at mapping runtime. This is not different from supplying any other parameter kinds to the mapping. For example, when calling MapForce Server at the command line, the syntax for a mapping like the one above is:

```
<exec> run mapping.mfx --p=username:admin --p=password:dj9JaVax
```

Where:

- `<exec>` is the path to the MapForce Server executable. This path can be either absolute or, if the current directory is the same as the executable, you can enter just the executable name.
- `username` and `password` are the names of the respective input parameters on the MapForce mapping.

When calling the MapForce Server API, you can authenticate the mapping by calling the `AddParameter` method before calling the `Run` method. For example, in C#, the code to achieve this could look as follows:

```csharp
try
{
    mfs.AddParameter("username", "admin");
    mfs.AddParameter("password", "dj9JaVax");
    mfs.WorkingDirectory = "C:\Work";
    if (mfs.Run("C:\Work\mapping.mfx"))
    {
        Console.WriteLine("Success");
    }
    else
    {
        Console.WriteLine(mfs.LastExecutionMessage);
    }
    Console.ReadLine();
}
catch(Exception ex)
{
    Console.WriteLine(ex);
}
```

Again, the `username` and `password` (first argument to the `AddParameter` method) must be the same as the names of the respective input parameters on the MapForce mapping.
4 MapForce Server Command Line

To run MapForce Server from the command line, you can call the executable from the following default locations:

- **Linux**
  
  `/opt/Altova/MapForceServer2020/bin/mapforceserver`

- **Mac**
  
  `/usr/local/Altova/MapForceServer2020/bin/mapforceserver`

- **Windows**
  
  `<ProgramFilesFolder>\Altova\MapForceServer2020\bin\MapForceServer.exe`

**Usage and list of CLI commands**

The command line syntax is:

```
mapforceserver --h | --help | --version | <command> [options] [arguments]
```

- **--help** (short form **--h**) displays the help text of the given command. If no command is named, then all commands of the executable are listed, each with a brief description of the command.
- **--version** displays the version number of MapForce Server.
- **<command>** is the command to execute. Commands are described in the sub-sections of this section (see list below).
- **[options]** are the options of a command; they are listed and described with their respective commands.
- **[arguments]** are the arguments of a command; they are listed and described with their respective commands.

**Casing and slashes on the command line**

- **MapForceServer** on Windows
- **mapforceserver** on Windows and Unix (Linux, Mac)

  * Note that lowercase (**mapforceserver**) works on all platforms (Windows, Linux, and Mac), while upper-lower (**MapForceServer**) works only on Windows and Mac.
  * Use forward slashes on Linux and Mac, backslashes on Windows.

**CLI commands**

Available commands are listed below and are explained in the sub-sections of this section.

- **assignlicense**: Uploads a license to LicenseServer and assigns this license to MapForce Server.
- **exportresourcestrings**: Exports all application resource strings to an XML file.
- **help**: Displays information about the command that is submitted in the argument (or about all commands if no argument is submitted).
- **licenseserver**: Registers MapForce Server with a LicenseServer on the local network.
- **run**: Runs a Mapping Execution File (.mfx) compiled with MapForce.
- **setdeflang**: Sets the default language of MapForce Server.
- **verifylicense**: Checks if current MapForce Server is licensed and, optionally, whether it is licensed with the given license key.
- **version**: Displays the version number of MapForce Server.
4.1 assignlicense (Windows only)

Syntax and description

The **assignlicense** command is available on Windows only (not on Linux or Mac systems). It uploads a license file to the Altova LicenseServer with which MapForce Server is registered (see the `licenseserver` command), and assigns the license to MapForce Server. It takes the path of a license file as its argument. The command also allows you to test the validity of a license.

```
mapforceserver assignlicense [options] FILE
```

- The `FILE` argument takes the path of the license file.
- The `--test-only` option uploads the license file to LicenseServer and validates the license, but does not assign the license to MapForce Server.

For details about licensing, see the LicenseServer documentation ([https://www.altova.com/manual/AltovaLicenseServer/](https://www.altova.com/manual/AltovaLicenseServer/)).

▼ Casing and slashes on the command line

**MapForceServer on Windows**

```
mapforceserver on Windows
```

**mapforceserver on Windows and Unix (Linux, Mac)**

* Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while upper-lower (MapForceServer) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

▼ Backslashes and spaces on Windows systems

On Windows systems: When spaces occur (for example in file or folder names, or company, person or product names), use quotes: for example, "My File". Note, however, that a backslash followed by a double-quotation mark (for example, "C:\My directory") might not be read correctly. This is because the backslash character is also used to indicate the start of an escape sequence, and the escape sequence \" stands for the double-quotation mark character. If you want to escape this sequence of characters, use a preceding backslash, like this: \". To summarize: If you need to write a file path that contains spaces and an end backslash, write it like this: "C:\My Directory\".

Examples

Examples of the **assignlicense** command:

```
mapforceserver assignlicense C:\licensepool\mylicensekey.lic
mapforceserver assignlicense --test-only=true C:\licensepool\mylicensekey.lic
```

- The first command above uploads the specified license to LicenseServer and assigns it to MapForce Server.
- The second command calls the server-executable to do the same thing as the first command.
- The third command uploads the specified license to LicenseServer and validates it, without assigning it to MapForce Server.
Options

Options are listed in short form (if available) and long form. You can use one or two dashes for both short and long forms. An option may or may not take a value. If it takes a value, it is written like this: `--option=value`. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required. If an option takes a Boolean value and no value is specified, then the option's default value is `true`. Use the `--h, --help` option to display information about the command.

```
$ test-only [t]
--t, --test-only = true|false
```

Values are `true|false`. If `true`, then the license file is uploaded to LicenseServer and validated, but not assigned.
4.2 exportresourcestrings

Syntax and description

The exportresourcestrings command outputs an XML file containing the resource strings of the MapForce Server application in the specified language. Available export languages are English (en), German (de), Spanish (es), French (fr), and Japanese (ja).

```
mapforceserver exportresourcestrings [options] LanguageCode XMLOutputFile
```

- The LanguageCode argument gives the language of the resource strings in the output XML file; this is the export language. Allowed export languages (with their language codes in parentheses) are: English (en), German (de), Spanish (es), French (fr), and Japanese (ja).
- The XMLOutputFile argument specifies the path and name of the output XML file.

How to create localizations is described below.

▼ Casing and slashes on the command line

MapForceServer on Windows
mapforceserver on Windows and Unix (Linux, Mac)

* Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while upper-lower (MapForceServer) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

▼ Backslashes and spaces on Windows systems

On Windows systems: When spaces occur (for example in file or folder names, or company, person or product names), use quotes: for example, "My File". Note, however, that a backslash followed by a double-quotation mark (for example, "C:\My directory\") might not be read correctly. This is because the backslash character is also used to indicate the start of an escape sequence, and the escape sequence \" stands for the double-quotation mark character. If you want to escape this sequence of characters, use a preceding backslash, like this: \". To summarize: If you need to write a file path that contains spaces and an end backslash, write it like this: "C:\My Directory\".

Examples

Examples of the exportresourcestrings command:

```
mapforceserver exportresourcestrings de c:\Strings.xml
```

- The first command above creates a file called Strings.xml at c:\ that contains the resource strings of MapForce Server in German.
- The second command calls the server-executable to do the same thing as the first example.

Creating localized versions of MapForce Server

You can create a localized version of MapForce Server for any language of your choice. Five localized versions (English, German, Spanish, French, and Japanese) are already available in the C:\Program Files (x86)
Create a localized version as follows:

1. Generate an XML file containing the resource strings by using the `exportresourcestrings` command (see command syntax above). The resource strings in this XML file will be one of the five supported languages: English (en), German (de), Spanish (es), French (fr), or Japanese (ja), according to the `LanguageCode` argument used with the command.

2. Translate the resource strings from one of the four supported languages into the target language. The resource strings are the contents of the `<string>` elements in the XML file. Do not translate variables in curly brackets, such as `{option}` or `{product}`.

3. Contact Altova Support to generate a localized MapForce Server DLL file from your translated XML file.

4. After you receive your localized DLL file from Altova Support, save the DLL in the `C:\Program Files (x86)\Altova\MapForceServer2020\bin` folder. Your DLL file will have a name of the form `MapForceServer2020_lc.dll`. The _lc part of the name contains the language code. For example, in `MapForceServer2020_de.dll`, the de part is the language code for German (Deutsch).

5. Run the `setdeflang` command to set your localized DLL file as the MapForce Server application to use. For the argument of the `setdeflang` command, use the language code that is part of the DLL name.

**Note:** Altova MapForce Server is delivered with support for five languages: English, German, Spanish, French, and Japanese. So you do not need to create a localized version of these languages. To set any of these languages as the default language, use MapForce Server's `setdeflang` command.
4.3 help

Syntax and description
The help command takes a single argument (Command), which is the name of the command for which help is required. It displays the command's syntax, its options, and other relevant information. If the Command argument is not specified, then all commands of the executable are listed, with each having a brief text description.

\[ \text{mapforceserver help Command} \]

▼ Casing and slashes on the command line
- MapForceServer on Windows
- mapforceserver on Windows and Unix (Linux, Mac)

* Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while upper-lower (MapForceServer) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Example
Example of the help command to display information about the licenserver command:

\[ \text{mapforceserver help licenserver} \]

The --help option
Help information about a command is also available by using the --help option of the command for which help information is required. The two commands below produce the same results:

\[ \text{mapforceserver licenseserver --help} \]

The command above uses the --help option of the licenseserver command.

\[ \text{mapforceserver help licenseserver} \]

The help command takes licenseserver as its argument.

Both commands display help information about the licenseserver command.
4.4 licenseserver

Syntax and description

The licenseserver command registers MapForce Server with the Altova LicenseServer specified by the Server-Or-IP-Address argument. For the licenseserver command to be executed successfully, the two servers (MapForce Server and LicenseServer) must be on the same network and LicenseServer must be running. You must also have administrator privileges in order to register MapForce Server with LicenseServer.

```
mapforceserver licenseserver [options] Server-Or-IP-Address
```

- The Server-Or-IP-Address argument takes the name or IP address of the LicenseServer machine.
- To request an evaluation license for MapForce Server, submit appropriate values for the --company, --email, and --name options. To request an evaluation license for an additional Altova product (that is, in addition to MapForce Server), add the --request-eval-license option with a value that is the name of that product. See the list of options below for more information.

Once MapForce Server has been successfully registered with LicenseServer, you will receive a message to this effect. The message will also display the URL of the LicenseServer. You can now go to LicenseServer to assign MapForce Server a license. For details about licensing, see the LicenseServer documentation (https://www.altova.com/manual/AltovaLicenseServer/).

Casing and slashes on the command line

- MapForceServer on Windows
- mapforceserver on Windows and Unix (Linux, Mac)

  * Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while upper-lower (MapForceServer) works only on Windows and Mac.
  * Use forward slashes on Linux and Mac, backslashes on Windows.

Backslashes and spaces on Windows systems

On Windows systems: When spaces occur (for example in file or folder names, or company, person or product names), use quotes: for example, "My File". Note, however, that a backslash followed by a double-quotation mark (for example, "C:\My directory\") might not be read correctly. This is because the backslash character is also used to indicate the start of an escape sequence, and the escape sequence \ stands for the double-quotation mark character. If you want to escape this sequence of characters, use a preceding backslash, like this: \". To summarize: If you need to write a file path that contains spaces and an end backslash, write it like this: "C:\My Directory\\".

Examples

Examples of the licenseserver command:

```
mapforceserver licenseserver DOC.altova.com
mapforceserver licenseserver localhost
mapforceserver licenseserver 127.0.0.1
```

The commands above specify, respectively, the machine named DOC.altova.com, and the user's machine
MapForce Server Command Line

(localhost and 127.0.0.1) as the machine running Altova LicenseServer. In each case, the command registers MapForce Server with the LicenseServer on the machine specified. The last command calls the server-executable to execute the command.

Options

Options are listed in short form (if available) and long form. You can use one or two dashes for both short and long forms. An option may or may not take a value. If it takes a value, it is written like this: **--option=value**. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required. If an option takes a Boolean value and no value is specified, then the option's default value is **TRUE**. Use the **--h, --help** option to display information about the command.

- **json [j]**
  ```
  --j, --json = true|false
  ```
  Values are true|false. If true, prints the result of the registration attempt as a machine-parsable JSON object.
4.5 run

The `run` command executes a MapForce Server execution file (.mfx file) supplied as argument. The MapForce Server execution file is created with MapForce; it essentially represents a mapping compiled for server execution.

Any input files required by the mapping are expected to be at the path specified at mapping design time in MapForce. If MapForce Server does not run on the same operating system as MapForce, the input files required by the mapping must be copied to the target machine alongside with the .mfx file, and must be referenced using a relative path. For information about configuring a mapping with respect to relative or absolute paths, refer to MapForce documentation (https://www.altova.com/documentation#mapforce). Other prerequisites may apply, depending on how you designed the mapping, see Preparing Mappings for Server Execution.

If the mapping returns a simple value such as string, this output is written in the `stdout` (standard output) stream. On the other hand, the success and error messages are available in the `stderr` (standard error) stream. If you do not want the standard output stream to be displayed on the screen together with the success or error messages, redirect either the standard output or the standard error stream (or both) to files. If neither the `stdout` nor the `stderr` streams are redirected, they are both displayed on the screen, combined.

For example, to redirect the standard output stream to a file, use:

```
mapforceserver run MyMapping.mfx > MyOutput.txt
```

To redirect the standard error stream to a file, use:

```
mapforceserver run MyMapping.mfx 2> Diagnostics.log
```

To redirect both streams simultaneously, use:

```
mapforceserver run MyMapping.mfx > MyOutput.txt 2> Diagnostics.log
```

For further information about stream redirection, refer to the documentation of your operating system's command shell.

Syntax

- **Windows**  
  `MapForceServer run [options] MfxFile`

- **Linux**  
  `mapforceserver run [options] MfxFile`

- **Mac**  
  `mapforceserver run [options] MfxFile`

**Casing and slashes on the command line**

- `MapForceServer on Windows`
- `mapforceserver on Unix (Linux, Mac)`
* Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while upper-lower (MapForceServer) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

On Windows systems, avoid using the end backslash and closing quote on the command line "", for example, as in: "C:\My directory". These two characters are interpreted by the command line parser as a literal double-quoation mark. Use the double backslash \ if spaces occur in the command line and you need the quotes (for example: "C:\My Directory\").

### Command options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--catalog</code></td>
<td>Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file. Form: <code>--catalog=FILE</code></td>
</tr>
<tr>
<td><code>--cert</code></td>
<td>This option is applicable to MapForce Server running on Linux. It specifies the path to the directory where any certificate files required by the mapping are stored. Form: <code>--certificatespath=DIRECTORY</code></td>
</tr>
<tr>
<td></td>
<td>See also <a href="#">Digital Certificate Management</a>.</td>
</tr>
<tr>
<td><code>--cred</code></td>
<td>Setting this option is meaningful if the mapping contains credentials that you have defined at mapping design time in MapForce. KEY is the credential name as it was defined in MapForce. VALUE consists of one or more name-value pairs, for example: name1=value1&amp;name2=value2. Where name is any of the following: - username - password When using multiple name-value pairs separated by ampersand, enclose the KEY:VALUE part within quotes. For examples, see <a href="#">Credentials</a>.</td>
</tr>
<tr>
<td><code>--gc</code></td>
<td>This option is applicable if the mapping consumes <a href="#">Global Resources</a>. It specifies the name of the global resource configuration (alias). This option must be used together with the <code>--globalresourcefile</code> option. Form: <code>--gc=VALUE</code></td>
</tr>
</tbody>
</table>

</tr>
<tr>
<td><code>--taxonomy-packages-config-file=FILE</code></td>
<td>Specifies the path to a configuration file called TaxonomyPackagesConfig.json, used to load XBRL taxonomy packages. This configuration file is updated every time when you add, remove, activate, or deactivate XBRL taxonomy packages from the graphical user interface of Altova XMLSpy, MapForce, or StyleVision. If you have added custom XBRL taxonomy packages using one of the products above, the file is located at C: \Users&lt;username&gt;\Documents\Altova.</td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

This example shows you how to run a mapping execution file (.mfx) with MapForce Server on Windows. The mapping used in this example reads an input file, `Employees.xml`, and produces two output files (`PersonList.xml` and `Contacts.xml`).

First, let's generate the MapForce Server execution (.mfx) file, as follows:

1. Run MapForce and open the following MapForce design file (.mfd file): C: \Users\<user>\Documents\Altova\MapForce2020\MapForceExamples\ChainedPersonList.mfd.
3. When prompted, save the .mfx file to C: \temp directory. This will be the working directory where the mapping will be executed by MapForce Server.

Next, let's open a command line prompt and change the working directory to C: \temp.
Finally, run the following command to execute **ChainedPersonList.mfx**. In this example, MapForce Server is called using an absolute path. (To call it with a relative path, add the executable's path to your system's `PATH` environment variable).

```
cd C:\temp
"C:\Program Files (x86)\Altova\MapForceServer2020\bin\MapForceServer.exe" run ChainedPersonList.mfx
```

The two output files (**PersonList.xml** and **Contacts.xml**) are generated in the working directory. Importantly, this mapping is configured to use absolute paths, which is why the mapping ran successfully and did not require that the input **Employees.xml** file exists in the working directory. The **Employees.xml** file actually exists in the MapForce Examples folder mentioned above and is referenced through an absolute path. To specify whether paths should be treated as absolute or relative, right-click the mapping in MapForce, select **Mapping Settings**, and then select or clear the **Make paths absolute in generated code** check box. Whenever you change the mapping settings, make sure to re-compile the mapping to .mfx. For more information, see [Preparing Mappings for Server Execution](#).
4.6 setdeflang

Syntax and description
The setdeflang command (short form is sdl) sets the default language of MapForce Server. Available languages are English (en), German (de), Spanish (es), French (fr), and Japanese (ja). The command takes a mandatory LanguageCode argument.

```
mapforceserver setdeflang [options] LanguageCode
```

- The LanguageCode argument is required and sets the default language of MapForce Server. The respective values to use are: en, de, es, fr, ja.
- Use the --h, --help option to display information about the command.

Casing and slashes on the command line
MapForceServer on Windows
mapforceserver on Windows and Unix (Linux, Mac)

* Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while uppercase (MapForceServer) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Examples
Examples of the setdeflang (sdl) command:

```
mapforceserver sdl de
mapforceserver setdeflang es
```

- The first command sets the default language of MapForce Server to German.
- The second command sets the default language of MapForce Server to Spanish.
- The third command is the same as the second command, but is executed by the server-executable.

Options
Use the --h, --help option to display information about the command.
4.7 verifylicense (Windows only)

Syntax and description

The verifylicense command checks whether the current product is licensed. Additionally, the --license-key option enables you to check whether a specific license key is already assigned to the product. This command is supported only on Windows systems. It is not supported on Linux or Mac systems.

```
mapforceserver verifylicense [options]
```

- To check whether a specific license is assigned to MapForce Server, supply the license key as the value of the --license-key option.

For details about licensing, see the LicenseServer documentation (https://www.altova.com/manual/AltovaLicenseServer/).

* Casing and slashes on the command line

  MapForceServer on Windows
  mapforceserver on Windows and Unix (Linux, Mac)

  * Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while upper-lower (MapForceServer) works only on Windows and Mac.
  * Use forward slashes on Linux and Mac, backslashes on Windows.

Examples

Example of the verifylicense command:

```
mapforceserver verifylicense
mapforceserver verifylicense --license-key=ABCD123-ABCD123-ABCD123-ABCD123-ABCD123-ABCD123
```

- The first command checks whether MapForce Server is licensed.
- The second command checks whether MapForce Server is licensed with the license key specified with the --license-key option.

Options

Options are listed in short form (if available) and long form. You can use one or two dashes for both short and long forms. An option may or may not take a value. If it takes a value, it is written like this: --option=value. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required. If an option takes a Boolean value and no value is specified, then the option's default value is TRUE. Use the --h, --help option to display information about the command.

* license-key [l]

  --l, --license-key = Value

  Checks whether MapForce Server is licensed with the license key specified as the value of this option.
4.8 version

Syntax and description
The `version` command displays the version number of MapForce Server.

```
mapforceserver version
```

▼ Casing and slashes on the command line

- **MapForceServer** on **Windows**
- mapforceserver on **Windows and Unix (Linux, Mac)**

* Note that lowercase (mapforceserver) works on all platforms (Windows, Linux, and Mac), while uppercase (MapForceServer) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Example

Example of the `version` command:

```
mapforceserver version
```
5 MapForce Server API

MapForce Server provides an application programming interface (API) that you can access programmatically from your .NET, Java, or COM-based code.

For an introduction to each platform, refer to the following topics:

- .NET Interface
- COM Interface
- Java Interface

For a technical description of the API, refer to the following topics:

- API Reference (COM, .NET)
- API Reference (Java)
5.1 .NET Interface

The .NET interface is built as a wrapper around the COM interface. It is provided as a primary interop assembly signed by Altova and uses the namespace `Altova.MapForceServer`. During installation, MapForce Server will be registered automatically as a COM server object, so there is no need for a manual registration.

In order to use MapForce Server in your .NET project, add a reference to the `Altova.MapForceServer.dll` file, as shown below. The `Altova.MapForceServer.dll` is located in the `bin` folder of the MapForce Server installation folder. This .dll file is automatically added to the Global Assembly Cache (GAC) during MapForce Server installation.

**Note:** Prior to .NET Framework 4.0, the GAC was located in the `%windir%\assembly` directory. Starting with .NET Framework 4.0, the GAC is located in the `%windir%\Microsoft.NET\assembly` directory. The `%windir%` part represents the Windows operating system directory, typically `C:\Windows`.

To add a reference to the MapForce Server DLL in a Visual Studio .NET project:

1. With the .NET project open in Visual Studio, click **Project | Add Reference**.
2. On the Browse tab, browse for the folder: `<MapForceServer application folder>/bin`, select the `Altova.MapForceServer.dll`, and click **OK**.
You can view the structure of the `Altova.MapForceServer` assembly using the Visual Studio Object Browser (to display the Object Browser, click **Object Browser** on the **View** menu).

### 5.1.1 C# Example

The following example illustrates how to run a mapping execution file (.mfx) from C# code. On Windows, the example files are available at the following path: `C:\Program Files\Altova\MapForceServer2020\etc\Examples`.

The example solution is in the "Program Files" directory, which requires administrative rights. Either run Visual Studio as administrator, or copy the solution to a different folder where you don’t need administrative rights.

**Prerequisites**

- MapForce Server is installed and licensed
- If you are creating a new Visual Studio project, add a reference to the MapForce Server assembly (see **.NET Interface**). You can skip this step if you are running the existing MapForce Server API example, because the example already references the MapForce Server assembly.
- On the **Build** menu of Visual Studio, click **Configuration Manager** and set a correct build platform, for example **Debug** | x86 (or **Debug** | x64, if applicable). Do not use "Any CPU" as platform.
- If you have installed MapForce Server 64-bit, then the application which calls the API (such as the sample one below) must also be built for the 64-bit platform in Visual Studio. Also, the path to the MapForce server executable must be adjusted accordingly in the code.

**Running the .mfx file**

The code below does the following:

- It creates a new instance of `Altova.MapForceServer.Server`. This is the object you will subsequently be working with.
- It sets a working directory where execution takes place. Input files are expected to exist in this directory if you referred to them using a relative path. Output files will also be created in this directory. Namely, the server execution file run by this example (`TokenizeString.mfx`) reads data from a file called `AltovaTools.xml`, which is accompanied by the `AltovaTools.xsd` schema. These files must exist in the working directory in order for the .mfx file to run successfully.
- It runs the `TokenizeString.mfx` file. The path to this file is supplied as argument to the **Run** method. Upon successful execution, a `.csv` file representing the mapping output will be created in the working directory.

```csharp
namespace MapForceServerAPI_sample
{
    class Program
    {
        static void Main(string[] args)
        {
            //Create a MapForce Server object
        }
    }
}
```
5.1.2 Visual Basic .NET Example

The following example illustrates how to run a mapping execution file (.mfx) from VB.NET code. On Windows, the example files are available at the following path: C:\Program Files\Altova\MapForceServer2020\etc\Examples.

```vbnet
//Set a working directory - used as a base for relative paths (you may need to adapt the path to the installation folder)
objMFS.WorkingDirectory = "C:\\Program Files\\Altova\\MapForceServer2020\\etc\\Examples";

//Default path to the MapForce Server executable is the installation path (same dir with the MapForceServer.dll)
//In case you moved the binaries on the disk, you need to explicitly set the path to the .exe file
//objMFS.ServerPath = "C:\\Program Files (x86)\\Altova\\MapForceServer2020\\bin\\MapForceServer.exe";

//Set global resource file and configuration, if your mapping uses global resources
//objMFS.SetOption( "globalresourcefile", "GlobalResource.xml" ); // "gr" can be used as short name for "globalresourcefile"
//objMFS.SetOption( "globalresourceconfig", "Default" ); // "gc" can be used as short name for "globalresourceconfig"

//Prepare the parameters, if your mapping uses parameters
//objMFS.AddParameter( "testparam1", "value 1" );

//Run the mapping; input and output paths are stored inside the MFX file
//NOTE Please adapt the path to the input file in order to run the sample
if (objMFS.Run("C:\\Program Files\\Altova\\MapForceServer2020\\etc\\Examples\\TokenizeString.mfx"))
    System.Console.WriteLine("Success - finished execution");
else
    System.Console.WriteLine(objMFS.LastExecutionMessage);
```

The example solution is in the "Program Files" directory, which requires administrative rights. Either run Visual Studio as administrator, or copy the solution to a different folder where you don't need administrative rights.

Prerequisites

- MapForce Server is installed and licensed
- If you are creating a new Visual Studio project, add a reference to the MapForce Server assembly (see .NET Interface). You can skip this step if you are running the existing MapForce Server API example, because the example already references the MapForce Server assembly.
- On the Build menu of Visual Studio, click Configuration Manager and set a correct build platform, for example Debug | x86 (or Debug | x64, if applicable). Do not use "Any CPU" as platform.
- If you have installed MapForce Server 64-bit, then the application which calls the API (such as the sample one below) must also be built for the 64-bit platform in Visual Studio. Also, the path to the
MapForce server executable must be adjusted accordingly in the code.

Running the .mfx file

The code below does the following:

- It creates a new instance of `Altova.MapForceServer.Server`. This is the object you will subsequently be working with.
- It sets a working directory where execution takes place. Input files are expected to exist in this directory if you referred to them using a relative path. Output files will also be created in this directory. Namely, the server execution file run by this example (TokenizeString.mfx) reads data from a file called `AltovaTools.xml`, which is accompanied by the `AltovaTools.xsd` schema. These files must exist in the working directory in order for the .mfx file to run successfully.
- It runs the `TokenizeString.mfx` file. The path to this file is supplied as argument to the `Run` method. Upon successful execution, a .csv file representing the mapping output will be created in the working directory.

```vbnet
Option Explicit On
Module Program
    Sub Main()
        'Create a MapForce Server object;

        'Set a working directory - used as a base for relative paths (you may need to adapt the path to the installation folder)
        objMFS.WorkingDirectory = "C:\Program Files (x86)\Altova\MapForceServer2020\etc\Examples"

        'Default path to the MapForce Server executable is the installation path (same dir with the MapForceServer.dll)
        'In case you moved the binaries on the disk, you need to explicitly set the path to the .exe file
        'objMFS.ServerPath = "C:\Program Files (x86)\Altova\MapForceServer2020\bin\MapForceServer.exe"

        'Set global resource file and configuration, if your mapping uses global resources
        'objMFS.SetOption("globalresourcefile", "GlobalResource.xml") "gr" can be used as short name for "globalresourcefile"
        'objMFS.SetOption("globalresourceconfig", "Config2") "gc" can be used as short name for "globalresourceconfig"

        'Prepare the parameters, if your mapping uses parameters
        'objMFS.AddParameter( "testparam1", "value 1" )

        'Run the mapping; input and output paths are stored inside the MFX file
        ' NOTE Please adapt the path to the input file in order to run the sample
        If (objMFS.Run("C:\Program Files (x86)\Altova\MapForceServer2020\etc\Examples\TokenizeString.mfx")) Then
            System.Console.WriteLine("Success - finished execution")
        Else
```
System.Console.WriteLine(objMFS.LastExecutionMessage)
End If
End Sub
End Module
5.2 COM Interface

MapForce Server is automatically registered as a COM server object during installation. To check whether the registration was successful, open the Registry Editor (for example, by typing `regedit.exe` command at the command line). If registration was successful, the Registry will contain the classes `MapForce.Server`. These two classes will typically be found under `HKEY_LOCAL_MACHINE\SOFTWARE\Classes`.

Once the COM server object is registered, you can invoke it from within applications and scripting languages that have programming support for COM calls. If you wish to change the location of the MapForce Server installation package, it is best to uninstall MapForce Server and then reinstall it at the required location. In this way, the necessary de-registration and registration are carried out by the installer process.

5.2.1 C++ Example

The following example illustrates how to run a mapping execution file (.mfx) from C++ code. On Windows, the example files are available at the following path: `C:\Program Files\Altova\MapForceServer2020\etc\Examples`.

Before running the code below, ensure the following prerequisites are met:

- MapForce Server is installed and licensed
- MapForce Server is available as a COM server object (normally, this process takes place automatically during MapForce Server installation; to check if registration was successful, see About the COM Interface).

```cpp
// MapForceServerAPI_sample.cpp : Defines the entry point for the console application.
//
#include <iostream>
#include "atlbase.h"

// 32-bit MapForce Server
#import "progid:MapForce.Server"
// 64-bit MapForce Server
// #import "progid:MapForce_x64.Server"

int _tmain(int argc, _TCHAR* argv[]) { 
    CoInitialize( NULL );
    try { 
        //Create a MapForce Server object
        MapForceServerLib::IServerPtr pMFS;
        CoCreateInstance( __uuidof( MapForceServerLib::Server ), NULL, CLSCTX_ALL,
        __uuidof( MapForceServerLib::IServer ), reinterpret_cast< void** >( &pMFS ) );

        //Set a working directory - used as a base for relative paths (you may need
to adapt the path to the installation folder)
        pMFS->WorkingDirectory = "C:\\Program Files (x86)\\Altova\\MapForceServer2020\\etc\\Examples";
    }
    catch(...) { 
    }
}
```

© 2019 Altova GmbH
// Default path to the MapForce Server executable is the installation path
declared with the MapForceServer.dll.
// In case you moved the binaries on the disk, you need to explicitly set the
// path to the .exe file
// pMFS->ServerPath = "C:\\Program Files (x86)\\Altova\\MapForceServer2020\\bin\\MapForceServer.exe";

// Set global resource file and configuration, if your mapping uses global
// resources
// pMFS->SetOption("globalresourcefile", "GlobalResource.xml"); // "gr" can be used as short name for "globalresourcefile"
// pMFS->SetOption("globalresourceconfig", "Default"); // "gc" can be used as short name for "globalresourceconfig"

// Prepare the parameters, if your mapping uses parameters
// pMFS->AddParameter("testparam1", "value 1");

// Run the mapping; the output will be stored at C:\temp\ExpReport.rtf
// NOTE Please adapt the path to the input file in order to run the sample
if (pMFS->Run("C:\\Program Files (x86)\\Altova\\MapForceServer2020\\etc\\Examples\\TokenizeString.mfx"))

std::cout << "Success - finished execution" << std::endl;
else

std::cout << pMFS->LastExecutionMessage << std::endl;

} catch (_com_error& err )
{

BSTR  bstrMessage;
(err).ErrorInfo()->GetDescription( &bstrMessage );
std::cout << "Exception occurred: " <<
_com_util::ConvertBSTRToString( bstrMessage ) << std::endl;

}

CoUninitialize();
return 0;

5.2.2 VBScript Example

The following example illustrates how to run a mapping execution file (.mfx) from VBScript code. On Windows, the example files are available at the following path: C:\Program Files\Altova\MapForceServer2020\etc\Examples.

Before running the code below, ensure the following prerequisites are met:

- MapForce Server is installed and licensed
- MapForce Server is available as a COM server object (normally, this process takes place automatically during MapForce Server installation; to check if registration was successful, see About the COM Interface).
Option Explicit

'Create a MapForce Server object; use "MapForce_x64.Server" if you want to use the 64-bit installation
Dim objMFS
Set objMFS = WScript.GetObject( "", "MapForce.Server" )

'Set a working directory - used as a base for relative paths (you may need to adapt the path)
objMFS.WorkingDirectory = "C:\Program Files (x86)\Altova\MapForceServer2020\etc\Examples"

'Default path to the MapForce Server executable is the installation path (same dir with the MapForceServer.dll)
'In case you moved the binaries on the disk, you need to explicitly set the path to the .exe file
'objMFS.ServerPath = "C:\Program Files (x86)\Altova\MapForceServer2020\bin\MapForceServer.exe"

'Set global resource file and configuration, if your mapping uses global resources
'Call objMFS.SetOption("globalresourcefile", "GlobalResource.xml") "gr" can be used as short name
'Call objMFS.SetOption("globalresourceconfig", "Config2") "gc" can be used as short name

'Prepare the parameters, if your mapping uses parameters
'Call objMFS.AddParameter( "testparam1", "value 1" )

' Run the mapping; input and output paths are stored inside the MFX file
' NOTE Please adapt the path to the input file in order to run the sample
If ( objMFS.Run( "C:\Program Files (x86)\Altova\MapForceServer2020\etc\Examples\TokenizeString.mfx" ) ) Then
  WScript.Echo( "Success - finished execution" )
Else
  WScript.Echo( objMFS.LastExecutionMessage )
End If

5.2.3 VBA Example

Microsoft Visual Basic for Applications (VBA) is primarily used for automating tasks in Microsoft Office. However, it is also possible to call the MapForce Server API from VBA and execute mappings. The following instructions have been tested on MapForce Server and the VBA for Microsoft Office 2013. Instructions may differ if you are using another VBA development environment.

Prerequisites

Before you can call the MapForce Server API functions from your VBA project, note the following prerequisites:

1. Microsoft Office and MapForce Server must be installed on the same machine.
2. The architecture of MapForce Server (32-bit or 64-bit) must match that of Microsoft Office. For example, if you run VBA on Microsoft Office 32-bit, make sure that you use MapForce Server 32-bit. To find out whether your Office product runs on 64-bit, click the File tab, click Account, and then click "About Excel" (or "About Word").
3. The MapForce Server library must be referenced from your VBA project (see instructions below).

How to add a reference to the MapForce Server Library from your VBA project

1. In a macro-enabled Microsoft Office document (.docm, .xlsm), on the Developer tab, click Visual Basic.
By default, the Developer tab is not enabled in Microsoft Office. To enable the Developer tab in an Office 2013 program, right-click the ribbon and select Customize the Ribbon from the context menu. Then, in the Options dialog box, select the Developer check box under "Main Tabs".

2. In the VBA development environment, in the Tools menu, click References.

3. Click to select the MapForce Server Type Library.

How to call the MapForce Server API

Once you have added a reference to the MapForce Server Library in your VBA project, you can enter the VBA code in the Code Editor window. For example, the following sample code calls MapForce Server and runs a mapping executable file (mapping.mfx) that takes an input parameter called "outfile" having the value "output.csv".

```vbnet
Sub RunMapping()
    ' Create a new instance of the MapForce Server
    Dim objMFS As New MapForceServerLib.Server
    With objMFS
        ' Set the working directory
        ' (used as base if the mapping has relative paths)
        .WorkingDirectory = "C:\temp\"
        ' If the mapping has parameters, supply them
        Call .AddParameter("outfile", "output.csv")
        ' Run the mapping
        .Run ("C:\temp\mapping.mfx")
    End With
End Sub
```
Press **F5** to debug the VBA code and run the mapping.
5.3 Java Interface

To access the MapForce Server API from Java, a reference to `MapForceServer.jar` library must be added to the Java CLASSPATH. You can find the `MapForceServer.jar` file in the `bin` folder of the MapForce Server installation folder. You can either reference the file from its original location or copy it to another location if this fits your project setup.

If you are using Eclipse as Java development environment, you can add the required library reference to the CLASSPATH by editing the properties of the Java project, as shown below. Optionally, you can also attach documentation in JavaDoc format to the .jar library. You can find the JavaDoc in the `bin` folder of the MapForce Server installation folder; the instructions below illustrate how to make the JavaDoc documentation visible from Eclipse.

**To add a reference to the MapForce Server library:**

1. With the project open in Eclipse, on the **Project** menu, click **Properties**.
2. Click **Java Build Path**.
3. On the **Libraries** tab, click **Add External JARs**, and then browse for the `MapForceServer.jar` file located in the MapForce Server installation folder.
4. Optionally, to add the JavaDoc archive, expand the `MapForceServer.jar` record, and then double-click the **Javadoc location: (None)** record.
5. Ensure that the **Javadoc in archive** and **External file** options are selected, and then browse for the `MapForceServer_JavaDoc.zip` file located in the MapForce Server installation folder.

![Screenshot of Eclipse with Java Build Path dialog open]

6. Click OK.

Below is an example of how the Eclipse `.classpath` file might look if you are referencing the files from the original installation folder, on a 64-bit Windows running 64-bit MapForce Server (the relevant lines are highlighted in yellow):

```xml
<?xml version="1.0" encoding="UTF-8"?>
<classpath>
    <classpathentry kind="src" path=""/>
    <classpathentry kind="lib" path="C:\Program Files\Altova\MapForceServer2019\bin\M"/>
</classpath>
```
5.3.1 Java Example

The following example illustrates how to run a mapping execution file (.mfx) from Java code. On Windows, all the example files are available at the following path: C:\Program Files\Altova\MapForceServer2020\etc\Examples. They are as follows:

- **TokenizeString.mfx** - A MapForce Server execution file that will be run by the Java program.
- **AltovaTools.xml** - An XML file that provides input data to the mapping program.
- **AltovaTools.xsd** - The schema of the source XML file.

On Linux and Mac platforms, no examples are pre-installed; however, you can prepare an executable .mfx file like the one run in this example as follows:

1. Open the desired mapping design file (.mfd) with MapForce on Windows.
2. On the **File** menu, select **Mapping Settings**, and clear the **Make paths absolute in generated code** check box if it is selected.
3. For each mapping component, open the **Properties** dialog box (by double-clicking the component's title bar, for example), and change all file paths from absolute to relative. Also, select the **Save all file paths relative to MFD file** check box. For convenience, you can copy all input files and schemas in the same folder as the mapping itself, and reference them just by the file name. Refer to MapForce documentation for more information about dealing with relative and absolute paths while designing mappings.
4. On the **File** menu, select **Compile to MapForce Server Execution file**. This generates the .mfx file that you will subsequently run with MapForce Server, as shown in the code listing below.

If you are using a custom .mfx file as shown above, there may be other prerequisites, depending on the kind of data processed by the mapping. For more information, see **Preparing Mappings for Server Execution**.

On Windows, the example Java project is in the "Program Files" directory, which requires administrative rights. You will either need to run your Java development environment (for example, Eclipse) as administrator, or copy the example to a different folder where you don't need administrative rights.

Before running the code below, ensure the following prerequisites are met:

- MapForce Server is installed and licensed
The Java CLASSPATH includes a reference to the `MapForceServer.jar` library (for an example, see About the Java Interface).

### Running the Java program

The code listing below first creates a MapForce Server object. Next, it sets the working directory where the application should look for any files that act as input to the mapping, and where it should generate the mapping output files. As mentioned above, the example mapping file reads data from a source XML file—so make sure that both the XML file and its schema exist in the working directory.

The `setServerPath` method specifies the path to the MapForce Server executable. For example, on Ubuntu, this would be `/opt/Altova/MapForceServer2020/bin/mapforceserver`. You can omit the `setServerPath` if you did not move the `MapForceServer.jar` from its default location.

Finally, the `run` method runs a mapping (.mfx file) that was compiled with MapForce (in this example, `TokenizeString.mfx`). On success, the program below generates a CSV file in the working directory. On error, the program attempts to print out the last execution message generated by MapForce Server.

```java
public class Program {
    public static void main(String[] args) {
        try {
            //Create a MapForce Server object

            //Set a working directory - used as a base for relative paths (you may need to adapt the path to the installation folder)
            objMFS.setWorkingDirectory( "C:\Program Files (x86)\Altova\MapForceServer2020\etc\Examples" );

            //Default path to the MapForce Server executable is the installation path (same dir with the MapForceServer.jar)
            //In case you copied the JAR file to a new location, you need to explicitly set the path to the .exe file
            objMFS.setServerPath( "C:\Program Files (x86)\Altova\MapForceServer2020\bin\MapForceServer.exe" );

            //Set global resource file and configuration, if your mapping uses global resources
            //objMFS.setOption( "globalresourcefile", "GlobalResource.xml" ); // "gr" can be used as short name for "globalresourcefile"
            //objMFS.setOption( "globalresourceconfig", "Default" ); // "gc" can be used as short name for "globalresourceconfig"

            //Prepare the parameters, if your design uses parameters
            //objMFS.addParameter( "testparam1", "value 1" );

            //Run the mapping; input and output paths are stored inside the MFX file
            //NOTE Please adapt the path to the input file in order to run the sample
```
```java
if ( objMFS.run( "C:\Program Files (x86)\Altova\MapForceServer2020\etc\Examples\TokenizeString.mfx" ) )
    System.out.println( "Success - finished execution" );
else
    System.out.println( objMFS.getLastExecutionMessage() );
}
catch ( Exception e)
{
    e.printStackTrace();
}
System.out.println( "Finished - exiting" );
```
5.4 API Reference (COM, .NET)

This section provides general reference to the MapForce Server API elements (such as interfaces and methods) applicable to code written for the COM or .NET platforms.

5.4.1 Interfaces

5.4.1.1 IServer

The IServer interface creates a new MapForce Server object instance, and provides access to the MapForce Server engine.

If you are using C++ under COM platform, the name of the main interface is IServer. If you are using a .NET language such as C# or VB.NET, the name of the main interface is Server.

Properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APIMajorVersion 69</td>
<td>Read-only. Gets the major version of the MapForce Server API. This can be different from the product version if the API is connected to another server.</td>

</tr>
<tr>
<td><strong>Run</strong></td>
<td>Executes a MapForce Server Execution file (.mfx file). Returns true in case of success; false otherwise.</td>
</tr>
<tr>
<td><strong>SetOption</strong></td>
<td>Sets an option before running the mapping. The first argument specifies the name of the option, while the second argument specifies the option value. This method is particularly useful when a mapping was designed to consume Global Resources (see Altova Global Resources). The currently supported options are as follows:</td>
</tr>
</tbody>
</table>

- **globalresourcefile (or gr)** - A Global Resource file path. (When this option is specified, then a Global Resource configuration name must also be specified, see next item).
- **globalresourceconfig (or gc)** - A Global Resource configuration name. (When this option is specified, then a Global Resource file path must also be specified, see previous item).
- **catalog** - The path to a custom RootCatalog.xml file. This option enables you to specify a custom catalog file used to resolve URLs used by the mapping. The default catalog is in the etc subdirectory of the program installation directory.
- **taxonomy-package** - The path to a custom XBRL taxonomy package, if one is required by the mapping.
- **taxonomy-packages-config-file** - The path to a custom XBRL taxonomy package configuration, if one is required by the mapping.

All set options are valid for the lifetime of the object. If you set an option with the same name twice, the previous option will be overridden. To explicitly clear all options, call the ClearOptions() method.

**Examples**
See the following examples that illustrate how to initialize and run MapForce Server in various languages:

- [C++ example](#)
- [C# example](#)
- [VBScript example](#)
- [VB.NET example](#)
5.4.1.1.1 Properties

5.4.1.1.1.1 APIMajorVersion

Gets the major version of the MapForce Server API. This can be different from the product version if the API is connected to another server.

**Signature**

APIMajorVersion : Integer

Generic signature

```
int APIMajorVersion { get; }
```

C#

```
HRESULT APIMajorVersion([out, retval] INT* pnVal);
```

C++

```
ReadOnly Property APIMajorVersion As Integer
```

VB.NET

5.4.1.1.1.2 APIMinorVersion

Gets the minor version of the MapForce Server API. This can be different from the product version if the API is connected to another server.

**Signature**

APIMinorVersion : Integer

Generic signature

```
int APIMinorVersion { get; }
```

C#

```
HRESULT APIMinorVersion([out, retval] INT* pnVal);
```

C++

```
ReadOnly Property APIMinorVersion As Integer
```
5.4.1.1.1.3  APIServicePackVersion

Gets the service pack version of the MapForce Server API. This can be different from the product version if the API is connected to another server.

Signature

APIServicePackVersion : Integer

Generic signature

int APIServicePackVersion { get; }

C#

HRESULT APIServicePackVersion([out, retval] INT* pnVal);

C++

ReadOnly Property APIServicePackVersion As Integer

VB.NET

5.4.1.1.1.4  Is64Bit

Returns true if the MapForce Server engine is a 64-bit executable.

Signature

Is64Bit : Boolean

Generic signature

bool Is64Bit { get; }

C#

HRESULT Is64Bit([out, retval] VARIANT_BOOL* pbVal);
### 5.4.1.1.5 LastExecutionMessage

Gets the message received during the last **Run** command.

**Signature**

```csharp
string LastExecutionMessage { get; }
```

### 5.4.1.1.6 MajorVersion

Gets the major version of the product, as number of years starting from 1998 (for example, "20" for Altova MapForce Server 2018).

**Signature**

```csharp
int MajorVersion { get; }
```
5.4.1.1.7 **MinorVersion**

Gets the minor version of the product (for example, "2" for Altova MapForce Server 2018 r2).

**Signature**

```c
MinorVersion : Integer
```

**Generic signature**

```c
int MinorVersion { get; }
```

5.4.1.1.8 **ProductName**

Gets the name of the product (for example, "Altova MapForce Server").

**Signature**

```c
ProductName : String
```

**Generic signature**

```c
string ProductName { get; }
```
C#

HRESULT ProductName([out, retval] BSTR* pstrVal);

C++

ReadOnly Property ProductName As String

VB.NET

5.4.1.1.1.9  ProductNameAndVersion

Gets the complete name and version of the product (for example, “Altova MapForce Server 2018 r2 sp1 (x64)”).

Signature

ProductNameAndVersion : String

Generic signature

string ProductNameAndVersion { get; }

C#

HRESULT ProductNameAndVersion([out, retval] BSTR* pstrVal);

C++

ReadOnly Property ProductNameAndVersion As String

VB.NET

5.4.1.1.1.10  ServerPath

Gets or sets the path of the MapForce Server executable.

Signature

ServerPath : String

Generic signature

string ServerPath { set; get; }
C#

HRESULT ServerPath([in] BSTR bstrServerFile );
HRESULT ServerPath([out, retval] BSTR* pbstrServerFile );

C++

Property ServerPath As String

VB.NET

5.4.1.1.11  ServicePackVersion

Gets the service pack version of the product (for example, "1" for Altova MapForce Server 2018 r2 sp1).

Signature

ServicePackVersion : Integer

Generic signature

int ServicePackVersion { get; }

C#

HRESULT ServicePackVersion([out, retval] INT* pnVal);

C++

ReadOnly Property ServicePackVersion As Integer

VB.NET

5.4.1.1.12  WorkingDirectory

Gets or sets the current directory for running jobs (relative paths will be evaluated against the working directory).

Signature

WorkingDirectory : String
5.4.1.1.2 Methods

5.4.1.1.2.1 AddCredentialProperty

Adds a property to the current credential (for example, the username, the password, or both). The first argument specifies the property name, and the second argument specifies the property value. Valid property names: username, password. In MapForce Server Advanced Edition, the property nameoauth:tokenis additionally supported.

This method must be called after calling BeginCredential() and before calling EndCredential().

Signature

AddCredentialProperty(in bstrName: System.String, in bstrValue: System.String) -> Void

Generic signature

void AddCredentialProperty(string bstrName, string bstrValue)
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bstrName</td>
<td>System.String</td>
<td>Specifies the name of the credential property.</td>
</tr>
<tr>
<td>bstrValue</td>
<td>System.String</td>
<td>Specifies the value of the credential property.</td>
</tr>
</tbody>
</table>

Examples

The following code listing illustrates how to declare a credential called "mycredential" in C#. The credential name must be the one given to the credential in MapForce at design time.

```csharp
//Create a MapForce Server object
objMFS.BeginCredential("mycredential");
objMFS.AddCredentialProperty("username", "altova");
objMFS.AddCredentialProperty("password", "b45ax78!");
objMFS.EndCredential();
```

**5.4.1.1.2.2 AddParameter**

Assigns a value to a parameter defined in the mapping. The first argument specifies the name of the parameter as defined on the mapping; the second argument specifies the parameter value.

**Signature**

AddParameter(in bstrName: String, in bstrValue: String) -> Void

Generic signature

void AddParameter(string bstrName, string bstrValue)

C#.

HRESULT AddParameter([in] BSTR bstrName, [in] BSTR bstrValue );

C++

Sub AddParameter(ByVal bstrName As String, ByVal bstrValue As String)
5.4.1.1.2.3  BeginCredential

Creates a new credential with the name supplied as argument. If you call this method, you must also add properties to it using AddCredentialProperty(), and finally close the credential by calling EndCredential().

**Signature**

```
BeginCredential(in bstrCredentialName: String) -> Void
```

**Generic signature**

```c
void BeginCredential(string bstrCredentialName)
```

**C#**

```c
HRESULT BeginCredential([in] BSTR bstrCredentialName);
```

**C++**

```c
Sub BeginCredential(ByVal bstrCredentialName As String)
```

**VB.NET**

```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bstrCredentialName</td>
<td>String</td>
<td>Specifies the name of the credential as it was defined in MapForce.</td>
</tr>
</tbody>
</table>

5.4.1.1.2.4  ClearCredentialList

Clears the list of credentials set previously. All credentials are valid for the lifetime of the object. Call this method if you need to explicitly clear all of the previously set credentials.
Signature

ClearCredentialList() -> Void

Generic signature

void ClearCredentialList()

C#

HRESULT ClearCredentialList();

C++

Sub ClearCredentialList()

VB.NET

5.4.1.2.5 ClearOptions

Clears the list of options previously set through the SetOption method. All options set through the SetOption method are valid for the lifetime of the object. Call this method if you need to explicitly clear all of the previously set options.

Signature

ClearOptions() -> Void

Generic signature

void ClearOptions()

C#

HRESULT ClearOptions();

C++

Sub ClearOptions()

VB.NET
5.4.1.1.2.6 ClearParameterList

Clears the list of parameters that were previously set using the AddParameter method.

**Signature**

```
ClearParameterList() -> Void
```

**Generic signature**

```
void ClearParameterList()
```

**C#**

```
HRESULT ClearParameterList();
```

**C++**

```
Sub ClearParameterList()
```

**VB.NET**

5.4.1.1.2.7 EndCredential

Closes a credential object that was previously created using the BeginCredential method.

**Signature**

```
EndCredential() -> Void
```

**Generic signature**

```
void EndCredential()
```

**C#**

```
HRESULT EndCredential();
```

**C++**

```
Sub EndCredential()
```

**VB.NET**

```
### 5.4.1.1.2.8 GetOutputParameter

Gets the string output generated by the last run command. Returns null if no output was generated. This function requires a string parameter which identifies the name of the output component in MapForce.

**Signature**

```plaintext
GetOutputParameter(in bstrName: String) -> String
```

**Generic signature**

```plaintext
string GetOutputParameter(string bstrName)
```

**C#**

```plaintext
HRESULT GetOutputParameter([in] BSTR bstrName, [out, retval] BSTR* pbstrValue );
```

**C++**

```plaintext
Function GetOutputParameter(bstrName As String) As String
```

**VB.NET**

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bstrName</td>
<td>String</td>
<td>Specifies the name of the output component as it appears in MapForce. This name is displayed in the title bar of each component on the mapping (or when you right-click the component header, and select Properties).</td>
</tr>
</tbody>
</table>

### 5.4.1.1.2.9 Run

Executes a MapForce Server Execution file (.mfx file). Returns true in case of success; false otherwise.

**Signature**

```plaintext
Run(in bstrMappingPath: String) -> Boolean
```

**Generic signature**
bool Run(string bstrMappingPath)

C#  

HRESULT Run( [in] BSTR bstrMappingPath, [out, retval] VARIANT_BOOL* pbSuccess );

C++

Function Run(ByVal bstrMappingPath As String) As Boolean

VB.NET

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bstrMappingPath</td>
<td>String</td>
<td>Specifies the path to the MapForce Server execution (.mfx) file. If you specify a relative path, then it will be resolved against the working directory. You can set the working directory from the WorkingDirectory property.</td>
</tr>
</tbody>
</table>

5.4.1.2.10 SetOption

Sets an option before running the mapping. The first argument specifies the name of the option, while the second argument specifies the option value. This method is particularly useful when a mapping was designed to consume Global Resources (see Altova Global Resources). The currently supported options are as follows:

- **globalresourcefile (or gr)** - A Global Resource file path. (When this option is specified, then a Global Resource configuration name must also be specified, see next item).
- **globalresourceconfig (or gc)** - A Global Resource configuration name. (When this option is specified, then a Global Resource file path must also be specified, see previous item).
- **catalog** - The path to a custom RootCatalog.xml file. This option enables you to specify a custom catalog file used to resolve URLs used by the mapping. The default catalog is in the etc subdirectory of the program installation directory.
- **taxonomy-package** - The path to a custom XBRL taxonomy package, if one is required by the mapping.
- **taxonomy-packages-config-file** - The path to a custom XBRL taxonomy package configuration, if one is required by the mapping.

All set options are valid for the lifetime of the object. If you set an option with the same name twice, the previous option will be overridden. To explicitly clear all options, call the ClearOptions() method.
**Signature**

```
SetOption(in bstrName: String, in bstrValue: String) -> Void
```

*Generic signature*

```
void SetOption(ByVal bstrName As String, ByVal bstrValue As String)
```

*C#*

```
HRESULT SetOption([in] BSTR bstrName, [in] BSTR bstrValue);
```

*C++*

```
Sub SetOption(ByVal bstrName As String, ByVal bstrValue As String)
```

*VB.NET*

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bstrName</td>
<td>String</td>
<td>Specifies the name of the option to set.</td>
</tr>
<tr>
<td>bstrValue</td>
<td>String</td>
<td>Specifies the value of the option to set.</td>
</tr>
</tbody>
</table>
5.5 API Reference (Java)

This section provides general reference to the MapForce Server API elements (such as classes and methods) applicable to code written for the Java platform.

5.5.1 Classes

5.5.1.1 MapForceServer

The MapForceServer class creates a new MapForce Server object instance, and provides access to the MapForce Server engine.

Methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addCredentialPropertiesFromMap</td>
<td>Adds properties from a credential property map to the current credential. This method takes as argument a credential property map (property_name, property_value). This method must be called after calling beginCredential() and before calling endCredential(). As an alternative to calling this method, you can also call AddCredentialProperty().</td>
</tr>
<tr>
<td>addCredentialProperty</td>
<td>Adds a property to the current credential (for example, the username, the password, or both). The first argument specifies the property name, and the second argument specifies the property value. Valid property names: username, password. In MapForce Server Advanced Edition, the property name oauth:token is additionally supported. This method must be called after calling beginCredential() and before calling endCredential(). As an alternative to calling this method, you can also call addCredentialProperty().</td>
</tr>
<tr>
<td>addParameter</td>
<td>Assigns a value to a parameter defined in the mapping.</td>
</tr>
<tr>
<td>beginCredential</td>
<td>Creates a new credential with the name supplied as argument. If you call this method, you must also add properties to it using addCredentialProperty() or addCredentialPropertiesFromMap(), and finally close the credential by calling endCredential().</td>

<td>All set options are valid for the lifetime of the object. If you set an option with the same name twice, the previous option will be overridden. To explicitly clear all options, call the <code>clearOptions()</code> method.</td>
</tr>
</tbody>
</table>

#### Examples

For an example of creating a new instance of MapForceServer in Java, see the [Java example](#).

### 5.5.1.1 Methods

#### 5.5.1.1.1 addCredentialPropertiesFromMap

Adds properties from a credential property map to the current credential. This method takes as argument a credential property map (`property_name, property_value`). This method must be called after calling `beginCredential()` and before calling `endCredential()`. As an alternative to calling this method, you can also call `AddCredentialProperty()`.
**addCredentialPropertiesFromMap**

signature:

```java
addCredentialPropertiesFromMap(arg0: Map) -> void
```

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>Map</td>
<td>A map that supplies the name of the credential property and its value.</td>
</tr>
</tbody>
</table>

**Examples**

The following code listing illustrates adding a credential called "mycredential" to the current context, using the `addCredentialPropertiesFromMap` method.

```java
//Create a MapForce Server object
objMFS.beginCredential("mycredential");
java.util.Map<String, String> credentialMap = new java.util.HashMap<String,String>();
credentialMap.put("username", "altova");
credentialMap.put("password", "b45ax78!");
objMFS.addCredentialPropertiesFromMap(credentialMap);
objMFS.endCredential();
```

### 5.5.1.1.1.2 addCredentialProperty

Adds a property to the current credential (for example, the username, the password, or both). The first argument specifies the property name, and the second argument specifies the property value. Valid property names: `username`, `password`. In MapForce Server Advanced Edition, the property name `oauth:token` is additionally supported.

This method must be called after calling `beginCredential()` and before calling `endCredential()`. As an alternative to calling this method, you can also call `addCredentialProperty()`.

**Signature**

```java
addCredentialProperty(arg0: String, arg1: String) -> void
```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>The name of the credential property (for example, &quot;username&quot; or &quot;password&quot;).</td>
</tr>
<tr>
<td>arg1</td>
<td>String</td>
<td>The value of the credential property.</td>
</tr>
</tbody>
</table>

Examples

The following code listing illustrates how to declare a credential called "mycredential". The credential name must be the one given to the credential in MapForce at design time.

```java
//Create a MapForce Server object
objMFS.beginCredential("mycredential");
objMFS.addCredentialProperty("username", "altova");
objMFS.addCredentialProperty("password", "b45ax78!" implication);  
objMFS.endCredential();
```

5.5.1.1.3 **addParameter**

Assigns a value to a parameter defined in the mapping.

**Signature**

```
addParameter(arg0: String, arg1: String) -> void
```

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>Specifies the parameter name.</td>
</tr>
<tr>
<td>arg1</td>
<td>String</td>
<td>Specifies the parameter value.</td>
</tr>
</tbody>
</table>

5.5.1.1.4 **beginCredential**

Creates a new credential with the name supplied as argument. If you call this method, you must also add properties to it using **addCredentialProperty()** or **addCredentialPropertiesFromMap()**, and finally close the credential by calling **endCredential()**.
Signature

```java
beginCredential(arg0: String) -> void
```

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>The name of the credential as it was defined in MapForce.</td>
</tr>
</tbody>
</table>

5.5.1.1.1.5 clearCredentialList

Clears the list of credentials set previously. All credentials are valid for the lifetime of the object. Call this method if you need to explicitly clear all of the previously set credentials.

Signature

```java
clearCredentialList() -> void
```

5.5.1.1.1.6 clearOptions

Clears the list of options previously set through the setOption() method. All options set through the setOption method are valid for the lifetime of the object. Call this method if you need to explicitly clear all of the previously set options.

Signature

```java
clearOptions() -> void
```

5.5.1.1.1.7 clearParameterList

Clears the list of parameters that were previously set using the addParameter method.

Signature

```java
clearParameterList() -> void
```
5.5.1.1.1.8  endCredential
Closes a credential object that was previously created using the `beginCredential` method.

Signature
```
endCredential() -> void
```

5.5.1.1.1.9  getAPIMajorVersion
Gets the major version of the MapForce Server API. This can be different from the product version if the API is connected to another server.

Signature
```
getAPIMajorVersion() -> int
```

5.5.1.1.1.10  getAPIMinorVersion
Gets the minor version of the MapForce Server API. This can be different from the product version if the API is connected to another server.

Signature
```
getAPIMinorVersion() -> int
```

5.5.1.1.1.11  getAPIServicePackVersion
Gets the service pack version of the MapForce Server API. This can be different from the product version if the API is connected to another server.

Signature
```
getAPIServicePackVersion() -> int
```

5.5.1.1.1.12  getLastExecutionMessage
Gets the message received during the last `run` command.

Signature
```
getLastExecutionMessage() -> java.lang.String
```
5.5.1.1.1.13  getMajorVersion

Gets the major version of the product, as number of years starting from 1998 (for example, "20" for Altova MapForce Server 2018).

Signature

getMajorVersion() -> int

5.5.1.1.1.14  getMinorVersion

Gets the minor version of the product (for example, "2" for Altova MapForce Server 2018 r2).

Signature

getMinorVersion() -> int

5.5.1.1.1.15  getOutputParameter

Gets the string output generated by the last run command. Returns null if no output was generated. This function requires a string parameter which identifies the name of the output component in MapForce.

Signature

ggetOutputParameter(arg0: String) -> java.lang.String

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>Specifies the name of the output component as it appears in MapForce. This name is displayed in the title bar of each component on the mapping (or when you right-click the component header, and select Properties).</td>
</tr>
</tbody>
</table>

5.5.1.1.1.16  getProductName

Gets the name of the product (for example, "Altova MapForce Server").
5.5.1.1.17  **getProductNameAndVersion**

Gets the complete name and version of the product (for example, "Altova MapForce Server 2018 r2 sp1 (x64)").

Signature

```java
getProductNameAndVersion() \rightarrow java.lang.String
```

5.5.1.1.18  **getServicePackVersion**

Gets the service pack version of the product (for example, "1" for Altova MapForce Server 2018 r2 sp1 (x64)).

Signature

```java
getServicePackVersion() \rightarrow int
```

5.5.1.1.19  **is64bit**

Returns **true** if the MapForce Server engine is a 64-bit executable.

Signature

```java
is64bit() \rightarrow boolean
```

5.5.1.1.20  **run**

Executes a MapForce Server Execution file (.mfx file). Returns **true** in case of success; **false** otherwise.

Signature

```java
run(arg0: String) \rightarrow boolean
```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>Specifies the path to the MapForce Server Execution file (.mfx file). If you specify a relative path, then it will be resolved against the working directory. You can set the working directory by calling the setWorkingDirectory method.</td>
</tr>
</tbody>
</table>

5.5.1.1.1.21  setOption

Sets an option before running the mapping. The first argument specifies the name of the option, while the second argument specifies the option value. This method is particularly useful when a mapping was designed to consume Global Resources (see Altova Global Resources). The currently supported options are as follows:

- **globalresourcefile (or gr)** - A Global Resource file path. (When this option is specified, then a Global Resource configuration name must also be specified, see next item).
- **globalresourceconfig (or gc)** - A Global Resource configuration name. (When this option is specified, then a Global Resource file path must also be specified, see previous item).
- **catalog** - The path to a custom RootCatalog.xml file. This option enables you to specify a custom catalog file used to resolve URLs used by the mapping. The default catalog is in the etc subdirectory of the program installation directory.
- **taxonomy-package** - The path to a custom XBRL taxonomy package, if one is required by the mapping.
- **taxonomy-packages-config-file** - The path to a custom XBRL taxonomy package configuration, if one is required by the mapping.

All set options are valid for the lifetime of the object. If you set an option with the same name twice, the previous option will be overridden. To explicitly clear all options, call the clearOptions() method.

Signature

```
setOption(arg0: String, arg1:String) -> void
```

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>Specifies the name of the option to set.</td>
</tr>
<tr>
<td>arg1</td>
<td>String</td>
<td>Specifies the value of the option to set.</td>
</tr>
</tbody>
</table>
5.5.1.1.1.22  setServerPath

Sets the path of the MapForce Server executable.

**Signature**

```
setServerPath(arg0: String) -> void
```

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>Specifies the path to the MapForce Server executable.</td>
</tr>
</tbody>
</table>

5.5.1.1.1.23  setWorkingDirectory

Sets the current directory for running jobs (relative paths will be evaluated against the working directory).

**Signature**

```
setWorkingDirectory(arg0: String) -> void
```

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg0</td>
<td>String</td>
<td>Specifies the path to the working directory.</td>
</tr>
</tbody>
</table>

5.5.1.2  MapForceServerException

The MapForceServerException class provides programmatic access to exceptions thrown by the MapForceServer class.

```
public class MapForceServerException extends Exception
```
Digital Certificate Management

Digital certificate management is an integral part of secure data exchange between a client computer and a Web server. Since mappings can be executed not only on Windows by MapForce, but also on a Windows, Linux or macOS server by MapForce Server (either standalone or in FlowForce Server execution), this section deals with managing HTTPS certificates on various platforms.

In the context of secure HyperText Transport Protocol (HTTPS), it is important to distinguish between server and client certificates.

Server certificates
A server certificate is what identifies a server as a trusted entity to a client application such as MapForce. The server certificate may be digitally signed by a commercial Certificate Authority, or it may be self-signed by your organization. In either case, while designing the mapping in MapForce, you can specify the following settings:

- Whether the server certificate must be checked.
- Whether the request must proceed if a mismatch has been detected between the name certificate and the name of the host.

These settings are available on the HTTP Security Settings dialog box of MapForce. When you enable server certificate checks, consider the following:

- If you are calling a Web server whose certificate is signed by a trusted Certificate Authority, your operating system will likely be already configured to trust the server certificate, and no additional configuration is necessary.
- If you are calling a Web server which provides a self-signed certificate (for example, a local network server within your organization), you will need to configure your operating system as well to trust that certificate.

In most cases, you can check the level of trust between your operating system and the Web server by typing the URL of the Web service in the browser's address bar. If the server is not trusted, or if your operating system is not configured to trust the server, your browser will display a message such as "This connection is untrusted", or "There is a problem with this website's certificate". Note that you cannot use the browser to check the level of trust with a Web server if the browser uses a certificate database other than that of the operating system (for example, Firefox 35.0.1 on Ubuntu 14.04).

On Windows, you can establish trust with the server by following the browser's instructions and importing or installing the required certificates into your system's Trusted Root Authorities store (see Trusting Server Certificates on Windows). On macOS, you can do the equivalent operation in Keychain Access (see Trusting Server Certificates on macOS). For instructions applicable to Linux, see Trusting Server Certificates on Linux.

Client certificates
While server certificates are used to identify a server as a trusted entity, client certificates are primarily used to authenticate the caller against the Web server. If you intend to call a Web server which requires client certificates, you may need to contact the administrator of the Web server for the client configuration instructions. Taking IIS (Internet Information Services) as an example, the Web server may be configured to handle HTTPS and client certificates in one of the following ways:
- Require HTTPS and ignore client certificate
- Require HTTPS and accept client certificate
- Require HTTPS and require client certificate

The success or failure of the Web service request depends both on the configuration of the Web server and the client application. For example, if the Web server is configured to require a client certificate, then, for the call to be successful, the calling application must present a valid client certificate.

From a MapForce perspective, the same is true for mappings which include Web service calls through HTTPS. In particular, to run such mappings successfully, it is assumed that the Web server has been configured to accept or require the client certificate, and that the operating system where the mapping runs provides the correct client certificate to the Web server.

The diagram below illustrates a scenario where a client certificate used in MapForce is transferred to a Linux server running MapForce Server. Once the certificate has been transferred to the target operating system, MapForce Server can use it to authenticate itself against the Web server and execute the mapping successfully.

Deploying mappings with client certificates to another computer

For HTTPS authentication in Web service calls, MapForce is capable of using Transport Layer Security (TLS) on top of HTTP, which is the successor of Secure Sockets Layer (SSL) protocol. Note that fallback to SSL may occur if either the client implementation or the server does not support TLS.

To support Web calls with client certificate authentication on multiple platforms, MapForce (and MapForce Server) relies on the certificate management implementation of each platform, thus ensuring that certificate management is always in the scope of the underlying operating system. Each operating system provides different support for certificate management, as shown in the table below.
Digital Certificate Management

<table>
<thead>
<tr>
<th>Platform</th>
<th>Certificate management and implementation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>On Windows, you can manage certificates using the Certificate snap-in (see Accessing the Certificate Stores on Windows). TLS support is available through the Secure Channel (also known as SChannel) library.</td>
</tr>
<tr>
<td>Linux</td>
<td>On Linux, you can manage certificates using the OpenSSL (openssl) command line tool and library. If OpenSSL support is not already available on the Linux machine where MapForce Server is installed, you will need to download and install it before you can manage certificates. TLS support is available through the OpenSSL library (<a href="https://www.openssl.org/">https://www.openssl.org/</a>).</td>
</tr>
<tr>
<td>macOS</td>
<td>On macOS, you can manage certificates using the Keychain Access Manager, located under Finder &gt; Applications &gt; Utilities. TLS support is provided by the Secure Transport library native to the operating system.</td>
</tr>
</tbody>
</table>

If you execute the mapping on a Windows operating system where you can already successfully consume the same Web service that you intend to call from MapForce, no additional certificate configuration is normally required (for the conditions to run the mapping successfully on Windows, see Client Certificates on Windows). However, if you design mappings with MapForce on a Windows computer, and then deploy them to another computer (which may run a different operating system), the client certificate is not stored or copied together with the deployed package. For the Web service call (and the mapping) to execute successfully, the client certificate must exist on the target operating system as well.

To transfer a certificate from a Windows system to another Windows-based computer, export the required certificate (with private key) from the source system (see Exporting Certificates from Windows). Then import the same certificate to the Current User\Personal store on the target operation system (see Client Certificates on Windows).

For instructions on how to transfer client certificates to the Linux and macOS platforms, see Client Certificates on Linux and Client Certificates on macOS, respectively.
Trusting Server Certificates on Linux

On Linux, you can import a trusted certificate into the system's certificate store as shown below.

Perform the following steps only if you are sure of the authenticity of the certificate you want to trust.

On Debian and Ubuntu, follow the steps below:

1. Copy the certificate file of the Web server to the following directory.
   
   ```bash
   sudo cp /home/downloads/server_cert.crt /usr/local/share/ca-certificates/
   ```

2. Update the certificate store as follows:
   
   ```bash
   sudo update-ca-certificates
   ```

On CentOS, follow the steps below:

1. Install the `ca-certificates` package:
   
   ```bash
   yum install ca-certificates
   ```

2. Enable the dynamic certificate authority configuration feature:
   
   ```bash
   update-ca-trust enable
   ```

3. Copy the server certificate to the following directory:
   
   ```bash
   cp server_cert.crt /etc/pki/ca-trust/source/anchors/
   ```

4. Use the command:
   
   ```bash
   update-ca-trust extract
   ```

For cases where you need to access the server only through the browser, it is sufficient to import the certificate into the browser certificate store. The exact instructions will vary for each browser. For example, in Firefox 59.0.2, you can do this as follows:

1. Under **Options | Privacy & Security**, click **View Certificates**.
2. On **Authorities** tab, click **Import** and browse for the root certificate file created previously.
3. When prompted, select **Trust this CA to identify websites**.
You have been asked to trust a new Certificate Authority (CA).

Do you want to trust "ODIN CA" for the following purposes?

- [x] Trust this CA to identify websites.
-  [ ] Trust this CA to identify email users.
-  [ ] Trust this CA to identify software developers.

Before trusting this CA for any purpose, you should examine its certificate and its policy and procedures (if available).

[View] Examine CA certificate

[Cancel]  [OK]
6.2  Trusting Server Certificates on macOS

On macOS, you can import a trusted certificate into Keychain Access as follows.

1. Run Keychain Access.
2. Click **System**, and then click **Certificates**.
3. On the **File** menu, click **Import Items**.
4. Browse for the trusted certificate, and click **Open**.
5. Enter the Keychain Access password when prompted, and then click **Modify Keychain**.
6. Double-click the certificate, expand the **Trust** section, and select **Always Trust**.
6.3 Trusting Server Certificates on Windows

On Windows, you can import a trusted certificate into the system certificates store as follows:

1. Open the Windows certificate store for the computer account, see Accessing Windows Certificate Store.

Perform the following steps only if you are sure of the authenticity of the Web server certificate.

2. Under "Trusted Root Certification Authorities", right-click Certificates, and select All Tasks | Import, and follow the certificate import wizard.

For more information, see https://technet.microsoft.com/en-us/library/cc754489(v=ws.11).aspx.
6.4 Accessing the Certificate Stores on Windows

On Windows, you can manage certificates from the Microsoft Management Console (MMC) snap-in, either for your user account, or for the computer account.

To open the Certificates snap-in (for the current Windows user):

- Run `certmgr.msc` at the command line.

To open the Certificates snap-in (for the computer account):

1. Run `mmc` at the command line.
2. On the **File** menu, click **Add/Remove Snap-in**.
3. Click **Certificates**, and then click **Add**.

4. Click **Computer account**, and click **Next**.
5. Click **Local computer**, and then click **Finish**.
6.5 Exporting Certificates from Windows

For mappings that call Web services through HTTPS and are deployed to a macOS or Linux server running MapForce Server or FlowForce Server, the same client certificate must be available on the non-Windows operating system as the one used on Windows to design and test the mapping. To execute such mappings on a non-Windows operating system with MapForce Server, export the required certificate with private key from Windows and then import it into the target operating system.

To export a certificate with private key from Windows:

1. On Windows, open the Certificates snap-in (see Accessing the Certificate Stores on Windows).
2. Right-click the certificate that you want to export, point to All Tasks, and then click Export.
3. Click Next.
4. Choose to export from Windows the certificate together with its private key, and then click Next.
5. Choose the *Personal Information Exchange - PKCS #12 (.pfx)* file format, and then click **Next**.
Note: Make sure not to select the option **Delete the private key if the export is successful**, otherwise you will not be able to make use of the certificate after it is exported.

6. Enter a password, and then click **Next**. You will need this password after you copy the certificate to the target operating system.
7. Browse for the location of the file to export, and then click **Next**.
8. Click **Finish**.
Completing the Certificate Export Wizard

You have successfully completed the Certificate Export wizard.

You have specified the following settings:

- **File Name**: C: Users
- **Export Keys**: Yes
- **Include all certificates in the certification path**: Yes
- **File Format**: Personal Information Exchange (PFX)

![Certificate Export Wizard dialog box](image)
6.6 Client Certificates on Linux

If your mappings include Web service authentication through HTTPS by means of client certificates, follow these steps to deploy such mappings to a Linux machine running MapForce Server:

1. Open in MapForce the mapping which calls the Web service.
2. Double-click the header of the Web Service component. The Component Settings dialog box appears.
3. Click Edit next to HTTP Security Settings.
4. In the HTTP Security Settings dialog box, click Client Certificate, and then select the required certificate from the Current User/Personal store on Windows.
5. Save the mapping and compile it to a mapping execution file or deploy it to FlowForce Server.
6. Transfer the client certificate required by the Web service call to the target operating system. Make sure that the certificate has a private key, and that the Enhanced Key Usage property of the certificate includes "Client authentication" as purpose.

To transfer the client certificate to Linux:

1. Export the client certificate with private key from Windows, in the Personal Information Exchange - PKCS #12 (.pfx) file format (see Exporting Certificates from Windows).
2. Copy the certificate file to the Linux machine.
3. Convert the .pfx file to .pem format using the command:

   ```bash
   openssl pkcs12 -in cert.pfx -out "John Doe.pem" -nodes
   ```

   This command parses the .pfx file and outputs a .pem file, without encrypting the private key. Certificates with an encrypted private key prompt for password and are not supported in server execution.

Executing the mapping

To instruct MapForce Server to use the .pem file as client certificate, set the --certificatespath parameter when running the mapping. The --certificatespath parameter defines the path of the directory where all certificates required by the current mapping are stored. For example, if the certificate file path is /home/John/John Doe.pem, then --certificatespath must be set to /home/John.

By default, if the --certificatespath parameter is not provided, MapForce Server looks for certificates in the directory $HOME/.config/altova/certificates of the current user.

For the mapping to execute successfully, the certificate file is expected to have the .pem extension and the file name must match the Common Name (CN) of the certificate, including spaces (for example, John Doe.pem). If the CN contains a forward slash (/), it must be replaced with an underscore (_) character.

If you intend to execute the mapping as a FlowForce Server job, copy the certificate file to the $HOME/.config/altova/certificates directory. When running the job, FlowForce Server will use this directory to look for any certificate files required by the mapping.

For security considerations, make sure that certificate files are not readable by other users, since they
contain sensitive information.
6.7 Client Certificates on macOS

If your mappings include Web service authentication through HTTPS client certificates, follow these steps to deploy such mappings to a macOS running MapForce Server:

1. Open in MapForce the mapping which calls the Web service.
2. Double-click the header of the Web Service component. The Component Settings dialog box appears.
3. Click Edit next to HTTP Security Settings.
4. In the HTTP Security Settings dialog box, click Client Certificate, and then select the required certificate.
5. If the certificate name does not match exactly the host name of the server, select Allow name mismatch between certificate and request.
6. Save and deploy the mapping to the target operating system.
7. Transfer the client certificate required by the Web service call to the target operating system. Make sure that the certificate has a private key, and that the Enhanced Key Usage property of the certificate includes "Client authentication" as purpose.

To transfer the client certificate to macOS:

1. Export the client certificate with private key from Windows, in the Personal Information Exchange - PKCS #12 (.pfx) file format (see Exporting Certificates from Windows) and copy the .pfx file to the macOS.
2. If this hasn't been done already, make sure that the operating system trusts the server certificate (see Trusting Server Certificates on Mac OS).
4. On the File menu, click Import Items.
5. Browse for the the client certificate exported from Windows in step 1 and select a destination keychain.
6. Click Open and enter the password with which the certificate was encrypted.

Executing the mapping

You are now ready to run the mapping using the MapForce Server run command. Note the following:

- If you execute the mapping remotely through SSH, first unlock the keychain with the security unlock-keychain command.
- If you execute the mapping through the macOS graphical user interface, when prompted to allow MapForce Server access to the keychain, click Allow.
mapforceserver wants to sign using key "privateKey" in your keychain.

The authenticity of "mapforceserver" cannot be verified. Do you want to allow access to this item?

- Always Allow
- Deny
- Allow
6.8 Client Certificates on Windows

When you run on Windows a mapping which requires client certificates, the conditions to run the mapping successfully are as follows:

- The client certificate must exist in the **Current User\Personal** certificate store (also referred to as the **My** store). For the certificate to exist in this store, it must be imported through the Certificate Import Wizard. For instructions, see [https://technet.microsoft.com/en-us/library/cc754489(v=ws.11).aspx](https://technet.microsoft.com/en-us/library/cc754489(v=ws.11).aspx).
- The certificate must have a private key.
- The **Enhanced Key Usage** property of the certificate must include "Client authentication" as purpose.

In the current version of MapForce, due to a limitation of the library used by MapForce, Windows will select the required certificate automatically from the certificate store when you run the mapping. The mapping will execute successfully if, after filtering the **Current User\Personal** certificate store, the server finds a suitable certificate. Note that the HTTPS authentication (and the certificate selection operation) is managed by Windows and is not controlled by MapForce or MapForce Server. In some cases, if multiple certificates exist in the **Current User\Personal** store, an unsuitable certificate may be selected automatically by the operating system, which causes the mapping execution to fail. This situation can be avoided by limiting the number of certificates.
available in the **Current User\Personal** store.
