Index
1 **About RaptorXML+XBRL Server**

*Altova RaptorXML+XBRL Server* (hereafter also called RaptorXML for short) is Altova’s third-generation, hyper-fast XML and XBRL* processor. It has been built to be optimized for the latest standards and parallel computing environments. Designed to be highly cross-platform capable, the engine takes advantage of today’s ubiquitous multi-core computers to deliver lightning fast processing of XML and XBRL data.

*Note:* XBRL processing is available only in RaptorXML+XBRL Server, not in RaptorXML Server.

**Altova website:** [XML validation server](https://www.altova.com/xmldiag), [XML validator](https://www.altova.com/xmlval)

### Editions and operating systems

There are two editions of RaptorXML, each suitable for a different set of requirements. These editions are described in the section Editions and Interfaces. RaptorXML is available for Windows, Linux, and macOS. For more details of system support, see the section System Requirements.

### Features and supported specifications

RaptorXML provides XML and XBRL validation, XSLT transformations, and XQuery executions, each with a wide range of powerful options. See the section Features for a broad list of available functionality and key features. The section Supported Specifications provides a detailed list of the specifications to which RaptorXML conforms. For more information, visit the RaptorXML page at the Altova website.

### XBRL certification

RaptorXML+XBRL Server has been [XBRL-certified by XBRL International](https://www.xbrl.org) (see here for details). For more information about XBRL certification, see [XBRL Software Certification](https://www.xbrl.org).

### This documentation

This documentation is delivered with the application and is also available online at the Altova website. Note that the Chrome browser has a limitation that prevents entries in the Table of Contents (TOC) pane expanding when the documentation is opened locally. The TOC in Chrome functions correctly, however, when the documentation is opened from a webserver.

This documentation is organized into the following sections:

- [About RaptorXML (this section)]
- Setting Up RaptorXML
- Command Line Interface
- Server APIs: HTTP, COM/.NET, Java
- Engine APIs: Python and .NET
- Additional Information
- Engine Information
- Altova LicenseServer

Last updated: 29 April 2019
1.1 Editions and Interfaces

Editions

RaptorXML is available in the following editions:

- **RaptorXML Server**, which is a fast server-based XML processing engine for the validation and processing of XML, XML Schema, XML Signature, XSLT, and XQuery documents.
- **RaptorXML+XBRL Server**, which provides all the functionality of RaptorXML Server plus a wide range of XBRL processing functionality.

See [here](#) for a list of the supported specifications.

Interfaces

After you install RaptorXML, you can access it in one or more of the following ways:

- **Command Line Interface (CLI)**: available for Windows, Linux, and macOS installations of RaptorXML
- **HTTP REST client interface**: uses RaptorXML's HTTP interface
- **COM/.NET server interface (Windows)**: uses RaptorXML's (i) COM/.NET API and (ii) HTTP REST interface
- **Java server interface (Windows, Linux, macOS)**: uses RaptorXML's (i) Java API and (ii) HTTP REST interface
- **Altova XMLSpy interface**: RaptorXML can be accessed from within the Altova XMLSpy user interface
- **Python engine interface**: uses (i) a RaptorXML Python-wheel in your Python environment and (ii) the Python API of RaptorXML in your Python script. In this way, RaptorXML functionality can be used in Python scripts together with third-party Python packages
- **.NET engine interface (Windows)**: uses (i) a RaptorXML DLL and (ii) the .NET API of RaptorXML to create independent .NET applications that use RaptorXML functionality

These seven interfaces can be organized into four groups:

- **Command Line Interface (CLI)**
- **Server APIs**: HTTP, COM/.NET, Java
- **Engine APIs**: Python and .NET
- **Altova XMLSpy**

**CLI, Server APIs, and Altova XMLSpy**

Access via the CLI, the Server APIs, and Altova XMLSpy can be visualized as in the figure below.

RaptorXML+XBRL Server defines an HTTP REST interface, which is used by clients to dispatch validation jobs to the server. Clients can either access the HTTP REST interface directly or use the high-level COM/.NET and Java Server APIs. These APIs provide easy to use COM/.NET and Java classes which manage the creation and dispatch of the HTTP REST requests. Additionally, Altova XMLSpy can be configured to run validation jobs on a remote RaptorXML+XBRL Server.
Command line interface (CLI)

- RaptorXML is licensed on the machine on which it is installed and this instance is accessed via the command line
- Can be installed on Windows, Linux, and macOS
- Provides command line usage for validation and processing of XML, XML Schema, XML Signature, XBRL, XQuery, and XSLT documents
- Python 3.5 is bundled in RaptorXML and will be used when a Python script is invoked with the --script option

HTTP REST client interface

- RaptorXML is licensed on the machine on which it is installed and this instance is accessed via an HTTP REST client interface
- Client requests are made in JSON format. Each request is assigned a job directory on the server, in which output files are saved. Server responses to the client include all relevant information about the job.
- Python 3.5 is bundled in RaptorXML and will be used when a Python script is invoked with the --script option

COM/.NET interface

- Available on Windows only
- RaptorXML is automatically registered as a COM server object when installed, and so can be invoked from within applications and scripting languages that have programming support for COM calls
- RaptorXML is licensed on the machine on which it is installed
- The .NET interface is built as a wrapper around the COM interface
The **COM/.NET Server API** of RaptorXML provides objects that can be used in COM/.NET scripting languages to access RaptorXML functionality.

Python 3.5 is bundled in RaptorXML and will be used when a Python script is invoked with the `--script` option.

**Java interface**

- RaptorXML is licensed on the machine on which it is installed and this instance is accessed via a Java program.
- RaptorXML functionality is available in the **Java Server API** as Java classes that can be used in Java programs.
- Python 3.5 is bundled in RaptorXML and will be used when a Python script is invoked with the `--script` option.

**Altova XMLSpy**

- If you have installed and licensed Altova XMLSpy and if XMLSpy can access RaptorXML+XBRL Server across a network, then you can use RaptorXML+XBRL Server from within the XMLSpy GUI to validate XML and XBRL documents, as well as run XSLT and XQuery transformations.
- You can validate the active document or all the documents in an XMLSpy project folder.
- The validation results are displayed in the Messages window of the XMLSpy GUI.
- In XMLSpy, you can (i) validate documents or (ii) run XSLT/XQuery transformation by using either XMLSpy's engines or RaptorXML Server.
- One of the main advantages of using Raptor is that you can configure individual validations by means of a large range of validation options. Furthermore, you can store a set of Raptor options as a "configuration" in XMLSpy, and then select one of your defined configurations for a particular Raptor validation. Using Raptor is also advantageous when large data collections are to be validated.

**Engine APIs**

The **Engine APIs** are different than the Server APIs in that RaptorXML is contained in the Python wheel and in the .NET DLL that are used, respectively, by Python programs and .NET applications (see figure below). These programs/applications must use, respectively, Raptor's **Python API** and Raptor's **.NET API** in order to access RaptorXML functionality.

**Note:** The functionality provided by the **Python API** and the **.NET API** are considerably greater than that provided by either the CLI or the Server APIs; for example, the ability to read documents and manipulate data.
**Python interface**

- RaptorXML is available in a Python wheel package that can be installed in your Python 3.5 environment.
- A Python program can then be written that uses objects from RaptorXML's Python API. This API provides much more functionality than is available in the CLI, and it can be combined with the functionality provided by third-party libraries in your Python environment.
- When RaptorXML functionality is called via RaptorXML's Python wheel, a check is carried out for a valid RaptorXML license on that machine before the command is executed.

**.NET interface**

- RaptorXML is available in a DLL that can be embedded in an application that supports the .NET Framework. See the section .NET Framework API for information about the API.
- RaptorXML's .NET API provides access to RaptorXML. The available functionality is much more than that which is available in the RaptorXML CLI.
- When RaptorXML functionality is called via a .NET application, a check is carried out for a valid RaptorXML license on that machine.
1.2 System Requirements

RaptorXML+XBRL Server is supported on the following operating systems:

- **Windows**
  - Windows 7 SP1 with Platform Update, Windows 8, Windows 10

- **Windows Server**
  - Windows Server 2008 R2 SP1 with Platform Update or newer

- **Linux**
  - CentOS 6 or newer
  - RedHat 6 or newer
  - Debian 8 or newer
  - Ubuntu 14.04 or newer

The following libraries are required as a prerequisite to install and run the application. If the packages below are not already available on your Linux machine, run the command `yum` (or `apt-get` if applicable) to install them.

<table>
<thead>
<tr>
<th>Required by</th>
<th>CentOS, RedHat</th>
<th>Debian</th>
<th>Ubuntu</th>
</tr>
</thead>
<tbody>
<tr>
<td>LicenseServer</td>
<td>krb5-libs</td>
<td>libgssapi-krb5-2</td>
<td>libgssapi-krb5-2</td>
</tr>
<tr>
<td>RaptorXML+XBRL Server</td>
<td>qt4, krb5-libs, qt-x11</td>
<td>libqtcore4, libqtdui4, libgssapi-krb5-2</td>
<td>libqtcore4, libqtdui4, libgssapi-krb5-2</td>
</tr>
</tbody>
</table>

**Note:** If you plan to use Altova’s Charts functionality, then at least one font must be installed on your system to ensure that charts will be rendered correctly. To list installed fonts, use, for example, the `fc-list` command of the Fontconfig library.

**Note:** On newly installed Ubuntu server 18.04.1 LTS, it was found that the `universe` repository needed to be enabled to apt (using the command: `sudo add-apt-repository universe`). Installation of `libqtdui4` was possible after this update.

- **macOS**
  - macOS 10.12 or newer

RaptorXML is available for both 32-bit and 64-bit machines. Specifically these are x86 and amd64 (x86-64) instruction-set based cores: Intel Core i5, i7, XEON E5. To use RaptorXML via a COM interface, users should have privileges to use the COM interface, that is, to register the application and execute the relevant applications and/or scripts.
1.3 Features

RaptorXML provides the functionality listed below. Most functionality is common to command line usage and COM interface usage. One major difference is that COM interface usage on Windows allows documents to be constructed from text strings via the application or scripting code (instead of referencing XML, XBRL, DTD, XML Schema, XSLT, or XQuery files).

**XML and XBRL Validation**

- Validates the supplied XML or XBRL document against internal or external DTDs or XML Schemas
- Checks well-formedness of XML, DTD, XML Schema, XSLT, and XQuery documents
- Validates XBRL taxonomies, and XBRL documents against XBRL taxonomies
- Execution of XBRL Formulas and Validation Assertions
- Rendering of XBRL tables
- Support for the XBRL 2.1, Dimensions 1.0, and Formula 1.0 specifications, and the Table Linkbase 1.0
- Support for Inline XBRL
- Support for XBRL Taxonomy Packages

**XSLT Transformations**

- Transforms XML using supplied XSLT 1.0, 2.0, or 3.0 document
- XML and XSLT documents can be provided as a file (via a URL) or, in the case of COM usage, as a text string
- Output is returned as a file (at a named location) or, in the case of COM usage, as a text string
- XSLT parameters can be supplied via the command line and via the COM interface
- Altova extension functions, as well as XBRL, Java and .NET extension functions, enable specialized processing. This allows, for example, the creation of such features as charts and barcode in output documents

**XQuery Execution**

- Executes XQuery 1.0 and 3.0 documents
- XQuery and XML documents can be provided as a file (via a URL) or, in the case of COM usage, as a text string
- Output is returned as a file (at a named location) or, in the case of COM usage, as a text string
- External XQuery variables can be supplied via the command line and via the COM interface
- Serialization options include: output encoding, output method (that is, whether the output is XML, XHTML, HTML, or text), omitting the XML declaration, and indentation

**JSON and Avro Validation/Conversion**

- Validation of JSON schema and Avro schema documents
- Validation JSON instances against JSON schemas and Avro schemas
• Validation of Avro binaries
• Conversion of Avro binaries to Avro schema and Avro data in JSON format
• Conversion of Avro JSON data to Avro binary

Hyper-performance Features

• Ultra-high performance code optimizations
  ◦ Native instruction-set implementations
  ◦ 32-bit and 64-bit version
• Ultra-low memory footprint
  ◦ Extremely compact in-memory representation of XML Information Set
  ◦ Streaming instance validation
• Cross platform capabilities
• Highly scalable code for multi-CPU/multi-core/parallel computing
• Parallel loading, validation, and processing by design

Developer Features

• Superior error reporting capabilities
• Windows server mode and Unix daemon mode (via command-line options)
• Python 3.x interpreter for scripting included
• RaptorXML functionality in a Python package enables import of the functionality as a Python library
• .NET Framework API allows access to underlying XML and XBRL data model
• COM API on Windows platform
• Java API everywhere
• XPath Extension functions Java, .NET, XBRL, and more
• Streaming serialization
• Built-in HTTP server with REST validation API

For more information, see the section Supported Specifications and the Altova website.
1.4 Supported Specifications

RaptorXML supports the following specifications.

W3C Recommendations
Website: World Wide Web Consortium (W3C)

- Extensible Markup Language (XML) 1.0 (Fifth Edition)
- Extensible Markup Language (XML) 1.1 (Second Edition)
- Namespaces in XML 1.0 (Third Edition)
- Namespaces in XML 1.1 (Second Edition)
- XML Information Set (Second Edition)
- XML Base (Second Edition)
- XML Inclusions (XInclude) Version 1.0 (Second Edition)
- XML Linking Language (XLink) Version 1.0
- W3C XML Schema Definition Language (XSD) 1.1 Part 1: Structures
- W3C XML Schema Definition Language (XSD) 1.1 Part 2: Datatypes
- XPointer Framework
- XPointer xmlns() Scheme
- XPointer element() Scheme
- XML Path Language (XPath) Version 1.0
- XSL Transformations (XSLT) Version 1.0
- XML Path Language (XPath) 2.0 (Second Edition)
- XSL Transformations (XSLT) Version 2.0
- XQuery 1.0: An XML Query Language (Second Edition)
- XQuery 1.0 and XPath 2.0 Functions and Operators (Second Edition)
- XSLT 2.0 and XQuery 1.0 Serialization (Second Edition)
- XML Path Language (XPath) 3.0
- XML Path Language (XPath) 3.1
- XQuery 3.0: An XML Query Language
- XQuery Update Facility 1.0
- XPath and XQuery Functions and Operators 3.0
- XSLT and XQuery Serialization 3.0

W3C Working Drafts & Candidate Recommendations
Website: World Wide Web Consortium (W3C)

- XSL Transformations (XSLT) Version 3.0 (subset)
- XQuery 3.1: An XML Query Language
- XPath and XQuery Functions and Operators 3.1
- XQuery Update Facility 3.0
- XSLT and XQuery Serialization 3.1

- Transformation Registry 3
- Taxonomy Packages 1.0
- XBRL Versioning 1.0
2 Setting Up RaptorXML

This section describes procedures for setting up RaptorXML+XBRL Server. It describes the following:

- Installation and licensing of RaptorXML on Windows, on Linux, and on macOS systems.
- How to use XML Catalogs.
- How to work with Altova global resources.
- Security issues related to RaptorXML.

RaptorXML has special options that support XML Catalogs and Altova global resources, both of which enhance portability and modularity. You can therefore leverage the use of these features in your environment to considerable advantage.

**Note:** Security concerns and how to set up important security solutions are described in the section Security Issues.
2.1 Setup on Windows

This section describes the installation and licensing of RaptorXML+XBRL Server on Windows systems.

**Installation on Windows**
- System requirements
- Installing RaptorXML+XBRL Server
- Altova LicenseServer
- LicenseServer versions
- Trial license
- Application folder location

**Licensing on Windows**
- Start ServiceController
- Start LicenseServer
- Start RaptorXML+XBRL Server
- Register RaptorXML+XBRL Server
- Assign a license
2.1.1 Installation on Windows

RaptorXML+XBRL Server is available for installation on Windows systems. Its installation and setup procedure is described below.

- System requirements
  - **Windows**
    - Windows 7 SP1 with Platform Update, Windows 8, Windows 10
  - **Windows Server**
    - Windows Server 2008 R2 SP1 with Platform Update or newer

- Installing RaptorXML+XBRL Server
  RaptorXML+XBRL Server can be installed on Windows systems as follows:
  
  - As a separate standalone server product called RaptorXML+XBRL Server. To install RaptorXML+XBRL Server, download and run the RaptorXML+XBRL Server installer. Follow the on-screen instructions.
  - As part of the FlowForce Server installation package. To install RaptorXML+XBRL Server as part of the FlowForce Server package, download and run the FlowForce Server installer. Follow the on-screen instructions and make sure you check the option for installing RaptorXML+XBRL Server.

The installers of both RaptorXML+XBRL Server and FlowForce Server are available at the Altova Download Center (http://www.altova.com/download.html).

After installation, the RaptorXML+XBRL Server executable will be located by default at:

```
<ProgramFilesFolder>\Altova\RaptorXMLXBRLServer2019\bin\RaptorXMLXBRL.exe
```

All the necessary registrations to use RaptorXML+XBRL Server via a COM interface, as a Java interface, and in the .NET environment will be done by the installer. This includes registering the RaptorXML+XBRL Server executable as a COM server object, installing RaptorXMLLib.dll (for Java interface usage) in the WINDIR\system32\ directory, and adding the Altova.RaptorXML.dll file to the .NET reference library.

- Altova LicenseServer
  
  - In order for RaptorXML+XBRL Server to work, it must be licensed via an Altova LicenseServer on your network.
  - When you install RaptorXML+XBRL Server or FlowForce Server on Windows systems, an option is available that allows you to download and install Altova LicenseServer together with RaptorXML+XBRL Server or FlowForce Server.
  - If an Altova LicenseServer is already installed on your network, you do not need to install another one—unless a newer version of Altova LicenseServer is required. (See next point, LicenseServer versions.)
  - During the installation process of RaptorXML+XBRL Server or FlowForce Server,
check or uncheck the option for installing Altova LicenseServer as appropriate.

See the section, Licensing on Windows, for more information about how to register and license RaptorXML+XBRL Server with Altova LicenseServer.

LicenseServer versions
- Altova server products must be licensed either with the version of LicenseServer that is appropriate to the installed RaptorXML+XBRL Server version, or with a later version of LicenseServer.
- The LicenseServer version that is appropriate for a particular version of RaptorXML+XBRL Server is displayed during the installation of RaptorXML+XBRL Server. You can install this version of LicenseServer along with RaptorXML+XBRL Server, or you can install LicenseServer separately.
- Before installing a newer version of LicenseServer, any older one must be deinstalled. The LicenseServer installer will do this automatically if it detects an older version.
- LicenseServer versions are backwards compatible. They will work with older versions of RaptorXML+XBRL Server.
- If you install a new version of RaptorXML+XBRL Server and if your installed LicenseServer version is older than the appropriate LicenseServer, install the latest version available on the Altova website.
- At the time of LicenseServer de-installation, all registration and licensing information held in the older version of LicenseServer will be saved to a database on your server machine. This data will be imported automatically into the newer version when the newer version is installed.
- The version number of the currently installed LicenseServer is given at the bottom of the LicenseServer configuration page (all tabs).

Current version: 3.2

Trial license
During the installation process, you will be given the option of requesting a 30-day trial license for RaptorXML+XBRL Server. After submitting the request, a trial license will be sent to the email address you registered.

Application folder location
The application will be installed in the following folder:

<table>
<thead>
<tr>
<th>Windows 7, 8, 10</th>
<th>C:\Program Files\Altova\</th>
</tr>
</thead>
<tbody>
<tr>
<td>32 bit Version on 64-bit OS</td>
<td>C:\Program Files (x86)\Altova\</td>
</tr>
</tbody>
</table>
2.1.2 Licensing on Windows

RaptorXML+XBRL Server must be licensed with Altova LicenseServer. Licensing is a two-step process:

1. **Register RaptorXML+XBRL Server** with LicenseServer. Registration is done from RaptorXML+XBRL Server.
2. **Assign a license** to RaptorXML+XBRL Server from LicenseServer. Download the latest version of LicenseServer from the Altova website, and install it on your local machine or a machine on your network.

The steps to carry out are given below in brief. For detailed information, see the LicenseServer user manual at the Altova website.

▼ Start ServiceController

Altova ServiceController is started in order to start Altova LicenseServer and Altova RaptorXML+XBRL Server.

Altova ServiceController (ServiceController for short) is an application for conveniently starting, stopping and configuring Altova services on Windows systems.

ServiceController is installed with Altova LicenseServer and with *Altova server products that are installed as services* (FlowForce Server, RaptorXML(+XBRL) Server, and Mobile Together Server). It can be started by clicking **Start | Altova LicenseServer | Altova ServiceController**. (This command is also available in the **Start** menu folders of *Altova server products that are installed as services* (FlowForce Server, RaptorXML(+XBRL) Server, and Mobile Together Server).) After ServiceController has been started, it can be accessed via the system tray (screenshot below).

To specify that ServiceController starts automatically on logging in to the system, click the **ServiceController** icon in the system tray to display the **ServiceController** menu (screenshot below), and then toggle on the command **Run Altova ServiceController at Startup**. (This command is toggled on by default.) To exit ServiceController, click the **ServiceController** icon in the system tray and, in the menu that appears (see screenshot below), click **Exit Altova ServiceController**.
Start LicenseServer
To start LicenseServer, click the ServiceController icon in the system tray, hover over Altova LicenseServer in the menu that pops up (see screenshot below), and then select Start Service from the LicenseServer submenu. If LicenseServer is already running, the Start Service option will be disabled.

Start RaptorXML+XBRL Server
To start RaptorXML+XBRL Server, click the ServiceController icon in the system tray, hover over Altova RaptorXML+XBRL Server in the menu that pops up (see screenshot below), and then select Start Service from the RaptorXML+XBRL Server submenu. If RaptorXML+XBRL Server is already running, the Start Service option will be disabled.
Note: If RaptorXML+XBRL Server has been licensed to run only single-thread executions (typically because your machine is multiple-core, but your license is single-core), then you can use only one instance of RaptorXML+XBRL Server at a time: either as a service or from the command line. This is because the single-core license will be assigned automatically to the first instance that is started and is currently running; a second instance cannot be started till the first instance stops running.

- If you wish to use RaptorXML+XBRL Server from the command line but the service is already running, then you must stop the service before using the command line.
- If you wish to start RaptorXML+XBRL Server as a service, make sure that no command line action is currently being executed. Otherwise, you will not be able to start the service.

Register RaptorXML+XBRL Server

To register RaptorXML+XBRL Server from the command line interface, use the licenseserver command:

```
RaptorXMLXBRL licenseserver [options] ServerName-Or-IP-Address
```

For example, if localhost is the name of the server on which LicenseServer is installed:

```
RaptorXMLXBRL licenseserver localhost
```

If RaptorXML+XBRL Server was installed as part of a FlowForce Server installation, registering FlowForce Server with LicenseServer will automatically also register RaptorXML+XBRL Server. Essentially: (i) Start Altova FlowForce Web as a service via ServiceController (see previous point); (ii) Enter your password to access the Setup page; (iii) Select the LicenseServer name or address and click Register with LicenseServer. For more information, see Register FlowForce Server.

After successful registration, go to the Server Management tab of LicenseServer's configuration page to assign a license to RaptorXML+XBRL Server.

Assign a license

After successfully registering RaptorXML+XBRL Server, it will be listed in the Server Management tab of the configuration page of LicenseServer. Go there and assign a license.
to RaptorXML+XBRL Server.

The licensing of Altova server products is based on the number of processor cores available on the product machine. For example, a dual-core processor has two cores, a quad-core processor four cores, a hexa-core processor six cores, and so on. The number of cores licensed for a product must be greater than or equal to the number of cores available on that server machine, whether the server is a physical or virtual machine. For example, if a server has eight cores (an octa-core processor), you must purchase at least one 8-core license. You can also combine licenses to achieve the core count. So, two 4-core licenses can also be used for an octa-core server instead of one 8-core license.

If you are using a computer server with a large number of CPU cores but only have a low volume to process, you may also create a virtual machine that is allocated a smaller number of cores, and purchase a license for that number. Such a deployment, of course, will have less processing speed than if all available cores on the server were utilized.

**Note:** Each Altova server product license can be used for only one client machine—the machine on which the Altova server product is installed—at a time, even if the license has unused licensing capacity. For example, if a 10-core license is used for a client machine that has 6 CPU cores, then the remaining 4 cores of licensing capacity cannot be used simultaneously for another client machine.
2.2 Setup on Linux

This section describes the installation and licensing of RaptorXML+XBRL Server on Linux systems (Debian, Ubuntu, CentOS, RedHat).

**Installation on Linux**
- System requirements
- Note about root user
- Uninstall old versions of Altova server products
- Download the Linux package
- Install RaptorXML+XBRL Server
- Altova LicenseServer
- LicenseServer versions

**Licensing on Linux**
- Note about root user
- Start LicenseServer
- Start RaptorXML+XBRL Server
- Register RaptorXML+XBRL Server
- Assign a license
2.2.1 Installation on Linux

RaptorXML+XBRL Server is available for installation on Linux systems. Its installation and setup procedure is described below.

- **System requirements**
  - **Linux**
    - CentOS 6 or newer
    - RedHat 6 or newer
    - Debian 8 or newer
    - Ubuntu 14.04 or newer

  The following libraries are required as a prerequisite to install and run the application. If the packages below are not already available on your Linux machine, run the command *yum* (or *apt-get* if applicable) to install them.

<table>
<thead>
<tr>
<th>Required by</th>
<th>CentOS, RedHat</th>
<th>Debian</th>
<th>Ubuntu</th>
</tr>
</thead>
<tbody>
<tr>
<td>LicenseServer</td>
<td>krb5-libs</td>
<td>libgssapi-krb5-2</td>
<td>libgssapi-krb5-2</td>
</tr>
<tr>
<td>RaptorXML+XBRL Server</td>
<td>qt4, krb5-libs, qt-x11</td>
<td>libqtcore4, libqtgui4, libgssapi-krb5-2</td>
<td>libqtcore4, libqtgui4, libgssapi-krb5-2</td>
</tr>
</tbody>
</table>

**Note:** If you plan to use Altova's Charts functionality, then at least one font must be installed on your system to ensure that charts will be rendered correctly. To list installed fonts, use, for example, the *fc-list* command of the Fontconfig library.

**Note:** On newly installed Ubuntu server 18.04.1 LTS, it was found that the *universe* repository needed to be enabled to apt (using the command: *sudo add-apt-repository universe*). Installation of *libqtgui4* was possible after this update.

- **FlowForce Server integration**

  If you are installing RaptorXML+XBRL Server together with FlowForce Server, it is recommended that you install FlowForce Server first. Otherwise, after having installed both RaptorXML+XBRL Server and FlowForce Server, run the following command:

  ```
cp /opt/Altova/RaptorXMLXBRLServer2019/etc/*.tool /opt/Altova/FlowForceServer2019/tools
```

  This command copies the *tool* file from */etc* directory of RaptorXML+XBRL Server to the FlowForce Server */tools* directory. The *tool* file is required by FlowForce Server; it contains the path to the RaptorXML+XBRL Server executable. You do not need to run this command if you install FlowForce Server before installing RaptorXML+XBRL Server.

- **Note about root user**

  You must have administrator (root) privileges to be able to install RaptorXML+XBRL Server.
Setting Up RaptorXML Setup on Linux

Installation must be done, therefore, as the root user. If you are logged in as root, you can leave out the sudo keyword from the commands listed below.

**Uninstall old versions of Altova server products**

If you need to uninstall a previous version, do this as follows. On the Linux command line interface (CLI), you can check which Altova server products are installed with the following command:

[Debian, Ubuntu]: `dpkg --list | grep Altova`

[CentOS, RedHat]: `rpm -qa | grep server`

If RaptorXML+XBRL Server is not installed, go ahead with the installation as documented below in *Installing RaptorXML+XBRL Server*.

If RaptorXML+XBRL Server is installed and you wish to install a newer version of RaptorXML +XBRL Server, uninstall the old version with the command:

[Debian, Ubuntu]: `sudo dpkg --remove raptorxmlxbrlserver`

[CentOS, RedHat]: `sudo rpm -e raptorxmlxbrlserver`

If you need to uninstall an old version of Altova LicenseServer, do this with the following command:

[Debian, Ubuntu]: `sudo dpkg --remove licenseserver`

[CentOS, RedHat]: `sudo rpm -e licenseserver`

**Download the Linux package**

RaptorXML+XBRL Server installation packages for the following Linux systems are available at the [Altova website](https://www.altova.com).

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Package extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian</td>
<td>.deb</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>.deb</td>
</tr>
<tr>
<td>CentOS</td>
<td>.rpm</td>
</tr>
<tr>
<td>RedHat</td>
<td>.rpm</td>
</tr>
</tbody>
</table>

After downloading the Linux package, copy it to any directory on the Linux system. Since you will need an Altova LicenseServer in order to run RaptorXML+XBRL Server, you may want to download LicenseServer from the [Altova website](https://www.altova.com) at the same time as you download RaptorXML+XBRL Server, rather than download it at a later time.

**Install RaptorXML+XBRL Server**

In a terminal window, switch to the directory where you have copied the Linux package. For example, if you copied it to a user directory called MyAltova (that is located, say, in the `/home/User` directory), then switch to this directory as follows:

`cd /home/User/MyAltova`
Install RaptorXML+XBRL Server with the following command:

[Debian]: sudo dpkg --install raptorxmlxbrlservlet-2019-debian.deb
[Ubuntu]: sudo dpkg --install raptorxmlxbrlservlet-2019-ubuntu.deb
[CentOS]: sudo rpm -ivh raptorxmlxbrlservlet-2019-1.x86_64.rpm
[RedHat]: sudo rpm -ivh raptorxmlxbrlservlet-2019-1.x86_64.rpm

The RaptorXML+XBRL Server package will be installed in the folder:
/opt/Altova/RaptorXMLXBRLServer2019

Altova LicenseServer

In order for any Altova Server product—including RaptorXML+XBRL Server—to run, that server product must be licensed via an Altova LicenseServer on your network.

On Linux systems, Altova LicenseServer will need to be installed separately. Download LicenseServer from the Altova website and copy the package to any directory on the Linux system. Install it just like you installed RaptorXML+XBRL Server (see previous step).

[Debian]: sudo dpkg --install licenseserver-3.2-debian.deb
[Ubuntu]: sudo dpkg --install licenseserver-3.2-ubuntu.deb
[CentOS]: sudo rpm -ivh licenseserver-3.2-1.x86_64.rpm
[RedHat]: sudo rpm -ivh licenseserver-3.2-1.x86_64.rpm

The LicenseServer package will be installed in:
/opt/Altova/LicenseServer

For information about how to register RaptorXML+XBRL Server with Altova LicenseServer and license it, see the section, Licensing on Linux. Also see the LicenseServer documentation for more detailed information.

LicenseServer versions

- Altova server products must be licensed either with the version of LicenseServer that is appropriate to the installed RaptorXML+XBRL Server version, or with a later version of LicenseServer.
- The LicenseServer version that is appropriate for a particular version of RaptorXML+XBRL Server is displayed during the installation of RaptorXML+XBRL Server. You can install this version of LicenseServer along with RaptorXML+XBRL Server, or you can install LicenseServer separately.
- Before installing a newer version of LicenseServer, any older one must be de-installed. The LicenseServer installer will do this automatically if it detects an older version.
- LicenseServer versions are backwards compatible. They will work with older versions of RaptorXML+XBRL Server.
- If you install a new version of RaptorXML+XBRL Server and if your installed LicenseServer version is older than the appropriate LicenseServer, install the latest version available on the Altova website.
- At the time of LicenseServer de-installation, all registration and licensing information held in the older version of LicenseServer will be saved to a database on your server machine. This data will be imported automatically into the newer version when the
newer version is installed.

- The version number of the currently installed LicenseServer is given at the bottom of the LicenseServer configuration page (all tabs).

  **Current version: 3.2**
## Licensing on Linux

RaptorXML+XBRL Server must be licensed with Altova LicenseServer. Licensing is a two-step process:

1. **Register RaptorXML+XBRL Server** with LicenseServer. Registration is done from RaptorXML+XBRL Server.
2. **Assign a license** to RaptorXML+XBRL Server from LicenseServer. Download the latest version of LicenseServer from the [Altova website](https://www.altova.com), and install it on your local machine or a machine on your network.

The steps to carry out are given below in brief. For detailed information, see the LicenseServer user manual at the [Altova website](https://www.altova.com).

### Note about root user

You must have administrator (root) privileges to be able to install RaptorXML+XBRL Server. Installation must be done, therefore, as the root user. If you are logged in as `root`, you can leave out the `sudo` keyword from the commands listed below.

### Start LicenseServer

To correctly register and license RaptorXML+XBRL Server with LicenseServer, LicenseServer must be running as a daemon on the network. Start LicenseServer as a daemon with the following command:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian 8</td>
<td><code>sudo /etc/init.d/licenseserver start</code></td>
</tr>
<tr>
<td>≥ Debian 8</td>
<td><code>sudo systemctl start licenseserver</code></td>
</tr>
<tr>
<td>CentOS 7</td>
<td><code>sudo initctl start licenseserver</code></td>
</tr>
<tr>
<td>≥ CentOS 7</td>
<td><code>sudo systemctl start licenseserver</code></td>
</tr>
<tr>
<td>Ubuntu 15</td>
<td><code>sudo initctl start licenseserver</code></td>
</tr>
<tr>
<td>≥ Ubuntu 15</td>
<td><code>sudo systemctl start licenseserver</code></td>
</tr>
<tr>
<td>RedHat</td>
<td><code>sudo initctl start licenseserver</code></td>
</tr>
</tbody>
</table>

If at any time you need to stop LicenseServer, replace `start` with `stop` in the above commands. For example:

```
sudo /etc/init.d/licenseserver stop
```

### Start RaptorXML+XBRL Server

Start RaptorXML+XBRL Server as a daemon with the following command:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian 8</td>
<td><code>sudo /etc/init.d/raptorxmlxbrlserver start</code></td>
</tr>
<tr>
<td>≥ Debian 8</td>
<td><code>sudo systemctl start raptorxmlxbrlserver</code></td>
</tr>
<tr>
<td>CentOS 7</td>
<td><code>sudo initctl start raptorxmlxbrlserver</code></td>
</tr>
</tbody>
</table>
Register RaptorXML+XBRL Server

To register RaptorXML+XBRL Server from the command line interface, use the licenseserver command:

```
sudo /opt/Altova/RaptorXMLXBRLServer2019/bin/raptorxmlxbrl licenseserver [options] ServerName-Or-IP-Address
```

For example, if `localhost` is the name of the server on which LicenseServer is installed:

```
sudo /opt/Altova/RaptorXMLXBRLServer2019/bin/raptorxmlxbrl licenseserver localhost
```

In the command above, `localhost` is the name of the server on which LicenseServer is installed. Notice also that the location of the RaptorXML+XBRL Server executable is:

```
/opt/Altova/RaptorXMLXBRLServer2019/bin/
```

After successful registration, go to the Server Management tab of LicenseServer's configuration page to assign a license to RaptorXML+XBRL Server.

Assign a license

After successfully registering RaptorXML+XBRL Server, it will be listed in the Server Management tab of the configuration page of LicenseServer. Go there and assign a license to RaptorXML+XBRL Server.

The licensing of Altova server products is based on the number of processor cores available on the product machine. For example, a dual-core processor has two cores, a quad-core processor four cores, a hexa-core processor six cores, and so on. The number of cores licensed for a product must be greater than or equal to the number of cores available on that server machine, whether the server is a physical or virtual machine. For example, if a server has eight cores (an octa-core processor), you must purchase at least one 8-core license. You can also combine licenses to achieve the core count. So, two 4-core licenses can also be used for an octa-core server instead of one 8-core license.

If you are using a computer server with a large number of CPU cores but only have a low volume to process, you may also create a virtual machine that is allocated a smaller number of cores, and purchase a license for that number. Such a deployment, of course, will have less processing speed than if all available cores on the server were utilized.

**Note:** Each Altova server product license can be used for only one client machine—the machine on which the Altova server product is installed—at a time, even if the license has unused licensing capacity. For example, if a 10-core license is used for a client machine that has 6 CPU cores, then the remaining 4 cores of licensing capacity cannot be used simultaneously for another client machine.
2.3 Setup on macOS

This section describes the installation and licensing of RaptorXML+XBRL Server on macOS systems.

**Installation on macOS**
- System requirements
- Note about root user
- Uninstall old versions of Altova server products
- Download the macOS package
- Install RaptorXML+XBRL Server
- Altova LicenseServer
- LicenseServer versions

**Licensing on macOS**
- Note about root user
- Start LicenseServer
- Start RaptorXML+XBRL Server
- Register RaptorXML+XBRL Server
- Assign a license
2.3.1 Installation on macOS

RaptorXML+XBRL Server is available for installation on macOS systems. Its installation and setup procedure is described below.

- **System requirements**
  - macOS
    - macOS 10.12 or newer

- **FlowForce Server integration**
  If you install RaptorXML+XBRL Server together with FlowForce Server, it is recommended that you install FlowForce Server first. If you install RaptorXML+XBRL Server before FlowForce Server, then, after having installed both RaptorXML+XBRL Server and FlowForce Server, run the following command:

  ```bash
  cp /usr/local/Altova/RaptorXMLXBRLServer2019/etc/*.tool /usr/local/Altova/
  FlowForceServer2019/tools
  ```

  This command copies the `.tool` file from `/etc` directory of RaptorXML+XBRL Server to the FlowForce Server `/tools` directory. The `.tool` file is required by FlowForce Server; it contains the path to the RaptorXML+XBRL Server executable. You do not need to run this command if you install FlowForce Server before installing RaptorXML+XBRL Server.

- **Note about root user**
  You must have administrator (root) privileges to be able to install RaptorXML+XBRL Server. Installation must be done, therefore, as the root user. If you are logged in as root, you can leave out the `sudo` keyword from the commands listed below.

- **Uninstall old versions of Altova server products**
  Before uninstalling RaptorXML+XBRL Server, stop the service with the following command:

  ```bash
  sudo launchctl unload /Library/LaunchDaemons/com.altova.RaptorXMLXBRLServer2019.plist
  ```

  To check whether the service has been stopped, open the Activity Monitor in Finder and make sure that RaptorXML+XBRL Server is not in the list. In the Applications folder in Finder, right-click the RaptorXML+XBRL Server icon and select **Move to Trash**. The application will be moved to Trash. You will, however, still need to remove the application from the `usr` folder. Do this with the command:

  ```bash
  sudo rm -rf /usr/local/Altova/RaptorXMLXBRLServer2019/
  ```

  If you need to uninstall an old version of Altova LicenseServer, you must first stop it running as a service. Do this with the following command:

  ```bash
  sudo launchctl unload /Library/LaunchDaemons/com.altova.LicenseServer.plist
  ```

  To check whether the service has been stopped, open the Activity Monitor in Finder and
make sure that LicenseServer is not in the list. Then proceed to uninstall in the same way as described above for RaptorXML+XBRL Server.

▼ Download the disk image file

Download the disk image (.dmg) file from the Altova website (http://www.altova.com/download.html).

▼ Install RaptorXML+XBRL Server

Click to open the downloaded disk image (.dmg). This causes the RaptorXML+XBRL Server installer to appear as a new virtual drive on your computer. On the new virtual drive, double-click the installer package (.pkg). Go through the successive steps of the installer wizard. These are self-explanatory and include one step in which you have to agree to the license agreement before being able to proceed. To eject the drive after installation, right-click it and select Eject.

The RaptorXML+XBRL Server package will be installed in the folder:

/usr/local/Altova/RaptorXMLXBRLServer2019 (application binaries)
/var/Altova/RaptorXMLXBRLServer (data files: database and logs)

RaptorXML+XBRL Server server daemon starts automatically after installation and a re-boot of the machine. You can start RaptorXML+XBRL Server as a daemon with the following command:

```
sudo launchctl load /Library/LaunchDaemons/com.altova.RaptorXMLXBRLServer2019.plist
```

▼ Altova LicenseServer

In order for any Altova Server product—including RaptorXML+XBRL Server—to run, that server product must be licensed via an Altova LicenseServer on your network.

The Altova LicenseServer installation package is available on the virtual drive you have mounted in the previous step. To install Altova LicenseServer, double-click the installer package included on the virtual drive and follow the on-screen instructions. You will need to accept the license agreement for installation to proceed.

Altova LicenseServer can also be downloaded and installed separately from the Altova website (http://www.altova.com/download.html).

The LicenseServer package will be installed in the folder:

/usr/local/Altova/LicenseServer

For information about how to register RaptorXML+XBRL Server with Altova LicenseServer and license it, see the section, Licensing on macOS.

▼ LicenseServer versions

- Altova server products must be licensed either with the version of LicenseServer that
is appropriate to the installed RaptorXML+XBRL Server version, or with a later version of LicenseServer.

- The LicenseServer version that is appropriate for a particular version of RaptorXML +XBRL Server is displayed during the installation of RaptorXML+XBRL Server. You can install this version of LicenseServer along with RaptorXML+XBRL Server, or you can install LicenseServer separately.
- Before installing a newer version of LicenseServer, any older one must be de-installed. The LicenseServer installer will do this automatically if it detects an older version.
- LicenseServer versions are backwards compatible. They will work with older versions of RaptorXML+XBRL Server.
- If you install a new version of RaptorXML+XBRL Server and if your installed LicenseServer version is older than the appropriate LicenseServer, install the latest version available on the Altova website.
- At the time of LicenseServer de-installation, all registration and licensing information held in the older version of LicenseServer will be saved to a database on your server machine. This data will be imported automatically into the newer version when the newer version is installed.
- The version number of the currently installed LicenseServer is given at the bottom of the LicenseServer configuration page (all tabs).

*Current version: 3.2*
2.3.2 Licensing on macOS

RaptorXML+XBRL Server must be licensed with Altova LicenseServer. Licensing is a two-step process:

1. **Register RaptorXML+XBRL Server** with LicenseServer. Registration is done from RaptorXML+XBRL Server.
2. **Assign a license** to RaptorXML+XBRL Server from LicenseServer. Download the latest version of LicenseServer from the Altova website, and install it on your local machine or a machine on your network.

The steps to carry out are given below in brief. For detailed information, see the LicenseServer user manual at the Altova website.

**Note about root user**

You must have administrator (root) privileges to be able to install RaptorXML+XBRL Server. Installation must be done, therefore, as the root user. If you are logged in as root, you can leave out the `sudo` keyword from the commands listed below.

**Start LicenseServer**

To correctly register and license RaptorXML+XBRL Server with LicenseServer, LicenseServer must be running as a daemon. Start LicenseServer as a daemon with the following command:

```
sudo launchctl load /Library/LaunchDaemons/com.altova.LicenseServer.plist
```

If at any time you need to stop LicenseServer, replace `load` with `unload` in the above command:

```
sudo launchctl unload /Library/LaunchDaemons/com.altova.LicenseServer.plist
```

**Start RaptorXML+XBRL Server**

RaptorXML+XBRL Server server daemon starts automatically after installation and a re-boot of the machine. You can start RaptorXML+XBRL Server as a daemon with the following command:

```
sudo launchctl load /Library/LaunchDaemons/com.altova.RaptorXMLXBRLServer2019.plist
```

If at any time you need to stop RaptorXML+XBRL Server, use:

```
sudo launchctl unload /Library/LaunchDaemons/com.altova.RaptorXMLXBRLServer2019.plist
```

**Register RaptorXML+XBRL Server**

To register RaptorXML+XBRL Server from the command line interface, use the `licenseserver` command:

```
sudo /usr/local/Altova/RaptorXMLXBRLServer2019/bin/RaptorXMLXBRL licenseserver [options] ServerName-Or-IP-Address
```
For example, if `localhost` is the name of the server on which LicenseServer is installed:

```bash
sudo /usr/local/Altova/RaptorXMLXBRLServer2019/bin/RaptorXMLXBRL licenseserver localhost
```

In the command above, `localhost` is the name of the server on which LicenseServer is installed. Notice also that the location of the RaptorXML+XBRL Server executable is:

```
/usr/local/Altova/RaptorXMLXBRLServer2019/bin/
```

After successful registration, go to the Server Management tab of LicenseServer's configuration page to assign a license to RaptorXML+XBRL Server.

### Assign a license

After successfully registering RaptorXML+XBRL Server, it will be listed in the Server Management tab of the configuration page of LicenseServer. Go there and assign a license to RaptorXML+XBRL Server.

The licensing of Altova server products is based on the number of processor cores available on the product machine. For example, a dual-core processor has two cores, a quad-core processor four cores, a hexa-core processor six cores, and so on. The number of cores licensed for a product must be greater than or equal to the number of cores available on that server machine, whether the server is a physical or virtual machine. For example, if a server has eight cores (an octa-core processor), you must purchase at least one 8-core license. You can also combine licenses to achieve the core count. So, two 4-core licenses can also be used for an octa-core server instead of one 8-core license.

If you are using a computer server with a large number of CPU cores but only have a low volume to process, you may also create a virtual machine that is allocated a smaller number of cores, and purchase a license for that number. Such a deployment, of course, will have less processing speed than if all available cores on the server were utilized.

**Note:** Each Altova server product license can be used for only one client machine—the machine on which the Altova server product is installed—at a time, even if the license has unused licensing capacity. For example, if a 10-core license is used for a client machine that has 6 CPU cores, then the remaining 4 cores of licensing capacity cannot be used simultaneously for another client machine.
2.4 XML Catalogs

The XML catalog mechanism enables files to be retrieved from local folders, thus increasing the overall processing speed, as well as improving the portability of documents—since only the catalog file URIs then need to be changed. See the section How Catalogs Work for details.

Altova's XML products use a catalog mechanism to quickly access and load commonly used files, such as DTDs and XML Schemas. This catalog mechanism can be customized and extended by the user, and it is described in the section Altova's XML Catalog Mechanism. The section Variables for System Locations list Windows variables for common system locations. These variables can be used in catalog files to locate commonly used folders.

This section is organized into the following sub-sections:

- How Catalogs Work
- Altova's XML Catalog Mechanism
- Variables for System Locations

For more information on catalogs, see the XML Catalogs specification.
2.4.1 How Catalogs Work

This section:

- Mapping public and system identifiers to local URLs
- Mapping filepaths, Web URLs, and names to local URLs

Catalogs are useful for redirecting calls to remote resources to a local URL. This is achieved by mapping, in the catalog file, public or system identifiers, URIs, or parts of identifiers or URIs to the required local URL.

Mapping public and system identifiers to local URLs

When the DOCTYPE declaration of a DTD in an XML file is read, the declaration’s public or system identifier locates the required resource. If the identifier selects a remote resource or if the identifier is not a locator, it can still be mapped via a catalog entry to a local resource.

For example, consider the following SVG file:

```xml
<?xml version="1.0" standalone="no"?>
<!DOCTYPE svg PUBLIC "-//W3C//DTD SVG 1.1//EN" "http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd">
<svg>
...
</svg>
```

Its public identifier is: -//W3C//DTD SVG 1.1//EN
Its system identifier is: http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd

A catalog entry could map the public identifier to a local URL, like this:

```xml
<public publicId="-//W3C//DTD SVG 1.1//EN" uri="schemas/svg/svg11.dtd"/>
```

Or, a catalog entry could map the system identifier to a local URL, like this:

```xml
<system systemId="http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd"
uri="schemas/svg/svg11.dtd"/>
```

If there is a match for the public or system identifier in the catalog, the URL to which it is mapped is used. (Relative paths are resolved with reference to an xml:base attribute in the redirecting catalog element; the fallback base URL is the URL of the catalog file.) If there is no match for the public or system identifier in the catalog, then the URL in the XML document will be used (in the example above: http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd).

Mapping relative or absolute filepaths, Web URLs, or just names, to local URLs

The uri element can be used to map a relative or absolute filepath or a Web URL, or just any name, to a local URL, like this:

- `<uri name="doc.xslt" uri="C:\Docs\doc.xslt"/>
- `<uri name="U:\Docs\2013\doc.xslt" uri="C:\Docs\doc.xslt"/>
- `<uri name="http://www.altova.com/schemas/doc.xslt" uri="C:\Docs..."/>
When the name value is encountered, it is mapped to the resource specified in the uri attribute. With a different catalog, the same name can be mapped to a different resource. For example, if you have:

\texttt{xsi:schemaLocation="http://www.altova.com/schemas/orgchart OrgChart.xsd"}

Normally, the URI part of the attribute's value (bold in the example above) is a path to the actual schema location. However, if the schema is referenced via a catalog, the URI part need not point to an actual XML Schema, but it does need to exist so that the lexical validity of the xsi:schemaLocation attribute is maintained. A value of foo, for example, would be sufficient for the URI part of the xsi:schemaLocation attribute's value (instead of Orgchart.xsd). The schema is located in the catalog by means of the namespace part of the xsi:schemaLocation attribute's value. In the example above, the namespace part is http://www.altova.com/schemas/orgchart.

In the catalog, the following entry would locate the schema on the basis of that namespace part.

\texttt{<uri name="http://www.altova.com/schemas/orgchart" uri="C:\MySchemas\OrgChart.xsd"/>}

For more information on these elements, see the \texttt{XML Catalogs specification}. 
Altova's XML Catalog Mechanism

This section:

- The root catalog file, RootCatalog.xml, contains the catalog files RaptorXML will look up.
- Altova's catalog extension files: CoreCatalog.xml, CustomCatalog.xml, and Catalog.xml.
- Supported catalog subset.

RootCatalog.xml

By default, RaptorXML will look up the file RootCatalog.xml (listed below) for the list of catalog files to use. RootCatalog.xml is located in the folder:

```
<ProgramFilesFolder>\Altova\RaptorXMLXBRLServer2019\etc
```

To use another file as the root catalog, use the --catalog option on the command line, the setCatalog method of the Java interface, or the Catalog method of the COM interface.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog"
    xmlns:spy="http://www.altova.com/catalog_ext"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="urn:oasis:names:tc:entity:xmlns:xml:catalog Catalog.xsd">
  <!-- Include all catalogs under common schemas folder on the first directory level -->
  <nextCatalog spy:recurseFrom="%AltovaCommonFolder%/Schemas" catalog="catalog.xml" spy:depth="1"/>

  <!-- Include all catalogs under common XBRL folder on the first directory level -->
  <nextCatalog spy:recurseFrom="%AltovaCommonFolder%/XBRL" catalog="catalog.xml" spy:depth="1"/>
</catalog>
```

Additional catalog files to look up are each listed in a nextCatalog element, and any number of these can be added. Each catalog file is looked up and the mappings in them are resolved.

In the listing above, notice that two catalogs are directly referenced: CoreCatalog.xml and CustomCatalog.xml. Additionally, catalogs named catalog.xml that are in the first level of subfolders of the Schemas and XBRL folders are also referenced. (The value of the %AltovaCommonFolder% variable is given in the section, Variables for System Locations.)

The catalog files in the Altova Common Folder map the pre-defined public and system identifiers of commonly used schemas (such as XML Schema and XHTML) to URIs that point to local copies.
of the respective schemas. These schemas are installed in the Altova Common Folder when RaptorXML is installed.

CoreCatalog.xml, CustomCatalog.xml, and Catalog.xml

The catalog files CoreCatalog.xml and CustomCatalog.xml are listed in RootCatalog.xml for lookup:

- CoreCatalog.xml contains certain Altova-specific mappings for locating schemas in the Altova Common Folder.
- CustomCatalog.xml is a skeleton file in which you can create your own mappings. You can add mappings to CustomCatalog.xml for any schema you require but that is not addressed by the catalog files in the Altova Common Folder. Do this using the supported elements of the OASIS catalog mechanism (see below).
- There are a number of Catalog.xml files inside the folder of a specific schema or XBRL taxonomy in the Altova Common Folder, and each maps public and/or system identifiers to URIs that point to locally saved copies of the respective schemas.

Both CoreCatalog.xml and CustomCatalog.xml are in the folder, `<ProgramFilesFolder>` \Altova\RaptorXMLXBRLServer2019\etc. The catalog.xml files are each in a specific schema folder, these schema folders being inside the folders: `%AltovaCommonFolder%\Schemas` and `%AltovaCommonFolder%\XBRL`.

Supported catalog subset

When creating entries in a catalog file that RaptorXML will use, use only the following elements of the OASIS catalog specification. Each of the elements below is listed with an explanation of its attribute values. For a more detailed explanation, see the XML Catalogs specification.

- `<public publicId="PublicID of Resource" uri="URL of local file"/>`
- `<system systemId="SystemID of Resource" uri="URL of local file"/>`
- `<uri name="filename" uri="URL of file identified by filename"/>`
- `<rewriteURI uriStartString="StartString of URI to rewrite" rewritePrefix="String to replace StartString"/>`
- `<rewriteSystem systemIdStartString="StartString of SystemID" rewritePrefix="Replacement string to locate resource locally"/>`

In cases where there is no public identifier, the system identifier can be directly mapped to a URL via the system element. Also, a URI can be mapped to another URI using the uri element. The rewriteURI and rewriteSystem elements enable the rewriting of the starting part of a URI or system identifier, respectively. This allows the start of a filepath to be replaced and consequently enables the targeting of another directory.

Note: Each element can take the xml:base attribute, which is used to specify the base URI of that element. If no xml:base element is present, the base URI will be the URI of the catalog file.

For more information on these elements, see the XML Catalogs specification.
2.4.3 Variables for Windows System Locations

Shell environment variables can be used in catalog files to specify the path to various Windows system locations. The following variables are supported:

- \%AltovaCommonFolder\%: C:\Program Files\Altova\Common2019
- \%DesktopFolder\%: Full path to the Desktop folder for the current user.
- \%ProgramMenuFolder\%: Full path to the Program Menu folder for the current user.
- \%CatalogFolder\%: Full path to the folder containing the XML catalog that is currently being processed.
- \%StartMenuFolder\%: Full path to Start Menu folder for the current user.
- \%StartUpFolder\%: Full path to Start Up folder for the current user.
- \%TemplateFolder\%: Full path to the Template folder for the current user.
- \%AdminToolsFolder\%: Full path to the file system directory that stores administrative tools for the current user.
- \%AppDataFolder\%: Full path to the Application Data folder for the current user.
- \%CommonAppDataFolder\%: Full path to the file directory containing application data for all users.
- \%FavoritesFolder\%: Full path of the Favorites folder for the current user.
- \%PersonalFolder\%: Full path to the Personal folder for the current user.
- \%SendToFolder\%: Full path to the SendTo folder for the current user.
- \%FontsFolder\%: Full path to the System Fonts folder.
- \%ProgramFilesFolder\%: Full path to the Program Files folder for the current user.
- \%CommonFilesFolder\%: Full path to the Common Files folder for the current user.
%WindowsFolder% Full path to the Windows folder for the current user.
%SystemFolder% Full path to the System folder for the current user.
%LocalAppDataFolder% Full path to the file system directory that serves as the data repository for local (non-roaming) applications.
%MyPicturesFolder% Full path to the MyPictures folder.
2.5 Global Resources

This section:

- About global resources
- Using global resources

About global resources

An Altova global resource file maps an alias to multiple resources via different configurations, as shown in the diagram below. An alias can therefore be switched to access a different resource by switching its configuration.

Global resources are defined in Altova products, such as Altova XMLSpy, and are saved in a global resources XML file. RaptorXML is able to use global resources as inputs. To do this, it requires the name and location of the global resources file, and the alias and configuration to be used.

The advantage of using global resources is that resource can be changed merely by switching the name of the configuration. When using RaptorXML, this means that by providing a different value of the `--globalresourcesconfig | --gc` option, a different resource can be used. (See the example below.)

Using global resources with RaptorXML

To specify a global resource as an input for a RaptorXML command, the following parameters are required:

- The global resources XML file (specified on the CLI with the option `--globalresourcesfile | --gr`)
- The required configuration (specified on the CLI with the option `--globalresourcesconfig | --gc`)
- The alias. This can be specified directly on the CLI where a file name is required, or it can be at a location inside an XML file where RaptorXML looks for a filename (such as in an `xsi:schemaLocation` attribute).

For example, if you wish to transform `input.xml` with `transform.xslt` to `output.html`, this would typically be achieved on the CLI with the following command that uses filenames:

```
raptorxmlxbrl xslt --input=input.xml --output=output.html transform.xslt
```

If, however, you have a global resource definition that matches the alias `MyInput` to the file
resource FirstInput.xml via a configuration called FirstConfig, then you could use the alias MyInput on the CLI as follows:

```
raptorxmlxbrl xslt --input=altova://file_resource/MyInput --gr=C:\MyGlobalResources.xml --gc=FirstConfig --output=Output.html transform.xslt
```

Now, if you have another file resource, say SecondInput.xml, that is matched to the alias MyInput via a configuration called SecondConfig, then this resource can be used by changing only the --gc option of the previous command:

```
raptorxmlxbrl xslt --input=altova://file_resource/MyInput --gr=C:\MyGlobalResources.xml --gc=SecondConfig --output=Output.html transform.xslt
```

Note: In the example above a file resource was used; a file resource must be prefixed with altova://file_resource/. You can also use global resources that are folders. To identify a folder resource, use: altova://folder_resource/AliasName. Note that, on the CLI, you can also use folder resources as part of a filepath. For example: altova://folder_resource/AliasName/input.xml.
2.6 Security Issues

This section:

- Security concerns related to the HTTP interface
- Making Python scripts safe

Some interface features of RaptorXML+XBRL Server pose security concerns. These are described below together with their solutions.

Security concerns related to the HTTP REST interface

The HTTP REST interface, by default, allows result documents to be written to any location specified by the client (that is accessible with the HTTP protocol). It is important therefore to consider this security aspect when configuring RaptorXML+XBRL Server.

If there is a concern that security might be compromised or that the interface might be misused, the server can be configured to write result documents to a dedicated output directory on the server itself. This is specified by setting the `server.unrestricted-filesystem-access` option of the server configuration file to false. When access is restricted in this way, the client can download result documents from the dedicated output directory with GET requests. Alternatively, an administrator can copy/upload result document files from the server to the target location.

Making Python scripts safe

When a Python script is specified in a command via HTTP to RaptorXML+XBRL Server, the script will only work if it is located in the trusted directory. The script is executed from the trusted directory. Specifying a Python script from any other directory will result in an error. The trusted directory is specified in the `server.script-root-dir` setting of the server configuration file, and a trusted directory must be specified if you wish to use Python scripts. Make sure that all Python scripts to be used are saved in this directory.

Though all output generated by the server for HTTP job requests is written to the job output directory (which is a sub-directory of the `output-root-directory`), this limitation does not apply to Python scripts, which can write to any location. The server administrator must review the Python scripts in the trusted directory for potential vulnerability issues.
3 Command Line Interface (CLI)

The RaptorXML+XBRL Server executable for use with the command line interface (CLI) is located by default at:

- **Windows**: `<ProgramFilesFolder>\Altova\RaptorXMLXBRLServer2019\bin\RaptorXMLXBRL.exe`
- **Linux**: `/opt/Altova/RaptorXMLXBRLServer2019/bin/raptorxmlxbrl`
- **Mac**: `/usr/local/Altova/RaptorXMLXBRLServer2019/bin/raptorxmlxbrl`

▼ Casing and slashes on the command line

- **RaptorXMLXBRL on Windows**
- **raptorxmlxbrl on Unix (Linux, Mac)**

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Usage

On the command line, send a command to the executable with the options and/or arguments you want. The command line syntax is:

- **Windows**: `RaptorXMLXBRL --h | --help | --version | <command> [options] [arguments]`
- **Linux**: `raptorxmlxbrl --h | --help | --version | <command> [options] [arguments]`
- **Mac**: `raptorxmlxbrl --h | --help | --version | <command> [options] [arguments]`

<table>

</table>
CLI commands
The available CLI commands are described in this section, organized by functionality.

- XML, DTD, XSD Validation Commands
- Well-formedness Check Commands
- XBRL Validation Commands
- XQuery Commands
- XSLT Commands
- JSON/Avro Commands
- XML Signature Commands
- Other commands: Validate Any, Script, Help and License, Localization
3.1 XML, DTD, XSD Validation Commands

The XML validation commands can be used to validate the following types of document:

- **XML**: Validates XML instance documents against a DTD (`valxml-withdtd | xml`) or an XML Schema 1.0/1.1 (`valxml-withxsd | xsi`).
- **DTD**: Checks that a DTD is well-formed and contains no error (`valdtd | dtd`).
- **XSD**: Validates a W3C XML Schema (XSD) document according to rules of the XML Schema specification (`valxsd | xsd`).

XML validation commands are described in detail in the sub-sections of this section:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`valxml-withdtd</td>
<td>xml`</td>
</tr>
<tr>
<td>`valdtd</td>
<td>dtd`</td>
</tr>
<tr>
<td>`valxsd</td>
<td>xsd`</td>
</tr>
</tbody>
</table>

**Note:** XBRL instance, XBRL taxonomy, XSLT, XQuery, JSON, and Avro documents can also be validated. These validation commands are described in their respective sections: [XBRL Validation Commands](#), [XSLT Commands](#), [XQuery Commands](#), [JSON/Avro Commands](#).
3.1.1 valxml-withdtd (xml)

The valxml-withdtd | xml command validates one or more XML instance documents against a DTD.

Windows  RaptorXMLXBRL valxml-withdtd | xml [options] InputFile
Linux    raptorxmlxbrl valxml-withdtd | xml [options] InputFile
Mac      raptorxmlxbrl valxml-withdtd | xml [options] InputFile

The InputFile argument is the XML document to validate. If a reference to a DTD exists in the XML document, the --dtd option is not required.

To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the InputFile argument together with the --listfile option set to true (see the Options list below).

Examples

* raptorxmlxbrl valxml-withdtd --dtd=c:\MyDTD.dtd c:\Test.xml
* raptorxmlxbrl xml c:\Test.xml
* raptorxmlxbrl xml --verbose=true c:\Test.xml
* raptorxmlxbrl xml --listfile=true c:\FileList.txt

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

Validation and processing

```
dtd
--dtd = FILE
```

Specifies the external DTD document to use for validation. If a reference to an external DTD is present in the XML document, then the CLI option overrides the external reference.
listfile
--listfile = true|false
If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)
Note: Boolean option values are set to true if the option is specified without a value.

amespaces
--namespaces = true|false
Enables namespace-aware processing. This is useful for checking the XML instance for errors due to incorrect namespaces. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

recurse
--recurse = true|false
Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: test.zip|zip\test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

streaming
--streaming = true|false
Enables streaming validation. Default is true. In streaming mode, data stored in memory is minimized and processing is faster. The downside is that information that might be required subsequently—for example, a data model of the XML instance document—will not be available. In situations where this is significant, streaming mode will need to be turned off (by giving --streaming a value of false). When using the --script option with the valxml-withxsd command, disable streaming. Note that the --streaming option is ignored if --parallel-assessment is set to true.
Note: Boolean option values are set to true if the option is specified without a value.

Catalogs and global resources

catalog
--catalog = FILE
Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

user-catalog
--user-catalog = FILE
Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.
enable-globalresources

--enable-globalresources = true|false
Enables global resources. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

globalresourceconfig [gc]

--gc | --globalresourceconfig = VALUE
Specifies the active configuration of the global resource (and enables global resources).

globalresourcefile [gr]

--gr | --globalresourcefile = FILE
Specifies the global resource file (and enables global resources).

Messages, errors, help, timeout, version

error-format

--error-format = text|shortxml|longxml
Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

error-limit

--error-limit = N | unlimited
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

help

--help
Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

log-output

--log-output = FILE
Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

network-timeout

--network-timeout = VALUE
Specifies the timeout in seconds for remote I/O operations. Default is: 40.

verbose

--verbose = true|false
A value of true enables output of additional information during validation. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.
### verbose-output

```bash
--verbose-output = FILE
```

Writes verbose output to `FILE`.

### version

```bash
--version
```

Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

### warning-limit

```bash
--warning-limit = N | unlimited
```

Specifies the warning limit in the range `1-65535` or `unlimited`. Processing continues if this limit is reached, but further warnings are not reported. The default value is `100`. 
3.1.2 valxml-withxsd (xsi)

The valxml-withxsd | xsi command validates one or more XML instance documents according to the W3C XML Schema Definition Language (XSD) 1.0 and 1.1 specifications.

Windows  RaptorXMLXBRL valxml-withxsd | xsi [options] InputFile
Linux    raptorxmlxbrl valxml-withxsd | xsi [options] InputFile
Mac      raptorxmlxbrl valxml-withxsd | xsi [options] InputFile

The InputFile argument is the XML document to validate. The --schemalocation-hints=true|false indicates whether the XSD reference in the XML document is to be used or not, with the default being true (the location is used). The --xsd=FILE option specifies the schema/s to use.

To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the InputFile argument together with the --listfile option set to true (see the Options list below).

Note: If using the --script option to run Python scripts, make sure to also specify --streaming=false.

Examples

- raptorxmlxbrl valxml-withxsd --schemalocation-hints=false --xsd=c:\MyXSD.xsd c:\HasNoXSDRef.xml
- raptorxmlxbrl xsi c:\HasXSDRef.xml
- raptorxmlxbrl xsi --xsd-version=1.1 --listfile=true c:\FileList.txt

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- Validation and processing
  
  --assessment-mode = lax|strict
Specifies the schema-validity assessment mode as defined in the XSD specifications. Default value is strict. The XML instance document will be validated according to the mode specified with this option.

**ct-restrict-mode**

```
--ct-restrict-mode = 1.0|1.1|default
```

Specifies how to check complex type restrictions. A value of 1.0 checks complex type restrictions as defined in the XSD 1.0 specification—even in XSD 1.1 validation mode. A value of 1.1 checks complex type restrictions as defined in the XSD 1.1 specification—even in XSD 1.0 validation mode. A value of default checks complex type restrictions as defined in the XSD specification of the current validation mode (1.0 or 1.1). The default value is default.

**listfile**

```
--listfile = true|false
```

If true, treats the command's `InputFile` argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the `--listfile` option applies only to arguments, and not to options. 

**Note:** Boolean option values are set to true if the option is specified without a value.

**parallel-assessment [pa]**

```
--pa | --parallel-assessment = true|false
```

If set to true, schema validity assessment is carried out in parallel. This means that if there are more than 128 elements at any level, these elements are processed in parallel using multiple threads. Very large XML files can therefore be processed faster if this option is enabled. Parallel assessment takes place on one hierarchical level at a time, but can occur at multiple levels within a single infoset. Note that parallel assessment does not work in streaming mode. For this reason, the `--streaming` option is ignored if `--parallel-assessment` is set to true. Also, memory usage is higher when the `--parallel-assessment` option is used. The default setting is false. Short form for the option is --pa.

**Note:** Boolean option values are set to true if the option is specified without a value.

**recurse**

```
--recurse = true|false
```

Used to select files within sub-directories, including in ZIP archives. If true, the command's `InputFile` argument will select the specified file also in subdirectories. For example: test.zip|zip\test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

**schema-imports**

```
--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only
```

Specifies the behaviour of `xs:import` elements, each of which has an optional
namespace attribute and an optional schemaLocation attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

The behavior is as follows:

- **load-by-schemalocation**: The value of the schemaLocation attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation**: If the schemaLocation attribute is present, it is used, taking account of catalog mappings. If no schemaLocation attribute is present, then the value of the namespace attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace**: The value of the namespace attribute is used to locate the schema via a catalog mapping.
- **load-combining-both**: If either the namespace or schemaLocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemaLocation attribute is used.
- **license-namespace-only**: The namespace is imported. No schema document is imported.

```
download schemalocation-hints
```

```bash
--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
```

Specifies the behavior of the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The load-by-schemalocation value uses the URL of the schema location in the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or XBRL instance documents. This is the default value.
- The load-by-namespace value takes the namespace part of xsi:schemaLocation and an empty string in the case of xsi:noNamespaceSchemaLocation and locates the schema via a catalog mapping.
- If load-combining-both is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is ignore, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

```
download schema-mapping
```

```bash
--schema-mapping = prefer-schemalocation | prefer-namespace
```

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the --schemalocation-hints or the --schema-imports option has a value of load-
combining-both, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the prefer-schemalocation value refers to the URL mapping.) Default is prefer-schemalocation.

- **script**
  ```
  --script = FILE
  ```
  Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

- **script-api-version**
  ```
  --api, --script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7
  ```
  Specifies the Python API version to be used for the script. The default value is the latest version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0 and 2.0, respectively.

- **script-output**
  ```
  --script-output = FILE
  ```
  Writes the script's standard output to the file named in FILE.

- **script-param**
  ```
  --script-param = KEY:VALUE
  ```
  Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

- **streaming**
  ```
  --streaming = true|false
  ```
  Enables streaming validation. Default is true. In streaming mode, data stored in memory is minimized and processing is faster. The downside is that information that might be required subsequently—for example, a data model of the XML instance document—will not be available. In situations where this is significant, streaming mode will need to be turned off (by giving --streaming a value of false). When using the --script option with the valxml-withxsd command, disable streaming. Note that the --streaming option is ignored if --parallel-assessment is set to true.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **xinclude**
  ```
  --xinclude = true|false
  ```
  Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude's include elements are ignored.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **xml-mode**
  ```
  --xml-mode = wf|id|valid
  ```
  Specifies the XML processing mode to use for the XML instance document:
  
  - **wf**=wellformed check;
  - **id**=wellformed with ID/IDREF checks;
  - **valid**=validation. Default
value is \texttt{wf}. Note that a value of \texttt{valid} requires that each instance document loaded during processing references a DTD. If no DTD exists, an error is reported.

\textbf{xml-mode-for-schemas}

\texttt{xml-mode-for-schemas = \texttt{wf|id|valid}}

Specifies the XML processing mode to use for XML schema documents: \texttt{wf=wellformed check}; \texttt{id=wellformed with ID/IDREF checks}; \texttt{valid=validation}. Default value is \texttt{wf}. Note that a value of \texttt{valid} requires that each schema document loaded during processing references a DTD. If no DTD exists, an error is reported.

\textbf{xsd}

\texttt{xsd = FILE}

Specifies one or more XML Schema documents to use for the validation of XML instance documents. Add the option multiple times to specify more than one schema document.

\textbf{xsd-version}

\texttt{xsd-version = \texttt{1.0|1.1|detect}}

Specifies the W3C Schema Definition Language (XSD) version to use. Default is 1.0. This option can also be useful to find out in what ways a schema which is 1.0-compatible is not 1.1-compatible. The \texttt{detect} option is an Altova-specific feature. It enables the version of the XML Schema document (1.0 or 1.1) to be detected by reading the value of the \texttt{vc:minVersion} attribute of the document's \texttt{<xs:schema>} element. If the value of the \texttt{@vc:minVersion} attribute is 1.1, the schema is detected as being version 1.1. For any other value, or if the \texttt{@vc:minVersion} attribute is absent, the schema is detected as being version 1.0.

\textbf{Catalogs and global resources}

\textbf{catalog}

\texttt{catalog = FILE}

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (\texttt{<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml}). See the section, XML Catalogs, for information about working with catalogs.

\textbf{user-catalog}

\texttt{user-catalog = FILE}

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

\textbf{enable-globalresources}

\texttt{enable-globalresources = \texttt{true|false}}

Enables global resources. Default value is \texttt{false}.

\textit{Note:} Boolean option values are set to \texttt{true} if the option is specified without a value.

\textbf{globalresourceconfig [gc]}

Command Line Interface (CLI)

XML, DTD, XSD Validation Commands

---gc | --globalresourceconfig = VALUE
Specifies the active configuration of the global resource (and enables global resources).

- globalresourcefile [gr]
  --gr | --globalresourcefile = FILE
  Specifies the global resource file (and enables global resources).

- Messages, errors, help, timeout, version
  - error-format
    --error-format = text|shortxml|longxml
    Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

  - error-limit
    --error-limit = N | unlimited
    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

  - help
    --help
    Displays help text for the command. For example, valany --h. (Alternately the help command can be used with an argument. For example: help valany.)

  - log-output
    --log-output = FILE
    Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

  - network-timeout
    --network-timeout = VALUE
    Specifies the timeout in seconds for remote I/O operations. Default is: 40.

  - verbose
    --verbose = true|false
    A value of true enables output of additional information during validation. Default value is false.
    Note: Boolean option values are set to true if the option is specified without a value.

  - verbose-output
    --verbose-output = FILE
    Writes verbose output to FILE.

  - version
    --version
Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

```
\textbf{warning-limit}

\texttt{--warning-limit = N | unlimited}

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
```
3.1.3 valdtd (dtd)

The `valdtd | dtd` command validates one or more DTD documents according to the XML 1.0 or XML 1.1 specification.

- **Windows**: `RaptorXMLXBRL valdtd | dtd [options] InputFile`
- **Linux**: `raptorxmlxbrl valdtd | dtd [options] InputFile`
- **Mac**: `raptorxmlxbrl valdtd | dtd [options] InputFile`

The `InputFile` argument is the DTD document to validate. To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to `true` (see the Options list below).

**Examples**

- `raptorxmlxbrl valdtd c:\Test.dtd`
- `raptorxmlxbrl dtd --verbose=true c:\Test.dtd`
- `raptorxmlxbrl dtd --listfile=true c:\FileList.txt`

**Casing and slashes on the command line**

- **RaptorXMLXBRL on Windows**
- **raptorxmlxbrl on Unix (Linux, Mac)**

  * Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
  * Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Validation and processing**

- **listfile**

  `--listfile = true|false`

  If true, treats the command's `InputFile` argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)

  Note: Boolean option values are set to true if the option is specified without a value.
**--recurse = true|false**

Used to select files within sub-directories, including in ZIP archives. If true, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

**script**

**--script = FILE**

Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

**script-api-version**

**--api, --script-api-version = 1|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7**

Specifies the Python API version to be used for the script. The default value is the latest version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0 and 2.0, respectively.

**script-output**

**--script-output = FILE**

Writes the script's standard output to the file named in `FILE`.

**script-param**

**--script-param = KEY:VALUE**

Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

**Catalogs and global resources**

**catalog**

**--catalog = FILE**

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, [XML Catalogs](#), for information about working with catalogs.

**user-catalog**

**--user-catalog = FILE**

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, [XML Catalogs](#), for information about working with catalogs.

**enable-globalresources**

**--enable-globalresources = true|false**

Enables [global resources](#). Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

- globalresourceconfig [gc]
  ```
  --gc | --globalresourceconfig = VALUE
  ```
  Specifies the active configuration of the global resource (and enables global resources).

- globalresourcefile [gr]
  ```
  --gr | --globalresourcefile = FILE
  ```
  Specifies the global resource file (and enables global resources).

- Messages, errors, help, timeout, version
  - error-format
    ```
    --error-format = text|shortxml|longxml
    ```
    Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

  - error-limit
    ```
    --error-limit = N | unlimited
    ```
    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

  - help
    ```
    --help
    ```
    Displays help text for the command. For example, `valany --h`. (Alternatively the `help` command can be used with an argument. For example: `help valany`.)

  - log-output
    ```
    --log-output = FILE
    ```
    Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

  - network-timeout
    ```
    --network-timeout = VALUE
    ```
    Specifies the timeout in seconds for remote I/O operations. Default is 40.

  - verbose
    ```
    --verbose = true|false
    ```
    A value of true enables output of additional information during validation. Default value is false.
    Note: Boolean option values are set to true if the option is specified without a value.

  - verbose-output
    ```
    --verbose-output = FILE
    ```
 Writes verbose output to FILE.

▼ version

--version
Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

▼ warning-limit

--warning-limit = N | unlimited
Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.1.4 **valxsd (xsd)**

The `valxsd | xsd` command validates one or more XML Schema documents (XSD documents) according to the W3C XML Schema Definition Language (XSD) 1.0 or 1.1 specification. Note that it is the schema itself that is validated against the XML Schema specification, not an XML instance document against an XML Schema.

### Windows

```
RaptorXMLXBRL valxsd | xsd [options] InputFile
```

### Linux

```
raptorxmlxbrl valxsd | xsd [options] InputFile
```

### Mac

```
raptorxmlxbrl valxsd | xsd [options] InputFile
```

The **InputFile** argument is the XML Schema document to validate. The `--xsd-version=1.0|1.1|detect` option specifies the XSD version to validate against, with the default being 1.0.

To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to true (see the Options list below).

### Examples

- `raptorxmlxbrl valxsd c:\Test.xsd`
- `raptorxmlxbrl xsd --verbose=true c:\Test.xsd`
- `raptorxmlxbrl xsd --listfile=true c:\FileList.txt`

### Casing and slashes on the command line

- **RaptorXMLXBRL on Windows**
- **raptorxmlxbrl on Unix (Linux, Mac)**

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

### Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- **Validation and processing**
  - `ct-restrict-mode`
    - `--ct-restrict-mode = 1.0|1.1|default`
      - Specifies how to check complex type restrictions. A value of 1.0 checks complex type restrictions as defined in the XSD 1.0 specification—even in XSD 1.1 validation mode. A value of 1.1 checks complex type restrictions as defined in the XSD 1.1 specification—
even in XSD 1.0 validation mode. A value of default checks complex type restrictions as defined in the XSD specification of the current validation mode (1.0 or 1.1). The default value is default.

### listfile

```
--listfile = true|false
```

If true, treats the command's `InputFile` argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the --listfile option applies only to arguments, and not to options.

**Note:** Boolean option values are set to true if the option is specified without a value.

### recurse

```
--recurse = true|false
```

Used to select files within sub-directories, including in ZIP archives. If true, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, `*.xml` will select all .xml files in the (zip) folder. The option's default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

### schema-imports

```
--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only
```

Specifies the behaviour of xs:import elements, each of which has an optional `namespace` attribute and an optional `schemalocation` attribute: `<import namespace="someNS" schemalocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

The behavior is as follows:

- **load-by-schemalocation**: The value of the `schemalocation` attribute is used to locate the schema, taking account of catalog mappings. If the `namespace` attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation**: If the `schemalocation` attribute is present, it is used, taking account of catalog mappings. If no `schemalocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace**: The value of the `namespace` attribute is used to locate the schema via a catalog mapping.
- **load-combining-both**: If either the `namespace` or `schemalocation` attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the `schemalocation` attribute is used.
- **license-namespace-only**: The namespace is imported. No schema document is imported.
schemalocation-hints

`--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore`

Specifies the behavior of the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: `load-by-schemalocation`.

- The `load-by-schemalocation` value uses the URL of the schema location in the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes in XML or XBRL instance documents. This is the default value.
- The `load-by-namespace` value takes the namespace part of `xsi:schemaLocation` and an empty string in the case of `xsi:noNamespaceSchemaLocation` and locates the schema via a catalog mapping.
- If `load-combining-both` is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the `-schema-mapping` option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is `ignore`, then the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes are both ignored.

schema-mapping

`--schema-mapping = prefer-schemalocation | prefer-namespace`

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the `schemalocation-hints` or the `schema-imports` option has a value of `load-combining-both`, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the `prefer-schemalocation` value refers to the URL mapping).) Default is `prefer-schemalocation`.

script

`--script = FILE`

Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

script-api-version

`--api, --script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7`

Specifies the Python API version to be used for the script. The default value is the latest version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0 and 2.0, respectively.

script-output

`--script-output = FILE`

Writes the script's standard output to the file named in `FILE`.

script-param

`--script-param = KEY:VALUE`
Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

- **xinclude**
  
  ```
  --xinclude = true|false
  ```

  Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude’s include elements are ignored. **Note**: Boolean option values are set to true if the option is specified without a value.

- **xml-mode**
  
  ```
  --xml-mode = wf|id|valid
  ```

  Specifies the XML processing mode to use for the XML instance document: `wf=`wellformed check; `id`=wellformed with ID/IDREF checks; `valid`=validation. Default value is `wf`. Note that a value of `valid` requires that each instance document loaded during processing references a DTD. If no DTD exists, an error is reported.

- **xml-mode-for-schemas**
  
  ```
  --xml-mode-for-schemas = wf|id|valid
  ```

  Specifies the XML processing mode to use for XML schema documents: `wf=`wellformed check; `id`=wellformed with ID/IDREF checks; `valid`=validation. Default value is `wf`. Note that a value of `valid` requires that each schema document loaded during processing references a DTD. If no DTD exists, an error is reported.

- **xsd-version**
  
  ```
  --xsd-version = 1.0|1.1|detect
  ```

  Specifies the W3C Schema Definition Language (XSD) version to use. Default is 1.0. This option can also be useful to find out in what ways a schema which is 1.0-compatible is not 1.1-compatible. The detect option is an Altova-specific feature. It enables the version of the XML Schema document (1.0 or 1.1) to be detected by reading the value of the `vc:minVersion` attribute of the document’s `<xs:schema>` element. If the value of the `vc:minVersion` attribute is `1.1`, the schema is detected as being version 1.1. For any other value, or if the `vc:minVersion` attribute is absent, the schema is detected as being version 1.0.

- **Catalogs and global resources**

  - **catalog**
    
    ```
    --catalog = FILE
    ```

    Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, XML Catalogs, for information about working with catalogs.

  - **user-catalog**
    
    ```
    --user-catalog = FILE
    ```

    Specifies the absolute path to an XML catalog to be used in addition to the root catalog.
See the section, XML Catalogs, for information about working with catalogs.

- **enable-globalresources**
  ```
  --enable-globalresources = true|false
  ```
  Enables global resources. Default value is false.
  **Note:** Boolean option values are set to true if the option is specified without a value.

- **globalresourceconfig [gc]**
  ```
  --gc | --globalresourceconfig = VALUE
  ```
  Specifies the active configuration of the global resource (and enables global resources).

- **globalresourcefile [gr]**
  ```
  --gr | --globalresourcefile = FILE
  ```
  Specifies the global resource file (and enables global resources).

- **Messages, errors, help, timeout, version**

  - **error-format**
    ```
    --error-format = text|shortxml|longxml
    ```
    Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

  - **error-limit**
    ```
    --error-limit = N | unlimited
    ```
    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

  - **help**
    ```
    --help
    ```
    Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

  - **log-output**
    ```
    --log-output = FILE
    ```
    Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

  - **network-timeout**
    ```
    --network-timeout = VALUE
    ```
    Specifies the timeout in seconds for remote I/O operations. Default is: 40.

  - **verbose**
    ```
    --verbose = true|false
    ```
    A value of true enables output of additional information during validation. Default value
is false.

Note: Boolean option values are set to true if the option is specified without a value.

- **verbose-output**
  
  \[--\text{verbose-output} = \text{FILE}\]
  
  Writes verbose output to \text{FILE}.

- **version**
  
  \[--\text{version}\]
  
  Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

- **warning-limit**
  
  \[--\text{warning-limit} = N | \text{unlimited}\]
  
  Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.2 Well-formedness Check Commands

The well-formedness check commands can be used to check the well-formedness of XML documents and DTDs. These commands are listed below and described in detail in the subsections of this section:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>wfxml</code></td>
<td>Checks the well-formedness of XML documents.</td>
</tr>
<tr>
<td><code>wfdtd</code></td>
<td>Checks the well-formedness of DTDs.</td>
</tr>
<tr>
<td><code>wfany</code></td>
<td>Checks the well-formedness of an XML document or DTD. Type is detected automatically.</td>
</tr>
</tbody>
</table>
3.2.1 wxml

The `wxml` command checks one or more XML documents for well-formedness according to the XML 1.0 or XML 1.1 specification.

`Windows`  `RaptorXMLXBRL wxml [options] InputFile`

`Linux`  `raptorxmlxbrl wxml [options] InputFile`

`Mac`  `raptorxmlxbrl wxml [options] InputFile`

The `InputFile` argument is the XML document to check for well-formedness. If you wish to check multiple documents, either: (i) list the files to be checked on the CLI, with each file separated from the next by a space; or (ii) list the files to be checked in a text file (.txt file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to `true` (see the Options list below).

Examples

- `raptorxmlxbrl wxml c:\Test.xml`
- `raptorxmlxbrl wxml --verbose=true c:\Test.xml`
- `raptorxmlxbrl wxml --listfile=true c:\FileList.txt`

Casing and slashes on the command line

- `RaptorXMLXBRL on Windows`
- `raptorxmlxbrl on Unix (Linux, Mac)`

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

Validation and processing

- `dtd`
  - `--dtd = FILE`
  
  Specifies the external DTD document to use for validation. If a reference to an external DTD is present in the XML document, then the CLI option overrides the external reference.

- `listfile`
  - `--listfile = true|false`

  If `true`, treats the command's `InputFile` argument as a text file containing one
filename per line. Default value is `false`. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the `--listfile` option applies only to arguments, and not to options.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

### namespaces

```
--namespaces = [true|false]
```

Enables namespace-aware processing. This is useful for checking the XML instance for errors due to incorrect namespaces. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

### recurse

```
--recurse = [true|false]
```

Used to select files within sub-directories, including in ZIP archives. If `true`, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

### streaming

```
--streaming = [true|false]
```

Enables streaming validation. Default is `true`. In streaming mode, data stored in memory is minimized and processing is faster. The downside is that information that might be required subsequently—for example, a data model of the XML instance document—will not be available. In situations where this is significant, streaming mode will need to be turned off (by giving `--streaming` a value of `false`). When using the `--script` option with the `valxml-withxsd` command, disable streaming. Note that the `--streaming` option is ignored if `--parallel-assessment` is set to `true`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

### Catalogs and global resources

#### catalog

```
--catalog = FILE
```

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, XML Catalogs, for information about working with catalogs.

#### user-catalog

```
--user-catalog = FILE
```

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

#### enable-globalresources

```
--enable-globalresources = [true|false]
```

[Header Image]
[Page Dimensions: 612.0x792.0]
[Image 118x625 to 124x631]
[Image 118x545 to 124x551]
[Image 118x429 to 124x435]
[Image 100x274 to 106x280]
[Image 118x257 to 124x263]
[Image 118x166 to 124x172]
[Image 118x98 to 124x104]
Enables global resources. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

```
\textbf{globalresourceconfig [gc]}
```
\textbf{--gc | --globalresourceconfig = VALUE}

Specifies the active configuration of the global resource (and enables global resources).

```
\textbf{globalresourcefile [gr]}
```
\textbf{--gr | --globalresourcefile = FILE}

Specifies the global resource file (and enables global resources).

```
\textbf{Messages, errors, help, timeout, version}
```

```
\textbf{error-format}
```
\textbf{--error-format = text|shortxml|longxml}

Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

```
\textbf{error-limit}
```
\textbf{--error-limit = N | unlimited}

Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

```
\textbf{help}
```
\textbf{--help}

Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

```
\textbf{log-output}
```
\textbf{--log-output = FILE}

Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

```
\textbf{network-timeout}
```
\textbf{--network-timeout = VALUE}

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

```
\textbf{verbose}
```
\textbf{--verbose = true|false}

A value of true enables output of additional information during validation. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

```
\textbf{verbose-output}
```
\textbf{--verbose-output = FILE}
Writes verbose output to $FILE$.

- **version**
  
  **--version**
  Displays the version of RaptorXML+XBRL Server. If used with a command, place **--version** before the command.

- **warning-limit**
  
  **--warning-limit = N | unlimited**
  Specifies the warning limit in the range $1-65535$ or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.2.2 wfdtd

The wfdtd command checks one or more DTD documents for well-formedness according to the XML 1.0 or XML 1.1 specification.

Windows  RaptorXMLXBRL wfdtd [options] InputFile
Linux    raptorxmlxbrl wfdtd [options] InputFile
Mac      raptorxmlxbrl wfdtd [options] InputFile

The InputFile argument is the DTD document to check for well-formedness. If you wish to check multiple documents, either: (i) list the files to be checked on the CLI, with each file separated from the next by a space; or (ii) list the files to be checked in a text file (.txt file), with one filename per line, and supply this text file as the InputFile argument together with the --listfile option set to true (see the Options list below).

Examples

- raptorxmlxbrl wfdtd c:\Test.dtd
- raptorxmlxbrl wfdtd --verbose=true c:\Test.dtd
- raptorxmlxbrl wfdtd --listfile=true c:\FileList.txt

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- Validation and processing
  - listfile
    --listfile = true|false
    If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)
    Note that the --listfile option applies only to arguments, and not to options.
    Note: Boolean option values are set to true if the option is specified without a value.
  - recurse
--reurse = true|false
Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: test.zip|zip\test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

▼ Catalogs and global resources

▼ catalog
--catalog = FILE
Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

▼ user-catalog
--user-catalog = FILE
Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

▼ enable-globalresources
--enable-globalresources = true|false
Enables global resources. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

▼ globalresourceconfig [gc]
--gc | --globalresourceconfig = VALUE
Specifies the active configuration of the global resource (and enables global resources).

▼ globalresourcefile [gr]
--gr | --globalresourcefile = FILE
Specifies the global resource file (and enables global resources).

▼ Messages, errors, help, timeout, version

▼ error-format
--error-format = text|shortxml|longxml
Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

▼ error-limit
--error-limit = N | unlimited
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor
use during validation/transformation.

- **help**
  ```
  --help
  Displays help text for the command. For example, valany --h. (Alternatively the help
  command can be used with an argument. For example: help valany.)
  ```

- **log-output**
  ```
  --log-output = FILE
  Writes the log output to the specified file URL. Ensure that the CLI has write permission
  to the output location.
  ```

- **network-timeout**
  ```
  --network-timeout = VALUE
  Specifies the timeout in seconds for remote I/O operations. Default is: 40.
  ```

- **verbose**
  ```
  --verbose = true|false
  A value of true enables output of additional information during validation. Default value
  is false.
  Note: Boolean option values are set to true if the option is specified without a value.
  ```

- **verbose-output**
  ```
  --verbose-output = FILE
  Writes verbose output to FILE.
  ```

- **version**
  ```
  --version
  Displays the version of RaptorXML+XBRL Server. If used with a command, place --
  version before the command.
  ```

- **warning-limit**
  ```
  --warning-limit = N | unlimited
  Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if
  this limit is reached, but further warnings are not reported. The default value is 100.
  ```
3.2.3  \texttt{wfany}

The \texttt{wfany} command checks an XML or DTD document for well-formedness according to the respective specification/s. The type of document is detected automatically.

\begin{itemize}
  \item \texttt{Windows} \quad \texttt{RaptorXMLXBRL \texttt{wfany} [options] InputFile}
  \item \texttt{Linux} \quad \texttt{raptorxmlxbrl \texttt{wfany} [options] InputFile}
  \item \texttt{Mac} \quad \texttt{raptorxmlxbrl \texttt{wfany} [options] InputFile}
\end{itemize}

The \texttt{InputFile} argument is the document to check for well-formedness. Note that only one document can be submitted as the argument of the command. The type of the submitted document is detected automatically.

\textbf{Examples}

\begin{itemize}
  \item \texttt{raptorxmlxbrl \texttt{wfany} c:\Test.xml}
  \item \texttt{raptorxmlxbrl \texttt{wfany} --error-format=text c:\Test.xml}
\end{itemize}

\textbf{Casing and slashes on the command line}

\begin{itemize}
  \item \texttt{RaptorXMLXBRL on Windows}
  \item \texttt{raptorxmlxbrl on Unix (Linux, Mac)}
\end{itemize}

* Note that lowercase (\texttt{raptorxmlxbrl}) works on all platforms (Windows, Linux, and Mac), while upper-lower (\texttt{RaptorXMLXBRL}) works only on Windows and Mac.

* Use forward slashes on Linux and Mac, backslashes on Windows.

\textbf{Options}

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

\textbf{Catalogs and global resources}

\begin{itemize}
  \item \texttt{catalog}
    \begin{itemize}
      \item \texttt{--catalog = FILE}
      \end{itemize}
    Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file ($<\text{installation-folder}>\text{\textbackslash Altova}\text{\textbackslash RaptorXMLXBRLServer2019}\text{\textbackslash etc}\text{\textbackslash RootCatalog.xml}$). See the section, \textbf{XML Catalogs}, for information about working with catalogs.
  \item \texttt{user-catalog}
    \begin{itemize}
      \item \texttt{--user-catalog = FILE}
      \end{itemize}
    Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, \textbf{XML Catalogs}, for information about working with catalogs.
  \item \texttt{enable-globalresources}
\end{itemize}
**Command Line Interface (CLI)**

**Well-formedness Check Commands**

```
--enable-globalresources = true|false
```

Enables global resources. Default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

```
--gc | --globalresourceconfig = VALUE
```

Specifies the active configuration of the global resource (and enables global resources).

```
--gr | --globalresourcefile = FILE
```

Specifies the global resource file (and enables global resources).

---

**Messages, errors, help, timeout, version**

```
--error-format = text|shortxml|longxml
```

Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

```
--error-limit = N | unlimited
```

Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

```
--help
```

Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

```
--log-output = FILE
```

Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

```
--network-timeout = VALUE
```

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

```
--verbose = true|false
```

A value of true enables output of additional information during validation. Default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

---
--verbose-output = FILE
Writes verbose output to FILE.

version
--version
Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

warning-limit
--warning-limit = N | unlimited
Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.3 XBRL Validation Commands

The XBRL validation commands can be used to validate XBRL instance documents and XBRL taxonomies according to the XBRL 2.1, Dimensions 1.0 and Formula 1.0 specifications. The available commands are listed below and described in detail in the sub-sections of this section:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>valxbrl</td>
<td>xbrl</td>
</tr>
<tr>
<td>valinlinexbrl</td>
<td>(ixbrl)</td>
</tr>
<tr>
<td>valxbrltaxonomy</td>
<td>dts</td>
</tr>
<tr>
<td>valltaxonomypackage</td>
<td>taxpkg</td>
</tr>
<tr>
<td>valxbrlver</td>
<td>Validates one or more XBRL versioning reports according to the XBRL Versioning 1.0 specification.</td>
</tr>
</tbody>
</table>
3.3.1 **valxbrl (xbrl)**

The `valxbrl` command validates one or more XBRL instance documents according to the XBRL 2.1, Dimensions 1.0 and Formula 1.0 specifications.

- **Windows**
  
  `RaptorXMLXBRL valxbrl | xbrl [options] InputFile`

- **Linux**
  
  `raptorxmlxbrl valxbrl | xbrl [options] InputFile`

- **Mac**
  
  `raptorxmlxbrl valxbrl | xbrl [options] InputFile`

The `InputFile` argument is the XBRL instance document to validate. To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (`.txt` file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to true (see the Options list below).

**Note:** The XBRL instance document must not be nested in another XML document and must have the `xbrl` element as its root element.  

```xml
<xbrl xmlns="http://www.xbrl.org/2003/instance"> ... </xbrl>
```

**EDGAR validation**

EDGAR (Electronic Data Gathering, Analysis, and Retrieval) is a system that performs automated collection, validation, and indexing of financial statements filed by companies to the United States SEC (Securities and Exchange Commission). `raptorxmlxbrl` supports EDGAR validation via Raptor's Python API. To run an EDGAR validation on an XBRL instance file, use the `--script` option to run the EDGAR validation Python script. In `raptorxmlxbrl`, this script, `efm-validation.py`, is located in the `etc\scripts\sec-edgar-tools` folder of the application folder:

```bash
valxbrl --script="C:\Program Files\Altova\RaptorXMLXBRLServer2019\etc\scripts\sec-edgar-tools\efm-validation.py" myinstance.xbrl
```

**Examples**

- `raptorxmlxbrl valxbrl c:\Test.xbrl`
- `raptorxmlxbrl xbrl --formula-execution=true --formula-output=c:\FormulaOutput.xml c:\Test.xbrl`
- `raptorxmlxbrl xbrl --formula-execution --assertions-output=c:\AssertionsOutput.xml c:\Test.xbrl`
- `raptorxmlxbrl xbrl --formula-execution --formula-output=c:\FormulaOutput.xml --assertions-output=c:\AssertionsOutput.xml c:\Test.xbrl`

**Casing and slashes on the command line**

- `RaptorXMLXBRL on Windows`
- `raptorxmlxbrl on Unix (Linux, Mac)`
**Note that lowercase** (raptorxmlxbrl) **works on all platforms (Windows, Linux, and Mac), while upper-lower** (RaptorXMLXBRL) **works only on Windows and Mac.**

* Use forward slashes on Linux and Mac, backslashes on Windows.

---

## Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

### XBRL validation and processing

- **additional-dts-entry-point**
  
  ```
  --additional-dts-entry-point = FILE
  ```

  Forces the specified entry-point file to be included in the DTS discovery process. Add the option multiple times to specify more than one entry point.

- **ct-restrict-mode**
  
  ```
  --ct-restrict-mode = 1.0|1.1|default
  ```

  Specifies how to check complex type restrictions. A value of 1.0 checks complex type restrictions as defined in the XSD 1.0 specification—even in XSD 1.1 validation mode. A value of 1.1 checks complex type restrictions as defined in the XSD 1.1 specification—even in XSD 1.0 validation mode. A value of default checks complex type restrictions as defined in the XSD specification of the current validation mode (1.0 or 1.1). The default value is default.

- **deduplicate**
  
  ```
  --deduplicate = true|false
  ```

  Enables de-duplication according to the Handling Duplicate Facts in XBRL and Inline XBRL 1.0 specification. Removes facts that are (i) complete duplicates, (ii) consistent duplicates (by definition these are numeric facts; the most accurate of the duplicates is retained for processing). Inconsistent and multi-language duplicates are not affected by this option. Default value is false. 

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **dimensions**
  
  ```
  --dimensions = true|false
  ```

  Enables XBRL Dimension 1.0 extensions. Default is true.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **dts**
  
  ```
  --dts = FILE
  ```

  Preloads the DTS entry point given in FILE, and uses it for the validation of instance files. Add the option multiple times to specify more than one entry point. Entry points in instance files will be ignored. The command is used to batch validate multiple instance files that all refer to the same taxonomy. The --dts option instructs the Raptor engine to load the DTS only a single time—and not for each instance in the file list. (A file list is given either on the CLI, or in a text file that is indicated as a file list by setting the --listfile option to true.) If an instance file in the file list references a different
taxonomy, then a warning is issued. This command can greatly speed up validation
time when validating many small instance files each that have a large supporting DTS; it
provides no advantage when validating a single instance file.

- **essence-alias-checks**
  
  `--essence-alias-checks = true|false`
  
  Enables reporting of essence-alias inconsistencies. Default value is `true`.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **extensible-enumerations**
  
  `--extensible-enumerations = true|false`
  
  If `true`, enables the **XBRL Extensible Enumerations 1.0** extension. Default is: `true`.

- **generic-links**
  
  `--generic-links = true|false`
  
  Enables the **XBRL Generic Links 1.0** extension. Default value is `true`.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **generic-preferred-label**
  
  `--generic-preferred-label = true|false`
  
  Enables the **XBRL Generic Preferred Label 1.0** extension. Default value is `true`.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **inconsistencies-limit**
  
  `--inconsistencies-limit = VALUE | unlimited`
  
  Specifies the XBRL inconsistencies limit, with values being in the range 1-65535 or
  unlimited. Processing continues if the limit is reached, but further inconsistencies are
  not reported. The default value is 100.

- **listfile**
  
  `--listfile = true|false`
  
  If `true`, treats the command's `InputFile` argument as a text file containing one
  filename per line. Default value is `false`. (An alternative is to list the files on the CLI with
  a space as separator. Note, however, that CLIs have a maximum-character limitation.)
  
  Note that the `--listfile` option applies only to arguments, and not to options.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **parallel-assessment [pa]**
  
  `--pa | --parallel-assessment = true|false`
  
  If set to `true`, schema validity assessment is carried out in parallel. This means that if
  there are more than 128 elements at any level, these elements are processed in parallel
  using multiple threads. Very large XML files can therefore be processed faster if this
  option is enabled. Parallel assessment takes place on one hierarchical level at a time,
  but can occur at multiple levels within a single infoset. Note that parallel assessment
does not work in streaming mode. For this reason, the `--streaming` option is ignored if
  `--parallel-assessment` is set to `true`. Also, memory usage is higher when the `--
  parallel-assessment` option is used. The default setting is `false`. Short form for the
option is --pa.

**Note:** Boolean option values are set to true if the option is specified without a value.

- **preload-xbrl-schemas**

  **--preload-xbrl-schemas =** true|false

  Preloads schemas of the XBRL 2.1 specification. Default is true.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **recurse**

  **--recurse =** true|false

  Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: test.zip|zip\test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **report-duplicates**

  **--report-duplicates =** all|complete|consistent|inconsistent|inconsistent-numeric|inconsistent-non-numeric|multi-language

  Enables the reporting of duplicate facts of the specified duplicate class. Add the option multiple times to specify more than one duplicate class. There is no default value. If no value is specified, then no check for duplicates is carried out.

- **report-duplicates-severity**

  **--report-duplicates-severity =** info|warning|inconsistency|error

  Specifies whether the detected duplicate facts should be reported as errors or warnings. If they are reported as errors, then the XBRL validation of the instance will fail. The default is error.

- **requires-element-checks**

  **--requires-element-checks =** true|false

  Enables reporting of requires-element inconsistencies. The default value is true.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **schema-imports**

  **--schema-imports =** load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only

  Specifies the behaviour of xs:import elements, each of which has an optional namespace attribute and an optional schemalocation attribute: `<import namespace="someNS" schemalocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

  The behavior is as follows:

  - load-by-schemalocation: The value of the schemalocation attribute is used to
locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).

- load-preferring-schemalocation: If the schemaLocation attribute is present, it is used, taking account of catalog mappings. If no schemaLocation attribute is present, then the value of the namespace attribute is used via a catalog mapping. This is the default value.

- load-by-namespace: The value of the namespace attribute is used to locate the schema via a catalog mapping.

- load-combining-both: If either the namespace or schemaLocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemaLocation attribute is used.

- license-namespace-only: The namespace is imported. No schema document is imported.

```
\[schema-mapping\]
```

```
--schema-mapping = prefer-schemalocation | prefer-namespace
```

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the --schemalocation-hints or the --schema-imports option has a value of load-combining-both, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the prefer-schemalocation value refers to the URL mapping).) Default is prefer-schemalocation.

```
\[schemalocation-hints\]
```

```
--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
```

Specifies the behavior of the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The load-by-schemalocation value uses the URL of the schema location in the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or XBRL instance documents. This is the default value.

- The load-by-namespace value takes the namespace part of xsi:schemaLocation and an empty string in the case of xsi:noNamespaceSchemaLocation and locates the schema via a catalog mapping.

- If load-combining-both is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.

- If the option's value is ignore, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

```
\[script\]
```

```
--script = FILE
```

Altova RaptorXML+XBRL Server 2019 © 2019 Altova GmbH
Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

- **script-api-version**
  
  `--api, --script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7`

  Specifies the Python API version to be used for the script. The default value is the latest version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0 and 2.0, respectively.

- **script-output**
  
  `--script-output = FILE`

  Writes the script's standard output to the file named in FILE.

- **script-param**
  
  `--script-param = KEY:VALUE`

  Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

- **summation-item-checks**
  
  `--summation-item-checks = true|false`

  Enables reporting of summation-item inconsistencies. The default value is true.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **taxonomy-package**
  
  `--taxonomy-package = FILE`

  Specifies the absolute path to an additional taxonomy package as described in the Taxonomy Package 1.0 and Taxonomy Packages 1.0 working drafts. The value of FILE gives the location of the taxonomy package. Add the option multiple times to specify more than one taxonomy package.

- **taxonomy-packages-config-file**
  
  `--taxonomy-packages-config-file = FILE`

  Specifies the path to the TaxonomyPackagesConfig.json file, which is used to load XBRL taxonomy packages. The file's convenience is that it serves as a catalog of taxonomy packages. The structure of the JSON file is as in the example listing below. The value of the uri key gives the location of the package. The active key (of a set of packages) switches on usage of those packages.

  ```json
  {
  \("taxonomies":
  \{"EIOPA Solvency II XBRL Taxonomy 2.1.0":
  \{"packages":[
  \{"uri":C:\\test\\XBRL\\EIOPA_SolvencyII_XBRL_Taxonomy_2.1.0.zip}\],
  \{"uri":C:\\test\\XBRL\AdditionalTestPkg.zip}\}
  ,"active":true
  },"Test Taxonomy":
  \{"packages":\{"uri":C:\\test\\XBRL\\test.zip\},"active":true
  }\}
  ```
treat-inconsistencies-as-errors

```
--treat-inconsistencies-as-errors = true|false
```

Causes XBRL validation to fail if the file contains any inconsistency as defined by the XBRL 2.1 specification. Default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

utr

```
--utr = true|false
```

If true, enables the XBRL Unit Registry 1.0 extension. Default is false.

utr-file

```
--utr-file = FILE
```

Specifies the path to the Units Registry file. The default is: http://www.xbrl.org/utr/utr.xml.

utr-status

```
--utr-status = PWD|CR|REC|NIE|PROPOSED|IWD|ACK|RR
```

Enables support of unit definitions with the given status in the Units Registry. Add the option multiple times to specify more than one unit status. Default is REC.

validate-dts-only

```
--validate-dts-only = true|false
```

The DTS is discovered by starting from the XBRL instance document. All referenced taxonomy schemas and linkbases are discovered and validated. The rest of the XBRL instance document is ignored. Default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

xinclude

```
--xinclude = true|false
```

Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude's include elements are ignored.

**Note:** Boolean option values are set to true if the option is specified without a value.

XBRL formulas and assertions

assertion-severity

```
--assertion-severity = true|false
```

Enables the Assertion Severity 1.0 extension. Default is true.

**Note:** Boolean option values are set to true if the option is specified without a value.

assertions-output

```
--assertions-output = FILE
```

Writes the output of the assertion evaluation to the specified FILE. If set, automatically specifies --formula-execution=true.
assertions-output-format

--assertions-output-format = json|xml
Specifies the output format of the assertion evaluation. Default is json.

evaluate-referenced-parameters-only

--evaluate-referenced-parameters-only = true|false
If false, forces evaluation of all parameters even if they are not referenced by any formulas/assertions/tables. Default is: true.

formula

--formula = true|false
Enables the XBRL Formula 1.0 extension. Default is true.

Note: Boolean option values are set to true if the option is specified without a value.

formula-assertion-set

--formula-assertion-set = VALUE
Limits formula execution to the given assertion set only. Add the option multiple times to specify more than one assertion set. Short form is --as. The VALUE is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special values ##none and ##all can also be used.

formula-execution

--formula-execution = true|false
Enables evaluation of XBRL formulas. Default is true. If true, automatically specifies --formula=true.

Note: Boolean option values are set to true if the option is specified without a value.

formula-output

--formula-output = FILE
Writes the output of formula evaluation to the specified FILE. If set, automatically specifies --formula-execution=true.

formula-parameters

--formula-parameters = JSON-ARRAY
Specifies parameters for XBRL formula evaluation as array of JSON maps directly on the CLI. See the section Formula Parameters for details.

formula-parameters-file

--formula-parameters-file = FILE
Specifies a FILE containing the parameters for XBRL formula evaluation. The file can be either an XML file or JSON file. See the section, Formula Parameters.

ignore-assertion

--ignore-assertion = VALUE
Excludes the given assertion from the execution. Add this option multiple times to specify more than one assertion.
- **ignore-assertions-file**
  ```
  --ignore-assertions-file = FILE
  ```
  Specifies a path to a file that contains a list of IDs/XPointers of assertions to exclude from processing. In the file, enter one assertion per line.

- **ignore-formula**
  ```
  --ignore-formula = VALUE
  ```
  Excludes the given formula from the execution. Add this option multiple times to specify more than one formula.

- **ignore-formulas-file**
  ```
  --ignore-formulas-file = FILE
  ```
  Specifies a path to a file that contains a list of formula IDs/XPointers to exclude from processing. In the file, enter one formula per line.

- **message-lang**
  ```
  --message-lang = VALUE
  ```
  Specifies the language to use when displaying validation messages. Default is: **en**. Other accepted values are **de**, **es**, **fr**, **ja**, **fr**, respectively, German, Spanish, French, and Japanese.

- **message-role**
  ```
  --message-role = VALUE
  ```
  Specifies the preferred message role to use when displaying validation messages. Default is: `http://www.xbrl.org/2010/role/message`.

- **preload-formula-schemas**
  ```
  --preload-formula-schemas = true|false
  ```
  Preloads schemas of the XBRL Formula 1.0 specification. Default is **false**.
  **Note:** Boolean option values are set to **true** if the option is specified without a value.

- **process-assertion [a]**
  ```
  --a | --process-assertion = VALUE
  ```
  Limits formula execution to the given assertion only. Add the option multiple times to specify more than one assertion. Short form is **--a**. The **VALUE** is either the value of the `@id` attribute, or a URI with an XPointer fragment that identifies the resource. The special values `##none` and `##all` can also be used.

- **process-assertion-set [as]**
  ```
  --as | --process-assertion-set = VALUE
  ```
  Limits formula execution to the given assertion set only. Add the option multiple times to specify more than one assertion set. Short form is **--as**. The **VALUE** is either the value of the `@id` attribute, or a URI with an XPointer fragment that identifies the resource. The special values `##none` and `##all` can also be used.

- **process-assertions-file**
  ```
  --process-assertions-file = FILE
  ```
Specifies a path to a file that contains a list of IDs/XPointers of assertions to execute. In the file, enter one assertion per line.

\[\text{process-formula} \{f\} \]
\[--f \mid --process-formula = \text{VALUE} \]
Limits formula execution to the given formula only. Add the option multiple times to specify more than one formula. Short form is \(--f\). The \text{VALUE} is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special values \#$none and \#$all can also be used.

\[\text{process-formulas-file} \]
\[--process-formulas-file = \text{FILE} \]
Specifies a path to a file that contains a list of IDs/XPointers of formulas to execute. In the file, enter one formula per line.

\[\text{report-unsatisfied-assertion-evaluations} \]
\[--report-unsatisfied-assertion-evaluations = true|false \]
Reports the evaluation of unsatisfied assertion as errors or warnings depending on the assigned assertion severity level. The default value is \text{false}.

\text{Note:} Boolean option values are set to \text{true} if the option is specified without a value.

\[\text{validate-formula-output} \]
\[--validate-formula-output = true|false \]
Enables XBRL validation of Formula output instance. The default value is \text{false}.

\text{Note:} Boolean option values are set to \text{true} if the option is specified without a value.

\[\text{variableset-execution-timeout} \]
\[--variableset-execution-timeout = \text{VALUE} \]
Applied when executing formulas (\(--formula-execution=true\)). Specifies the maximum time allowed for executing a single variable set (a formula or a value, or an existence or consistency assertion). The time is specified in minutes and must be a positive number. The default is 30min. If a particular variable set doesn’t finish execution before the timeout is reached, then it is aborted. An error message is displayed (and entered in the a verbose log). Note, however, that the timeout check is carried out only after every variable set evaluation—and not during execution of individual XPath expressions. So, if a single XPath expression takes long to execute, the timeout limit might be crossed. Execution of a variable set is aborted only once a complete variable set evaluation has been executed.

\[\text{XBRL tables} \]
\[\text{aspect-node-order} \]
\[--aspect-node-order = \text{lexical}|\text{instance} \]
Specifies the layout order of an open aspectNode. The default is \text{lexical}.

\[\text{concept-label-linkrole} \]
\[--concept-label-linkrole = \text{VALUE} \]
Specifies the preferred extended link role to use when rendering concept labels.

- concept-label-role
  --concept-label-role = VALUE
  Specifies the preferred label role to use when rendering concept labels. Default is: http://www.xbrl.org/2003/role/label.

- generic-label-linkrole
  --generic-label-linkrole = VALUE
  Specifies the preferred extended link role to use when rendering generic labels.

- label-lang
  --label-lang = VALUE
  Specifies the preferred language to use when rendering labels. Default is: en.

- preload-table-schemas
  --preload-table-schemas = true|false
  Preloads schemas of the XBRL Table 1.0 specification. Default is false.
  Note: Boolean option values are set to true if the option is specified without a value.

- process-table [t]
  --t | --process-table = VALUE
  Limits formula execution to the given table only. Add the option multiple times to specify more than one table. Short form is --t. The VALUE is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special values ##none and ##all can also be used.

- table
  --table = true|false
  Enables the XBRL Table 1.0 extension. Default value is true. If true, automatically specifies --formula=true and --dimensions=true.
  Note: Boolean option values are set to true if the option is specified without a value.

- table-elimination
  --table-elimination = true|false
  Enables elimination of empty table rows/columns in HTML output. Default is true.
  Note: Boolean option values are set to true if the option is specified without a value.

- table-execution
  --table-execution = true|false
  Enables evaluation of XBRL tables. Default is false. Will be set to true if --table-
output is specified. If true, automatically specifies --table=true.

Note: Boolean option values are set to true if the option is specified without a value.

- **table-linkbase-namespace**

  --table-linkbase-namespace = ##detect | http://xbrl.org/PWD/2013-05-17/table |
  | http://xbrl.org/PWD/2013-08-28/table |
  | http://xbrl.org/FR/2013-12-18/table |
  | http://xbrl.org/2014/table

Enables loading of table linkbases written with a previous draft specification. Table linkbase validation, resolution, and layout is, however, always performed according to the Table Linkbase 1.0 Recommendation of 18 March 2014. Use ##detect to enable auto-detection.

- **table-output**

  --table-output = FILE

  Writes the table output to the specified FILE. If set, automatically specifies --table-execution=true.

- **table-output-format**

  --table-output-format = xml|html

  Specifies the format of the table output. Default is xml.

---

**Catalogs and global resources**

- **catalog**

  --catalog = FILE

  Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

- **user-catalog**

  --user-catalog = FILE

  Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

- **enable-globalresources**

  --enable-globalresources = true|false

  Enables global resources. Default value is false.

  Note: Boolean option values are set to true if the option is specified without a value.

- **globalresourceconfig [gc]**

  --gc | --globalresourceconfig = VALUE
Specifies the active configuration of the global resource (and enables global resources).

- **globalresourcefile** [gr]

  --gr | --globalresourcefile = FILE

  Specifies the global resource file (and enables global resources).

- **Messages, errors, help, timeout, version**

  - **error-format**

    --error-format = text|shortxml|longxml

    Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

  - **error-limit**

    --error-limit = N | unlimited

    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

  - **help**

    --help

    Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

  - **log-output**

    --log-output = FILE

    Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

  - **network-timeout**

    --network-timeout = VALUE

    Specifies the timeout in seconds for remote I/O operations. Default is 40.

  - **verbose**

    --verbose = true|false

    A value of true enables output of additional information during validation. Default value is false.

    **Note:** Boolean option values are set to true if the option is specified without a value.

  - **verbose-output**

    --verbose-output = FILE

    Writes verbose output to FILE.
Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

```
warning-limit
--warning-limit = N | unlimited
```

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.3.2 valinlinexbrl (ixbrl)

The valinlinexbrl | ixbrl command validates one or more Inline XBRL (iXBRL) documents according to the Inline XBRL 1.0 or Inline XBRL 1.1 specification. An XBRL file is generated from the Inline XBRL and can be saved.

Windows    RaptorXMLXBRL valinlinexbrl | ixbrl [options] InputFile
Linux       raptorxmlxbrl valinlinexbrl | ixbrl [options] InputFile
Mac         raptorxmlxbrl valinlinexbrl | ixbrl [options] InputFile

The InputFile argument specifies the Inline XBRL document (typically, an XHTML document) to validate. In the first step of the validation, command execution transforms the XHTML to XBRL by extracting the Inline XBRL. If no error is generated in this first step and if the --validate-xbrl option is set to true, then the generated XBRL is validated against the XBRL taxonomy specified in the Inline XBRL.

To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the InputFile argument together with the --listfile option set to true (see the Options list below). Note that even when multiple Inline XBRL input files are processed, only one XBRL document is generated.

Examples

- raptorxmlxbrl valinlinexbrl c:\MyIXBRL.xhtml
- raptorxmlxbrl valinlinexbrl --ixbrl-version=1.1 c:\MyIXBRL.xhtml
- raptorxmlxbrl ixbrl --validate-xbrl=true --xbrl-output=C:\MyOutXBRL.xbrl C:\MyIXBRL.xhtml
- raptorxmlxbrl ixbrl --validate-xbrl=false --xbrl-output=C:\MyOutXBRL.xbrl C:\MyIXBRL.xhtml
- raptorxmlxbrl ixbrl --xbrl-output=C:\MyOutXBRL.xbrl --document-set=true --listfile=true C:\MyFileList.txt

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command’s options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.
XBRL validation and processing

- `additional-dts-entry-point`
  
  `--additional-dts-entry-point = FILE`
  
  Forces the specified entry-point file to be included in the DTS discovery process. Add the option multiple times to specify more than one entry point.

- `ct-restrict-mode`
  
  `--ct-restrict-mode = 1.0|1.1|default`
  
  Specifies how to check complex type restrictions. A value of `1.0` checks complex type restrictions as defined in the XSD 1.0 specification—even in XSD 1.1 validation mode. A value of `1.1` checks complex type restrictions as defined in the XSD 1.1 specification—even in XSD 1.0 validation mode. A value of `default` checks complex type restrictions as defined in the XSD specification of the current validation mode (1.0 or 1.1). The default value is `default`.

- `deduplicate`
  
  `--deduplicate = true|false`
  
  Enables de-duplication according to the Handling Duplicate Facts in XBRL and Inline XBRL 1.0 specification. Removes facts that are (i) complete duplicates, (ii) consistent duplicates (by definition these are numeric facts; the most accurate of the duplicates is retained for processing). Inconsistent and multi-language duplicates are not affected by this option. Default value is `false`.

  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- `dimensions`
  
  `--dimensions = true|false`
  
  Enables XBRL Dimension 1.0 extensions. Default is `true`.

  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- `dts`
  
  `--dts = FILE`
  
  Preloads the DTS entry point given in `FILE`, and uses it for the validation of instance files. Add the option multiple times to specify more than one entry point. Entry points in instance files will be ignored. The command is used to batch validate multiple instance files that all refer to the same taxonomy. The `--dts` option instructs the Raptor engine to load the DTS only a single time—and not for each instance in the file list. (A file list is given either on the CLI, or in a text file that is indicated as a file list by setting the `--listfile` option to `true`.) If an instance file in the file list references a different taxonomy, then a warning is issued. This command can greatly speed up validation time when validating many small instance files each that have a large supporting DTS; it provides no advantage when validating a single instance file.

- `essence-alias-checks`
  
  `--essence-alias-checks = true|false`
  
  Enables reporting of essence-alias inconsistencies. Default value is `true`.

  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- `extensible-enumerations`
--extensible-enumerations = true|false
If true, enables the XBRL Extensible Enumerations 1.0 extension. Default is: true.

**generic-links**

--generic-links = true|false
Enables the XBRL Generic Links 1.0 extension. Default value is true.
*Note:* Boolean option values are set to true if the option is specified without a value.

**generic-preferred-label**

--generic-preferred-label = true|false
Enables the XBRL Generic Preferred Label 1.0 extension. Default value is true.
*Note:* Boolean option values are set to true if the option is specified without a value.

**inconsistencies-limit**

--inconsistencies-limit = VALUE | unlimited
Specifies the XBRL inconsistencies limit, with values being in the range 1-65535 or unlimited. Processing continues if the limit is reached, but further inconsistencies are not reported. The default value is 100.

**listfile**

--listfile = true|false
If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the --listfile option applies only to arguments, and not to options.
*Note:* Boolean option values are set to true if the option is specified without a value.

**parallel-assessment [pa]**

--pa | --parallel-assessment = true|false
If set to true, schema validity assessment is carried out in parallel. This means that if there are more than 128 elements at any level, these elements are processed in parallel using multiple threads. Very large XML files can therefore be processed faster if this option is enabled. Parallel assessment takes place on one hierarchical level at a time, but can occur at multiple levels within a single infoset. Note that parallel assessment does not work in streaming mode. For this reason, the --streaming option is ignored if --parallel-assessment is set to true. Also, memory usage is higher when the --parallel-assessment option is used. The default setting is false. Short form for the option is --pa.
*Note:* Boolean option values are set to true if the option is specified without a value.

**preload-xbrl-schemas**

--preload-xbrl-schemas = true|false
Preloads schemas of the XBRL 2.1 specification. Default is true.
*Note:* Boolean option values are set to true if the option is specified without a value.

**recurse**

--recurse = true|false
Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: test.zip|zip|test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

\[\text{report-duplicates}\]

\[\text{--report-duplicates} = \text{all|complete|consistent|inconsistent|inconsistent-numeric|inconsistent-non-numeric|multi-language}\]

Enables the reporting of duplicate facts of the specified duplicate class. Add the option multiple times to specify more than one duplicate class. There is no default value. If no value is specified, then no check for duplicates is carried out.

\[\text{report-duplicates-severity}\]

\[\text{--report-duplicates-severity} = \text{info|warning|inconsistency|error}\]

Specifies whether the detected duplicate facts should be reported as errors or warnings. If they are reported as errors, then the XBRL validation of the instance will fail. The default is error.

\[\text{requires-element-checks}\]

\[\text{--requires-element-checks} = \text{true|false}\]

Enables reporting of requires-element inconsistencies. The default value is true.

Note: Boolean option values are set to true if the option is specified without a value.

\[\text{schema-imports}\]

\[\text{--schema-imports} = \text{load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only}\]

Specifies the behaviour of xs:import elements, each of which has an optional namespace attribute and an optional schemalocation attribute: `<import namespace="someNS" schemalocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

The behavior is as follows:

- load-by-schemalocation: The value of the schemalocation attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- load-preferring-schemalocation: If the schemalocation attribute is present, it is used, taking account of catalog mappings. If no schemalocation attribute is present, then the value of the namespace attribute is used via a catalog mapping. This is the default value.
- load-by-namespace: The value of the namespace attribute is used to locate the schema via a catalog mapping.
- load-combining-both: If either the namespace or schemalocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option)
decides which mapping is used. If no catalog mapping is present, the
schemaLocation attribute is used.
• license-namespace-only: The namespace is imported. No schema document is
imported.

\section*{schema-mapping}
\texttt{--schema-mapping = prefer-schemalocation | prefer-namespace}
If schema location and namespace are both used to find a schema document,
specifies which of them should be preferred during catalog lookup. (If either the --
schemalocation-hints or the --schema-imports option has a value of load-
combining-both, and if the namespace and URL parts involved both have catalog
mappings, then the value of this option specifies which of the two mappings to use
(namespace mapping or URL mapping; the prefer-schemalocation value refers to the
URL mapping.) Default is prefer-schemalocation.

\section*{schemalocation-hints}
\texttt{--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore}
Specifies the behavior of the xsi:schemaLocation and
xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document,
and, if yes, which information should be used to find it. Default: load-by-
schemalocation.

• The load-by-schemalocation value uses the URL of the schema location in the
xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or
XBRL instance documents. This is the default value.
• The load-by-namespace value takes the namespace part of xsi:schemaLocation
and an empty string in the case of xsi:noNamespaceSchemaLocation and locates
the schema via a catalog mapping.
• If load-combining-both is used and if either the namespace part or the URL part
has a catalog mapping, then the catalog mapping is used. If both have catalog
mappings, then the value of the --schema-mapping option (XBRL option and XML/
XSD option) decides which mapping is used. If neither the namespace nor URL has
a catalog mapping, the URL is used.
• If the option's value is ignore, then the xsi:schemaLocation and
xsi:noNamespaceSchemaLocation attributes are both ignored.

\section*{script}
\texttt{--script = FILE}
Executes the Python script in the submitted file after validation has been completed.
Add the option multiple times to specify more than one script.

\section*{script-api-version}
\texttt{--api, --script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7}
Specifies the Python API version to be used for the script. The default value is the latest
version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0
and 2.0, respectively.

\section*{script-output}
--script-output = FILE
Writes the script's standard output to the file named in FILE.

- script-param
  --script-param = KEY:VALUE
  Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

- summation-item-checks
  --summation-item-checks = true|false
  Enables reporting of summation-item inconsistencies. The default value is true.  
  Note: Boolean option values are set to true if the option is specified without a value.

- taxonomy-package
  --taxonomy-package = FILE
  Specifies the absolute path to an additional taxonomy package as described in the Taxonomy Package 1.0 and Taxonomy Packages 1.0 working drafts. The value of FILE gives the location of the taxonomy package. Add the option multiple times to specify more than one taxonomy package.

- taxonomy-packages-config-file
  --taxonomy-packages-config-file = FILE
  Specifies the path to the TaxonomyPackagesConfig.json file, which is used to load XBRL taxonomy packages. The file's convenience is that it serves as a catalog of taxonomy packages. The structure of the JSON file is as in the example listing below. The value of the uri key gives the location of the package. The active key (of a set of packages) switches on usage of those packages.

```json
{"taxonomies":
  {"EIOPA Solvency II XBRL Taxonomy 2.1.0":
   {"packages":[
    {"uri":"C:\test\XBRL\EIOPA_SolvencyII_XBRL_Taxonomy_2.1.0.zip"},
    {"uri":"C:\test\XBRL\AdditionalTestPkg.zip"}
   ],"active":true
  },"Test Taxonomy":
  {"packages": [{"uri":"C:\test\XBRL\test.zip"}],"active":true
  }
}
```

- treat-inconsistencies-as-errors
  --treat-inconsistencies-as-errors = true|false
  Causes XBRL validation to fail if the file contains any inconsistency as defined by the XBRL 2.1 specification. Default value is false.  
  Note: Boolean option values are set to true if the option is specified without a value.

- utr
  --utr = true|false
  If true, enables the XBRL Unit Registry 1.0 extension. Default is: false.
utr-file

--utr-file = FILE

Specifies the path to the Units Registry file. The default is: http://www.xbrl.org/utr/utr.xml.

utr-status

--utr-status = PWD|CR|REC|NIE|PROPOSED|IWD|ACK|RR

Enables support of unit definitions with the given status in the Units Registry. Add the option multiple times to specify more than one unit status. Default is REC.

validate-dts-only

--validate-dts-only = true|false

The DTS is discovered by starting from the XBRL instance document. All referenced taxonomy schemas and linkbases are discovered and validated. The rest of the XBRL instance document is ignored. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

xinclude

--xinclude = true|false

Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude's include elements are ignored.

Note: Boolean option values are set to true if the option is specified without a value.

Inline XBRL

document-set

--document-set = true|false

If set to true, all submitted files (the Inline XBRL documents) will be treated as an Inline XBRL Document Set. The default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

ixbrl-version

--ixbrl-version = 1.0|1.1|detect

Specifies the version of the Inline XBRL specification to use for validation. The default is detect.

transformation-registry

--transformation-registry =

#all |
| http://www.xbrl.org/2008/inlineXBRL/transformation |
| http://www.xbrl.org/inlineXBRL/transformation/2010-04-20 |
| http://www.xbrl.org/inlineXBRL/transformation/2015-02-26 |

In Inline XBRL, date and numeric types may be rendered in a variety of lexical formats, but in XBRL these types have specific formats. For example, a date in the Inline XBRL
might be given as 01 January 2017, but in XBRL the format of this date would be 2017-01-01. The Inline XBRL Transformation Registries specify the conversion rules to follow when date and numeric values are converted from Inline XBRL to XBRL. The transformation-registry option limits the registry that will be used to that which you specify. Add the option multiple times to specify more than one transformation registry. The default value is #all, which selects all available transformation registries. (For the list of available transformation registries in your version of RaptorXML+XBRL Server, check the description of the command on the CLI.)

\textbf{uri-transformation}

\texttt{--uri-transformation = none|make-absolute|make-relative|keep-relative}

Specifies how URIs should written to the generated XBRL document.

- none: Copy URI verbatim to target document
- make-absolute: Make any relative URIs absolute by resolving against the in-scope base URI at the respective element in the input document. For example: if the input file is \texttt{c:\test\inlinexbrl.xhtml}, and it contains a relative reference to a schema, \texttt{schemas\schema.xsd}, then the relative reference would be resolved to: \texttt{c:\test\schemas\schema.xsd}. Note that xml:base attributes in the input document can change the base URI.
- make-relative: If possible, make any absolute and relative URIs relative to the output document (otherwise write the resolved absolute URI)
- keep-relative: If possible, make only the relative URIs relative to the output document (and copy any absolute URI)

\textbf{validate-xbrl}

\texttt{--validate-xbrl = true|false}

If set to true, enables validation of the XBRL document that is generated from the Inline XBRL document. If set to false, then validation stops after the first step that generates the XBRL. The default value is true.

\textit{Note:} Boolean option values are set to true if the option is specified without a value.

\textbf{xbrl-output}

\texttt{--xbrl-output = FILE}

Writes the generated XBRL output to the file location specified in this option. Note that even when multiple Inline XBRL input files are processed, only one XBRL document is generated.

\textbf{XBRL formulas and assertions}

\textbf{assertion-severity}

\texttt{--assertion-severity = true|false}

Enables the Assertion Severity 1.0 extension. Default is true.

\textit{Note:} Boolean option values are set to true if the option is specified without a value.

\textbf{assertions-output}

\texttt{--assertions-output = FILE}

Writes the output of the assertion evaluation to the specified FILE. If set, automatically
specifies --formula-execution=true.

- assertions-output-format
  --assertions-output-format = json|xml
  Specifies the output format of the assertion evaluation. Default is json.

- evaluate-referenced-parameters-only
  --evaluate-referenced-parameters-only = true|false
  If false, forces evaluation of all parameters even if they are not referenced by any formulas/assertions/tables. Default is: true.

- formula
  --formula = true|false
  Enables the XBRL Formula 1.0 extension. Default is true.
  _Note:_ Boolean option values are set to true if the option is specified without a value.

- formula-assertion-set [[DEPRECATED]]
  --formula-assertion-set = VALUE
  Limits formula execution to the given assertion set only. Add the option multiple times to specify more than one assertion set. Short form is --as. The VALUE is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special values ##none and ##all can also be used.

- formula-execution
  --formula-execution = true|false
  Enables evaluation of XBRL formulas. Default is true. If true, automatically specifies --formula=true.
  _Note:_ Boolean option values are set to true if the option is specified without a value.

- formula-output
  --formula-output = FILE
  Writes the output of formula evaluation to the specified FILE. If set, automatically specifies --formula-execution=true.

- formula-parameters
  --formula-parameters = JSON-ARRAY
  Specifies parameters for XBRL formula evaluation as array of JSON maps directly on the CLI. See the section Formula Parameters for details.

- formula-parameters-file
  --formula-parameters-file = FILE
  Specifies a FILE containing the parameters for XBRL formula evaluation. The file can be either an XML file or JSON file. See the section Formula Parameters.

- ignore-assertion
  --ignore-assertion = VALUE
  Excludes the given assertion from the execution. Add this option
multiple times to specify more than one assertion.

- **ignore-assertions-file**
  ```
  --ignore-assertions-file = FILE
  ```
  Specifies a path to a file that contains a list of IDs/XPointers of assertions to exclude from processing. In the file, enter one assertion per line.

- **ignore-formula**
  ```
  --ignore-formula = VALUE
  ```
  Excludes the given formula from the execution. Add this option multiple times to specify more than one formula.

- **ignore-formulas-file**
  ```
  --ignore-formulas-file = FILE
  ```
  Specifies a path to a file that contains a list of formula IDs/XPointers to exclude from processing. In the file, enter one formula per line.

- **message-lang**
  ```
  --message-lang = VALUE
  ```
  Specifies the language to use when displaying validation messages. Default is: `en`. Other accepted values are `de`, `es`, `fr`, `ja`, for, respectively, German, Spanish, French, and Japanese.

- **message-role**
  ```
  --message-role = VALUE
  ```
  Specifies the preferred message role to use when displaying validation messages. Default is: `http://www.xbrl.org/2010/role/message`.

- **preload-formula-schemas**
  ```
  --preload-formula-schemas = true|false
  ```
  Preloads schemas of the XBRL Formula 1.0 specification. Default is `false`. **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **process-assertion**
  ```
  --a | --process-assertion = VALUE
  ```
  Limits formula execution to the given assertion only. Add the option multiple times to specify more than one assertion. Short form is `--a`. The `VALUE` is either the value of the `@id` attribute, or a URI with an XPointer fragment that identifies the resource. The special values `##none` and `##all` can also be used.

- **process-assertion-set**
  ```
  --as | --process-assertion-set = VALUE
  ```
  Limits formula execution to the given assertion set only. Add the option multiple times to specify more than one assertion set. Short form is `--as`. The `VALUE` is either the value of the `@id` attribute, or a URI with an XPointer fragment that identifies the resource. The special values `##none` and `##all` can also be used.
process-assertions-file

--process-assertions-file = FILE

Specifies a path to a file that contains a list of IDs/XPointers of assertions to execute. In the file, enter one assertion per line.

process-formula [f]

--f | --process-formula = VALUE

Limits formula execution to the given formula only. Add the option multiple times to specify more than one formula. Short form is --f. The VALUE is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special values ##none and ##all can also be used.

process-formulas-file

--process-formulas-file = FILE

Specifies a path to a file that contains a list of IDs/XPointers of formulas to execute. In the file, enter one formula per line.

report-unsatisfied-assertion-evaluations

--report-unsatisfied-assertion-evaluations = true|false

Reports the evaluation of unsatisfied assertion as errors or warnings depending on the assigned assertion severity level. The default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

variableset-execution-timeout

--variableset-execution-timeout = VALUE

Applied when executing formulas (--formula-execution=true). Specifies the maximum time allowed for executing a single variable set (a formula or a value, or an existence or consistency assertion). The time is specified in minutes and must be a positive number. The default is 30min. If a particular variable set doesn’t finish execution before the timeout is reached, then it is aborted. An error message is displayed (and entered in the a verbose log). Note, however, that the timeout check is carried out only after every variable set evaluation—and not during execution of individual XPath expressions. So, if a single XPath expression takes long to execute, the timeout limit might be crossed. Execution of a variable set is aborted only once a complete variable set evaluation has been executed.

XBRL tables

aspect-node-order

--aspect-node-order = lexical|instance

Specifies the layout order of an open aspectNode. The default is lexical.

collect-label-linkrole

--collect-label-linkrole = VALUE

Specifies the preferred extended link role to use when rendering concept labels.

collect-label-role
--cconcept-label-role = VALUE
Specifies the preferred label role to use when rendering concept labels. Default is:

- generic-label-linkrole
  --generic-label-linkrole = VALUE
  Specifies the preferred extended link role to use when rendering generic labels.

- generic-label-role
  --generic-label-role = VALUE
  Specifies the preferred label role to use when rendering generic labels. Default is: http://

- label-lang
  --label-lang = VALUE
  Specifies the preferred language to use when rendering labels. Default is: en.

- preload-table-schemas
  --preload-table-schemas = true|false
  Preloads schemas of the XBRL Table 1.0 specification. Default is false.
  Note: Boolean option values are set to true if the option is specified without a value.

- process-table [t]
  --t | --process-table = VALUE
  Limits formula execution to the given table only. Add the option multiple times to
  specify more than one table. Short form is --t. The VALUE is either the value of the @id
  attribute, or a URI with an XPointer fragment that identifies the resource. The special
  values ##none and ##all can also be used.

- table
  --table = true|false
  Enables the XBRL Table 1.0 extension. Default value is true. If true, automatically
  specifies --formula=true and --dimensions=true.
  Note: Boolean option values are set to true if the option is specified without a value.

- table-elimination
  --table-elimination = true|false
  Enables elimination of empty table rows/columns in HTML output. Default is true.
  Note: Boolean option values are set to true if the option is specified without a value.

- table-execution
  --table-execution = true|false
  Enables evaluation of XBRL tables. Default is false. Will be set to true if --table-
  output is specified. If true, automatically specifies --table=true.
  Note: Boolean option values are set to true if the option is specified without a value.

- table-linkbase-namespace
Command Line Interface (CLI) XBRL Validation Commands

--table-linkbase-namespace =

**#detect**

- http://xbrl.org/FWD/2013-05-17/table
- http://xbrl.org/FWD/2013-08-28/table
- http://xbrl.org/PR/2013-12-18/table
- http://xbrl.org/2014/table

Enables loading of table linkbases written with a previous draft specification. Table linkbase validation, resolution, and layout is, however, always performed according to the Table Linkbase 1.0 Recommendation of 18 March 2014. Use **#detect** to enable auto-detection.

### table-output

**--table-output =** `FILE`

Writes the table output to the specified `FILE`. If set, automatically specifies **--table-execution=true**.

### table-output-format

**--table-output-format =** `xml|html`

Specifies the format of the table output. Default is `xml`.

### Catalogs and global resources

#### catalog

**--catalog =** `FILE`

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\raptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, XML Catalogs, for information about working with catalogs.

#### user-catalog

**--user-catalog =** `FILE`

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

#### enable-globalresources

**--enable-globalresources =** `true|false`

Enables global resources. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

#### globalresourceconfig [gc]

**--gc | --globalresourceconfig =** `VALUE`

Specifies the active configuration of the global resource (and enables global resources).

#### globalresourcefile [gr]

**--gr | --globalresourcefile =** `FILE`
Specifies the global resource file (and enables global resources).

- **Messages, errors, help, timeout, version**
  - **error-format**
    ```plaintext
    --error-format = text|shortxml|longxml
    ```
    Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

  - **error-limit**
    ```plaintext
    --error-limit = N | unlimited
    ```
    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

- **help**
  ```plaintext
  --help
  ```
  Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

- **log-output**
  ```plaintext
  --log-output = FILE
  ```
  Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

- **network-timeout**
  ```plaintext
  --network-timeout = VALUE
  ```
  Specifies the timeout in seconds for remote I/O operations. Default is: 40.

- **verbose**
  ```plaintext
  --verbose = true|false
  ```
  A value of true enables output of additional information during validation. Default value is false.
  *Note:* Boolean option values are set to true if the option is specified without a value.

- **verbose-output**
  ```plaintext
  --verbose-output = FILE
  ```
  Writes verbose output to FILE.

- **version**
  ```plaintext
  --version
  ```
  Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

- **warning-limit**
  ```plaintext
  --warning-limit = N | unlimited
  ```
Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.3.3 valxbrltaxonomy (dts)

The `valxbrltaxonomy | dts` command validates one or more XBRL taxonomies (schemas) according to the XBRL 2.1, Dimensions 1.0 and Formula 1.0 specifications.

```
Windows  RaptorXMLXBRL valxbrltaxonomy | dts [options] InputFile
Linux     raptorxmlxbrl valxbrltaxonomy | dts [options] InputFile
Mac       raptorxmlxbrl valxbrltaxonomy | dts [options] InputFile
```

The `InputFile` argument is the XBRL taxonomy to validate. To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to `true` (see the Options list below).

**Examples**

```
• raptorxmlxbrl valxbrltaxonomy c:\Test.xsd
• raptorxmlxbrl dts --listfile c:\FileList.txt
```

**Casing and slashes on the command line**

<table>
<thead>
<tr>
<th>RaptorXMLXBRL on Windows</th>
<th>raptorxmlxbrl on Unix (Linux, Mac)</th>
</tr>
</thead>
<tbody>
<tr>
<td>* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.</td>
<td></td>
</tr>
<tr>
<td>* Use forward slashes on Linux and Mac, backslashes on Windows.</td>
<td></td>
</tr>
</tbody>
</table>

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

** XBRL validation and processing **

```
• ct-restrict-mode

  --ct-restrict-mode = 1.0|1.1|default

  Specifies how to check complex type restrictions. A value of 1.0 checks complex type restrictions as defined in the XSD 1.0 specification—even in XSD 1.1 validation mode. A value of 1.1 checks complex type restrictions as defined in the XSD 1.1 specification—even in XSD 1.0 validation mode. A value of default checks complex type restrictions as defined in the XSD specification of the current validation mode (1.0 or 1.1). The default value is default.
```

```
• assertion-severity
```
---assertion-severity = true|false
Enables the Assertion Severity 1.0 extension. Default is true.

Note: Boolean option values are set to true if the option is specified without a value.

dimensions
---dimensions = true|false
Enables XBRL Dimension 1.0 extensions. Default is true.

Note: Boolean option values are set to true if the option is specified without a value.

evaluate-referenced-parameters-only
---evaluate-referenced-parameters-only = true|false
If false, forces evaluation of all parameters even if they are not referenced by any formulas/assertions/tables. Default is: true.

extensible-enumerations
---extensible-enumerations = true|false
If true, enables the XBRL Extensible Enumerations 1.0 extension. Default is: true.

inconsistencies-limit
---inconsistencies-limit = VALUE | unlimited
Specifies the XBRL inconsistencies limit, with values being in the range 1-65535 or unlimited. Processing continues if the limit is reached, but further inconsistencies are not reported. The default value is 100.

formula
---formula = true|false
Enables the XBRL Formula 1.0 extension. Default is true.

Note: Boolean option values are set to true if the option is specified without a value.

formula-parameters
---formula-parameters = JSON-ARRAY
Specifies parameters for XBRL formula evaluation as array of JSON maps directly on the CLI. See the section Formula Parameters for details.

formula-parameters-file
---formula-parameters-file = FILE
Specifies a FILE containing the parameters for XBRL formula evaluation. The file can be either an XML file or JSON file. See the section Formula Parameters.

generic-links
---generic-links = true|false
Enables the XBRL Generic Links 1.0 extension. Default value is true.

Note: Boolean option values are set to true if the option is specified without a value.

generic-preferred-label
---generic-preferred-label = true|false
Enables the XBRL Generic Preferred Label 1.0 extension. Default value is true.
Note: Boolean option values are set to `true` if the option is specified without a value.

- **listfile**
  ```
  --listfile = true|false
  ```
  If `true`, treats the command's `InputFile` argument as a text file containing one filename per line. Default value is `false`. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)
  Note that the `--listfile` option applies only to arguments, and not to options.
  Note: Boolean option values are set to `true` if the option is specified without a value.

- **preload-formula-schemas**
  ```
  --preload-formula-schemas = true|false
  ```
  Preloads schemas of the XBRL Formula 1.0 specification. Default is `false`.
  Note: Boolean option values are set to `true` if the option is specified without a value.

- **preload-xbrl-schemas**
  ```
  --preload-xbrl-schemas = true|false
  ```
  Preloads schemas of the XBRL 2.1 specification. Default is `true`.
  Note: Boolean option values are set to `true` if the option is specified without a value.

- **recurse**
  ```
  --recurse = true|false
  ```
  Used to select files within sub-directories, including in ZIP archives. If `true`, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is `false`.
  Note: Boolean option values are set to `true` if the option is specified without a value.

- **schema-imports**
  ```
  --schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only
  ```
  Specifies the behaviour of `xs:import` elements, each of which has an optional `namespace` attribute and an optional `schemaLocation` attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: `load-preferring-schemalocation`.
  The behavior is as follows:

  - `load-by-schemalocation`: The value of the `schemaLocation` attribute is used to locate the schema, taking account of catalog mappings. If the `namespace` attribute is present, the namespace is imported (licensed).
  - `load-preferring-schemalocation`: If the `schemaLocation` attribute is present, it is used, taking account of catalog mappings. If no `schemaLocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This is the default value.
  - `load-by-namespace`: The value of the `namespace` attribute is used to locate the
schema via a catalog mapping.

- load-combining-both: If either the namespace or schemaLocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemaLocation attribute is used.
- license-namespace-only: The namespace is imported. No schema document is imported.

```
\textbf{schema-mapping}
```

\texttt{--schema-mapping = prefer-schemalocation | prefer-namespace}

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the --schemalocation-hints or the --schema-imports option has a value of load-combining-both, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the prefer-schemalocation value refers to the URL mapping).) Default is prefer-schemalocation.

```
\textbf{schemalocation-hints}
```

\texttt{--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore}

Specifies the behavior of the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The load-by-schemalocation value uses the URL of the schema location in the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or XBRL instance documents. This is the default value.
- The load-by-namespace value takes the namespace part of xsi:schemaLocation and an empty string in the case of xsi:noNamespaceSchemaLocation and locates the schema via a catalog mapping.
- If load-combining-both is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option’s value is ignore, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

```
\textbf{script}
```

\texttt{--script = FILE}

Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

```
\textbf{script-api-version}
```

\texttt{--api, --script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7}

Specifies the Python API version to be used for the script. The default value is the latest
Command Line Interface (CLI)  
XBRL Validation Commands  113

version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0 and 2.0, respectively.

**script-output**

```bash
--script-output = FILE
```

Write the script's standard output to the file named in FILE.

**script-param**

```bash
--script-param = KEY:VALUE
```

Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

**taxonomy-package**

```bash
--taxonomy-package = FILE
```

Specifies the absolute path to an additional taxonomy package as described in the Taxonomy Package 1.0 and Taxonomy Packages 1.0 working drafts. The value of FILE gives the location of the taxonomy package. Add the option multiple times to specify more than one taxonomy package.

**taxonomy-packages-config-file**

```bash
--taxonomy-packages-config-file = FILE
```

Specifies the path to the TaxonomyPackagesConfig.json file, which is used to load XBRL taxonomy packages. The file's convenience is that it serves as a catalog of taxonomy packages. The structure of the JSON file is as in the example listing below. The value of the uri key gives the location of the package. The active key (of a set of packages) switches on usage of those packages.

```json
{"taxonomies":
 {"EIOPA Solvency II XBRL Taxonomy 2.1.0":
  {"packages":[
   {"uri":"C:\test\XBRL\EIOPA_SolvencyII_XBRL_Taxonomy_2.1.0.zip"},
   {"uri":"C:\test\XBRL\AdditionalTestPkg.zip"}
  ],"active":true
 },"Test Taxonomy":
 {"packages":[{"uri":"C:\test\XBRL\test.zip"}],"active":true
 }
 }
```

**treat-inconsistencies-as-errors**

```bash
--treat-inconsistencies-as-errors = true|false
```

Causes XBRL validation to fail if the file contains any inconsistency as defined by the XBRL 2.1 specification. Default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

**xinclude**

```bash
--xinclude = true|false
```

Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude's include elements are ignored.
Note: Boolean option values are set to true if the option is specified without a value.

**XBRL tables**

- **aspect-node-order**
  
  ```
  --aspect-node-order = lexical|instance
  ```
  
  Specifies the layout order of an open aspectNode. The default is lexical.

- **concept-label-linkrole**
  
  ```
  --concept-label-linkrole = VALUE
  ```
  
  Specifies the preferred extended link role to use when rendering concept labels.

- **concept-label-role**
  
  ```
  --concept-label-role = VALUE
  ```
  
  Specifies the preferred label role to use when rendering concept labels. Default is: http://www.xbrl.org/2003/role/label.

- **evaluate-referenced-parameters-only**
  
  ```
  --evaluate-referenced-parameters-only = true|false
  ```
  
  If false, forces evaluation of all parameters even if they are not referenced by any formulas/assertions/tables. Default is: true.

- **generic-label-linkrole**
  
  ```
  --generic-label-linkrole = VALUE
  ```
  
  Specifies the preferred extended link role to use when rendering generic labels.

- **generic-label-role**
  
  ```
  --generic-label-role = VALUE
  ```
  
  Specifies the preferred label role to use when rendering generic labels. Default is: http://www.xbrl.org/2003/role/label.

- **label-lang**
  
  ```
  --label-lang = VALUE
  ```
  
  Specifies the preferred language to use when rendering labels. Default is: en.

- **preload-table-schemas**
  
  ```
  --preload-table-schemas = true|false
  ```
  
  Preloads schemas of the XBRL Table 1.0 specification. Default is false. Note: Boolean option values are set to true if the option is specified without a value.

- **process-table [t]**
  
  ```
  --t | --process-table = VALUE
  ```
  
  Limits formula execution to the given table only. Add the option multiple times to specify more than one table. Short form is --t. The VALUE is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special
values **##none** and **##all** can also be used.

**table**

```bash
--table = true|false
```

Enables the XBRL Table 1.0 extension. Default value is true. If true, automatically specifies **--formula=true** and **--dimensions=true**.

*Note:* Boolean option values are set to true if the option is specified without a value.

**table-execution**

```bash
--table-execution = true|false
```

Enables evaluation of XBRL tables. Default is false. Will be set to true if **--table-output** is specified. If true, automatically specifies **--table=true**.

*Note:* Boolean option values are set to true if the option is specified without a value.

**table-linkbase-namespace**

```bash
```

Enables loading of table linkbases written with a previous draft specification. Table linkbase validation, resolution, and layout is, however, always performed according to the Table Linkbase 1.0 Recommendation of 18 March 2014. Use **##detect** to enable auto-detection.

**table-output**

```bash
--table-output = FILE
```

Writes the table output to the specified FILE. If set, automatically specifies **--table-execution=true**.

**table-output-format**

```bash
--table-output-format = xml|html
```

Specifies the format of the table output. Default is xml.

**Catalogs and global resources**

**catalog**

```bash
--catalog = FILE
```

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (**<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml**). See the section, XML Catalogs, for information about working with catalogs.
---user-catalog = FILE
Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

enable-globalresources
---enable-globalresources = true|false
Enables global resources. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

globalresourceconfig [gc]
---gc | --globalresourceconfig = VALUE
Specifies the active configuration of the global resource (and enables global resources).

globalresourcefile [gr]
---gr | --globalresourcefile = FILE
Specifies the global resource file (and enables global resources).

Messages, errors, help, timeout, version
error-format
---error-format = text|shortxml|longxml
Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

error-limit
---error-limit = N | unlimited
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

help
---help
Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

log-output
---log-output = FILE
Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

network-timeout
---network-timeout = VALUE
Specifies the timeout in seconds for remote I/O operations. Default is: 40.

verbose
---verbose = true|false
A value of `true` enables output of additional information during validation. Default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

- **verbose-output**
  ```
  --verbose-output = FILE
  ```
  Writes verbose output to `FILE`.

- **version**
  ```
  --version
  ```
  Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

- **warning-limit**
  ```
  --warning-limit = N | unlimited
  ```
  Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.3.4 valtaxonomypackage (taxpkg)

The `valtaxonomypackage | taxpkg` command validates one or more XBRL taxonomy packages according to the Taxonomy 1.0 Packages specification.

Windows  `raptorXMLXBRL valtaxonomypackage | taxpkg [options] TaxonomyPackage`

Linux  `raptorxmlxbrl valtaxonomypackage | taxpkg [options] TaxonomyPackage`

Mac  `raptorxmlxbrl valtaxonomypackage | taxpkg [options] TaxonomyPackage`

The `TaxonomyPackage` argument is the XBRL taxonomy package to validate. The taxonomy package is typically a ZIP file. To validate multiple taxonomy packages, either: (i) list the packages to be validated on the CLI, with each package separated from the next by a space; or (ii) list the packages to be validated in a text file (.txt file), with one filename per line, and supply this text file as the `TaxonomyPackage` argument together with the `--listfile` option set to `true` (see the Options list below).

Examples

- `raptorxmlxbrl valxtaxonomypackage c:\Test.zip`
- `raptorxmlxbrl taxpkg --listfile=true c:\TaxonomyPackageList.txt`
- `raptorxmlxbrl taxpkg --listfile c:\TaxonomyPackageList.txt`

Casing and slashes on the command line

- `RaptorXMLXBRL on Windows`
- `raptorxmlxbrl on Unix (Linux, Mac)`

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
  * Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- **Processing**
  - `--listfile = true|false`
    - If `true`, treats the command's `InputFile` argument as a text file containing one filename per line. Default value is `false`. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)
Note that the --listfile option applies only to arguments, and not to options.

**Note:** Boolean option values are set to true if the option is specified without a value.

### recurse

**--recurse = true|false**

Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, `*.xml` will select all .xml files in the (zip) folder. The option's default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

### schema-imports

**--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only**

Specifies the behaviour of xs:import elements, each of which has an optional namespace attribute and an optional schemalocation attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

The behavior is as follows:

- **load-by-schemalocation:** The value of the schemalocation attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation:** If the schemalocation attribute is present, it is used, taking account of catalog mappings. If no schemalocation attribute is present, then the value of the namespace attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace:** The value of the namespace attribute is used to locate the schema via a catalog mapping.
- **load-combining-both:** If either the namespace or schemalocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemalocation attribute is used.
- **license-namespace-only:** The namespace is imported. No schema document is imported.

### schema-mapping

**--schema-mapping = prefer-schemalocation | prefer-namespace**

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the --schemalocation-hints or the --schema-imports option has a value of load-combining-both, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the prefer-schemalocation value refers to the URL mapping).) Default is prefer-schemalocation.
\textbf{schemalocation-hints}

---schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore

Specifies the behavior of the \texttt{xsi:schemaLocation} and \texttt{xsi:noNamespaceSchemaLocation} attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The \texttt{load-by-schemalocation} value uses the URL of the schema location in the \texttt{xsi:schemaLocation} and \texttt{xsi:noNamespaceSchemaLocation} attributes in XML or XBRL instance documents. This is the \textbf{default value}.
- The \texttt{load-by-namespace} value takes the namespace part of \texttt{xsi:schemaLocation} and an empty string in the case of \texttt{xsi:noNamespaceSchemaLocation} and locates the schema via a \texttt{catalog mapping}.
- If \texttt{load-combining-both} is used and if either the namespace part or the URL part has a \texttt{catalog mapping}, then the \texttt{catalog mapping} is used. If both have \texttt{catalog mappings}, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is \texttt{ignore}, then the \texttt{xsi:schemaLocation} and \texttt{xsi:noNamespaceSchemaLocation} attributes are both ignored.

\textbf{script}

---script = FILE

Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

\textbf{script-api-version}

---api, --script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7

Specifies the Python API version to be used for the script. The default value is the latest version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0 and 2.0, respectively.

\textbf{script-output}

---script-output = FILE

Writes the script's standard output to the file named in \texttt{FILE}.

\textbf{script-param}

---script-param = \texttt{KEY:VALUE}

Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

\textbf{Catalogs and global resources}

\textbf{catalog}

---catalog = FILE
Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (\installation-folder\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

- **user-catalog**

  --user-catalog = **FILE**
  Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

- **enable-globalresources**

  --enable-globalresources = **true|false**
  Enables global resources. Default value is false. **Note:** Boolean option values are set to true if the option is specified without a value.

- **globalresourceconfig [gc]**

  --gc | --globalresourceconfig = **VALUE**
  Specifies the active configuration of the global resource (and enables global resources).

- **globalresourcefile [gr]**

  --gr | --globalresourcefile = **FILE**
  Specifies the global resource file (and enables global resources).

- **Messages, errors, help, timeout, version**

  - **error-format**

    --error-format = **text|shortxml|longxml**
    Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

  - **error-limit**

    --error-limit = **N | unlimited**
    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

  - **help**

    --help
    Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

  - **log-output**

    --log-output = **FILE**
    Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.
network-timeout

--network-timeout = VALUE

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

verbose

--verbose = true|false

A value of true enables output of additional information during validation. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

verbose-output

--verbose-output = FILE

Writes verbose output to FILE.

version

--version

Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

warning-limit

--warning-limit = N | unlimited

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.3.5 valxbrlver

The `valxbrlver` command validates one or more XBRL versioning reports according to the [XBRL Versioning 1.0 specification](https://www.xbrl.org/specifications/xbrlversioning/).

For `Windows`:

```
RaptorXMLXBRL valxbrlver [options] InputFile
```

For `Linux`

```
raptorxmlxbrl valxbrlver [options] InputFile
```

For `Mac`

```
raptorxmlxbrl valxbrlver [options] InputFile
```

The `InputFile` argument is the XBRL versioning report, which is an XML document (with a `.xml` extension). To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to `true` (see the Options list below).

**Examples**

```
  raptorxmlxbrl valxbrlver c:\MyXBRLVersioningReport.xml
  raptorxmlxbrl valxbrlver c:\MyXBRLVersioningReports.txt
```

**Casing and slashes on the command line**

```
RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)
```

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.

* Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Messages, errors, help, timeout, version**

```
error-format

```

```
--error-format = text|shortxml|longxml
```

Specifies the format of the error output. Default value is `text`. The other options generate XML formats, with `longxml` generating more detail.

```
error-limit

```

```
--error-limit = N | unlimited
```

Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.
Command Line Interface (CLI) XBRL Validation Commands

- **help**
  ```markdown
  --help
  Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)
  ```

- **log-output**
  ```markdown
  --log-output = FILE
  Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.
  ```

- **network-timeout**
  ```markdown
  --network-timeout = VALUE
  Specifies the timeout in seconds for remote I/O operations. Default is: 40.
  ```

- **verbose**
  ```markdown
  --verbose = true|false
  A value of true enables output of additional information during validation. Default value is false.
  Note: Boolean option values are set to true if the option is specified without a value.
  ```

- **verbose-output**
  ```markdown
  --verbose-output = FILE
  Writes verbose output to FILE.
  ```

- **version**
  ```markdown
  --version
  Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.
  ```

- **warning-limit**
  ```markdown
  --warning-limit = N | unlimited
  Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
  ```

### Catalogs and global resources

- **catalog**
  ```markdown
  --catalog = FILE
  Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.
  ```

- **user-catalog**
  ```markdown
  --user-catalog = FILE
  ```
Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

- enable-globalresources
  --enable-globalresources = true|false
  Enables global resources. Default value is false.
  **Note:** Boolean option values are set to true if the option is specified without a value.

- globalresourceconfig [gc]
  --gc | --globalresourceconfig = VALUE
  Specifies the active configuration of the global resource (and enables global resources).

- globalresourcefile [gr]
  --gr | --globalresourcefile = FILE
  Specifies the global resource file (and enables global resources).

- XML Schema
  - schema-imports
    --schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only
    Specifies the behaviour of xs:import elements, each of which has an optional namespace attribute and an optional schemaLocation attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.
    The behavior is as follows:
    - load-by-schemalocation: The value of the schemaLocation attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
    - load-preferring-schemalocation: If the schemaLocation attribute is present, it is used, taking account of catalog mappings. If no schemaLocation attribute is present, then the value of the namespace attribute is used via a catalog mapping. This is the default value.
    - load-by-namespace: The value of the namespace attribute is used to locate the schema via a catalog mapping.
    - load-combining-both: If either the namespace or schemaLocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemaLocation attribute is used.
    - license-namespace-only: The namespace is imported. No schema document is imported.

- schema-mapping
--schema-mapping = prefer-schemalocation | prefer-namespace
If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the --schemalocation-hints or the --schema-imports option has a value of load-combining-both, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the prefer-schemalocation value refers to the URL mapping).) Default is prefer-schemalocation.

```
  schemalocation-hints
```

--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
Specifies the behavior of the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The load-by-schemalocation value uses the URL of the schema location in the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or XBRL instance documents. This is the default value.
- The load-by-namespace value takes the namespace part of xsi:schemaLocation and an empty string in the case of xsi:noNamespaceSchemaLocation and locates the schema via a catalog mapping.
- If load-combining-both is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is ignore, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

```
  Miscellaneous
```

```
  listfile
```

--listfile = true|false
If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the --listfile option applies only to arguments, and not to options.

**Note:** Boolean option values are set to true if the option is specified without a value.

```
  xinclude
```

--xinclude = true|false
Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude's include elements are ignored.

**Note:** Boolean option values are set to true if the option is specified without a value.
3.4 XQuery Commands

The XQuery commands are:

- `xquery`: for executing XQuery documents, optionally with an input document
- `xqueryupdate`: for executing an XQuery update, using an XQuery document and, optionally, the input XML document to update
- `valxquery`: for validating XQuery documents
- `valxqueryupdate`: for validating an XQuery (update) document

The arguments and options for each command are listed in the sub-sections, `xquery` and `valxquery`.
3.4.1 xquery

The `xquery` command takes an XQuery file as its single argument and executes it with an optional input file to produce an output file. The input and output files are specified as options.

Windows  RaptorXMLXBRL xquery [options] XQuery-File

Linux    raptorxmlxbrl xquery [options] XQuery-File

Mac      raptorxmlxbrl xquery [options] XQuery-File

The argument `XQuery-File` is the path and name of the XQuery file to be executed. You can use XQuery 1.0 or 3.0. By default XQuery 3.0 is used.

Examples

- `raptorxmlxbrl xquery --output=c:\Output.xml c:\TestQuery.xq`
- `raptorxmlxbrl xquery --input=c:\Input.xml --output=c:\Output.xml --param=company:"Altova" --p=date:"2006-01-01" c:\TestQuery.xq`
- `raptorxmlxbrl xquery --input=c:\Input.xml --output=c:\Output.xml --param=source:" doc( 'c:\test\books.xml' )//book "`
- `raptorxmlxbrl xquery --output=c:\Output.xml --omit-xml-declaration=false --output-encoding=ASCII c:\TestQuery.xq`

Casing and slashes on the command line

<table>
<thead>
<tr>
<th>RaptorXMLXBRL on Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>raptorxmlxbrl on Unix (Linux, Mac)</td>
</tr>
</tbody>
</table>

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.*

* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**XQuery Processing**

- `--indent-characters = VALUE`
  Specifies the character string to be used as indentation.

- `--input = FILE`
  The URL of the XML file to be transformed.
### Command Line Interface (CLI)

#### XQuery Commands

- **omit-xml-declaration**
  - `--omit-xml-declaration = true|false`
  - Serialization option to specify whether the XML declaration should be omitted from the output or not. If `true`, there will be no XML declaration in the output document. If `false`, an XML declaration will be included. Default value is `false`.
  - **Note**: Boolean option values are set to `true` if the option is specified without a value.

- **output, xsltoutput**
  - `output = FILE, xsltoutput = FILE`
  - The URL of the primary-output file. For example, in the case of multiple-file HTML output, the primary-output file will be the location of the entry point HTML file. Additional output files, such as generated image files, are reported as `xslt-additional-output-files`. If no `--output` or `--xsltoutput` option is specified, output is written to standard output.

- **output-encoding**
  - `--output-encoding = VALUE`
  - The value of the encoding attribute in the output document. Valid values are names in the IANA character set registry. Default value is `UTF-8`.

- **output-indent**
  - `--output-indent = true|false`
  - If `true`, the output will be indented according to its hierarchic structure. If `false`, there will be no hierarchical indentation. Default is `false`.
  - **Note**: Boolean option values are set to `true` if the option is specified without a value.

- **output-method**
  - `--output-method = xml|html|xhtml|text`
  - Specifies the output format. Default value is `xml`.

- **param [p]**
  - `--p | --param = KEY:VALUE`
  - **XQuery**
  - Specifies the value of an external parameter. An external parameter is declared in the XQuery document with the `declare variable` declaration followed by a variable name and then the `external` keyword followed by the trailing semi-colon. For example:
    ```xml
    declare variable $foo as xs:string external;
    ```
    Because of the `external` keyword `$foo` becomes an external parameter, the value of which is passed at runtime from an external source. The external parameter is given a value with the CLI command. For example:
    ```xml
    --param=foo:'MyName'
    ```
    In the description statement above, `KEY` is the external parameter name, `VALUE` is the value of the external parameter, given as an XPath expression. Parameter names used on the CLI must be declared in the XQuery document. If multiple external parameters are passed values on the CLI, each must be given a separate `--param` option. Double quotes must be used if the XPath expression contains spaces.
**XSLT**

Specifies a global stylesheet parameter. **KEY** is the parameter name, **VALUE** is an XPath expression that provides the parameter value. Parameter names used on the CLI must be declared in the stylesheet. If multiple parameters are used, the **--param** switch must be used before each parameter. Double quotes must be used around the XPath expression if it contains a space—whether the space is in the XPath expression itself or in a string literal in the expression. For example:

```
raptorxmlxbrl xslt --input=c:\Test.xml --output=c:\Output.xml --
param=date://node[1]/@att1 --p=title:'stringwithoutspace' --
param=title:"'string with spaces'" --p=amount:456 c:\Test.xslt
```
decides which mapping is used. If no catalog mapping is present, the
schemaLocation attribute is used.
- license-namespace-only: The namespace is imported. No schema document is
imported.

- schemalocation-hints
  --schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
  Specifies the behavior of the xsi:schemaLocation and
  xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document,
  and, if yes, which information should be used to find it. Default: load-by-
  schemalocation.
  - The load-by-schemalocation value uses the URL of the schema location in the
    xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or
    XBRL instance documents. This is the default value.
  - The load-by-namespace value takes the namespace part of xsi:schemaLocation
    and an empty string in the case of xsi:noNamespaceSchemaLocation and locates
    the schema via a catalog mapping.
  - If load-combining-both is used and if either the namespace part or the URL part
    has a catalog mapping, then the catalog mapping is used. If both have catalog
    mappings, then the value of the --schema-mapping option (XBRL option and XML/
    XSD option) decides which mapping is used. If neither the namespace nor URL has
    a catalog mapping, the URL is used.
  - If the option's value is ignore, then the xsi:schemaLocation and
    xsi:noNamespaceSchemaLocation attributes are both ignored.

- schema-mapping
  --schema-mapping = prefer-schemalocation | prefer-namespace
  If schema location and namespace are both used to find a schema document,
  specifies which of them should be preferred during catalog lookup. (If either the --
  schemalocation-hints or the --schema-imports option has a value of load-
  combining-both, and if the namespace and URL parts involved both have catalog
  mappings, then the value of this option specifies which of the two mappings to use
  (namespace mapping or URL mapping; the prefer-schemalocation value refers to the
  URL mapping).) Default is prefer-schemalocation.

- xinclude
  --xinclude = true|false
  Enables XML Inclusions (XInclude) support. Default value is false. When false,
  XInclude's include elements are ignored.
  Note: Boolean option values are set to true if the option is specified without a value.

- xml-mode
  --xml-mode = wf|id|valid
  Specifies the XML processing mode to use for the XML instance document:
  wf=wellformed check; id=wellformed with ID/IDREF checks; valid=validation. Default
  value is wf. Note that a value of valid requires that each instance document loaded
  during processing references a DTD. If no DTD exists, an error is reported.
xml-mode-for-schemas

```
--xml-mode-for-schemas = wf|id|valid
```

Specifies the XML processing mode to use for XML schema documents: `wf` = well-formed check; `id` = well-formed with ID/IDREF checks; `valid` = validation. Default value is `wf`. Note that a value of `valid` requires that each schema document loaded during processing references a DTD. If no DTD exists, an error is reported.

xml-validation-error-as-warning

```
--xml-validation-error-as-warning = true|false
```

If `true`, treats validation errors as warnings. If errors are treated as warnings, additional processing, such as XSLT transformations, will continue regardless of errors. Default is `false`.

xsd

```
--xsd = FILE
```

Specifies one or more XML Schema documents to use for the validation of XML instance documents. Add the option multiple times to specify more than one schema document.

xsd-version

```
--xsd-version = 1.0|1.1|detect
```

Specifies the W3C Schema Definition Language (XSD) version to use. Default is `1.0`. This option can also be useful to find out in what ways a schema which is 1.0-compatible is not 1.1-compatible. The `detect` option is an Altova-specific feature. It enables the version of the XML Schema document (1.0 or 1.1) to be detected by reading the value of the `vc:minVersion` attribute of the document's `<xs:schema>` element. If the value of the `@vc:minVersion` attribute is `1.1`, the schema is detected as being version 1.1. For any other value, or if the `@vc:minVersion` attribute is absent, the schema is detected as being version 1.0.

Catalogs and global resources

catalog

```
--catalog = FILE
```

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, XML Catalogs, for information about working with catalogs.

user-catalog

```
--user-catalog = FILE
```

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

enable-globalresources

```
--enable-globalresources = true|false
```

Enables **global resources**. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

```
--gc | --globalresourceconfig = VALUE
```

Specifies the active configuration of the **global resource** (and enables **global resources**).

```
--gr | --globalresourcefile = FILE
```

Specifies the **global resource file** (and enables **global resources**).

### Extensions

These options define the handling of special extension functions that are available in a number of Enterprise-level Altova products (such as XMLSpy Enterprise Edition). Their use is described in the user manuals of these products.

```
--chartext-disable = true|false
```

Disables chart extensions. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

```
--dotnetext-disable = true|false
```

Disables .NET extensions. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

```
--jvm-location = FILE
```

**FILE** specifies the location of the Java Virtual Machine (DLL on Windows, shared object on Linux). The JVM is needed if you use Java extension functions in your XSLT/XQuery code. Default is `false`.

```
--javaext-barcode-location = FILE
```

Specifies the path to the folder that contains the barcode extension file `AltovaBarcodeExtension.jar`. The path must be given in one of the following forms:

- A file URL, for example: `--javaext-barcode-location=file:///C:/Program Files/Altova/RaptorXMLXBRLServer2019/etc/jar/`
- A Windows path with backslashes escaped, for example: `--javaext-barcode-location="C:\\Program Files\\Altova\\RaptorXMLXBRLServer2019\\etc\\jar\\"

```
--javaext-disable = true|false
```

Disables Java extensions. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.
Message, errors, help, timeout, version

error-format

```
--error-format = text|shortxml|longxml
```

Specifies the format of the error output. Default value is `text`. The other options generate XML formats, with `longxml` generating more detail.

error-limit

```
--error-limit = N | unlimited
```

Specifies the error limit with a value range of 1 to 9999 or `unlimited`. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

cmdline help text for the command. For example, `valany --h`. (Alternatively the `help` command can be used with an argument. For example: `help valany`.)

log-output

```
--log-output = FILE
```

Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

network-timeout

```
--network-timeout = VALUE
```

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

verbose

```
--verbose = true|false
```

A value of `true` enables output of additional information during validation. Default value is `false`.

**Note**: Boolean option values are set to `true` if the option is specified without a value.

verbose-output

```
--verbose-output = FILE
```

Writes `verbose` output to `FILE`.

version

```
--version
```

Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

warning-limit

```
--warning-limit = N | unlimited
```

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.4.2 xqueryupdate

The xqueryupdate command takes an XQuery file as its single argument and executes it with an optional input file to produce an updated output file. The input and output files are specified as options.

Windows  RaptorXMLXBRL xqueryupdate [options] XQuery-File
Linux    raptorxmlxbrl xqueryupdate [options] XQuery-File
Mac      raptorxmlxbrl xqueryupdate [options] XQuery-File

The argument XQuery-File is the path and name of the XQuery file to be executed. You can specify whether XQuery Update 1.0 or 3.0 should be used. By default XQuery Update 3.0 is used.

Examples

- raptorxmlxbrl xqueryupdate --output=c:\Output.xml c:\TestQuery.xq
- raptorxmlxbrl xqueryupdate --input=c:\Input.xml --output=c:\Output.xml
- raptorxmlxbrl xqueryupdate --input=c:\Input.xml --output=c:\Output.xml
- raptorxmlxbrl xqueryupdate --param=company:"Altova" --param=date:"2006-01-01" c:\TestQuery.xq
- raptorxmlxbrl xqueryupdate --input=c:\Input.xml --output=c:\Output.xml
- raptorxmlxbrl xqueryupdate --output=c:\Output.xml --omit-xml-declaration=false --output-encoding=ASCII c:\TestQuery.xq

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- XQuery Update Processing
  - indent-characters
    --indent-characters = VALUE
    Specifies the character string to be used as indentation.
  - input
    --input = FILE
XQuery Commands

**Command Line Interface (CLI)**

The URL of the XML file to be transformed.

- **omit-xml-declaration**
  
  `--omit-xml-declaration = true|false`
  
  Serialization option to specify whether the XML declaration should be omitted from the output or not. If true, there will be no XML declaration in the output document. If false, an XML declaration will be included. Default value is false.
  
  **Note:** Boolean option values are set to true if the option is specified without a value.

- **output, xsltoutput**
  
  `output = FILE, xsltoutput = FILE`
  
  The URL of the primary-output file. For example, in the case of multiple-file HTML output, the primary-output file will be the location of the entry point HTML file. Additional output files, such as generated image files, are reported as `xslt-additional-output-files`. If no `--output` or `--xsltoutput` option is specified, output is written to standard output.

- **output-encoding**
  
  `--output-encoding = VALUE`
  
  The value of the encoding attribute in the output document. Valid values are names in the IANA character set registry. Default value is `UTF-8`.

- **output-indent**
  
  `--output-indent = true|false`
  
  If true, the output will be indented according to its hierarchic structure. If false, there will be no hierarchical indentation. Default is false.
  
  **Note:** Boolean option values are set to true if the option is specified without a value.

- **output-method**
  
  `--output-method = xml|html|xhtml|text`
  
  Specifies the output format. Default value is `xml`.

- **param [p]**
  
  `--p | --param = KEY:VALUE`
  
  XQuery
  
  Specifies the value of an external parameter. An external parameter is declared in the XQuery document with the `declare variable` declaration followed by a variable name and then the `external` keyword followed by the trailing semi-colon. For example:
  
  ```
  declare variable $foo as xs:string external;
  ```
  
  Because of the `external` keyword `$foo` becomes an external parameter, the value of which is passed at runtime from an external source. The external parameter is given a value with the CLI command. For example:
  
  ```
  --param=foo:'MyName'
  ```
  
  In the description statement above, `KEY` is the external parameter name, `VALUE` is the value of the external parameter, given as an XPath expression. Parameter names used on the CLI must be declared in the XQuery document. If multiple
external parameters are passed values on the CLI, each must be given a separate
--param option. Double quotes must be used if the XPath expression contains
spaces.

XSLT

Specifies a global stylesheet parameter. KEY is the parameter name, VALUE is an
XPath expression that provides the parameter value. Parameter names used on
the CLI must be declared in the stylesheet. If multiple parameters are used, the --
param switch must be used before each parameter. Double quotes must be used
around the XPath expression if it contains a space—whether the space is in the
XPath expression itself or in a string literal in the expression. For example:

```bash
raptorxmlxbrl xslt --input=c:\Test.xml --output=c:\Output.xml --
param=date://node[1]/@att1 --p=title:'stringwithoutspace' --
param=title:'string with spaces'" --p=amount:456 c:\Test.xslt
```

xquery-update-version

--xquery-update-version = 1|1.0|3|3.0|

Specifies whether the XQuery processor should use XQuery Update Facility 1.0 or
XQuery Update Facility 3.0. Default value is 3.

keep-formatting

--keep-formatting = true|false

Keeps the formatting of the target document to the maximum extent that this is
possible. Default is: true.

updated-xml

--updated-xml = discard|writeback|asmainresult

Specifies how the updated XML file should be handled. The updates can be either:

- discarded and not written to file (discard)
- written back to the input XML file that is specified with the --input option
  (writeback)
- saved either to standard output or to the location specified in the --output
  option (if this is defined)

Default is: discard.

XML Schema and XML instance

load-xml-with-psvi

--load-xml-with-psvi = true|false

Enables validation of input XML files and generates post-schema-validation information
for them. Default is: true.

schema-imports

--schema-imports = load-by-schemalocation | load-preferring-
schemalocation | load-by-namespace | load-combining-both | license-
namespace-only
Specifies the behaviour of xs:import elements, each of which has an optional namespace attribute and an optional schemaLocation attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

The behavior is as follows:

- **load-by-schemalocation**: The value of the schemaLocation attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation**: If the schemaLocation attribute is present, it is used, taking account of catalog mappings. If no schemaLocation attribute is present, then the value of the namespace attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace**: The value of the namespace attribute is used to locate the schema via a catalog mapping.
- **load-combining-both**: If either the namespace or schemaLocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemaLocation attribute is used.
- **license-namespace-only**: The namespace is imported. No schema document is imported.

```schemalocation-hints
--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
```

Specifies the behavior of the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The load-by-schemalocation value uses the URL of the schema location in the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or XBRL instance documents. This is the default value.
- The load-by-namespace value takes the namespace part of xsi:schemaLocation and an empty string in the case of xsi:noNamespaceSchemaLocation and locates the schema via a catalog mapping.
- If load-combining-both is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is ignore, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

```schema-mapping
--schema-mapping = prefer-schemalocation | prefer-namespace
```

If schema location and namespace are both used to find a schema document,
specifies which of them should be preferred during catalog lookup. (If either the --schemalocation-hints or the --schema-imports option has a value of load-combining-both, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the prefer-schemalocation value refers to the URL mapping).) Default is prefer-schemalocation.

\[ xinclude \]

\[ --xinclude = true|false \]

Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude’s include elements are ignored.

*Note:* Boolean option values are set to true if the option is specified without a value.

\[ xml-mode \]

\[ --xml-mode = wf|id|valid \]

Specifies the XML processing mode to use for the XML instance document: 
\textit{wf} = wellformed check; \textit{id} = wellformed with ID/IDREF checks; \textit{valid} = validation. Default value is \textit{wf}. Note that a value of \textit{valid} requires that each instance document loaded during processing references a DTD. If no DTD exists, an error is reported.

\[ xml-mode-for-schemas \]

\[ --xml-mode-for-schemas = wf|id|valid \]

Specifies the XML processing mode to use for XML schema documents: \textit{wf} = wellformed check; \textit{id} = wellformed with ID/IDREF checks; \textit{valid} = validation. Default value is \textit{wf}. Note that a value of \textit{valid} requires that each schema document loaded during processing references a DTD. If no DTD exists, an error is reported.

\[ xml-validation-error-as-warning \]

\[ --xml-validation-error-as-warning = true|false \]

If \textit{true}, treats validation errors as warnings. If errors are treated as warnings, additional processing, such as XSLT transformations, will continue regardless of errors. Default is \textit{false}.

\[ xsd \]

\[ --xsd = FILE \]

Specifies one or more XML Schema documents to use for the validation of XML instance documents. Add the option multiple times to specify more than one schema document.

\[ xsd-version \]

\[ --xsd-version = 1.0|1.1|detect \]

Specifies the W3C Schema Definition Language (XSD) version to use. Default is 1.0. This option can also be useful to find out in what ways a schema which is 1.0-compatible is not 1.1-compatible. The detect option is an Altova-specific feature. It enables the version of the XML Schema document (1.0 or 1.1) to be detected by reading the value of the \texttt{@vc:minVersion} attribute of the document’s \texttt{<xs:schema>} element. If the value of the \texttt{@vc:minVersion} attribute is 1.1, the schema is detected as being version 1.1. For any other value, or if the \texttt{@vc:minVersion} attribute is absent, the
schema is detected as being version 1.0.

▼ Catalogs and global resources

▼ catalog

--catalog = FILE

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (\installation-folder\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

▼ user-catalog

--user-catalog = FILE

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

▼ enable-globalresources

--enable-globalresources = true|false

Enables global resources. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

▼ globalresourceconfig [gc]

--gc | --globalresourceconfig = VALUE

Specifies the active configuration of the global resource (and enables global resources).

▼ globalresourcefile [gr]

--gr | --globalresourcefile = FILE

Specifies the global resource file (and enables global resources).

▼ Extensions

These options define the handling of special extension functions that are available in a number of Enterprise-level Altova products (such as XMLSpy Enterprise Edition). Their use is described in the user manuals of these products.

▼ chartext-disable

--chartext-disable = true|false

Disables chart extensions. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

▼ dotnetext-disable

--dotnetext-disable = true|false

Disables .NET extensions. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

▼ jvm-location

--jvm-location = FILE
FILE specifies the location of the Java Virtual Machine (DLL on Windows, shared object on Linux). The JVM is needed if you use Java extension functions in your XSLT/XQuery code. Default is false.

javaext-barcode-location

--javaext-barcode-location = FILE
Specifies the path to the folder that contains the barcode extension file AltovaBarcodeExtension.jar. The path must be given in one of the following forms:

- A file URI, for example: --javaext-barcode-location="file:///C:/Program Files/Altova/RaptorXMLXBRLServer2019/etc/jar/"
- A Windows path with backslashes escaped, for example: --javaext-barcode-location="C:\Program Files\Altova\RaptorXMLXBRLServer2019\etc\jar\"

javaext-disable

--javaext-disable = true|false
Disables Java extensions. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

Messages, errors, help, timeout, version

error-format

--error-format = text|shortxml|longxml
Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

error-limit

--error-limit = N | unlimited
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

help

--help
Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

log-output

--log-output = FILE
Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

network-timeout

--network-timeout = VALUE
Specifies the timeout in seconds for remote I/O operations. Default is 40.

**verbose**

___

```
--verbose = true|false
```

A value of `true` enables output of additional information during validation. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

**verbose-output**

___

```
--verbose-output = FILE
```

 Writes verbose output to `FILE`.

**version**

___

```
--version
```

Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

**warning-limit**

___

```
--warning-limit = N | unlimited
```

Specifies the warning limit in the range 1-65535 or `unlimited`. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.4.3 valxquery

The valxquery command takes an XQuery file as its single argument and validates it.

Windows  RaptorXMLXBRL valxquery [options] XQuery-File
Linux     raptorxmlxbrl valxquery [options] XQuery-File
Mac       raptorxmlxbrl valxquery [options] XQuery-File

The XQuery-File argument is the path and name of the XQuery file to be validated.

Examples

- raptorxmlxbrl valxquery c:\Test.xquery
- raptorxmlxbrl valxquery --xquery-version=1 c:\Test.xquery

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- **XQuery processing**

  - **omit-xml-declaration**
    
    --omit-xml-declaration = true|false

    Serialization option to specify whether the XML declaration should be omitted from the output or not. If true, there will be no XML declaration in the output document. If false, an XML declaration will be included. Default value is false.

    Note: Boolean option values are set to true if the option is specified without a value.

  - **xquery-version**
    
    --xquery-version = 1|1.0|3|3.0|3.1

    Specifies whether the XQuery processor should use XQuery 1.0 or XQuery 3.0. Default value is 3.1.
**load-xml-with-psvi**

```
--load-xml-with-psvi = true|false
```

Enables validation of input XML files and generates post-schema-validation information for them. Default is: true.

**schema-imports**

```
--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only
```

Specifies the behaviour of `xs:import` elements, each of which has an optional `namespace` attribute and an optional `schemaLocation` attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: `load-preferring-schemalocation`.

The behavior is as follows:

- **load-by-schemalocation**: The value of the `schemaLocation` attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation**: If the `schemaLocation` attribute is present, it is used, taking account of catalog mappings. If no `schemaLocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace**: The value of the `namespace` attribute is used to locate the schema via a catalog mapping.
- **load-combining-both**: If either the `namespace` or `schemaLocation` attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the `--schema-mapping` option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the `schemaLocation` attribute is used.
- **license-namespace-only**: The namespace is imported. No schema document is imported.

**schemalocation-hints**

```
--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
```

Specifies the behavior of the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: `load-by-schemalocation`.

- The `load-by-schemalocation` value uses the URL of the schema location in the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes in XML or XBRL instance documents. This is the default value.
- The `load-by-namespace` value takes the namespace part of `xsi:schemaLocation` and an empty string in the case of `xsi:noNamespaceSchemaLocation` and locates the schema via a catalog mapping.
- If `load-combining-both` is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the `--schema-mapping` option (XBRL option and XML/XSD option) decides which mapping is used.
**XSD option** decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is **ignore**, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

**schema-mapping**

```xml
--schema-mapping = prefer-schemalocation | prefer-namespace
```

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the `--schemalocation-hints` or the `--schema-imports` option has a value of load-combining-both, and if the namespace and URL parts involved both have **catalog mappings**, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the `prefer-schemalocation` value refers to the URL mapping).) Default is `prefer-schemalocation`.

**xinclude**

```xml
--xinclude = true|false
```

Enables XML Inclusions (XInclude) support. Default value is `false`. When `false`, XInclude's include elements are ignored.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**xml-mode**

```xml
--xml-mode = wf|id|valid
```

Specifies the XML processing mode to use for the XML instance document:
- `wf` = wellformed check;
- `id` = wellformed with ID/IDREF checks;
- `valid` = validation. Default value is `wf`. Note that a value of `valid` requires that each instance document loaded during processing references a DTD. If no DTD exists, an error is reported.

**xml-mode-for-schemas**

```xml
--xml-mode-for-schemas = wf|id|valid
```

Specifies the XML processing mode to use for XML schema documents:
- `wf` = wellformed check;
- `id` = wellformed with ID/IDREF checks;
- `valid` = validation. Default value is `wf`. Note that a value of `valid` requires that each schema document loaded during processing references a DTD. If no DTD exists, an error is reported.

**xsd-version**

```xml
--xsd-version = 1.0|1.1|detect
```

Specifies the W3C Schema Definition Language (XSD) version to use. Default is `1.0`. This option can also be useful to find out in what ways a schema which is 1.0-compatible is not 1.1-compatible. The `detect` option is an Altova-specific feature. It enables the version of the XML Schema document (1.0 or 1.1) to be detected by reading the value of the `vc:minVersion` attribute of the document's `<xs:schema>` element. If the value of the `@vc:minVersion` attribute is `1.1`, the schema is detected as being version 1.1. For any other value, or if the `@vc:minVersion` attribute is absent, the schema is detected as being version 1.0.

**Catalogs and global resources**
### catalog

---catalog = FILE

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`\installation-folder\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, [XML Catalogs](#), for information about working with catalogs.

---

### user-catalog

--user-catalog = FILE

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, [XML Catalogs](#), for information about working with catalogs.

---

### enable-globalresources

--enable-globalresources = true|false

Enables [global resources](#). Default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

---

### globalresourceconfig [gc]

--gc | --globalresourceconfig = VALUE

Specifies the active configuration of the global resource (and enables [global resources](#)).

---

### globalresourcefile [gr]

--gr | --globalresourcefile = FILE

Specifies the global resource file (and enables [global resources](#)).

---

### Extensions

These options define the handling of special extension functions that are available in a number of Enterprise-level Altova products (such as XMLSpy Enterprise Edition). Their use is described in the user manuals of these products.

---

### chartext-disable

--chartext-disable = true|false

Disables chart extensions. Default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

---

### dotnetext-disable

--dotnetext-disable = true|false

Disables .NET extensions. Default value is false.

**Note:** Boolean option values are set to true if the option is specified without a value.

---

### jvm-location

--jvm-location = FILE

FILE specifies the location of the Java Virtual Machine (DLL on Windows, shared object on Linux). The JVM is needed if you use [Java extension functions](#) in your XSLT/XQuery code. Default is false.

---

### javaext-barcode-location
--javaext-barcode-location = FILE
Specifies the path to the folder that contains the barcode extension file
AltovaBarcodeExtension.jar. The path must be given in one of the following forms:

- A file URI, for example: --javaext-barcode-location="file:///C:/Program
  Files/Altova/RaptorXMLXBRLServer2019/etc/jar/
- A Windows path with backslashes escaped, for example: --javaext-barcode-
  location="C:\Program Files\Altova\RaptorXMLXBRLServer2019\etc\jar"

javaext-disable
--javaext-disable = true|false
Disables Java extensions. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

Messages, errors, help, timeout, version
error-format
--error-format = text|shortxml|longxml
Specifies the format of the error output. Default value is text. The other options
generate XML formats, with longxml generating more detail.

error-limit
--error-limit = N | unlimited
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value
is 100. Processing stops when the error limit is reached. Useful for limiting processor
use during validation/transformation.

help
--help
Displays help text for the command. For example, valany --h. (Alternatively the help
cmd command can be used with an argument. For example: help valany.)

log-output
--log-output = FILE
Writes the log output to the specified file URL. Ensure that the CLI has write permission
to the output location.

network-timeout
--network-timeout = VALUE
Specifies the timeout in seconds for remote I/O operations. Default is: 40.

verbose
--verbose = true|false
A value of true enables output of additional information during validation. Default value
is false.
Note: Boolean option values are set to true if the option is specified without a value.
% verbose-output
\indent --verbose-output = FILE
writes verbose output to FILE.

% version
\indent --version
\indent displays the version of RaptorXML+XBRL Server. If used with a command, place --
\indent version before the command.

% warning-limit
\indent --warning-limit = N | unlimited
\indent specifies the warning limit in the range 1-65535 or unlimited. Processing continues if
\indent this limit is reached, but further warnings are not reported. The default value is 100.
3.4.4 valxqueryupdate

The valxqueryupdate command takes an XQuery file as its single argument and validates it.

Windows  RaptorXMLXBRL valxqueryupdate [options] XQuery-File

Linux    raptorxmlxbtrl valxqueryupdate [options] XQuery-File

Mac      raptorxmlxbtrl valxqueryupdate [options] XQuery-File

The XQuery-File argument is the path and name of the XQuery file to be validated.

Examples

- raptorxmlxbbrl valxqueryupdae c:\Test.xqu
- raptorxmlxbbrl valxqueryupdate --xquery-version=1 c:\Test.xqu

- Casing and slashes on the command line

  RaptorXMLXBRL on Windows
  raptorxmlxbbrl on Unix (Linux, Mac)

  * Note that lowercase (raptorxmlxbbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
  * Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command’s options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

XQuery processing

- omit-xml-declaration

  --omit-xml-declaration = true|false

  Serialization option to specify whether the XML declaration should be omitted from the output or not. If true, there will be no XML declaration in the output document. If false, an XML declaration will be included. Default value is false.

  Note:  Boolean option values are set to true if the option is specified without a value.

- xquery-update-version

  --xquery-update-version = 1|1.0|3|3.0|

  Specifies whether the XQuery processor should use XQuery Update Facility 1.0 or XQuery Update Facility 3.0. Default value is 3.
load-xml-with-psvi

```--load-xml-with-psvi = true|false```
Enables validation of input XML files and generates post-schema-validation information for them. Default is: true.

schema-imports

```--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only```
Specifies the behaviour of `xs:import` elements, each of which has an optional `namespace` attribute and an optional `schemaLocation` attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

The behavior is as follows:

- **load-by-schemalocation**: The value of the `schemaLocation` attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation**: If the `schemaLocation` attribute is present, it is used, taking account of catalog mappings. If no `schemaLocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace**: The value of the `namespace` attribute is used to locate the schema via a catalog mapping.
- **load-combining-both**: If either the `namespace` or `schemaLocation` attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the `schemaLocation` attribute is used.
- **license-namespace-only**: The namespace is imported. No schema document is imported.

schemalocation-hints

```--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore```
Specifies the behavior of the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The **load-by-schemalocation** value uses the URL of the schema location in the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes in XML or XBRL instance documents. This is the default value.
- The **load-by-namespace** value takes the namespace part of `xsi:schemaLocation` and an empty string in the case of `xsi:noNamespaceSchemaLocation` and locates the schema via a catalog mapping.
- If **load-combining-both** is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used.
XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.

- If the option's value is ignore, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

xinclude

--xinclude = true|false

Enables XML Inclusions (XInclude) support. Default value is false. When false, XInclude's include elements are ignored.

Note: Boolean option values are set to true if the option is specified without a value.

xml-mode

--xml-mode = wf|id|valid

Specifies the XML processing mode to use for the XML instance document: 
wf=wellformed check; id=wellformed with ID/IDREF checks; valid=validation. Default value is wf. Note that a value of valid requires that each instance document loaded during processing references a DTD. If no DTD exists, an error is reported.

xml-mode-for-schemas

--xml-mode-for-schemas = wf|id|valid

Specifies the XML processing mode to use for XML schema documents: wf=wellformed check; id=wellformed with ID/IDREF checks; valid=validation. Default value is wf. Note that a value of valid requires that each schema document loaded during processing references a DTD. If no DTD exists, an error is reported.

xsd-version

--xsd-version = 1.0|1.1|detect

Specifies the W3C Schema Definition Language (XSD) version to use. Default is 1.0. This option can also be useful to find out in what ways a schema which is 1.0-compatible is not 1.1-compatible. The detect option is an Altova-specific feature. It enables the version of the XML Schema document (1.0 or 1.1) to be detected by reading the value of the vc:minVersion attribute of the document's <xs:schema> element. If the value of the @vc:minVersion attribute is 1.1, the schema is detected as being version 1.1. For any other value, or if the @vc:minVersion attribute is absent, the schema is detected as being version 1.0.

Catalogs and global resources
catalog

--catalog = FILE
Specifies the absolute path to a root catalog file that is not the installed root catalog file.
The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

user-catalog

--user-catalog = FILE
Specifies the absolute path to an XML catalog to be used in addition to the root catalog.
See the section, XML Catalogs, for information about working with catalogs.

enable-globalresources

--enable-globalresources = true|false
Enables global resources. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

globalresourceconfig [gc]

--gc | --globalresourceconfig = VALUE
Specifies the active configuration of the global resource (and enables global resources).

globalresourcefile [gr]

--gr | --globalresourcefile = FILE
Specifies the global resource file (and enables global resources).

Extensions

These options define the handling of special extension functions that are available in a number of Enterprise-level Altova products (such as XMLSpy Enterprise Edition). Their use is described in the user manuals of these products.

chartext-disable

--chartext-disable = true|false
Disables chart extensions. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

dotnetext-disable

--dotnetext-disable = true|false
Disables .NET extensions. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

jvm-location

--jvm-location = FILE
FILE specifies the location of the Java Virtual Machine (DLL on Windows, shared object on Linux). The JVM is needed if you use Java extension functions in your XSLT/XQuery code. Default is false.

javaext-barcode-location
**--javaext-barcode-location = FILE**

Specifies the path to the folder that contains the barcode extension file AltovaBarcodeExtension.jar. The path must be given in one of the following forms:

- A file URI, for example: `--javaext-barcode-location="file:///C:/Program Files/Altova/RaptorXMLXBRLServer2019/etc/jar/"
- A Windows path with backslashes escaped, for example: `--javaext-barcode-location="C:\Program Files\Altova\RaptorXMLXBRLServer2019\etc\jar\"

**javaext-disable**

**--javaext-disable = true|false**

Disables Java extensions. Default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

**Messages, errors, help, timeout, version**

**error-format**

**--error-format = text|shortxml|longxml**

Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

**error-limit**

**--error-limit = N | unlimited**

Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

**help**

**--help**

Displays help text for the command. For example, `valany --h`. (Alternatively the help command can be used with an argument. For example: `help valany`.)

**log-output**

**--log-output = FILE**

Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

**network-timeout**

**--network-timeout = VALUE**

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

**verbose**

**--verbose = true|false**

A value of true enables output of additional information during validation. Default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.
- `verbose-output`
  
  ```
  --verbose-output = FILE
  ```

  Writes verbose output to `FILE`.

- `version`
  
  ```
  --version
  ```

  Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

- `warning-limit`
  
  ```
  --warning-limit = N | unlimited
  ```

  Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.5 XSLT Commands

The XSLT commands are:

- `xslt`: for transforming XML documents with an XSLT document
- `valxslt`: for validating XSLT documents

The arguments and options for each command are listed in the sub-sections, `xslt` and `valxslt`. 
3.5.1  **xslt**

The `xslt` command takes an XSLT file as its single argument and uses it to transform an input XML file to produce an output file. The input and output files are specified as **options**.

- **Windows**  `RaptorXMLXBRL xslt [options] XSLT-File`
- **Linux**  `raptorxmlxbrl xslt [options] XSLT-File`
- **Mac**  `raptorxmlxbrl xslt [options] XSLT-File`

The **XSLT-File** argument is the path and name of the XSLT file to use for the transformation. An input XML file (`--input`) or a named template entry point (`--template-entry-point`) is required. If no `--output` option is specified, output is written to standard output. You can use XSLT 1.0, 2.0, or 3.0. By default XSLT 3.0 is used.

**Examples**

- `raptorxmlxbrl xslt --input=c:\Test.xml --output=c:\Output.xml c:\Test.xslt`
- `raptorxmlxbrl xslt --template-entry-point=StartTemplate --output=c:\Output.xml c:\Test.xslt`
- `raptorxmlxbrl xslt --input=c:\Test.xml --output=c:\Output.xml --param=date://node[1]/@att1 --p=title:'stringwithoutspace' --param=title:'string with spaces' --p=amount:456 c:\Test.xslt`

**Casing and slashes on the command line**

- `RaptorXMLXBRL` on Windows
- `raptorxmlxbrl` on Unix (Linux, Mac)

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**XSLT processing**

- **indent-characters**
  - `--indent-characters = VALUE`  Specifies the character string to be used as indentation.

- **function-param**
  - `--function-param = VALUE`
Specifies the functions that will be passed to the initial function. To specify more than one function, use the option multiple times. Note, however, that order is important.

- **global-context-item**
  
  **--global-context-item** = **VALUE**
  
  Specifies the context item that is to be used to evaluate global variables.

- **initial-function**
  
  **--initial-function** = **VALUE**
  
  The name of a function that is to be executed as the entry point of the transformation.

- **initial-match-selection**
  
  **--initial-match-selection** = **VALUE**
  
  Specifies the value (sequence) of the initial match selection.

- **initial-mode, template-mode**
  
  **--initial-mode, --template-mode** = **VALUE**
  
  Specifies the template mode to use for the transformation.

- **initial-template, template-entry-point**
  
  **--initial-template, --template-entry-point** = **VALUE**
  
  Gives the name of a named template in the XSLT stylesheet that is the entry point of the transformation.

- **input**
  
  **--input** = **FILE**
  
  The URL of the XML file to be transformed.

- **output, xsltoutput**
  
  **output** = **FILE**, **xsltoutput** = **FILE**
  
  The URL of the primary-output file. For example, in the case of multiple-file HTML output, the primary-output file will be the location of the entry point HTML file. Additional output files, such as generated image files, are reported as **xsit-additional-output-files**. If no **--output** or **--xsltoutput** option is specified, output is written to standard output.

- **param**
  
  **--p | --param** = **KEY:VALUE**

  **XQuery**
  
  Specifies the value of an external parameter. An external parameter is declared in the XQuery document with the **declare variable** declaration followed by a variable name and then the **external** keyword followed by the trailing semi-colon. For example:
  
  ```xquery
  declare variable $foo as xs:string external;
  ```
  
  Because of the **external** keyword $foo becomes an external parameter, the value of which is passed at runtime from an external source. The external parameter is
given a value with the CLI command. For example:

```bash
--param=foo:'MyName'
```

In the description statement above, **KEY** is the external parameter name, **VALUE** is the value of the external parameter, given as an XPath expression. Parameter names used on the CLI must be declared in the XQuery document. If multiple external parameters are passed values on the CLI, each must be given a separate `--param` option. Double quotes must be used if the XPath expression contains spaces.

**XSLT**

Specifies a global stylesheet parameter. **KEY** is the parameter name, **VALUE** is an XPath expression that provides the parameter value. Parameter names used on the CLI must be declared in the stylesheet. If multiple parameters are used, the `--param` switch must be used before each parameter. Double quotes must be used around the XPath expression if it contains a space—whether the space is in the XPath expression itself or in a string literal in the expression. For example:

```bash
raptorxmlxbxml xslt --input=c:\Test.xml --output=c:\Output.xml --
param=date://node[1]/@att1 --p=title:'stringwithoutspace' --
param=title:'string with spaces' --p=amount:456 c:\Test.xslt
```

- **streaming-serialization-enabled**
  
  ```bash
  --streaming-serialization-enabled = true|false
  ```

  Enables streaming serialization. Default value is true.

  **Note:** Boolean option values are set to true if the option is specified without a value.

- **template-param**
  
  ```bash
  --template-param = KEY:VALUE
  ```

  Specifies parameters that will be passed to the initial template only (and not to any descending template call). To specify multiple parameters, use the option once for each parameter.

- **tunnel-param**
  
  ```bash
  --tunnel-param = KEY:VALUE
  ```

  Specifies parameters that will be passed to the initial template and to descending template calls. To specify multiple parameters, use the option once for each parameter.

- **xslt-version**
  
  ```bash
  --xslt-version = 1|1.0|2|2.0|3|3.0|3.1
  ```

  Specifies whether the XSLT processor should use XSLT 1.0, XSLT 2.0, or XSLT 3.0. Default value is 3.

- **XML Schema and XML instance**

- **load-xml-with-psvi**
  
  ```bash
  --load-xml-with-psvi = true|false
  ```
Enables validation of input XML files and generates post-schema-validation information for them. Default is: true.

**schema-imports**

```
--schema-imports = load-by-schemalocation | load-prefering-schemalocation | load-by-namespace | load-combining-both | license-namespace-only
```

Specifies the behaviour of `xs:import` elements, each of which has an optional `namespace` attribute and an optional `schemaLocation` attribute: `<import namespace="someNS" schemaLocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: `load-prefering-schemalocation`.

The behavior is as follows:

- **load-by-schemalocation**: The value of the `schemaLocation` attribute is used to locate the schema, taking account of catalog mappings. If the `namespace` attribute is present, the namespace is imported (licensed).
- **load-prefering-schemalocation**: If the `schemaLocation` attribute is present, it is used, taking account of catalog mappings. If no `schemaLocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace**: The value of the `namespace` attribute is used to locate the schema via a catalog mapping.
- **load-combining-both**: If either the `namespace` or `schemaLocation` attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the `--schema-mapping` option (XBRL option and XML/XSD option) decides which mapping is used. If neither the `namespace` nor `URL` has a catalog mapping, the `URL` is used.
- **license-namespace-only**: The namespace is imported. No schema document is imported.

**schemalocation-hints**

```
--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
```

Specifies the behavior of the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: `load-by-schemalocation`.

- The **load-by-schemalocation** value uses the URL of the schema location in the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes in XML or XBRL instance documents. This is the default value.
- The **load-by-namespace** value takes the namespace part of `xsi:schemaLocation` and an empty string in the case of `xsi:noNamespaceSchemaLocation` attributes and locates the schema via a catalog mapping.
- If **load-combining-both** is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the `--schema-mapping` option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is `ignore`, then the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes are both ignored.

```
  --schema-mapping = prefer-schemalocation | prefer-namespace
```

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the `--schemalocation-hints` or the `--schema-imports` option has a value of `load-combining-both`, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the `prefer-schemalocation` value refers to the URL mapping).) Default is `prefer-schemalocation`.

```
  --xinclude = true|false
```

Enables XML Inclusions (XInclude) support. Default value is `false`. When `false`, XInclude's `include` elements are ignored.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

```
  --xml-mode = wf|id|valid
```

Specifies the XML processing mode to use for the XML instance document: `wf` = wellformed check; `id` = wellformed with ID/IDREF checks; `valid` = validation. Default value is `wf`. Note that a value of `valid` requires that each instance document loaded during processing references a DTD. If no DTD exists, an error is reported.

```
  --xml-mode-for-schemas = wf|id|valid
```

Specifies the XML processing mode to use for XML schema documents: `wf` = wellformed check; `id` = wellformed with ID/IDREF checks; `valid` = validation. Default value is `wf`. Note that a value of `valid` requires that each schema document loaded during processing references a DTD. If no DTD exists, an error is reported.

```
  --xml-validation-error-as-warning = true|false
```

If `true`, treats validation errors as warnings. If errors are treated as warnings, additional processing, such as XSLT transformations, will continue regardless of errors. Default is `false`.

```
  --xsd = FILE
```

Specifies one or more XML Schema documents to use for the validation of XML instance documents. Add the option multiple times to specify more than one schema document.

```
  --xsd-version = 1.0|1.1|detect
```

© 2019 Altova GmbH

Altova RaptorXML+XBRL Server 2019
Specifies the W3C Schema Definition Language (XSD) version to use. Default is 1.0. This option can also be useful to find out in what ways a schema which is 1.0-compatible is not 1.1-compatible. The detect option is an Altova-specific feature. It enables the version of the XML Schema document (1.0 or 1.1) to be detected by reading the value of the vc:minVersion attribute of the document's <xs:schema> element. If the value of the @vc:minVersion attribute is 1.1, the schema is detected as being version 1.1. For any other value, or if the @vc:minVersion attribute is absent, the schema is detected as being version 1.0.

**Catalogs and global resources**

- **catalog**
  ```
  --catalog = FILE
  ```
  Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, XML Catalogs, for information about working with catalogs.

- **user-catalog**
  ```
  --user-catalog = FILE
  ```
  Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

- **enable-globalresources**
  ```
  --enable-globalresources = true|false
  ```
  Enables global resources. Default value is false.
  **Note:** Boolean option values are set to true if the option is specified without a value.

- **globalresourceconfig [gc]**
  ```
  --gc | --globalresourceconfig = VALUE
  ```
  Specifies the active configuration of the global resource (and enables global resources).

- **globalresourcefile [gr]**
  ```
  --gr | --globalresourcefile = FILE
  ```
  Specifies the global resource file (and enables global resources).

**Extensions**

These options define the handling of special extension functions that are available in a number of Enterprise-level Altova products (such as XMLSpy Enterprise Edition). Their use is described in the user manuals of these products.

- **chartext-disable**
  ```
  --chartext-disable = true|false
  ```
  Disables chart extensions. Default value is false.
  **Note:** Boolean option values are set to true if the option is specified without a value.
--dotnetext-disable = true|false
Disables .NET extensions. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

jvm-location
--jvm-location = FILE
FILE specifies the location of the Java Virtual Machine (DLL on Windows, shared object on Linux). The JVM is needed if you use Java extension functions in your XSLT/XQuery code. Default is false.

javaext-barcode-location
--javaext-barcode-location = FILE
Specifies the path to the folder that contains the barcode extension file, AltovaBarcodeExtension.jar. The path must be given in one of the following forms:

- A file URI, for example: --javaext-barcode-location="file:///C:/Program Files/Altova/RaptorXMLXBRLServer2019/etc/jar/"
- A Windows path with backslashes escaped, for example: --javaext-barcode-location="C:\\Program Files\\Altova\\\RaptorXMLXBRLServer2019\\etc\\\jar\\"

javaext-disable
--javaext-disable = true|false
Disables Java extensions. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

Messages, errors, help, timeout, version
error-format
--error-format = text|shortxml|longxml
Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

error-limit
--error-limit = N | unlimited
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

help
--help
Displays help text for the command. For example, valany --h. (Alternatively, the help command can be used with an argument. For example: help valany.)

log-output
--log-output = FILE
Writes the log output to the specified file URL. Ensure that the CLI has write permission.
to the output location.

▼ network-timeout

```
--network-timeout = VALUE
```

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

▼ verbose

```
--verbose = true|false
```

A value of true enables output of additional information during validation. Default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

▼ verbose-output

```
--verbose-output = FILE
```

Writes verbose output to FILE.

▼ version

```
--version
```

Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

▼ warning-limit

```
--warning-limit = N | unlimited
```

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.5.2 valxslt

The valxslt command takes an XSLT file as its single argument and validates it.

* Windows  RaptorXMLXBRL valxslt [options] XSLT-File
* Linux  raptorxmlxbrl valxslt [options] XSLT-File
* Mac  raptorxmlxbrl valxslt [options] XSLT-File

The XSLT-File argument is the path and name of the XSLT file to be validated. Validation can be according to the XSLT 1.0, 2.0, or 3.0 specification. By default XSLT 3.0 is the specification used.

Examples

* raptorxmlxbrl valxslt c:\Test.xslt
* raptorxmlxbrl valxslt --xslt-version=2 c:\Test.xslt

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac),
while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

XSLT processing

initial-mode, template-mode

--initial-mode, --template-mode = VALUE
Specifies the template mode to use for the transformation.

initial-template, template-entry-point

--initial-template, --template-entry-point = VALUE
Gives the name of a named template in the XSLT stylesheet that is the entry point of the transformation.

xslt-version

--xslt-version = 1|1.0|2|2.0|3|3.0|3.1
Specifies whether the XSLT processor should use XSLT 1.0, XSLT 2.0, or XSLT 3.0. Default value is 3.
XML Schema and XML instance

load-xml-with-psvi

```--load-xml-with-psvi = true|false```

Enables validation of input XML files and generates post-schema-validation information for them. Default is: true.

schema-imports

```--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only```

Specifies the behaviour of `xs:import` elements, each of which has an optional `namespace` attribute and an optional `schemaLocation` attribute:

```<import namespace="someNS" schemaLocation="someURL">```

The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: load-preferring-schemalocation.

The behavior is as follows:

- **load-by-schemalocation**: The value of the `schemaLocation` attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation**: If the `schemaLocation` attribute is present, it is used, taking account of catalog mappings. If no `schemaLocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This is the **default value**.
- **load-by-namespace**: The value of the `namespace` attribute is used to locate the schema via a catalog mapping.
- **load-combining-both**: If either the `namespace` or `schemaLocation` attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the `--schema-mapping` option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the `schemaLocation` attribute is used.
- **license-namespace-only**: The namespace is imported. No schema document is imported.

schemalocation-hints

```--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore```

Specifies the behavior of the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The **load-by-schemalocation** value uses the URL of the schema location in the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes in XML or XBRL instance documents. This is the **default value**.
- The **load-by-namespace** value takes the namespace part of `xsi:schemaLocation`
and an empty string in the case of xsi:noNamespaceSchemaLocation and locates
the schema via a catalog mapping.
- If load-combining-both is used and if either the namespace part or the URL part
has a catalog mapping, then the catalog mapping is used. If both have catalog
mappings, then the value of the --schema-mapping option (XBRL option and XML/
XSD option) decides which mapping is used. If neither the namespace nor URL has
a catalog mapping, the URL is used.
- If the option's value is ignore, then the xsi:schemaLocation and
xsi:noNamespaceSchemaLocation attributes are both ignored.

```
schema-mapping
  --schema-mapping = prefer-schemalocation | prefer-namespace
```
If schema location and namespace are both used to find a schema document,
specifies which of them should be preferred during catalog lookup. (If either the --
schemalocation-hints or the --schema-imports option has a value of load-
combining-both, and if the namespace and URL parts involved both have catalog
mappings, then the value of this option specifies which of the two mappings to use
(namespace mapping or URL mapping; the prefer-schemalocation value refers to the
URL mapping). Default is prefer-schemalocation.

```
xinclude
  --xinclude = true|false
```
Enables XML Inclusions (XInclude) support. Default value is false. When false,
XInclude's include elements are ignored.

**Note:** Boolean option values are set to true if the option is specified without a value.

```
xml-mode
  --xml-mode = wf|id|valid
```
Specifies the XML processing mode to use for the XML instance document:
wf=wellformed check; id=wellformed with ID/IDREF checks; valid=validation. Default
value is wf. Note that a value of valid requires that each instance document loaded
during processing references a DTD. If no DTD exists, an error is reported.

```
xml-mode-for-schemas
  --xml-mode-for-schemas = wf|id|valid
```
Specifies the XML processing mode to use for XML schema documents: wf=wellformed
check; id=wellformed with ID/IDREF checks; valid=validation. Default value is wf.
Note that a value of valid requires that each schema document loaded during
processing references a DTD. If no DTD exists, an error is reported.

```
xsd-version
  --xsd-version = 1.0|1.1|detect
```
Specifies the W3C Schema Definition Language (XSD) version to use. Default is 1.0.
This option can also be useful to find out in what ways a schema which is 1.0-
compatible is not 1.1-compatible. The detect option is an Altova-specific feature. It
enables the version of the XML Schema document (1.0 or 1.1) to be detected by
reading the value of the vc:minVersion attribute of the document's <xs:schema>
 element. If the value of the @vc:minVersion attribute is 1.1, the schema is detected as
being version 1.1. For any other value, or if the @vc:minVersion attribute is absent, the
schema is detected as being version 1.0.

Catalogs and global resources

- **catalog**
  ```
  --catalog = FILE
  ```
  Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, **XML Catalogs**, for information about working with catalogs.

- **user-catalog**
  ```
  --user-catalog = FILE
  ```
  Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, **XML Catalogs**, for information about working with catalogs.

- **enable-globalresources**
  ```
  --enable-globalresources = true|false
  ```
  Enables **global resources**. Default value is `false`.
  
  **Note**: Boolean option values are set to `true` if the option is specified without a value.

- **globalresourceconfig**
  ```
  --globalresourceconfig = VALUE
  ```
  Specifies the active configuration of the **global resource** (and enables **global resources**).

- **globalresourcefile**
  ```
  --globalresourcefile = FILE
  ```
  Specifies the **global resource file** (and enables **global resources**).

Extensions

These options define the handling of special extension functions that are available in a number of Enterprise-level Altova products (such as XMLSpy Enterprise Edition). Their use is described in the user manuals of these products.

- **chartext-disable**
  ```
  --chartext-disable = true|false
  ```
  Disables chart extensions. Default value is `false`.
  
  **Note**: Boolean option values are set to `true` if the option is specified without a value.

- **dotnetext-disable**
  ```
  --dotnetext-disable = true|false
  ```
  Disables .NET extensions. Default value is `false`.
  
  **Note**: Boolean option values are set to `true` if the option is specified without a value.

- **jvm-location**
  ```
  --jvm-location = FILE
  ```
**FILE** specifies the location of the Java Virtual Machine (DLL on Windows, shared object on Linux). The JVM is needed if you use [Java extension functions](#) in your XSLT/XQuery code. Default is false.

**javaext-barcode-location**

```
--javaext-barcode-location = FILE
```

Specify the path to the folder that contains the barcode extension file AltovaBarcodeExtension.jar. The path must be given in one of the following forms:

- A file URI, for example: `--javaext-barcode-location=file:///C:/Program Files/Altova/RaptorXMLXBRLServer2019/etc/jar/`
- A Windows path with backslashes escaped, for example: `--javaext-barcode-location=C:\Program Files\Altova\RaptorXMLXBRLServer2019\etc\jar\`

**javaext-disable**

```
--javaext-disable = true|false
```

Disables Java extensions. Default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

**Messages, errors, help, timeout, version**

**error-format**

```
--error-format = text|shortxml|longxml
```

Specify the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

**error-limit**

```
--error-limit = N | unlimited
```

Specify the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/ transformation.

**help**

```
--help
```

Displays help text for the command. For example, `valany --h`. (Alternatively the help command can be used with an argument. For example: help valany.)

**log-output**

```
--log-output = FILE
```

Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

**network-timeout**

```
--network-timeout = VALUE
```

Specifies the timeout in seconds for remote I/O operations. Default is 40.
- **verbose**
  
  ```--verbose = true|false```
  
  A value of `true` enables output of additional information during validation. Default value is `false`.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **verbose-output**
  
  ```--verbose-output = FILE```
  
  Writes verbose output to `FILE`.

- **version**
  
  ```--version```
  
  Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

- **warning-limit**
  
  ```--warning-limit = N | unlimited```
  
  Specifies the warning limit in the range `1-65535` or `unlimited`. Processing continues if this limit is reached, but further warnings are not reported. The default value is `100`. 
3.6 JSON/Avro Commands

The JSON commands can be used to check the validity and well-formedness of JSON schema and instance documents. These commands are listed below and described in detail in the subsections of this section:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>avroextractschema</td>
<td>Extracts the Avro schema from an Avro binary file</td>
</tr>
<tr>
<td>valavro</td>
<td>Validates the data in one or more Avro binaries against the respective Avro schema of each binary</td>
</tr>
<tr>
<td>valavrojson</td>
<td>Validates one or more JSON data files against an Avro schema</td>
</tr>
<tr>
<td>valavroschema</td>
<td>Validates an Avro schema against the Avro schema specification</td>
</tr>
<tr>
<td>valjsonschema</td>
<td>Checks the validity of JSON schema documents.</td>
</tr>
<tr>
<td>valjson</td>
<td>Checks the validity of JSON documents.</td>
</tr>
<tr>
<td>wfjson</td>
<td>Checks the well-formedness of JSON documents.</td>
</tr>
</tbody>
</table>
3.6.1 avroextractschema

An Avro binary file contains an Avro data block preceded by the Avro schema that defines the structure of the data block. The `avroextractschema` command extracts the Avro schema from the Avro binary and serializes the Avro schema as JSON.

Windows  
```bash
RaptorXMLXBRL avroextractschema [options] --
    avrooutput=AvroSchemaFile AvroBinaryFile
```

Linux  
```bash
raptorxmlxbrl avroextractschema [options] --
    avrooutput=AvroSchemaFile AvroBinaryFile
```

Mac  
```bash
raptorxmlxbrl avroextractschema [options] --
    avrooutput=AvroSchemaFile AvroBinaryFile
```

The `AvroBinaryFile` argument specifies the Avro binary file from which the Avro schema is to be extracted. The `--avrooutput` option specifies the location of the extracted Avro schema.

Examples

- `raptorxmlxbrl avroextractschema --avrooutput=c:\MyAvroSchema.avsc c:\MyAvroBinary.avro`

**Casing and slashes on the command line**

- RaptorXMLXBRL on Windows
- raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Processing**

- **output, avrooutput**
  
  ```bash
  --output = FILE, --avrooutput = FILE
  ```
  Sets the location of the Avro output file.

- **recurse**
  
  ```bash
  --recurse = true|false
  ```
  Used to select files within sub-directories, including in ZIP archives. If true, the command's `InputFile` argument will select the specified file also in subdirectories. For
example: `test.zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

### Catalogs and global resources

**catalog**

```
--catalog = FILE
```

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, [XML Catalogs](#), for information about working with catalogs.

**user-catalog**

```
--user-catalog = FILE
```

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, [XML Catalogs](#), for information about working with catalogs.

**enable-globalresources**

```
--enable-globalresources = true|false
```

Enables global resources. Default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**globalresourceconfig [gc]**

```
--gc | --globalresourceconfig = VALUE
```

Specifies the active configuration of the global resource (and enables global resources).

**globalresourcefile [gr]**

```
--gr | --globalresourcefile = FILE
```

Specifies the global resource file (and enables global resources).

### Messages, errors, help, timeout, version

**error-format**

```
--error-format = text|shortxml|longxml
```

Specifies the format of the error output. Default value is `text`. The other options generate XML formats, with `longxml` generating more detail.

**error-limit**

```
--error-limit = N | unlimited
```

Specifies the error limit with a value range of `1` to `9999` or `unlimited`. The default value is `100`. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

**help**
**--help**
Displays help text for the command. For example, `valany --h`. (Alternatively the `help` command can be used with an argument. For example: `help valany`.)

**--log-output**
```
--log-output = FILE
```
Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

**--network-timeout**
```
--network-timeout = VALUE
```
Specifies the timeout in seconds for remote I/O operations. Default is: 40.

**--verbose**
```
--verbose = true|false
```
A value of `true` enables output of additional information during validation. Default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**--verbose-output**
```
--verbose-output = FILE
```
Writes verbose output to `FILE`.

**--version**
```
--version
```
Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

**--warning-limit**
```
--warning-limit = N | unlimited
```
Specifies the warning limit in the range `1-65535` or `unlimited`. Processing continues if this limit is reached, but further warnings are not reported. The default value is `100`. 

3.6.2  valavro (avro)

The `valavro | avro` command validates the data block in one or more Avro binary files against the respective Avro schemas in each binary file.

```
Windows     RaptorXMLXBRL valavro | avro [options] AvroBinaryFile
Linux       raptorxmlxbrl valavro | avro [options] AvroBinaryFile
Mac         raptorxmlxbrl valavro | avro [options] AvroBinaryFile
```

The `AvroBinaryFile` argument specifies one or more Avro binary files to validate. Specifically, the data block in each Avro binary file is validated against the Avro schema in that binary file. To validate multiple Avro binaries, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the `AvroBinaryFile` argument together with the `--listfile` option set to true (see the Options list below).

**Examples**

```
• raptorxmlxbrl valavro c:\MyAvroBinary.avro
• raptorxmlxbrl valavro c:\MyAvroBinary01.avro c:\MyAvroBinary02.avro
• raptorxmlxbrl avro--listfile=true c:\MyFileList.txt
```

**Casing and slashes on the command line**

```
RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)
```

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Processing**

```
--listfile = true|false
```

If `true`, treats the command's `InputFile` argument as a text file containing one filename per line. Default value is `false`. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)

Note:  Boolean option values are set to `true` if the option is specified without a value.
### recurse

```bash
--recurse = true|false
```

Used to select files within sub-directories, including in ZIP archives. If `true`, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

### Catalogs and global resources

#### catalog

```bash
--catalog = FILE
```

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, [XML Catalogs](#xml-catalogs), for information about working with catalogs.

#### user-catalog

```bash
--user-catalog = FILE
```

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, [XML Catalogs](#xml-catalogs), for information about working with catalogs.

#### enable-globalresources

```bash
--enable-globalresources = true|false
```

Enables global resources. Default value is `false`.

**Note:** Boolean option values are set to `true` if the option is specified without a value.

#### globalresourceconfig [gc]

```bash
--gc | --globalresourceconfig = VALUE
```

Specifies the active configuration of the global resource (and enables global resources).

#### globalresourcefile [gr]

```bash
--gr | --globalresourcefile = FILE
```

Specifies the global resource file (and enables global resources).

### Messages, errors, help, timeout, version

#### error-format

```bash
--error-format = text|shortxml|longxml
```

Specifies the format of the error output. Default value is `text`. The other options generate XML formats, with `longxml` generating more detail.

#### error-limit
--error-limit = \( N \mid \text{unlimited} \)
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

▼ help
--help
Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

▼ log-output
--log-output = \( \text{FILE} \)
Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

▼ network-timeout
--network-timeout = \( \text{VALUE} \)
Specifies the timeout in seconds for remote I/O operations. Default is: 40.

▼ verbose
--verbose = true|false
A value of true enables output of additional information during validation. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

▼ verbose-output
--verbose-output = \( \text{FILE} \)
Writes verbose output to \( \text{FILE} \).

▼ version
--version
Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

▼ warning-limit
--warning-limit = \( N \mid \text{unlimited} \)
Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.6.3 valavrojson (avrojson)

The `valavrojson` | `avrojson` command validates a JSON document against an Avro schema.

`Windows`  
`RaptorXMLXBRL valavrojson | avrojson [options] --avroschema=AvroSchema JSONFile`

`Linux`  
`raptorxmlxbrl valavrojson | avrojson [options] --avroschema=AvroSchema JSONFile`

`Mac`  
`raptorxmlxbrl valavrojson | avrojson [options] --avroschema=AvroSchema JSONFile`

The `JSONFile` argument specifies the JSON document to validate. The `--avroschema` option specifies the Avro schema against which the JSON document is to be validated. To validate multiple JSON files, either: (i) list the files on the CLI, with each file separated from the next by a space; or (ii) list the files to validate in a text file (.txt file), with one filename per line, and supply this text file as the `JSONFile` argument together with the `--listfile` option set to `true` (see the Options list below).

Examples

- `raptorxmlxbrl valavrojson --avroschema=c:\MyAvroSchema.avsc c:\MyJSONDataFile.json`
- `raptorxmlxbrl avrojson --avroschema=c:\MyAvroSchema.avsc c:\MyJSONDataFile.json`

Casing and slashes on the command line

- `RaptorXMLXBRL` on Windows
- `raptorxmlxbrl` on Unix (Linux, Mac)

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- Processing
  - `listfile`
    - `--listfile = true|false`
      - If `true`, treats the command's `InputFile` argument as a text file containing one filename per line. Default value is `false`. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)
Note that the \texttt{--listfile} option applies only to arguments, and not to options. 
\textit{Note:} Boolean option values are set to true if the option is specified without a value.

\texttt{--recurse}
\begin{verbatim}
  --recurse = true|false
\end{verbatim}

Used to select files within sub-directories, including in ZIP archives. If true, the command's \texttt{InputFile} argument will select the specified file also in subdirectories. For example: \texttt{test.zip|zip\test.xml} will select files named \texttt{test.xml} at all folder levels of the zip folder. The wildcard characters \* and ? may be used. So, \*\texttt{.xml} will select all .xml files in the (zip) folder. The option's default value is false. 
\textit{Note:} Boolean option values are set to true if the option is specified without a value.

\textbf{Catalogs and global resources}

\textbf{catalog}
\begin{verbatim}
  --catalog = FILE
\end{verbatim}

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (\texttt{<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml}). See the section, XML Catalogs, for information about working with catalogs.

\textbf{user-catalog}
\begin{verbatim}
  --user-catalog = FILE
\end{verbatim}

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

\textbf{enable-globalresources}
\begin{verbatim}
  --enable-globalresources = true|false
\end{verbatim}

Enables global resources. Default value is false. 
\textit{Note:} Boolean option values are set to true if the option is specified without a value.

\textbf{globalresourceconfig [gc]}
\begin{verbatim}
  --gc | --globalresourceconfig = VALUE
\end{verbatim}

Specifies the \textit{active configuration of the global resource} (and enables global resources).

\textbf{globalresourcefile [gr]}
\begin{verbatim}
  --gr | --globalresourcefile = FILE
\end{verbatim}

Specifies the \textit{global resource file} (and enables global resources).

\textbf{Messages, errors, help, timeout, version}

\textbf{error-format}
\begin{verbatim}
  --error-format = text|shortxml|longxml
\end{verbatim}

Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.
error-limit

    --error-limit = N | unlimited
    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

help

    --help
    Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

log-output

    --log-output = FILE
    Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

network-timeout

    --network-timeout = VALUE
    Specifies the timeout in seconds for remote I/O operations. Default is 40.

verbose

    --verbose = true|false
    A value of true enables output of additional information during validation. Default value is false.
    Note: Boolean option values are set to true if the option is specified without a value.

verbose-output

    --verbose-output = FILE
    Writes verbose output to FILE.

version

    --version
    Displays the version of RaptorXML+XBRL Server. If used with a command, place -- version before the command.

warning-limit

    --warning-limit = N | unlimited
    Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.6.4  valavroschema (avroschema)

The valavroschema | avroschema command validates one or more Avro schema documents against the Avro schema specification.

Windows    RaptorXMLXBRL valavroschema | avroschema [options] AvroSchema

Linux       raptorxmlxbrl valavroschema | avroschema [options] AvroSchema

Mac         raptorxmlxbrl valavroschema | avroschema [options] AvroSchema

The AvroSchema argument is the Avro schema document to validate. To validate multiple Avro schemas, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the AvroSchema argument together with the --listfile option set to true (see the Options list below).

Examples

• raptorxmlxbrl valavroschema c:\MyAvroSchema.avsc
• raptorxmlxbrl valavroschema c:\MyAvroSchema01.avsc c:\MyAvroSchema02.avsc
• raptorxmlxbrl avroschema--listfile=true c:\MyFileList.txt

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

Processing

• listfile

   --listfile = true|false

   If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.)
   Note that the --listfile option applies only to arguments, and not to options.

   **Note:** Boolean option values are set to true if the option is specified without a value.
**reurse**  
```bash  
--recurse = true|false  
```  
Used to select files within sub-directories, including in ZIP archives. If true, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is `false`.  
*Note:* Boolean option values are set to `true` if the option is specified without a value.

**Catalogs and global resources**

**catalog**  
```bash  
--catalog = FILE  
```  
Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, XML Catalogs, for information about working with catalogs.

**user-catalog**  
```bash  
--user-catalog = FILE  
```  
Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

**enable-globalresources**  
```bash  
--enable-globalresources = true|false  
```  
Enables global resources. Default value is `false`.  
*Note:* Boolean option values are set to `true` if the option is specified without a value.

**globalresourceconfig [gc]**  
```bash  
--gc | --globalresourceconfig = VALUE  
```  
Specifies the active configuration of the global resource (and enables global resources).

**globalresourcefile [gr]**  
```bash  
--gr | --globalresourcefile = FILE  
```  
Specifies the global resource file (and enables global resources).

**Messages, errors, help, timeout, version**

**error-format**  
```bash  
--error-format = text|shortxml|longxml  
```  
Specifies the format of the error output. Default value is `text`. The other options generate XML formats, with `longxml` generating more detail.

**error-limit**  
```bash  
--error-limit = N | unlimited  
```  
Specifies the error limit with a value range of 1 to 9999 or `unlimited`. The default value
is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

**Help**

```
--help
```

Displays help text for the command. For example, `valany --h`. (Alternatively the `help` command can be used with an argument. For example: `help valany`.)

**Log-output**

```
--log-output = FILE
```

Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

**Network-timeout**

```
--network-timeout = VALUE
```

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

**Verbose**

```
--verbose = true|false
```

A value of `true` enables output of additional information during validation. Default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**Verbose-output**

```
--verbose-output = FILE
```

Writes verbose output to `FILE`.

**Version**

```
--version
```

Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

**Warning-limit**

```
--warning-limit = N | unlimited
```

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.6.5 valjsonschema (jsonschema)

The valjsonschema | jsonschema command validates one or more JSON schema documents according to the JSON Schema Draft 4, Draft 6, or Draft 7 specifications.

Windows  RaptorXMLXBRL valjsonschema | jsonschema [options] InputFile
Linux    raptorxmlxbrl valjsonschema | jsonschema [options] InputFile
Mac      raptorxmlxbrl valjsonschema | jsonschema [options] InputFile

The InputFile argument is the JSON schema document to validate. To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the InputFile argument together with the --listfile option set to true (see the Options list below).

Examples

- raptorxmlxbrl valjsonschema c:\MyJSONSchema.json
- raptorxmlxbrl jsonschema c:\MyJSONSchema-01.json c:\MyJSONSchema-02.json
- raptorxmlxbrl jsonschema --listfile=true c:\FileList.txt

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

- Validation and processing

  listfile

    --listfile = true|false

    If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the --listfile option applies only to arguments, and not to options.

    * Note: Boolean option values are set to true if the option is specified without a value.
**Command Line Interface (CLI)**

**recurse**

```bash
--recurse = true|false
```

Used to select files within sub-directories, including in ZIP archives. If `true`, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**JSON validation options**

**disable-format-checks**

```bash
--disable-format-checks = true|false
```

Disables the semantic validation imposed by the format attribute. Default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**jsonschema-version**

```bash
--jsonschema-version = draft04|draft06|draft07|latest|detect
```

Specifies which version of the JSON Schema specification draft version to use. Default is `detect`.

**Catalogs and global resources**

**catalog**

```bash
--catalog = FILE
```

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (`<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml`). See the section, [XML Catalogs](#), for information about working with catalogs.

**user-catalog**

```bash
--user-catalog = FILE
```

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, [XML Catalogs](#), for information about working with catalogs.

**enable-globalresources**

```bash
--enable-globalresources = true|false
```

Enables `global resources`. Default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**globalresourceconfig [gc]**

```bash
--gc | --globalresourceconfig = VALUE
```

Specifies the active configuration of the global resource (and enables `global resources`).

**globalresourcefile [gr]**

- **--gr | --globalresourcefile = FILE**
  Specifies the global resource file (and enables global resources).

- **Messages, errors, help, timeout, version**
  - **error-format**
    --error-format = text|shortxml|longxml
    Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.
  - **error-limit**
    --error-limit = N | unlimited
    Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.
  - **help**
    --help
    Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)
  - **log-output**
    --log-output = FILE
    Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.
  - **network-timeout**
    --network-timeout = VALUE
    Specifies the timeout in seconds for remote I/O operations. Default is: 40.
  - **verbose**
    --verbose = true|false
    A value of true enables output of additional information during validation. Default value is false.
    **Note:** Boolean option values are set to true if the option is specified without a value.
  - **verbose-output**
    --verbose-output = FILE
    Writes verbose output to FILE.
  - **version**
    --version
    Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

- **warning-limit**
--warning-limit = N | unlimited

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.6.6 **valjson (json)**

The `valjson` command validates one or more JSON instance documents according to the JSON schema supplied with the `--schema` option.

*Windows* 
\[\text{RaptorXMLXBRL valjson | json [options] --jsonschema=File InputFile}\]

*Linux* 
\[\text{raptorxmlxbrl valjson | json [options] --jsonschema=File InputFile}\]

*Mac* 
\[\text{raptorxmlxbrl valjson | json [options] --jsonschema=File InputFile}\]

The `InputFile` argument is the JSON instance document to validate. To validate multiple documents, either: (i) list the files to be validated on the CLI, with each file separated from the next by a space; or (ii) list the files to be validated in a text file (.txt file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to `true` (see the Options list below).

### Examples

- `raptorxmlxbrl valjson --jsonschema=c:\MyJSONSchema.json c:\MyJSONInstance.json`
- `raptorxmlxbrl json --jsonschema=c:\MyJSONSchema.json c:\MyJSONInstance-01.json c:\MyJSONInstance-02.json`
- `raptorxmlxbrl json --jsonschema=c:\MyJSONSchema.json --listfile=true c:\FileList.txt`

**Casing and slashes on the command line**

* RaptorXMLXBRL on Windows
* raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

### Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Validation and processing**

* **schema, jsonschema**

  \[\text{--schema} = \text{FILE}, \text{--jsonschema} = \text{FILE}\]

  Specifies the path to the JSON Schema document to use for the validation of JSON instance documents.
listfile

--listfile = true|false

If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the --listfile option applies only to arguments, and not to options.

Note: Boolean option values are set to true if the option is specified without a value.

recurse

--recurse = true|false

Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: test.zip|zip\test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

json5

--json5 = true|false

Enables JSON5 support. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

jsonschema-version

--jsonschema-version = draft04|draft06|draft07|latest|detect

Specifies which version of the JSON Schema specification draft version to use. Default is detect.

disable-format-checks

--disable-format-checks = true|false

Disables the semantic validation imposed by the format attribute. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

Catalogs and global resources

catalog

--catalog = FILE

Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

user-catalog

--user-catalog = FILE

Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.
enable-globalresources
--enable-globalresources = true|false
Enables global resources. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

globalresourceconfig [gc]
--gc | --globalresourceconfig = VALUE
Specifies the active configuration of the global resource (and enables global resources).

globalresourcefile [gr]
--gr | --globalresourcefile = FILE
Specifies the global resource file (and enables global resources).

Messages, errors, help, timeout, version
error-format
--error-format = text|shortxml|longxml
Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

error-limit
--error-limit = N | unlimited
Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

help
--help
Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

log-output
--log-output = FILE
Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

network-timeout
--network-timeout = VALUE
Specifies the timeout in seconds for remote I/O operations. Default is: 40.

verbose
--verbose = true|false
A value of true enables output of additional information during validation. Default value is false.
Note: Boolean option values are set to true if the option is specified without a value.

- verbose-output
  --verbose-output = FILE
  Writes verbose output to FILE.

- version
  --version
  Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

- warning-limit
  --warning-limit = N | unlimited
  Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.6.7  **wfjson**

The **wfjson** command checks one or more JSON documents according to the ECMA-404 specification for well-formedness.

```
Windows  RaptorXMLXBRL wfjson [options] InputFile
Linux    raptorxmlxb1r wfjson [options] InputFile
Mac      raptorxmlxb1r wfjson [options] InputFile
```

The `InputFile` argument is the JSON document (schema or instance) to check for well-formedness. To check multiple documents, either: (i) list the files to be checked on the CLI, with each file separated from the next by a space; or (ii) list the files to be checked in a text file (.txt file), with one filename per line, and supply this text file as the `InputFile` argument together with the `--listfile` option set to true (see the Options list below).

**Examples**

- `raptorxmlxb1r wfjson c:\MyJSONFile.json`
- `raptorxmlxb1r wfjson c:\MyJSONFile-01.json c:\MyJSONFile-02.json`
- `raptorxmlxb1r wfjson --listfile=true c:\FileList.txt`

**Casing and slashes on the command line**

<table>
<thead>
<tr>
<th>RaptorXMLXBRL on Windows</th>
<th>raptorxmlxb1r on Unix (Linux, Mac)</th>
</tr>
</thead>
<tbody>
<tr>
<td>* Note that lowercase (raptorxmlxb1r) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.</td>
<td></td>
</tr>
<tr>
<td>* Use forward slashes on Linux and Mac, backslashes on Windows.</td>
<td></td>
</tr>
</tbody>
</table>

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Validation and processing**

- **json5**
  - `--json5 = true|false`
  - Enables JSON5 support. Default value is false.
  - **Note**: Boolean option values are set to true if the option is specified without a value.

- **listfile**
  - `--listfile = true|false`
  - If true, treats the command's `InputFile` argument as a text file containing one
filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Not that the --listfile option applies only to arguments, and not to options.

Note: Boolean option values are set to true if the option is specified without a value.

-** recurse**
  -- recurse = true|false
  Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: test.zip|zip\test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.
  Note: Boolean option values are set to true if the option is specified without a value.

** Catalogs and global resources **

-** catalog**
  -- catalog = FILE
  Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.

-** user-catalog**
  -- user-catalog = FILE
  Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.

-** enable-globalresources**
  -- enable-globalresources = true|false
  Enables global resources. Default value is false.
  Note: Boolean option values are set to true if the option is specified without a value.

-** globalresourceconfig [gc]**
  -- gc | -- globalresourceconfig = VALUE
  Specifies the active configuration of the global resource (and enables global resources).

-** globalresourcefile [gr]**
  -- gr | -- globalresourcefile = FILE
  Specifies the global resource file (and enables global resources).

-** Messages, errors, help, timeout, version **

-** error-format**
  -- error-format = text|shortxml|longxml
  Specifies the format of the error output. Default value is text. The other options...
generate XML formats, with `longxml` generating more detail.

- **error-limit**
  ```
  --error-limit = N | unlimited
  ```
  Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

- **help**
  ```
  --help
  ```
  Displays help text for the command. For example, `valany --h`. (Alternatively the `help` command can be used with an argument. For example: `help valany`.)

- **log-output**
  ```
  --log-output = FILE
  ```
  Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

- **network-timeout**
  ```
  --network-timeout = VALUE
  ```
  Specifies the timeout in seconds for remote I/O operations. Default is: 40.

- **verbose**
  ```
  --verbose = true|false
  ```
  A value of true enables output of additional information during validation. Default value is false.
  **Note:** Boolean option values are set to true if the option is specified without a value.

- **verbose-output**
  ```
  --verbose-output = FILE
  ```
  Writes verbose output to FILE.

- **version**
  ```
  --version
  ```
  Displays the version of RaptorXML+XBRL Server. If used with a command, place `--version` before the command.

- **warning-limit**
  ```
  --warning-limit = N | unlimited
  ```
  Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.7 XML Signature Commands

The XML Signature commands can be used to sign an XML document and to verify a signed document. These commands are listed below and described in detail in the sub-sections of this section:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xmlsignature-sign</code></td>
<td>Creates an XML signature output document from an input document</td>
</tr>
<tr>
<td><code>xmlsignature-verify</code></td>
<td>Verifies an XML signature document</td>
</tr>
<tr>
<td><code>xmlsignature-update</code></td>
<td>Updates the signature of a (modified) XML document</td>
</tr>
<tr>
<td><code>xmlsignature-remove</code></td>
<td>Removes the signature of an XML document</td>
</tr>
</tbody>
</table>
3.7.1 xmlsignature-sign

The xmlsignature-sign | xsign command takes an XML document as input and creates an XML signature output document using the specified signing options.

**Windows**

```
RaptorXMLXBRL xmlsignature-sign [options] --output=File --
signature-type=Value
--signature-canonicalization-method=Value InputFile
```

**Linux**

```
raptorxmlxbrl xmlsignature-sign [options] --output=File --
signature-type=Value
--signature-canonicalization-method=Value InputFile
```

**Mac**

```
raptorxmlxbrl xmlsignature-sign [options] --output=File --
signature-type=Value
--signature-canonicalization-method=Value InputFile
```

The **InputFile** argument is the XML document to sign. The --output option specifies the location of the the document that contains the XML signature.

**Examples**

- `raptorxmlxbrl xsign --output=c:\SignedFile.xml --signature-type=enveloped
--signature-canonicalization-method=xml-c14n11 c:\SomeUnsigned.xml`

**Casing and slashes on the command line**

- **RaptorXMLXBRL on Windows**
- **raptorxmlxbrl on Unix (Linux, Mac)**

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while uppercase (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Common options**

- **output**
  
  **output = FILE**
  
  The URL of the output document that is created with the new XML signature.

- **verbose**
  
  **--verbose = true|false**
  
  A value of true enables output of additional information during validation. Default value
is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

## XML Signature options

### absolute-reference-uri

```
--absolute-reference-uri = true|false
```

Specifies whether the URI of the signed document is to be read as absolute (true) or relative (false). Default is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

### certname, certificate-name

```
--certname, --certificate-name = VALUE
```

The name of the certificate used for signing.

**Windows**

This is the Subject name of a certificate from the selected `--certificate-store`.

*Example to list the certificates (under PowerShell)*

```powershell
% ls cert://CurrentUser/My
PSParentPath: Microsoft.PowerShell.Security\Certificate::CurrentUser\My
Thumbprint Subject
---------- -------
C9DF64BB0AAF5FA73474D78B7CCFFC37C95BFC6C CN=certificate1
... CN=...
```

*Example:* `--certificate-name==certificate1`

**Linux/MacOS**

`--certname` specifies the file name of a PEM encoded X.509v3 certificate with the private key. Such files usually have the extension .pem.

*Example:* `--certificate-name=/path/to/certificate1.pem`

### certstore, certificate-store

```
--certstore, --certificate-store = VALUE
```

The location where the the certificate specified with `--certificate-name` is stored.

**Windows**

The name of a certificate store under `cert://CurrentUser`. The available certificate stores can be listed (under PowerShell) by using `% ls cert://CurrentUser/`. Certificates would then be listed as follows:

- Name: TrustedPublisher
- Name: ClientAuthIssuer
- Name: Root
Name: UserDS  
Name: CA  
Name: ACRS  
Name: REQUEST  
Name: AuthRoot  
Name: MSIEHistoryJournal  
Name: TrustedPeople  
Name: MyCertStore  
Name: Local NonRemovable Certificates  
Name: SmartCardRoot  
Name: Trust  
Name: Disallowed  

Example: --certificate-store==MyCertStore  

**Linux/MacOS**  
The **--certstore** option is currently not supported.  

```bash  
--digest, --digest-method = sha1|sha256|sha384|sha512|base64  
The algorithm that is used to compute the digest value over the input XML file. Available values are: sha1|sha256|sha384|sha512|base64.  
```

```bash  
--hmackey, --hmac-secret-key = VALUE  
The HMAC shared secret key; must have a minimum length of six characters.  
Example: --hmackey=secretpassword  
```

```bash  
--hmaclen, --hmac-output-length = LENGTH  
Truncates the output of the HMAC algorithm to length bits. If specified, this value must be  
- a multiple of 8  
- larger than 80  
- larger than half of the underlying hash algorithm's output length  
```

```bash  
--keyinfo, --append-keyinfo = true|false  
Specifies whether to include the KeyInfo element in the signature or not. The default is false.  
```

```bash  
--sigc14nmeth, --signature-canonicalization-method = VALUE  
Specifies the canonicalization algorithm to apply to the SignedInfo element. The value must be one of:  
- REC-xml-c14n-20010315
• xml-c14n11
• xml-exc-c14n#

**sigmeth, signature-method**

```
--sigmeth, --signature-method = VALUE
```

Specifies the algorithm to use for generating the signature.

*When a certificate is used*

If a certificate is specified, then SignatureMethod is optional and the value for this parameter is derived from the certificate. If specified, it must match the algorithm used by the certificate. Example: rsa-sha256.

*When --hmac-secret-key is used*

When HMACSecretKey is used, then SignatureMethod is mandatory. The value must be one of the supported HMAC algorithms:

- hmac-sha256
- hmac-sha384
- hmac-sha512
- hmac-shal (discouraged by the specification)

Example: hmac-sha256

**sigtype, signature-type**

```
--sigtype, --signature-type = detached | enveloping | enveloped
```

Specifies the type of signature to be generated.

**transforms**

```
--transforms = VALUE
```

Specifies the XML Signature transformations applied to the input document. The supported values are:

- REC+xml-c14n-20010315 for Canonical XML 1.0 (omit comments)
- xml-c14n11 for Canonical XML 1.1 (omit comments)
- xml-exc-c14n# for Exclusive XML Canonicalization 1.0 (omit comments)
- REC+xml-c14n-20010315#WithComments for Canonical XML 1.0 (with comments)
- xml-c14n11#WithComments for Canonical XML 1.1 (with comments)
- xml-exc-c14n#WithComments for Exclusive XML Canonicalization 1.0 (with comments)
- base64
- strip-whitespaces Altova extension

Example: --transforms=xml-c14n11

**Note:** This option can be specified multiple times. If specified multiple times, then the order of specification is significant. The first specified transformation receives the input document. The last specified transformation is used immediately before calculation of the digest value.
write-default-attributes

--write-default-attributes = true|false
Specifies whether to include default attribute values from the DTD in the signed document.

Help and version options

help

--help
Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

version

--version
Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.
3.7.2 xmlsignature-verify

The `xmlsignature-verify` command verifies the XML signature of the input file. If the verification is successful, a `result="OK"` message is displayed; otherwise, a `result="Failed"` message is displayed.

```
Windows    RaptorXMLXBRL xmlsignature-verify [options] InputFile
Linux      raptorxmlxbrl xmlsignature-verify [options] InputFile
Mac        raptorxmlxbrl xmlsignature-verify [options] InputFile
```

The `InputFile` argument is the signed XML document to verify.

Examples

```
• raptorxmlxbrl xverify c:\SignedFile.xml
```

Casing and slashes on the command line

```
RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)
```

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

Common options

```
• verbose

    --verbose = true|false
    A value of true enables output of additional information during validation. Default value is false.
    Note: Boolean option values are set to true if the option is specified without a value.
```

XML Signature options

```
• certname, certificate-name

    --certname, --certificate-name = VALUE
    The name of the certificate used for signing.
```

Windows
This is the **Subject** name of a certificate from the selected `--certificate-store`.

**Example to list the certificates (under PowerShell)**

% ls cert://CurrentUser/My
PSParentPath: Microsoft.PowerShell.Security\Certificate::CurrentUser\My
Thumbprint Subject
---------- -------
C9DF64BB0AAF5FA73474D78B7CCFFC37C95BFC6C CN=certificate1
... CN=...

**Example:** `--certificate-name==certificate1`

**Linux/MacOS**

`--certname` specifies the file name of a PEM encoded X.509v3 certificate with the private key. Such files usually have the extension `.pem`.

**Example:** `--certificate-name==/path/to/certificate1.pem`

▶ certstore, certificate-store

`--certstore, --certificate-store = VALUE`

The location where the the certificate specified with `--certificate-name` is stored.

**Windows**

The name of a certificate store under `cert://CurrentUser`. The available certificate stores can be listed (under PowerShell) by using `% ls cert://CurrentUser/`. Certificates would then be listed as follows:

- Name: TrustedPublisher
- Name: ClientAuthIssuer
- Name: Root
- Name: UserDS
- Name: CA
- Name: ACRS
- Name: REQUEST
- Name: AuthRoot
- Name: MSIEHistoryJournal
- Name: TrustedPeople
- Name: **MyCertStore**
- Name: Local NonRemovable Certificates
- Name: SmartCardRoot
- Name: Trust
- Name: Disallowed

**Example:** `--certificate-store==MyCertStore`

**Linux/MacOS**

The `--certstore` option is currently not supported.

▶ hmackey, hmac-secret-key
Command Line Interface (CLI)

XML Signature Commands

--hmackey, --hmac-secret-key = VALUE
The HMAC shared secret key; must have a minimum length of six characters.

Example: --hmackey=secretpassword

▼ Help and version options

▼ help

--help
Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

▼ version

--version
Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.
3.7.3 xmlsignature-update

The `xmlsignature-update` command updates the XML signature in the signed input file. If the document has been modified, the updated XML signature will be different; otherwise, the updated signature will be the same as the previous signature.

*Windows*  
`RaptorXMLXBRL xmlsignature-update [options] --output=File SignedFile`

*Linux*  
`raptorxmlxbrl xmlsignature-update [options] --output=File SignedFile`

*Mac*  
`raptorxmlxbrl xmlsignature-update [options] --output=File SignedFile`

The `SignedFile` argument is the signed XML document to update. Either (i) the `hmac-secret-key` option or (ii) the `certificate-name` and `certificate-store` options must be specified. If the `certificate-name` and `certificate-store` options are specified, then they must match those that were used to sign the XML document previously. (Note that the `certificate-store` option is currently not supported on Linux and macOS.)

Examples

- `raptorxmlxbrl xupdate --output=c:\UpdatedSignedFile.xml --certname=certificate1 --certstore=MyCertStore c:\SomeSignedFile.xml`
- `raptorxmlxbrl xupdate --output=c:\UpdatedSignedFile.xml --hmackey=SecretPassword c:\SomeSignedFile.xml`

**Casing and slashes on the command line**

| RaptorXMLXBRL on Windows  
raptorxmlxbrl on Unix (Linux, Mac) |
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>* Note that lowercase (<code>raptorxmlxbrl</code>) works on all platforms (Windows, Linux, and Mac), while upper-lower (<code>RaptorXMLXBRL</code>) works only on Windows and Mac.</td>
</tr>
<tr>
<td>* Use forward slashes on Linux and Mac, backslashes on Windows.</td>
</tr>
</tbody>
</table>

**Options**

The command's options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Common options**

- **output**
  - `output = FILE`
    - The URL of the output document that is created with the new XML signature.
**XML Signature Commands**

**Command Line Interface (CLI)**

**--verbose** = *true*|false

A value of *true* enables output of additional information during validation. Default value is *false*.

*Note:* Boolean option values are set to *true* if the option is specified without a value.

**XML Signature options**

**--certname, --certificate-name** = VALUE

The name of the certificate used for signing.

**Windows**

This is the **Subject** name of a certificate from the selected **--certificate-store**.

*Example to list the certificates (under PowerShell)*

```bash
% ls cert://CurrentUser/My
PSParentPath: Microsoft.PowerShell.Security\Certificate::CurrentUser\My
Thumbprint Subject
---------- -------
C9DF64BB0AAF5FA73474D78B77CCFFC37C95BFC6C CN=certificat1
... CN=...

*Example:* **--certificate-name==certificate1**
```

**Linux/MacOS**

**--certname** specifies the file name of a PEM encoded X.509v3 certificate with the private key. Such files usually have the extension *.pem*.

*Example:* **--certificate-name==/path/to/certificate1.pem**

**--certstore, --certificate-store** = VALUE

The location where the the certificate specified with **--certificate-name** is stored.

**Windows**

The name of a certificate store under **cert://CurrentUser**. The available certificate stores can be listed (under PowerShell) by using `% ls cert://CurrentUser/`. Certificates would then be listed as follows:

- Name : TrustedPublisher
- Name : ClientAuthIssuer
- Name : Root
- Name : UserDS
- Name : CA
- Name : ACRS
- Name : REQUEST
- Name : AuthRoot

© 2019 Altova GmbH
Name : MSIEHistoryJournal
Name : TrustedPeople
Name : **MyCertStore**
Name : Local NonRemovable Certificates
Name : SmartCardRoot
Name : Trust
Name : Disallowed

*Example:* --certificate-store=MyCertStore

**Linux/MacOS**
The **--certstore** option is currently not supported.

**hmackey, hmac-secret-key**

```bash
--hmackey, --hmac-secret-key = VALUE
```

The HMAC shared secret key; must have a minimum length of six characters.

*Example:* --hmackey=secretpassword

**Help and version options**

**help**

```bash
--help
```

Displays help text for the command. For example, `valany --h`. (Alternatively the `help` command can be used with an argument. For example: `help valany`.)

**version**

```bash
--version
```

Displays the version of RaptorXML+XBRL Server. If used with a command, place **--version** before the command.
3.7.4 xmlsignature-remove

The `xmlsignature-remove` command removes the XML signature of the signed input file, and saves the resulting unsigned document to an output location that you specify.

```
Windows  RaptorXMLXBRL xmlsignature-remove [options] --output=File
           SignedFile
Linux     raptorxmlxbrl xmlsignature-remove [options] --output=File
           SignedFile
Mac       raptorxmlxbrl xmlsignature-remove [options] --output=File
           SignedFile
```

The `SignedFile` argument is the signed XML document from which you want to remove the XML signature. The `--output` option specifies the location of the unsigned XML document that is generated.

Examples

```
  * raptorxmlxbrl xremove --output=c:\UnsignedFile.xml
c:\SignedFile.xml
```

Casing and slashes on the command line

```
RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)
* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac),
while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.
```

Options

The command’s options are listed below, organized into groups. Values can be specified without quotes except in two cases: (i) when the value string contains spaces, or (ii) when explicitly stated in the description of the option that quotes are required.

**Common options**

```
  ▼ output
  output = FILE
  The URL of the output document that is created with the XML signature removed.
```

```
  ▼ verbose
  --verbose = true|false
  A value of true enables output of additional information during validation. Default value
  is false.
  * Note: Boolean option values are set to true if the option is specified without a value.
```
Help and version options

help
  --help
  Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

version
  --version
  Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.
3.8 Valany Command

The *valany* command is a general command that validates a document on the basis of what type of document it is. The type of the input document is detected automatically, and the corresponding validation is carried out according to the respective specification. The *InputFile* argument is the document to validate. Note that only one document can be submitted as the argument of the command.

*Windows*  
```
RaptorXMLXBRL valany [options] InputFile
```

*Linux*  
```
raptorxmlxbrl valany [options] InputFile
```

*Mac*  
```
raptorxmlxbrl valany [options] InputFile
```

The *valany* command covers the following types of validation. Its options are those that are available for the corresponding individual validation command. See the description of the respective validation commands for a list of their respective options.

- `valdtd (dtd)`
- `valxsd (xsd)`
- `valxml-withdtd (xml)`
- `valxml-withxsd (xsi)`
- `valxslt`
- `valxquery`
- `valxbrl (xbrl)`
- `valxbrlinlinexbrl (ixbrl)`
- `valxbrltaxonomy (dts)`
- `valavrojson (avrojson)`

**Examples**

- `raptorxmlxbrl valany c:\Test.xsd`
- `raptorxmlxbrl valany --error-format=text c:\Test.xbrl`

**Casing and slashes on the command line**

<table>
<thead>
<tr>
<th>Platform</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>RaptorXMLXBRL</td>
</tr>
<tr>
<td></td>
<td>on Windows</td>
</tr>
<tr>
<td></td>
<td>raptorxmlxbrl</td>
</tr>
<tr>
<td></td>
<td>on Unix (Linux, Mac)</td>
</tr>
</tbody>
</table>

* Note that lowercase (*raptorxmlxbrl*) works on all platforms (Windows, Linux, and Mac), while upper-lower (*RaptorXMLXBRL*) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

See the description of the respective validation commands for a list of their respective options. Note, however, that while most individual validation commands accept multiple input documents, the *valany* command accepts only one input document. Options such as the `--listfile` option will therefore not apply to *valany*. 
3.9 Script Command

The script command executes a Python 3.5 script that uses the RaptorXML Python API.

- **Windows**
  `RaptorXMLXBRL script [options] File`

- **Linux**
  `raptorxmlxbrl script [options] File`

- **Mac**
  `raptorxmlxbrl script [options] File`

The `File` argument is the path to the Python script you want to execute. Additional options are available. To obtain a list of these options, run the following command:

- **Windows**
  `RaptorXMLXBRL script [-h | --help]`

- **Linux**
  `raptorxmlxbrl script [-h | --help]`

- **Mac**
  `raptorxmlxbrl script [-h | --help]`

**Examples**

- `raptorxmlxbrl script c:\MyPythonScript.py`
- `raptorxmlxbrl script -h`
- `raptorxmlxbrl script # Without a script file, an interactive Python shell is started`
- `raptorxmlxbrl script -m pip # Loads and executes the pip module; see the Options section below`

**Casing and slashes on the command line**

- **RaptorXMLXBRL on Windows**
- **raptorxmlxbrl on Unix (Linux, Mac)**

  * Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
  * Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

Any options and arguments after the `script` command are forwarded directly to the Python interpreter. Please consult the Python documentation page [https://docs.python.org/3.5/using/cmdline.html](https://docs.python.org/3.5/using/cmdline.html) for a complete listing of available options.
3.10 Help and License Commands

This section describes two important features of RaptorXML+XBRL Server:

- **Help Command**: Describes how to display information about available commands, or about a command's arguments and options
- **Licensing**: Describes how to license RaptorXML
3.10.1 help

The `help` command takes a single argument: the name of the command for which help is required. It displays the syntax of the command and other information relevant to the correct execution of the command.

* Windows: `RaptorXMLXBRL help Command`
* Linux: `raptorxmlxbrl help Command`
* Mac: `raptorxmlxbrl help Command`

**Note:** When no argument is submitted, running the `help` command causes all available commands to be displayed, each with a short description of what it does.

**Example**

Example of the `help` command:

```
raptorxmlxbrl help valany
```

The command above contains one argument: the command `valany`, for which help is required. When this command is executed, it will display help information about the `valany` command.

**Casing and slashes on the command line**

* RaptorXMLXBRL on Windows
* raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

**The `--help` option**

Help information about a command is also available by using the `--help` option with that command. For example, using the `--help` option with the `valany` command, as follows:

```
raptorxmlxbrl valany --help
```

achieves the same result as does using the `help` command with an argument of `valany`:

```
raptorxmlxbrl help valany
```

In both cases, help information about the `valany` command is displayed.

**Casing and slashes on the command line**

* RaptorXMLXBRL on Windows
* raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac),
while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.
3.10.2 licenseserver

The licenseserver command registers RaptorXML+XBRL Server with Altova LicenseServer. It takes as its argument the name or IP address of the server running LicenseServer.

- **Windows**  
  `RaptorXMLXBRL licenseserver [options] Server-Or-IP-Address`

- **Linux**  
  `raptorxmlxbrl licenseserver [options] Server-Or-IP-Address`

- **Mac**  
  `raptorxmlxbrl licenseserver [options] Server-Or-IP-Address`

On successfully registering RaptorXML+XBRL Server with LicenseServer, the URL of the LicenseServer web interface will be returned. Enter the URL in a browser window to access the web interface, and then go through the licensing process as described in the LicenseServer documentation.

**Example**

Here's an example of the licenseserver command:

```
raptorxmlxbrl licenseserver DOC.altova.com
```

The command specifies that the machine named `DOC.altova.com` is the machine running Altova LicenseServer.

- **Casing and slashes on the command line**
  
  - **RaptorXMLXBRL on Windows**
  - **raptorxmlxbrl on Unix (Linux, Mac)**

  * Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.

  * Use forward slashes on Linux and Mac, backslashes on Windows.

**Options**

The following options are available:

- **--json=true|false**
  
  Prints the result of the registration attempt as a machine-parsable JSON object.

- **--help**
  
  Displays the command's help text.

- **--version**
  
  Displays the version number of RaptorXML+XBRL Server. The option should be placed before the command. So: `raptorxmlxbrl --version licenseserver`. 
3.10.3 assignlicense

The assignlicense command is available on Windows only. It uploads a license file to the Altova LicenseServer with which RaptorXML+XBRL Server is registered (see the licenseserver command), licensed, and assigns the license to RaptorXML+XBRL Server. It takes the URL of a license file as its argument. The command also allows you to test the validity of a license.

Windows  RaptorXMLXBRL assignlicense [options] LICENSE-FILE
Linux     not applicable
Mac       not applicable

Example

•  raptorxmlxbrl assignlicense C:\licensepool\mylicensekey.lic
•  raptorxmlxbrl assignlicense --test-only=true C:\licensepool \mylicensekey.lic

Casing and slashes on the command line

RaptorXMLXBRL on Windows
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (raptorxmlxbrl) works on all platforms (Windows, Linux, and Mac), while upper-lower (RaptorXMLXBRL) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The following options are available:

--t|test-only=true|false
If the value is true, then the license is uploaded to LicenseServer and validated, but not assigned.

Note: Boolean option values are set to true if the option is specified without a value.

--h|help
Displays the command's help text.

--version
Displays the version number of RaptorXML+XBRL Server. The option should be placed before the command. So: raptorxmlxbrl --version licenseserver.
3.10.4 verifylicense

The `verifylicense` command is available on Windows only. It checks whether RaptorXML+XBRL Server is licensed, and optionally checks whether a given license key is already assigned to RaptorXML+XBRL Server. It takes a license key as an option. The command returns a statement about the license status or validity of the submitted license key.

- **Windows** `RaptorXMLXBRL verifylicense [options]`
- **Linux** `not applicable`
- **Mac** `not applicable`

Example

- `raptorxmlxbrl verifylicense`
- `raptorxmlxbrl verifylicense --license-key=a-39-character-long-license-code-(7x5, plus 4 hyphens)`
- `raptorxmlxbrl verifylicense --l=a-39-character-long-license-code-(7x5, plus 4 hyphens)`

Return statements are of this kind:

- The product has a valid license
- The product does not have a valid license
- The license key AAAAAA-BBBBBB-CCCCCCC-DDDDDDD-EEEEE is assigned to the product
- The license key AAAAAA-BBBBBB-CCCCCCC-DDDDDDD-EEEEE is not assigned to the product

Casing and slashes on the command line

RaptorXMLXBRL on Windows  
raptorxmlxbrl on Unix (Linux, Mac)

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

Options

The following options are available:

- `--l|license-key=VALUE`
  VALUE is the 39-character-long license key without any delimiters. The key consists of five blocks of seven characters separated by hyphens.

- `--h|help`
  Displays the command's help text.

- `--version`
Displays the version number of RaptorXML+XBRL Server. The option should be placed before the command. So: `raptorxmlxbrl --version licenseserver.`
3.11 Localization Commands

You can create a localized version of the RaptorXML application for any language of your choice. Five localized versions (English, German, Spanish, French, and Japanese) are already available in the `<ProgramFilesFolder>\Altova\RaptorXMLXBRLServer2019\bin\` folder. These five language versions therefore do not need to be created.

Create a localized version in another language as follows:

1. Generate an XML file containing the resource strings. Do this with the `exportresourcestrings` command. The resource strings in the generated XML file will be one of the five supported languages: English (`en`), German (`de`), Spanish (`es`), French (`fr`), or Japanese (`ja`), according to the argument used with the command.
2. Translate the resource strings from the language of the generated XML file into the target language. The resource strings are the contents of the `<string>` elements in the XML file. Do not translate variables in curly brackets, such as `{option}` or `{product}`.
3. Contact Altova Support to generate a localized RaptorXML DLL file from your translated XML file.
4. After you receive your localized DLL file from Altova Support, save the DLL in the `<ProgramFilesFolder>\Altova\RaptorXMLXBRLServer2019\bin\` folder. Your DLL file will have a name of the form `RaptorXMLXBRLServer_lc.dll`. The `_lc` part of the name contains the language code. For example, in `RaptorXMLXBRLServer_de.dll`, the `de` part is the language code for German (Deutsch).
5. Run the `setdeflang` command to set your localized DLL file as the RaptorXML application to use. For the argument of the `setdeflang` command, use the language code that is part of the DLL name.

Note: Altova RaptorXML+XBRL Server is delivered with support for five languages: English, German, Spanish, French, and Japanese. So you do not need to create a localized version of these languages. To set any of these five languages as the default language, use the CLI's `setdeflang` command.
3.11.1 exportresourcestrings

The `exportresourcestrings` command outputs an XML file containing the RaptorXML resource strings. The command takes two arguments: (i) the language of the resource strings in the output XML file, and (ii) the path and name of the output XML file. Allowed export languages (with their language codes in parentheses) are: English (`en`), German (`de`), Spanish (`es`), French (`fr`), and Japanese (`ja`).

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command Name</th>
<th>Command Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>RaptorXMLXBRL exportresourcestrings</td>
<td><code>LanguageCode XMLOutputFile</code></td>
</tr>
<tr>
<td>Linux</td>
<td>raptorxmlxbrl exportresourcestrings</td>
<td><code>LanguageCode XMLOutputFile</code></td>
</tr>
<tr>
<td>Mac</td>
<td>raptorxmlxbrl exportresourcestrings</td>
<td><code>LanguageCode XMLOutputFile</code></td>
</tr>
</tbody>
</table>

Arguments

The `exportresourcestrings` command takes the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LanguageCode</td>
<td>Specifies the target language of the export, that is, the language of resource strings in the exported XML file. Supported languages are: <code>en</code>, <code>de</code>, <code>es</code>, <code>fr</code>, <code>ja</code></td>
</tr>
<tr>
<td>XMLOutputFile</td>
<td>Specifies the location and name of the exported XML file.</td>
</tr>
</tbody>
</table>

Example

This command creates a file called `Strings.xml` at `c:\` that contains all the resource strings of the RaptorXML application translated into German.

```
raptorxmlxbrl exportresourcestrings de c:\Strings.xml
```

Casing and slashes on the command line

- **RaptorXMLXBRL on Windows**
  - `raptorxmlxbrl` on Unix (Linux, Mac)

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.

* Use forward slashes on Linux and Mac, backslashes on Windows.
3.11.2 setdeflang

The `setdeflang` command (short form is `sdl`) sets the default language of RaptorXML. It takes a mandatory `LanguageCode` argument.

\[
\begin{align*}
\text{Windows} & \quad \text{RaptorXMLXBRL setdeflang | sdl LanguageCode} \\
\text{Linux} & \quad \text{raptorxmlxbrl setdeflang | sdl LanguageCode} \\
\text{Mac} & \quad \text{raptorxmlxbrl setdeflang | sdl LanguageCode}
\end{align*}
\]

**Example**

This command sets the default language of the application's messages to German.

```
raptorxmlxbrl setdeflang de
```

\[\text{Casing and slashes on the command line}\]

\[
\begin{align*}
\text{RaptorXMLXBRL on Windows} \\
\text{raptorxmlxbrl on Unix (Linux, Mac)}
\end{align*}
\]

* Note that lowercase (`raptorxmlxbrl`) works on all platforms (Windows, Linux, and Mac), while upper-lower (`RaptorXMLXBRL`) works only on Windows and Mac.
* Use forward slashes on Linux and Mac, backslashes on Windows.

**Supported languages**

The table below lists the languages currently supported together with their language codes.

<table>
<thead>
<tr>
<th>Language Code</th>
<th>Language</th>
</tr>
</thead>
<tbody>
<tr>
<td>en</td>
<td>English</td>
</tr>
<tr>
<td>de</td>
<td>German</td>
</tr>
<tr>
<td>es</td>
<td>Spanish</td>
</tr>
<tr>
<td>fr</td>
<td>French</td>
</tr>
<tr>
<td>ja</td>
<td>Japanese</td>
</tr>
</tbody>
</table>
3.12 Options

This section contains a description of all CLI options, organized by functionality. To find out which options may be used with each command, see the description of the respective commands.

- Catalogs, Global Resources, ZIP Files
- Messages, Errors, Help
- Processing
- XBRL
- XML
- XSD
- XQuery
- XSLT
- JSON/Avro
- XML Signatures
3.12.1 Catalogs, Global Resources, ZIP Files

- **catalog**
  ```
  --catalog = FILE
  Specifies the absolute path to a root catalog file that is not the installed root catalog file. The default value is the absolute path to the installed root catalog file (<installation-folder>\Altova\RaptorXMLXBRLServer2019\etc\RootCatalog.xml). See the section, XML Catalogs, for information about working with catalogs.
  ```

- **user-catalog**
  ```
  --user-catalog = FILE
  Specifies the absolute path to an XML catalog to be used in addition to the root catalog. See the section, XML Catalogs, for information about working with catalogs.
  ```

- **enable-globalresources**
  ```
  --enable-globalresources = true|false
  Enables global resources. Default value is false.
  Note: Boolean option values are set to true if the option is specified without a value.
  ```

- **globalresourceconfig [gc]**
  ```
  --gc | --globalresourceconfig = VALUE
  Specifies the active configuration of the global resource (and enables global resources).
  ```

- **globalresourcefile [gr]**
  ```
  --gr | --globalresourcefile = FILE
  Specifies the global resource file (and enables global resources).
  ```

- **recurse**
  ```
  --recurse = true|false
  Used to select files within sub-directories, including in ZIP archives. If true, the command's InputFile argument will select the specified file also in subdirectories. For example: test.zip|zip\test.xml will select files named test.xml at all folder levels of the zip folder. The wildcard characters * and ? may be used. So, *.xml will select all .xml files in the (zip) folder. The option's default value is false.
  Note: Boolean option values are set to true if the option is specified without a value.
  ```
3.12.2 Messages, Errors, Help, Timeout, Version

error-format

```bash
--error-format = text|shortxml|longxml
```

Specifies the format of the error output. Default value is text. The other options generate XML formats, with longxml generating more detail.

error-limit

```bash
--error-limit = N | unlimited
```

Specifies the error limit with a value range of 1 to 9999 or unlimited. The default value is 100. Processing stops when the error limit is reached. Useful for limiting processor use during validation/transformation.

help

```bash
--help
```

Displays help text for the command. For example, valany --h. (Alternatively the help command can be used with an argument. For example: help valany.)

log-output

```bash
--log-output = FILE
```

Writes the log output to the specified file URL. Ensure that the CLI has write permission to the output location.

network-timeout

```bash
--network-timeout = VALUE
```

Specifies the timeout in seconds for remote I/O operations. Default is: 40.

verbose

```bash
--verbose = true|false
```

A value of true enables output of additional information during validation. Default value is false.

Note: Boolean option values are set to true if the option is specified without a value.

verbose-output

```bash
--verbose-output = FILE
```

Writes verbose output to FILE.

version

```bash
--version
```

Displays the version of RaptorXML+XBRL Server. If used with a command, place --version before the command.

warning-limit

```bash
--warning-limit = N | unlimited
```

Specifies the warning limit in the range 1-65535 or unlimited. Processing continues if this limit is reached, but further warnings are not reported. The default value is 100.
3.12.3 Processing

- **listfile**
  
  ```
  --listfile = true|false
  ```
  
  If true, treats the command's InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the --listfile option applies only to arguments, and not to options.
  
  **Note:** Boolean option values are set to true if the option is specified without a value.

- **parallel-assessment [pa]**
  
  ```
  --pa | --parallel-assessment = true|false
  ```
  
  If set to true, schema validity assessment is carried out in parallel. This means that if there are more than 128 elements at any level, these elements are processed in parallel using multiple threads. Very large XML files can therefore be processed faster if this option is enabled. Parallel assessment takes place on one hierarchical level at a time, but can occur at multiple levels within a single infoset. Note that parallel assessment does not work in streaming mode. For this reason, the --streaming option is ignored if --parallel-assessment is set to true. Also, memory usage is higher when the --parallel-assessment option is used. The default setting is false. Short form for the option is --pa.
  
  **Note:** Boolean option values are set to true if the option is specified without a value.

- **script**
  
  ```
  --script = FILE
  ```
  
  Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

- **script-api-version**
  
  ```
  --api, --script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7
  ```
  
  Specifies the Python API version to be used for the script. The default value is the latest version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0 and 2.0, respectively.

- **script-param**
  
  ```
  --script-param = KEY:VALUE
  ```
  
  Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

- **streaming**
  
  ```
  --streaming = true|false
  ```
  
  Enables streaming validation. Default is true. In streaming mode, data stored in memory is minimized and processing is faster. The downside is that information that might be required subsequently—for example, a data model of the XML instance document—will not be available. In situations where this is significant, streaming mode will need to be turned off (by giving --streaming a value of false). When using the --script option with the valxml-withxsd command, disable streaming. Note that the --streaming option is ignored if --parallel-assessment is set to true.
  
  **Note:** Boolean option values are set to true if the option is specified without a value.
xml-validation-error-as-warn

```xml
--xml-validation-error-as-warning = true|false
```

If `true`, treats validation errors as warnings. If errors are treated as warnings, additional processing, such as XSLT transformations, will continue regardless of errors. Default is `false`. 
3.12.4 XBRL

- XBRL validation and processing options
  - additional-dts-entry-point
    ```
    --additional-dts-entry-point = FILE
    ```
    Forces the specified entry-point file to be included in the DTS discovery process. Add the option multiple times to specify more than one entry point.
  
  - ct-restrict-mode
    ```
    --ct-restrict-mode = 1.0|1.1|default
    ```
    Specifies how to check complex type restrictions. A value of 1.0 checks complex type restrictions as defined in the XSD 1.0 specification—even in XSD 1.1 validation mode. A value of 1.1 checks complex type restrictions as defined in the XSD 1.1 specification—even in XSD 1.0 validation mode. A value of default checks complex type restrictions as defined in the XSD specification of the current validation mode (1.0 or 1.1). The default value is default.

  - deduplicate
    ```
    --deduplicate = true|false
    ```
    Enables de-duplication according to the Handling Duplicate Facts in XBRL and Inline XBRL 1.0 specification. Removes facts that are (i) complete duplicates, (ii) consistent duplicates (by definition these are numeric facts; the most accurate of the duplicates is retained for processing). Inconsistent and multi-language duplicates are not affected by this option. Default value is false.
    
    **Note:** Boolean option values are set to true if the option is specified without a value.

  - dimensions
    ```
    --dimensions = true|false
    ```
    Enables XBRL Dimension 1.0 extensions. Default is true.
    
    **Note:** Boolean option values are set to true if the option is specified without a value.

  - dts
    ```
    --dts = FILE
    ```
    Preloads the DTS entry point given in FILE, and uses it for the validation of instance files. Add the option multiple times to specify more than one entry point. Entry points in instance files will be ignored. The command is used to batch validate multiple instance files that all refer to the same taxonomy. The --dts option instructs the Raptor engine to load the DTS only a single time—and not for each instance in the file list. (A file list is given either on the CLI, or in a text file that is indicated as a file list by setting the --listfile option to true.) If an instance file in the file list references a different taxonomy, then a warning is issued. This command can greatly speed up validation time when validating many small instance files each that have a large supporting DTS; it provides no advantage when validating a single instance file.

  - essence-alias-checks
    ```
    --essence-alias-checks = true|false
    ```
    Enables reporting of essence-alias inconsistencies. Default value is true.
**Note:** Boolean option values are set to true if the option is specified without a value.

### extensible-enumerations

```
--extensible-enumerations = true|false
```

If true, enables the XBRL Extensible Enumerations 1.0 extension. Default is: true.

### generic-links

```
--generic-links = true|false
```

Enables the XBRL Generic Links 1.0 extension. Default value is true.

**Note:** Boolean option values are set to true if the option is specified without a value.

### generic-preferred-label

```
--generic-preferred-label = true|false
```

Enables the XBRL Generic Preferred Label 1.0 extension. Default value is true.

**Note:** Boolean option values are set to true if the option is specified without a value.

### inconsistencies-limit

```
--inconsistencies-limit = VALUE | unlimited
```

Specifies the XBRL inconsistencies limit, with values being in the range 1-65535 or unlimited. Processing continues if the limit is reached, but further inconsistencies are not reported. The default value is 100.

### listfile

```
--listfile = true|false
```

If true, treats the command’s InputFile argument as a text file containing one filename per line. Default value is false. (An alternative is to list the files on the CLI with a space as separator. Note, however, that CLIs have a maximum-character limitation.) Note that the --listfile option applies only to arguments, and not to options.

**Note:** Boolean option values are set to true if the option is specified without a value.

### parallel-assessment [pa]

```
--pa | --parallel-assessment = true|false
```

If set to true, schema validity assessment is carried out in parallel. This means that if there are more than 128 elements at any level, these elements are processed in parallel using multiple threads. Very large XML files can therefore be processed faster if this option is enabled. Parallel assessment takes place on one hierarchical level at a time, but can occur at multiple levels within a single infoset. Note that parallel assessment does not work in streaming mode. For this reason, the --streaming option is ignored if --parallel-assessment is set to true. Also, memory usage is higher when the --parallel-assessment option is used. The default setting is false. Short form for the option is --pa.

**Note:** Boolean option values are set to true if the option is specified without a value.

### preload-xbrl-schemas

```
--preload-xbrl-schemas = true|false
```

Preloads schemas of the XBRL 2.1 specification. Default is true.

**Note:** Boolean option values are set to true if the option is specified without a value.
### Options

#### recurse

```
--recurse = true|false
```

Used to select files within sub-directories, including in ZIP archives. If `true`, the command's `InputFile` argument will select the specified file also in subdirectories. For example: `test.zip|zip\test.xml` will select files named `test.xml` at all folder levels of the zip folder. The wildcard characters `*` and `?` may be used. So, `*.xml` will select all `.xml` files in the (zip) folder. The option's default value is `false`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

#### report-duplicates

```
--report-duplicates = all|complete|consistent|inconsistent|inconsistent-numeric|inconsistent-non-numeric|multi-language
```

Enables the reporting of duplicate facts of the specified duplicate class. Add the option multiple times to specify more than one duplicate class. There is no default value. If no value is specified, then no check for duplicates is carried out.

#### report-duplicates-severity

```
--report-duplicates-severity = info|warning|inconsistency|error
```

Specifies whether the detected duplicate facts should be reported as errors or warnings. If they are reported as errors, then the XBRL validation of the instance will fail. The default is `error`.

#### requires-element-checks

```
--requires-element-checks = true|false
```

Enables reporting of requires-element inconsistencies. The default value is `true`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

#### schema-imports

```
--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only
```

Specifies the behaviour of `xs:import` elements, each of which has an optional `namespace` attribute and an optional `schemaLocation` attribute:

```xml
<import namespace="someNS" schemaLocation="someURL">.
```

The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: `load-preferring-schemalocation`.

The behavior is as follows:

- **load-by-schemalocation:** The value of the `schemaLocation` attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
- **load-preferring-schemalocation:** If the `schemaLocation` attribute is present, it is used, taking account of catalog mappings. If no `schemaLocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This is the default value.
- **load-by-namespace:** The value of the `namespace` attribute is used to locate the schema via a catalog mapping.
• load-combining-both: If either the namespace or schemaLocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemaLocation attribute is used.

• license-namespace-only: The namespace is imported. No schema document is imported.

```bash
--schema-mapping = prefer-schemalocation | prefer-namespace
```

If schema location and namespace are both used to find a schema document, specifies which of them should be preferred during catalog lookup. (If either the --schemalocation-hints or the --schema-imports option has a value of load-combining-both, and if the namespace and URL parts involved both have catalog mappings, then the value of this option specifies which of the two mappings to use (namespace mapping or URL mapping; the prefer-schemalocation value refers to the URL mapping).) Default is prefer-schemalocation.

```bash
--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore
```

Specifies the behavior of the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: load-by-schemalocation.

- The load-by-schemalocation value uses the URL of the schema location in the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes in XML or XBRL instance documents. This is the default value.
- The load-by-namespace value takes the namespace part of xsi:schemaLocation and an empty string in the case of xsi:noNamespaceSchemaLocation and locates the schema via a catalog mapping.
- If load-combining-both is used and if either the namespace part or the URL part has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If neither the namespace nor URL has a catalog mapping, the URL is used.
- If the option's value is ignore, then the xsi:schemaLocation and xsi:noNamespaceSchemaLocation attributes are both ignored.

```bash
--script = FILE
```

Executes the Python script in the submitted file after validation has been completed. Add the option multiple times to specify more than one script.

```bash
--script-api-version = 1|2|2.1|2.2|2.3|2.4|2.4.1|2.5|2.6|2.7
```

Specifies the Python API version to be used for the script. The default value is the latest version, currently 2.7. Instead of the values 1 and 2, you can also use the values 1.0
and 2.0, respectively.

- **script-output**
  
  ```
  --script-output = FILE
  ```
  
  Writes the script's standard output to the file named in `FILE`.

- **script-param**
  
  ```
  --script-param = KEY:VALUE
  ```
  
  Additional user-specified parameters that can be accessed during the execution of Python scripts. Add the option multiple times to specify more than one script parameter.

- **summation-item-checks**
  
  ```
  --summation-item-checks = true|false
  ```
  
  Enables reporting of summation-item inconsistencies. The default value is `true`.

  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **taxonomy-package**
  
  ```
  --taxonomy-package = FILE
  ```
  
  Specifies the absolute path to an additional taxonomy package as described in the Taxonomy Package 1.0 and Taxonomy Packages 1.0 working drafts. The value of `FILE` gives the location of the taxonomy package. Add the option multiple times to specify more than one taxonomy package.

- **taxonomy-packages-config-file**
  
  ```
  --taxonomy-packages-config-file = FILE
  ```
  
  Specifies the path to the `TaxonomyPackagesConfig.json` file, which is used to load XBRL taxonomy packages. The file's convenience is that it serves as a catalog of taxonomy packages. The structure of the JSON file is as in the example listing below. The value of the `uri` key gives the location of the package. The `active` key (of a set of packages) switches on usage of those packages.

  ```json
  {
    "taxonomies": {
      "EIOPA Solvency II XBRL Taxonomy 2.1.0": {
        "packages": [
          {
            "uri": "C:\test\XBRL\EIOPA_SolvencyII_XBRL_Taxonomy_2.1.0.zip"},
          {
            "uri": "C:\test\XBRL\AdditionalTestPkg.zip"
          }
        ],
        "active": true
      },
      "Test Taxonomy": {
        "packages": [{
          "uri": "C:\test\XBRL\test.zip"},
        "active": true
      }
    }
  }
  ```

- **treat-inconsistencies-as-errors**
  
  ```
  --treat-inconsistencies-as-errors = true|false
  ```
  
  Causes XBRL validation to fail if the file contains any inconsistency as defined by the XBRL 2.1 specification. Default value is `false`.

  **Note:** Boolean option values are set to `true` if the option is specified without a value.
utr

```bash
--utr = [true|false]
```

If `true`, enables the XBRL Unit Registry 1.0 extension. Default is: `false`.

utr-file

```bash
--utr-file = FILE
```

Specifies the path to the Units Registry file. The default is: `http://www.xbrl.org/utr/utr.xml`.

utr-status

```bash
--utr-status = [PWD|CR|REC|NIE|PROPOSED|IWD|ACK|RR]
```

Enables support of unit definitions with the given status in the Units Registry. Add the option multiple times to specify more than one unit status. Default is `REC`.

validate-dts-only

```bash
--validate-dts-only = [true|false]
```

The DTS is discovered by starting from the XBRL instance document. All referenced taxonomy schemas and linkbases are discovered and validated. The rest of the XBRL instance document is ignored. Default value is `false`.

**Note**: Boolean option values are set to `true` if the option is specified without a value.

xinclude

```bash
--xinclude = [true|false]
```

Enables XML Inclusions (XInclude) support. Default value is `false`. When `false`, XInclude's `include` elements are ignored.

**Note**: Boolean option values are set to `true` if the option is specified without a value.

**XBRL formula and assertion options**

assertion-severity

```bash
--assertion-severity = [true|false]
```

Enables the Assertion Severity 1.0 extension. Default is `true`.

**Note**: Boolean option values are set to `true` if the option is specified without a value.

assertions-output

```bash
--assertions-output = FILE
```

Writes the output of the assertion evaluation to the specified `FILE`. If set, automatically specifies `--formula-execution=true`.

assertions-output-format

```bash
--assertions-output-format = [json|xml]
```

Specifies the output format of the assertion evaluation. Default is `json`.

evaluate-referenced-parameters-only

```bash
--evaluate-referenced-parameters-only = [true|false]
```

If `false`, forces evaluation of all parameters even if they are not referenced by any
formulas/assertions/tables. Default is: true.

- formula
  --formula = true|false
  Enables the XBRL Formula 1.0 extension. Default is true.
  Note: Boolean option values are set to true if the option is specified without a value.

- formula-assertion-set [[DEPRECATED]]
  --formula-assertion-set = VALUE
  Limits formula execution to the given assertion set only. Add the option multiple times to specify more than one assertion set. Short form is --as. The VALUE is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special values ##none and ##all can also be used.

- formula-execution
  --formula-execution = true|false
  Enables evaluation of XBRL formulas. Default is true. If true, automatically specifies --formula=true.
  Note: Boolean option values are set to true if the option is specified without a value.

- formula-output
  --formula-output = FILE
  Writes the output of formula evaluation to the specified FILE. If set, automatically specifies --formula-execution=true.

- formula-parameters
  --formula-parameters = JSON-ARRAY
  Specifies parameters for XBRL formula evaluation as array of JSON maps directly on the CLI. See the section Formula Parameters for details.

- formula-parameters-file
  --formula-parameters-file = FILE
  Specifies a FILE containing the parameters for XBRL formula evaluation. The file can be either an XML file or JSON file. See the section Formula Parameters.

- ignore-assertion
  --ignore-assertion = VALUE
  Excludes the given assertion from the execution. Add this option multiple times to specify more than one assertion.

- ignore-assertions-file
  --ignore-assertions-file = FILE
  Specifies a path to a file that contains a list of IDs/XPointers of assertions to exclude from processing. In the file, enter one assertion per line.

- ignore-formula
  --ignore-formula = VALUE
Excludes the given formula from the execution. Add this option multiple times to specify more than one formula.

- **ignore-formulas-file**
  
  ```
  --ignore-formulas-file = FILE
  ```
  
  Specifies a path to a file that contains a list of formula IDs/XPointers to exclude from processing. In the file, enter one formula per line.

- **message-lang**
  
  ```
  --message-lang = VALUE
  ```
  
  Specifies the language to use when displaying validation messages. Default is `en`. Other accepted values are `de`, `es`, `fr`, `ja`, for, respectively, German, Spanish, French, and Japanese.

- **message-role**
  
  ```
  --message-role = VALUE
  ```
  
  Specifies the preferred message role to use when displaying validation messages. Default is: `http://www.xbrl.org/2010/role/message`.

- **preload-formula-schemas**
  
  ```
  --preload-formula-schemas = true|false
  ```
  
  Preloads schemas of the XBRL Formula 1.0 specification. Default is `false`.

  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **process-assertion [a]**
  
  ```
  --a | --process-assertion = VALUE
  ```
  
  Limits formula execution to the given assertion only. Add the option multiple times to specify more than one assertion. Short form is `-a`. The `VALUE` is either the value of the `@id` attribute, or a URI with an XPointer fragment that identifies the resource. The special values `##none` and `##all` can also be used.

- **process-assertion-set [as]**
  
  ```
  --as | --process-assertion-set = VALUE
  ```
  
  Limits formula execution to the given assertion set only. Add the option multiple times to specify more than one assertion set. Short form is `-as`. The `VALUE` is either the value of the `@id` attribute, or a URI with an XPointer fragment that identifies the resource. The special values `##none` and `##all` can also be used.

- **process-assertions-file**
  
  ```
  --process-assertions-file = FILE
  ```
  
  Specifies a path to a file that contains a list of IDs/XPointers of assertions to execute. In the file, enter one assertion per line.

- **process-formula [f]**
  
  ```
  --f | --process-formula = VALUE
  ```
  
  Limits formula execution to the given formula only. Add the option multiple times to specify more than one formula. Short form is `-f`. The `VALUE` is either the value of the `
@id attribute, or a URI with an XPointer fragment that identifies the resource. The special values ##none and ##all can also be used.

**process-formulas-file**

--process-formulas-file = FILE

Specifies a path to a file that contains a list of IDs/XPointers of formulas to execute. In the file, enter one formula per line.

**report-unsatisfied-assertion-evaluations**

--report-unsatisfied-assertion-evaluations = true|false

Reports the evaluation of unsatisfied assertion as errors or warnings depending on the assigned assertion severity level. The default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

**validate-formula-output**

--validate-formula-output = true|false

Enables XBRL validation of Formula output instance. The default value is false.

*Note:* Boolean option values are set to true if the option is specified without a value.

**variablesset-execution-timeout**

--variablesset-execution-timeout = VALUE

Applied when executing formulas (--formula-execution=true). Specifies the maximum time allowed for executing a single variable set (a formula or a value, or an existence or consistency assertion). The time is specified in minutes and must be a positive number. The default is 30min. If a particular variable set doesn't finish execution before the timeout is reached, then it is aborted. An error message is displayed (and entered in the a verbose log). Note, however, that the timeout check is carried out only after every variable set evaluation—and not during execution of individual XPath expressions. So, if a single XPath expression takes long to execute, the timeout limit might be crossed. Execution of a variable set is aborted only once a complete variable set evaluation has been executed.

**XBRL table options**

**aspect-node-order**

--aspect-node-order = lexical|instance

Specifies the layout order of an open aspectNode. The default is lexical.

**concept-label-linkrole**

--concept-label-linkrole = VALUE

Specifies the preferred extended link role to use when rendering concept labels.

**concept-label-role**

--concept-label-role = VALUE

Specifies the preferred label role to use when rendering concept labels. Default is:
evaluate-referenced-parameters-only

---evaluate-referenced-parameters-only = true|false
If false, forces evaluation of all parameters even if they are not referenced by any formulas/assertions/tables. Default is: true.

generic-label-linkrole

---generic-label-linkrole = VALUE
Specifies the preferred extended link role to use when rendering generic labels.

generic-label-role

---generic-label-role = VALUE
Specifies the preferred label role to use when rendering generic labels. Default is: http://www.xbrl.org/2003/role/label.

label-lang

---label-lang = VALUE
Specifies the preferred language to use when rendering labels. Default is: en.

preload-table-schemas

---preload-table-schemas = true|false
Preloads schemas of the XBRL Table 1.0 specification. Default is false.

Note: Boolean option values are set to true if the option is specified without a value.

process-table [t]

---t | --process-table = VALUE
Limits formula execution to the given table only. Add the option multiple times to specify more than one table. Short form is --t. The value is either the value of the @id attribute, or a URI with an XPointer fragment that identifies the resource. The special values ##none and ##all can also be used.

table

---table = true|false
Enables the XBRL Table 1.0 extension. Default value is true. If true, automatically specifies --formula=true and --dimensions=true.

Note: Boolean option values are set to true if the option is specified without a value.

table-elimination

---table-elimination = true|false
Enables elimination of empty table rows/columns in HTML output. Default is true.

Note: Boolean option values are set to true if the option is specified without a value.

table-execution

---table-execution = true|false
Enables evaluation of XBRL tables. Default is false. Will be set to true if --table-output is specified. If true, automatically specifies --table=true.

Note: Boolean option values are set to true if the option is specified without a value.
### table-linkbase-namespace

```
--table-linkbase-namespace =
  ##detect |
  http://xbrl.org/PWD/2013-05-17/table |
  http://xbrl.org/PWD/2013-08-28/table |
  http://xbrl.org/PR/2013-12-18/table |
  http://xbrl.org/2014/table
```

Enables loading of table linkbases written with a previous draft specification. Table linkbase validation, resolution, and layout is, however, always performed according to the Table Linkbase 1.0 Recommendation of 18 March 2014. Use `##detect` to enable auto-detection.

### table-output

```
--table-output = FILE
```

Writes the table output to the specified `FILE`. If set, automatically specifies `--table-execution=true`.

### table-output-format

```
--table-output-format = xml|html
```

Specifies the format of the table output. Default is `xml`. 
3.12.5 XML

- **assessment-mode**
  
  ```bash
  --assessment-mode = lax|strict
  ```
  Specifies the schema-validity assessment mode as defined in the XSD specifications. Default value is `strict`. The XML instance document will be validated according to the mode specified with this option.

- **dtd**
  
  ```bash
  --dtd = FILE
  ```
  Specifies the external DTD document to use for validation. If a reference to an external DTD is present in the XML document, then the CLI option overrides the external reference.

- **load-xml-with-psvi**
  
  ```bash
  --load-xml-with-psvi = true|false
  ```
  Enables validation of input XML files and generates post-schema-validation information for them. Default is: `true`.

- **namespaces**
  
  ```bash
  --namespaces = true|false
  ```
  Enables namespace-aware processing. This is useful for checking the XML instance for errors due to incorrect namespaces. Default value is `false`.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **xinclude**
  
  ```bash
  --xinclude = true|false
  ```
  Enables XML Inclusions (XInclude) support. Default value is `false`. When `false`, XInclude's `include` elements are ignored.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- **xml-mode**
  
  ```bash
  --xml-mode = wf|id|valid
  ```
  Specifies the XML processing mode to use for the XML instance document: `wf`=wellformed check; `id`=wellformed with ID/IDREF checks; `valid`=validation. Default value is `wf`. Note that a value of `valid` requires that each instance document loaded during processing references a DTD. If no DTD exists, an error is reported.

- **xml-validation-error-as-warning**
  
  ```bash
  --xml-validation-error-as-warning = true|false
  ```
  If `true`, treats validation errors as warnings. If errors are treated as warnings, additional processing, such as XSLT transformations, will continue regardless of errors. Default is `false`.

- **xsd**
  
  ```bash
  --xsd = FILE
  ```
  Specifies one or more XML Schema documents to use for the validation of XML instance documents. Add the option multiple times to specify more than one schema document.
3.12.6 XSD

- assessment-mode
  
  `--assessment-mode = lax|strict`
  
  Specifies the schema-validity assessment mode as defined in the XSD specifications. Default value is `strict`. The XML instance document will be validated according to the mode specified with this option.

- namespaces
  
  `--namespaces = true|false`
  
  Enables namespace-aware processing. This is useful for checking the XML instance for errors due to incorrect namespaces. Default value is `false`.
  
  **Note:** Boolean option values are set to `true` if the option is specified without a value.

- schema-imports
  
  `--schema-imports = load-by-schemalocation | load-preferring-schemalocation | load-by-namespace | load-combining-both | license-namespace-only`
  
  Specifies the behaviour of `xs:import` elements, each of which has an optional namespace attribute and an optional schemaLocation attribute: `<import namespace="someNS" schemalocation="someURL">`. The option specifies whether to load a schema document or just license a namespace, and, if a schema document is to be loaded, which information should be used to find it. Default: `load-preferring-schemalocation`.
  
  The behavior is as follows:

  - **load-by-schemalocation**: The value of the schemaLocation attribute is used to locate the schema, taking account of catalog mappings. If the namespace attribute is present, the namespace is imported (licensed).
  - **load-preferring-schemalocation**: If the schemaLocation attribute is present, it is used, taking account of catalog mappings. If no schemaLocation attribute is present, then the value of the namespace attribute is used via a catalog mapping. This is the default value.
  - **load-by-namespace**: The value of the namespace attribute is used to locate the schema via a catalog mapping.
  - **load-combining-both**: If either the namespace or schemaLocation attribute has a catalog mapping, then the mapping is used. If both have catalog mappings, then the value of the --schema-mapping option (XBRL option and XML/XSD option) decides which mapping is used. If no catalog mapping is present, the schemaLocation attribute is used.
  - **license-namespace-only**: The namespace is imported. No schema document is imported.

- schemalocation-hints
  
  `--schemalocation-hints = load-by-schemalocation | load-by-namespace | load-combining-both | ignore`
  
  Specifies the behavior of the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes: Whether to load a schema document, and, if yes, which information should be used to find it. Default: `load-by-schemalocation`.

  - The **load-by-schemalocation** value uses the URL of the schema location in the `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes in XML or XBRL.
instance documents. This is the default value.
- The load-by-namespace value takes the namespace part of xsi:schemaLocation and
an empty string in the case of xsi:noNamespaceSchemaLocation and locates the
schema via a catalog mapping.
- If load-combining-both is used and if either the namespace part or the URL part has
a catalog mapping, then the catalog mapping is used. If both have catalog mappings,
then the value of the --schema-mapping option (XBRL option and XML/XSD option)
decides which mapping is used. If neither the namespace nor URL has a catalog
mapping, the URL is used.
- If the option's value is ignore, then the xsi:schemaLocation and
xsi:noNamespaceSchemaLocation attributes are both ignored.

```schema-mapping
--schema-mapping = prefer-schemalocation | prefer-namespace
```
If schema location and namespace are both used to find a schema document, specifies
which of them should be preferred during catalog lookup. (If either the --schemalocation-
hints or the --schema-imports option has a value of load-combining-both, and if the
namespace and URL parts involved both have catalog mappings, then the value of this option
specifies which of the two mappings to use (namespace mapping or URL mapping; the
prefer-schemalocation value refers to the URL mapping).) Default is prefer-
schemalocation.

```xsd-version
--xsd-version = 1.0|1.1|detect
```
Specifies the W3C Schema Definition Language (XSD) version to use. Default is 1.0. This
option can also be useful to find out in what ways a schema which is 1.0-compatible is not
1.1-compatible. The detect option is an Altova-specific feature. It enables the version of the
XML Schema document (1.0 or 1.1) to be detected by reading the value of the
vc:minVersion attribute of the document’s <xs:schema> element. If the value of the
@vc:minVersion attribute is 1.1, the schema is detected as being version 1.1. For any
other value, or if the @vc:minVersion attribute is absent, the schema is detected as being
version 1.0.
3.12.7 XQuery

- **indent-characters**
  ```
  --indent-characters = VALUE
  ```
  Specifies the character string to be used as indentation.

- **input**
  ```
  --input = FILE
  ```
  The URL of the XML file to be transformed.

- **keep-formatting**
  ```
  --keep-formatting = [true|false]
  ```
  Keeps the formatting of the target document to the maximum extent that this is possible. Default is true.

- **omit-xml-declaration**
  ```
  --omit-xml-declaration = [true|false]
  ```
  Serialization option to specify whether the XML declaration should be omitted from the output or not. If true, there will be no XML declaration in the output document. If false, an XML declaration will be included. Default value is false. **Note:** Boolean option values are set to true if the option is specified without a value.

- **output, xsltoutput**
  ```
  output = FILE, xsltoutput = FILE
  ```
  The URL of the primary-output file. For example, in the case of multiple-file HTML output, the primary-output file will be the location of the entry point HTML file. Additional output files, such as generated image files, are reported as xslt-additional-output-files. If no --output or --xsltoutput option is specified, output is written to standard output.

- **output-encoding**
  ```
  --output-encoding = VALUE
  ```
  The value of the encoding attribute in the output document. Valid values are names in the IANA character set registry. Default value is UTF-8.

- **output-indent**
  ```
  --output-indent = [true|false]
  ```
  If true, the output will be indented according to its hierarchic structure. If false, there will be no hierarchical indentation. Default is false. **Note:** Boolean option values are set to true if the option is specified without a value.

- **output-method**
  ```
  --output-method = xml|html|xhtml|text
  ```
  Specifies the output format. Default value is xml.

- **param [p]**
  ```
  --p | --param = KEY:VALUE
  ```
  XQuery
Specifies the value of an external parameter. An external parameter is declared in the XQuery document with the `declare variable` declaration followed by a variable name and then the `external` keyword followed by the trailing semi-colon. For example:

```xml
declare variable $foo as xs:string external;
```

Because of the `external` keyword `$foo` becomes an external parameter, the value of which is passed at runtime from an external source. The external parameter is given a value with the CLI command. For example:

```
--param=foo:'MyName'
```

In the description statement above, `KEY` is the external parameter name, `VALUE` is the value of the external parameter, given as an XPath expression. Parameter names used on the CLI must be declared in the XQuery document. If multiple external parameters are passed values on the CLI, each must be given a separate `--param` option. Double quotes must be used if the XPath expression contains spaces.

**XSLT**

Specifies a global stylesheet parameter. `KEY` is the parameter name, `VALUE` is an XPath expression that provides the parameter value. Parameter names used on the CLI must be declared in the stylesheet. If multiple parameters are used, the `--param` switch must be used before each parameter. Double quotes must be used around the XPath expression if it contains a space—whether the space is in the XPath expression itself or in a string literal in the expression. For example:

```bash
raptorxmlxbir xslt --input=c:\Test.xml --output=c:\Output.xml --
param=date://node[1]/@att1 --p=title:'stringwithoutspace' --
param=title:"'string with spaces'" --p=amount:456 c:\Test.xslt
```

**updated-xml**

```
--updated-xml = discard|writeback|asmainresult
```

Specifies how the updated XML file should be handled. The updates can be either:

- discarded and not written to file (discard)
- written back to the input XML file that is specified with the `--input` option (writeback)
- saved either to standard output or to the location specified in the `--output` option (if this is defined)

Default is: discard.

**xquery-update-version**

```
--xquery-update-version = 1|1.0|3|3.0|
```

Specifies whether the XQuery processor should use XQuery Update Facility 1.0 or XQuery Update Facility 3.0. Default value is 3.

**xquery-version**

```
--xquery-version = 1|1.0|3|3.0|3.1
```

Specifies whether the XQuery processor should use XQuery 1.0 or XQuery 3.0. Default value is 3.1.
3.12.8 XSLT

- **chartext-disable**
  
  \[--\text{chartext\text{-}disable} = \text{true}|\text{false}\]  
  Disables chart extensions. Default value is \text{false}.  
  \text{Note}: Boolean option values are set to \text{true} if the option is specified without a value.

- **dotnetext-disable**
  
  \[--\text{dotnetext\text{-}disable} = \text{true}|\text{false}\]  
  Disables .NET extensions. Default value is \text{false}.  
  \text{Note}: Boolean option values are set to \text{true} if the option is specified without a value.

- **indent-characters**
  
  \[--\text{indent\text{-}characters} = \text{VALUE}\]  
  Specifies the character string to be used as indentation.

- **input**
  
  \[--\text{input} = \text{FILE}\]  
  The URL of the XML file to be transformed.

- **javaext-barcode-location**
  
  \[--\text{javaext\text{-}barcode\text{-}location} = \text{FILE}\]  
  Specifies the path to the folder that contains the barcode extension file AltovaBarcodeExtension.jar. The path must be given in one of the following forms:

  - A file URI, for example: \[--\text{javaext\text{-}barcode\text{-}location}="file:///C:/Program Files/Altova/RaptorXMLXBRLServer2019/etc/jar/"\]
  - A Windows path with backslashes escaped, for example: \[--\text{javaext\text{-}barcode\text{-}location}="C:\\Program Files\\Altova\\RaptorXMLXBRLServer2019\\etc\\jar\\"

- **javaext-disable**
  
  \[--\text{javaext\text{-}disable} = \text{true}|\text{false}\]  
  Disables Java extensions. Default value is \text{false}.  
  \text{Note}: Boolean option values are set to \text{true} if the option is specified without a value.

- **output, xsltoutput**
  
  \[\text{output} = \text{FILE}, \text{xsltoutput} = \text{FILE}\]  
  The URL of the primary-output file. For example, in the case of multiple-file HTML output, the primary-output file will be the location of the entry point HTML file. Additional output files, such as generated image files, are reported as xslt-additional-output-files. If no \text{output} or \text{xsltoutput} option is specified, output is written to standard output.

- **param [p]**
  
  \[--\text{p} | --\text{param} = \text{KEY:VALUE}\]  
  \text{XQuery}  
  Specifies the value of an external parameter. An external parameter is declared in the
XQuery document with the `declare variable` declaration followed by a variable name and then the `external` keyword followed by the trailing semi-colon. For example:
```
declare variable $foo as xs:string external;
```
Because of the `external` keyword $foo becomes an external parameter, the value of which is passed at runtime from an external source. The external parameter is given a value with the CLI command. For example:
```
--param=foo:'MyName'
```
In the description statement above, `KEY` is the external parameter name, `VALUE` is the value of the external parameter, given as an XPath expression. Parameter names used on the CLI must be declared in the XQuery document. If multiple external parameters are passed values on the CLI, each must be given a separate `--param` option. Double quotes must be used if the XPath expression contains spaces.

**XSLT**

Specifies a global stylesheet parameter. `KEY` is the parameter name, `VALUE` is an XPath expression that provides the parameter value. Parameter names used on the CLI must be declared in the stylesheet. If multiple parameters are used, the `--param` switch must be used before each parameter. Double quotes must be used around the XPath expression if it contains a space—whether the space is in the XPath expression itself or in a string literal in the expression. For example:
```
  raptorxmlxbrl xslt --input=c:\Test.xml --output=c:\Output.xml --param=date://node[1]/@att1 --p=title:'stringwithoutspace' -- param=title:_CLI_quote"string with spaces"_CLI_quote --p=amount:456 c:\Test.xslt
```

**streaming**

`--streaming` = `true`|`false`

Enables streaming validation. Default is `true`. In streaming mode, data stored in memory is minimized and processing is faster. The downside is that information that might be required subsequently—for example, a data model of the XML instance document—will not be available. In situations where this is significant, streaming mode will need to be turned off (by giving `--streaming` a value of `false`). When using the `--script` option with the `valxml-withxsd` command, disable streaming. Note that the `--streaming` option is ignored if `--parallel-assessment` is set to `true`.

*Note:* Boolean option values are set to `true` if the option is specified without a value.

**initial-template, template-entry-point**

`--initial-template`, `--template-entry-point` = `VALUE`

Gives the name of a named template in the XSLT stylesheet that is the entry point of the transformation.

**initial-mode, template-mode**

`--initial-mode`, `--template-mode` = `VALUE`

Specifies the template mode to use for the transformation.

**xslt-version**

`--xslt-version` = `1`|`1.0`|`2`|`2.0`|`3`|`3.0`|`3.1`

Specifies whether the XSLT processor should use XSLT 1.0, XSLT 2.0, or XSLT 3.0. Default value is 3.
3.12.9 JSON/Avro

- schema, jsonschema
  --schema = FILE, --jsonschema = FILE
  Specifies the path to the JSON Schema document to use for the validation of JSON instance documents.

- codec
  --codec = null|deflate
  Specifies the Avro compression codec to use. Default value is null.
3.12.10 XML Signatures

- **absolute-reference-uri**
  
  **--absolute-reference-uri =** `true`|false
  
  Specifies whether the URI of the signed document is to be read as absolute (`true`) or relative (`false`). Default is `false`.
  
  *Note*: Boolean option values are set to `true` if the option is specified without a value.

- **certname, certificate-name**
  
  **--certname, --certificate-name =** `VALUE`
  
  The name of the certificate used for signing.

  **Windows**
  
  This is the Subject name of a certificate from the selected `--certificate-store`.

  **Example to list the certificates (under PowerShell)**
  
  ```
  % ls cert://CurrentUser/My
  PSParentPath: Microsoft.PowerShell.Security\Certificate::CurrentUser\My
  Thumbprint Subject
  ---------- -------
  C9DF64BB0AAF5FA73474D7CCFCC37C95BFC6C  CN=certificate1
  ...
 Example: --certificate-name=certificate1
  ```

  **Linux/MacOS**
  
  `--certname` specifies the file name of a PEM encoded X.509v3 certificate with the private key. Such files usually have the extension `.pem`.

  **Example**: `--certificate-name=/path/to/certificate1.pem`

- **certstore, certificate-store**
  
  **--certstore, --certificate-store =** `VALUE`
  
  The location where the certificate specified with `--certificate-name` is stored.

  **Windows**
  
  The name of a certificate store under `cert://CurrentUser`. The available certificate stores can be listed (under PowerShell) by using `% ls cert://CurrentUser/`. Certificates would then be listed as follows:

  ```
  Name : TrustedPublisher
  Name : ClientAuthIssuer
  Name : Root
  Name : UserDS
  Name : CA
  Name : ACRS
  Name : REQUEST
  Name : AuthRoot
  ```
Name: MSIEHistoryJournal
Name: TrustedPeople
Name: MyCertStore
Name: Local NonRemovable Certificates
Name: SmartCardRoot
Name: Trust
Name: Disallowed

Example: --certificate-store=MyCertStore

**Linux/MacOS**
The **--certstore** option is currently not supported.

**digest, digest-method**

```bash
--digest, --digest-method = sha1|sha256|sha384|sha512|base64
```
The algorithm that is used to compute the digest value over the input XML file. Available values are: sha1|sha256|sha384|sha512|base64.

**hmacKey, hmac-secret-key**

```bash
--hmacKey, --hmac-secret-key = VALUE
```
The HMAC shared secret key; must have a minimum length of six characters.

Example: --hmacKey=secretpassword

**hmaclen, hmac-output-length**

```bash
--hmaclen, --hmac-output-length = LENGTH
```
Truncates the output of the HMAC algorithm to length bits. If specified, this value must be
- a multiple of 8
- larger than 80
- larger than half of the underlying hash algorithm's output length

**keyinfo, append-keyinfo**

```bash
--keyinfo, --append-keyinfo = true|false
```
Specifies whether to include the KeyInfo element in the signature or not. The default is false.

**sigc14nmeht, signature-canonicalization-method**

```bash
--sigc14nmeht, --signature-canonicalization-method = VALUE
```
Specifies the canonicalization algorithm to apply to the SignedInfo element. The value must be one of:
- REC-xml-c14n-20010315
- xml-c14n11
- xml-exc-c14n#

**sigmeth, signature-method**

```bash
--sigmeth, --signature-method = VALUE
```
Specifies the algorithm to use for generating the signature.
When a certificate is used
If a certificate is specified, then SignatureMethod is optional and the value for this parameter is derived from the certificate. If specified, it must match the algorithm used by the certificate.
Example: rsa-sha256.

When --hmac-secret-key is used
When HMACSecretKey is used, then SignatureMethod is mandatory. The value must be one of the supported HMAC algorithms:
- hmac-sha256
- hmac-sha386
- hmac-sha512
- hmac-sha1 (discouraged by the specification)
Example: hmac-sha256

--sigtype, --signature-type = detached | enveloping | enveloped
Specifies the type of signature to be generated.

--transforms = VALUE
Specifies the XML Signature transformations applied to the input document. The supported values are:
- REC-xml-c14n-20010315 for Canonical XML 1.0 (omit comments)
- xml-c14n11 for Canonical XML 1.1 (omit comments)
- xml-exc-c14n# for Exclusive XML Canonicalization 1.0 (omit comments)
- REC-xml-c14n-20010315#WithComments for Canonical XML 1.0 (with comments)
- xml-c14n11#WithComments for Canonical XML 1.1 (with comments)
- xml-exc-c14n#WithComments for Exclusive XML Canonicalization 1.0 (with comments)
- base64
- strip-whitespaces Altova extension
Example: --transforms=xml-c14n11

Note: This option can be specified multiple times. If specified multiple times, then the order of specification is significant. The first specified transformation receives the input document. The last specified transformation is used immediately before calculation of the digest value.

--write-default-attributes = true|false
Specifies whether to include default attribute values from the DTD in the signed document.
4 Server APIs: HTTP REST, COM/.NET, Java

RaptorXML+XBRL Server defines an HTTP REST interface, which is used by clients to dispatch validation jobs to the server. Clients can either access the HTTP REST interface directly or use the high-level COM/.NET and Java Server APIs. These APIs provide easy-to-use COM/.NET and Java classes which manage the creation and dispatch of the HTTP REST requests. The figure below shows a summary of the available HTTP REST client methods to communicate with the RaptorXML server.

![Server APIs Diagram]

There are three server APIs that can be used to communicate with RaptorXML via the HTTP REST interface (also see figure above).

- HTTP REST client interface
- COM/.NET API
- Java API

Note: The server APIs offer similar functionality as the command line interface (CLI). This includes validation and document transformations. If you wish to use advanced functionality, such as reading, extracting, and analysing data, then use the Engine APIs. The Engine APIs can provide additional information such as the count of elements, their positions in the document, and complex XBRL data access and manipulation.

Usage

RaptorXML+XBRL Server should be installed on a machine that is accessible by clients over the local network. Once the RaptorXML+XBRL Server service has been started, clients can connect to the server and issue commands. The following access methods are labeled as Server APIs because they provide a way to communicate with a remote RaptorXML server.

- HTTP REST client interface: Client requests are made in JSON format as described in the section HTTP REST Client Interface. Each request is assigned a job directory on the server, in which output files are saved. The server responds to the client with all the information relevant to the job.
- COM/.NET API and Java API: Applications and scripts in COM/.NET programming languages and Java applications use objects of the RaptorXML Server API to access functionality of RaptorXML+XBRL Server. The RaptorXML Server API will issue the
corresponding HTTP REST requests on behalf of the client. See the respective sub-
sections for more information.

Licensing
RaptorXML+XBRL Server is licensed on the machine on which it is installed. Connections to
RaptorXML+XBRL Server are made via HTTP.
4.1 HTTP REST Client Interface

RaptorXML+XBRL Server accepts validation jobs submitted via HTTP (or HTTPS). The job description as well as the results are exchanged in JSON format. The basic workflow is as shown in the diagram below.

HTTP Client

1. POST

2. Result-Doc-URI

3. GET

4. Result Document

5. GET

6. Requested Doc/s

7. DELETE

RaptorXML Server as HTTP Server

1) HTTP POST request with JSON body sent to RaptorXML Server.

2) RaptorXML returns URI of result document in JSON format.

3) HTTP GET request for result doc uses sent URI, after job status on server not equal to ‘RUNNING’.

4) RaptorXML returns JSON result document.

5) HTTP GET request to fetch logs and output documents listed in JSON result document.

6) RaptorXML returns requested document/s.

7) HTTP DELETE request deletes resource on server, freeing hard disk space.
Security concerns related to the HTTP REST interface

The HTTP REST interface, by default, allows result documents to be written to any location specified by the client (that is accessible with the HTTP protocol). It is important therefore to consider this security aspect when configuring RaptorXML+XBRL Server.

If there is a concern that security might be compromised or that the interface might be misused, the server can be configured to write result documents to a dedicated output directory on the server itself. This is specified by setting the `server.unrestricted-filesystem-access` option of the server configuration file to `false`. When access is restricted in this way, the client can download result documents from the dedicated output directory with `GET` requests. Alternatively, an administrator can copy/upload result document files from the server to the target location.

In this section

Before sending a client request, RaptorXML+XBRL Server must be started and properly configured. How to do this is described in the section Server Setup. How to send client requests is described in the section Client Requests.
4.1.1 Server Setup

RaptorXML must be licensed on the machine on which it is installed. This installation can then be accessed via an HTTP REST Interface. To correctly set up RaptorXML+XBRL Server, do the following. We assume that RaptorXML+XBRL Server has already been correctly installed.

1. RaptorXML+XBRL Server must be either started as a service or an application in order for it to be correctly accessed via HTTP or HTTPS. How to do this differs according to operating system and is described here: on **Windows**, on **Linux**, on **macOS**.

2. Use the initial server configuration to test the connection to the server. (The initial server configuration is the default configuration you get on installation.) You can use a simple HTTP GET request like `http://localhost:8087/v1/version` to test the connection. (The request can also be typed in the address bar of a browser window.) If the service is running you must get a response to an HTTP test request such as the version request above.

3. Look at the server configuration file, `server_config.xml`. If you wish to change any settings in the file, edit the server configuration file and save the changes. HTTPS is disabled by default, and will need to be enabled in the configuration file.

4. If you have edited the server configuration file, then restart RaptorXML+XBRL Server as a service so that the new configuration settings are applied. Test the connection again to make sure that the service is running and accessible.

**Note:** Server startup errors, the server configuration file that is used, and license errors are reported in the system log. So, refer to the system log if there are problems with the server.

For more information about HTTPS, see the section HTTPS Settings.

4.1.1.1 Starting the Server

*This section:*

- Location of the Server executable
- Starting RaptorXML as a service on Windows
- Starting RaptorXML as a service on Linux
- Starting RaptorXML as a service on macOS

Location of the Server executable file

The RaptorXML+XBRL Server executable is installed by default in the folder:

```
<ProgramFilesFolder>\Altova\RaptorXMLXBRLServer2019\bin\RaptorXMLXBRL.exe
```

The executable can be used to start RaptorXML+XBRL Server as a service.

Starting as a service on Windows

The installation process will have registered RaptorXML+XBRL Server as a service on Windows. You must, however, start RaptorXML+XBRL Server as a service. You can do this in the following ways:
Via the Altova ServiceController, which is available as an icon in the system tray. If the icon is not available, you can start Altova ServiceController and add its icon to the system tray by going to the Start menu, then selecting All Programs | Altova | Altova LicenseServer | Altova ServiceController.

Via the Windows Services Management Console: Control Panel | All Control Panel Items | Administrative Tools | Services.

Via the command prompt started with administrator rights. Use the following command under any directory: net start "AltovaRaptorXMLXBRLServer".

Via the RaptorXML+XBRL Server executable in a command prompt window: RaptorXMLXBRLServer.exe debug. This starts the server, with server activity information going directly to the command prompt window. The display of server activity information can be turned on and off with the http.log-screen setting of the server configuration file. To stop the server, press Ctrl+Break (or Ctrl+Pause). When the server is started this way—rather than as a service as described in the three previous steps—the server will stop when the command line console is closed or when the user logs off.

Starting as a service on Linux
Start RaptorXML+XBRL Server as a service with the following command:

<table>
<thead>
<tr>
<th>OS</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian 8</td>
<td>sudo /etc/init.d/raptorxmlxbrlserver start</td>
</tr>
<tr>
<td>CentOS 7</td>
<td>sudo initctl start raptorxmlxbrlserver</td>
</tr>
<tr>
<td>Ubuntu 15</td>
<td>sudo initctl start raptorxmlxbrlserver</td>
</tr>
</tbody>
</table>

If at any time you need to stop RaptorXML+XBRL Server, use:

<table>
<thead>
<tr>
<th>OS</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian 8</td>
<td>sudo /etc/init.d/raptorxmlxbrlserver stop</td>
</tr>
<tr>
<td>CentOS 7</td>
<td>sudo initctl stop raptorxmlxbrlserver</td>
</tr>
<tr>
<td>Ubuntu 15</td>
<td>sudo initctl stop raptorxmlxbrlserver</td>
</tr>
</tbody>
</table>

Starting as a service on macOS
Start RaptorXML+XBRL Server as a service with the following command:

`sudo launchctl load /Library/LaunchDaemons/com.altova.RaptorXMLXBRLServer2019.plist`
If at any time you need to stop RaptorXML+XBRL Server, use:

```bash
sudo launchctl unload /Library/LaunchDaemons/com.altova.RaptorXMLXBRLServer2019.plist
```

### 4.1.1.2 Testing the Connection

**This section:**

- **GET request to test the connection**
- **Server response and JSON data structure listing**

**GET request to test the connection**

After RaptorXML+XBRL Server has been started, test the connection using a `GET` request. (You can also type this request in the address bar of a browser window.)

```plaintext
http://localhost:8087/v1/version
```

**Note:** The interface and port number of RaptorXML+XBRL Server is specified in the server configuration file, `server_config.xml`, which is described in the next section, **Server Configuration**.

**Server response and JSON data structure listing**

If the service is running and the server is correctly configured, the request should never fail. RaptorXML+XBRL Server will return its version information as a JSON data structure (listing below).

```json
{
  "copyright": "Copyright (c) 1998-2013 Altova GmbH. ...",
  "name": "Altova RaptorXML+XBRL Server 2013 rel. 2 sp1",
  "eula": "http://www.altova.com/server_software_license_agreement.html"
}
```

**Note:** If you modify the server configuration—by editing the **server configuration file**—you should test the connection again.

### 4.1.1.3 Configuring the Server

**This section:**

- **Server configuration file: initial settings**
- **Server configuration file: modifying the initial settings, reverting to initial settings**
- **Server configuration file: listing and settings**
Server configuration file: description of settings

Configuring the server address

Server configuration file: initial settings

RaptorXML+XBRL Server is configured by means of a configuration file called server_config.xml, which is located by default at:

C:\Program Files (x86)\Altova\RaptorXMLXBRLServer2019\etc\server_config.xml

The initial configuration for RaptorXML+XBRL Server defines the following:

- A port number of 8087 as the server’s port.
- That the server listens only for local connections (localhost).
- That the server writes output to C:\ProgramData\Altova\RaptorXMLXBRLServer2019\Output."

Other default settings are shown in the listing of server_config.xml below.

Server configuration file: modifying the initial settings, reverting to initial settings

If you wish to change the initial settings, you must edit the server configuration file, server_config.xml (see listing below), save it, and then restart RaptorXML+XBRL Server as a service.

If you wish to recreate the original server configuration file (so that the server is configured with the initial settings again), run the command createconfig:

```
RaptorXMLXBRL.exe createconfig
```

On running this command, the initial settings file will be recreated and will overwrite the file server_config.xml. The createconfig command is useful if you wish to reset server configuration to the initial settings.

Server configuration file: listing and settings

The server configuration file, server_config.xml, is listed below with initial settings. Settings available in it are explained below the listing.

```xml
<config xmlns="http://www.altova.com/schemas/altova/raptorxml/config"

  xsi:schemaLocation="http://www.altova.com/schemas/altova/raptorxml/config
  http://www.altova.com/schemas/altova/raptorxml/config.xsd"

  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

  xmlns:xsi="http://www.w3.org/2001/XMLSchema">

  <language>en</language>

  <server.unrestricted-filesystem-access>true</server.unrestricted-filesystem-access>

  <server.output-root-dir>C:\ProgramData\Altova\RaptorXMLXBRLServer2019\output
  \</server.output-root-dir>

  <server.script-root-dir>C:\Program Files\Altova\RaptorXMLXBRLServer2019\etc
```
Settings

language
Sets the language of server messages, in an optional language element. The default value is en (English). Allowed values are en|de|es|fr|ja (English, German, Spanish, French, and Japanese, respectively). See Localization Commands for an overview of how to localize RaptorXML.

server.unrestricted-filesystem-access

- When set to true (the default value), output files will be written directly to the location specified by the user and in Python scripts (possibly overwriting existing files of the same name). Note, however, that local file paths cannot be used to access files from a remote machine via HTTP. So, if RaptorXML+XBRL Server is running on a remote machine, set the value of this option to false. Setting the value to true is only viable if the client and server are on the same machine and you want to write the output files to a directory on that machine.
- When set to false, files will be written to the job's directory in the output directory, and the URIs of these files will be included in the result document. Setting the value to false provides a layer of security, since files can be written to disk only in a dedicated and known job directory on the server. Job output files can subsequently be copied by trusted means to other locations.

server.output-root-dir
Directory in which the output of all submitted jobs is saved.

**server.script-root-dir**
Directory in which trusted Python scripts are to be saved. The `script` option, when used via the HTTP interface, will only work when scripts from this trusted directory are used. Specifying a Python script from any other directory will result in an error. See 'Making Python Scripts Safe'.

**server.default-script-api-version**
Default Python API version used to run Python scripts. By default the newest version of the Python API is used. Currently supported values are 1 and 2.

**server.catalog-file**
URL of the XML catalog file to use. By default, the catalog file `RootCatalog.xml`, which is located in the folder `<ProgramFilesFolder>\Altova\RaptorXMLXBRLServer2019\etc`, will be used. Use the `server.catalog-file` setting only if you wish to change the default catalog file.

**server.log-file**
Name and location of the server log file. Events on the server, like *Server started/stopped*, are logged continuously in the system's event log and displayed in a system event viewer such as Windows Event Viewer. In addition to the viewer display, log messages can also be written to the file specified with the `server.log-file` option. The server log file will contain information about all activities on the server, including server startup errors, the configuration file used, and license errors.

**http.enable**
A boolean value to enable or disable HTTP: `true` | `false`. HTTP can be enabled/disabled independently of HTTPS, and both can be active concurrently.

**http.environment**
Internal environments of raptorxml: *production* | *development*. The Development environment will be more geared to the needs of developers, allowing easier debugging than when the Production environment is used.

**http.socket-host**
The interface via which RaptorXML+XBRL Server is accessed. If you wish RaptorXML+XBRL Server to accept connections from remote machines, uncomment the element and set its content to: `0.0.0.0`, like this: `<http.socket-host>0.0.0.0</http.socket-host>`. This hosts the service on every addressable interface of the server machine. In this case, ensure that firewall settings are suitably configured. Inbound firewall exceptions for Altova products must be registered as follows: Altova LicenseServer: port 8088; Altova RaptorXML+XBRL Server: port 8087; Altova FlowForce Server: port 8082.

**http.socket-port**
The port via which the service is accessed. The port must be fixed and known so that HTTP requests can be correctly addressed to the service.
http.log-screen
If RaptorXML+XBRL Server is started with the command `RaptorXMLXBRLServer.exe debug` (see Starting the Server) and if `http.log-screen` is set to `true`, then server activity is displayed in the command line console. Otherwise server activity is not displayed. The log screen is displayed in addition to the writing of log files.

http.access-file
Name and location of the HTTP access file. The access file contains information about access-related activity. It contains information that is useful for resolving connection issues.

http.error-file
Name and location of the HTTP error file. The error file contains errors related to traffic to and from the server. If there are connection problems, this file can provide useful information towards resolving them.

http.max_request_body_size
This option specifies the maximum size of the request body that RaptorXML+XBRL Server accepts. The default value is 100MB. If the site of a request body is larger than the value specified for this option, then the server responds with HTTP Error 413: Request entity too large. The option's value must be greater than or equal to zero. The limit can be disabled with `http.max_request_body_size=0`.

https.enable
A boolean value to enable or disable HTTPS: `true` | `false`. HTTPS can be enabled/disabled independently of HTTP, and both can be active concurrently. HTTPS support is disabled by default and must be enabled by changing the value of this setting to `true`.

https.socket-host
Takes a string value which is the host address on which HTTP connections are accepted. To accept connections from the local host only, set `localhost` or `127.0.0.1`. If you wish RaptorXML+XBRL Server to accept connections from all remote machines, set the value to: `0.0.0.0`, like this: `<http.socket-host>0.0.0.0</http.socket-host>`. This hosts the service on every addressable interface of the server machine. In this case, ensure that firewall settings are suitably configured. Inbound firewall exceptions for Altova products must be registered as follows: Altova LicenseServer: port 8088; Altova RaptorXML+XBRL Server: port 8087; Altova FlowForce Server: port 8082. You can also use IPv6 addresses such as: `::`.

https.socket-port
An integer value that is the port on which HTTPS is accepted. The port must be fixed and known so that HTTP requests can be correctly addressed to the service.

https.private-key, https.certificate
URIs that are the paths, respectively, to the server's private key and certificate files. Both are required. See HTTPS Settings and Setting Up SSL Encryption for more information. On Windows
machines, you can also use Windows paths.

https.certificate-chain
An optional setting, this is a URI which locates the intermediate certificate file. If you have two intermediate certificates (primary and secondary), then combine them into one file as described in Step 7 at Setting Up SSL Encryption. See HTTPS Settings and Setting Up SSL Encryption for more information.

### The RaptorXML+XBRL Server address

The HTTP address of the server consists of the socket-host and socket-port:

```
http://{socket-host}:{socket-port}/
```

The address as set up with the initial configuration will be:

```
http://localhost:8087/
```

To change the address, modify the `http.socket-host` and `http.socket-port` settings in the server configuration file, `server_config.xml`. For example, say the server machine has an IP address of 123.12.123.1, and that the following server configuration settings have been made:

```
<http.socket-host>0.0.0.0</http.socket-host>
<http.socket-port>8087</http.socket-port>
```

RaptorXML+XBRL Server can then be addressed with:

```
http://123.12.123.1:8087/
```

**Note:** After `server_config.xml` has been modified, RaptorXML+XBRL Server must be restarted for the new values to be applied.

**Note:** If there are problems connecting to RaptorXML+XBRL Server, information in the files named in `http.access-file` and `http.error-file` can help resolve issues.

**Note:** Messages submitted to RaptorXML+XBRL Server must contain path names that are valid on the server machine. Documents on the server machine can be accessed either locally or remotely (in the latter case with HTTP URIs, for example).

### 4.1.1.4 HTTPS Settings

RaptorXML+XBRL Server supports startup not only as an HTTP server, but also as an HTTPS server. Both types of connection may be active concurrently.

**Enabling HTTPS**

HTTPS support is disabled by default. To enable HTTPS, in the server configuration file, `server_config.xml`, change the `https.enable` setting to `true`. Modify the various HTTPS
settings of the configuration file according to your server requirements.

Private key and certificate
You can obtain a private key and certificate files in one of the following ways:

- From a certificate authority: Follow the steps described in the section Setting Up SSL Encryption.
- Create a self-signed certificate by using the following OpenSSL command (suitably modified for your environment):

  ```
  openssl req -x509 -newkey rsa:4096 -nodes -keyout key.pem -out cert.pem -days 365 -subj "/C=AT/ST=vienna/L=vienna/O=Altova Gmbh/OU=dev/CN=www.altova.com"
  ```

Testing the connection
A good way to test your connection is via the curl command line tool for transferring data with URLs. You can use the following command:

  ```
  curl.exe https://localhost:443/v1/version
  ```

If the certificate is not trusted, use the -k option, like this:

  ```
  curl.exe -k https://localhost:443/v1/version
  ```

The following command executes the HTTP Python example that is distributed with RaptorXML+XBRL Server:

  ```
  python3.exe examples\ServerAPI\python\RunRaptorXML.py --host localhost -p 443 -s
  ```

4.1.1.5 Setting Up SSL Encryption

If you wish to encrypt your RaptorXML+XBRL Server data transfers using the SSL protocol, you will need to:

- Generate an SSL private key and create an SSL public key certificate file
- Set up RaptorXML+XBRL Server for SSL communication.

The steps to do this are listed below.

This method uses the open-source OpenSSL toolkit to manage SSL encryption. The steps listed below, therefore, need to be carried out on a computer on which OpenSSL is available. OpenSSL typically comes pre-installed on most Linux distributions and on macOS machines. It can also be installed on Windows computers. For download links to installer binaries, see the OpenSSL Wiki.

To generate a private key and obtain a certificate from a certificate authority, do the following:
1. Generate a private key

SSL requires that a **private key** is installed on RaptorXML+XBRL Server. This private key will be used to encrypt all RaptorXML+XBRL Server data. To create the private key, use the following OpenSSL command:

```
openssl genrsa -out private.key 2048
```

This creates a file called `private.key`, which contains your private key. Note where you save the file. You will need the private key to (i) generate the Certificate Signing Request (CSR), and (ii) be installed on RaptorXML+XBRL Server.

2. Certificate Signing Requests (CSRs)

A Certificate Signing Request (CSR) is sent to a certificate authority (CA), such as VeriSign or Thawte, to request a public key certificate. The CSR is based on your private key and contains information about your organization. Create a CSR with the following OpenSSL command (which provides the private-key file, `private.key`, that was created in Step 1, as one of its parameters):

```
openssl req -new -nodes -key private.key -out my.csr
```

During generation of the CSR you will need to give information about your organization, such as that listed below. This information will be used by the certificate authority to verify your company's identity.

- **Country**
- **Locality** (the city where your business is located)
- **Organization** (your company name). Do not use special characters; these will invalidate your certificate
- **Common Name** (the DNS name of your server). This must exactly match your server's official name, that is, the DNS name client apps will use to connect to the server
- A **challenge password**. Keep this entry blank!

3. Buy an SSL certificate

Purchase an SSL certificate from a recognized certificate authority (CA), such as VeriSign or Thawte. For the rest of these instructions, we follow the VeriSign procedure. The procedure with other CAs is similar.

- Go to the [VeriSign website](https://www.verisign.com).
- Click **Buy SSL Certificates**.
- Different types of SSL certificates are available. For RaptorXML+XBRL Server, Secure Site or Secure Site Pro certificates should be sufficient. EV (extended verification) is not necessary, since there is no "green address bar" for users to see.
- Proceed through the sign-up process, and fill in the information required to place your order.
- When prompted for the CSR (**created in Step 2**), copy and paste the content of the `my.csr` file into the order form.
- Pay for the certificate with your credit card.
Allow time for obtaining a certificate

Obtaining public key certificates from an SSL certificate authority (CA) typically takes **two to three business days**. Please take this into account when setting up your RaptorXML+XBRL Server.

4. Receive public key from CA

Your certificate authority will complete the enrollment process over the next two to three business days. During this time you might get emails or phone calls to check whether you are authorized to request an SSL certificate for your DNS domain. Please work with the authority to complete the process.

After the authorization and enrollment process has been completed, you will get an email containing the **public key** of your SSL certificate. The public key will be in plain text form or attached as a `.cer` file.

5. Save public key to file

For use with RaptorXML+XBRL Server, the public key must be saved in a `.cer` file. If the public key was supplied as text, copy-paste all the lines from

```
--BEGIN CERTIFICATE--
...
--END CERTIFICATE--
```

into a text file that we will call `mycertificate.cer`.

6. Save CA's intermediate certificates to file

To complete your SSL certificate, you will need two additional certificates: the **primary** and **secondary intermediate certificates**. Your certificate authority (CA) will list content of intermediate certificates on its website.

- Verisign's intermediate certificates for its Secure Site product: [https://knowledge.verisign.com/support/ssl-certificates-support/index?page=content&id=AR1735](https://knowledge.verisign.com/support/ssl-certificates-support/index?page=content&id=AR1735)

Copy-paste both intermediate certificates (primary and secondary) into separate text files and save them on your computer.

7. Optionally combine certificates in one public key certificate file

You now have three certificate files:
• Public key (mycertificate.cer)
• Secondary intermediate certificate
• Primary intermediate certificate

You can integrate your intermediate certificates into your public key certificate if you like. How to do this is described below. (Alternatively, you can use the https.certificate-chain configuration file setting to specify the location of intermediate certificates.)

Each contains text blocks bracketed by lines that look like this:

```
--BEGIN CERTIFICATE--
...
--END CERTIFICATE--
```

Now copy-paste all three certificates into one file so that they are in sequence. The order of the sequence is important: (i) public key, (ii) secondary intermediate certificate, (iii) primary intermediate certificate. Ensure that there are no lines between certificates.

```
--BEGIN CERTIFICATE--
  public key from mycertificate.cer (see Step 5)
--END CERTIFICATE--
--BEGIN CERTIFICATE--
  secondary intermediate certificate (see Step 6)
--END CERTIFICATE--
--BEGIN CERTIFICATE--
  primary intermediate certificate (see Step 6)
--END CERTIFICATE--
```

Save the resulting combined certificate text to a file named publickey.cer. This is the public key certificate file of your SSL certificate. It includes your public key certificate as well as the complete chain of trust in the form of the intermediate certificates that were used by the CA to sign your certificate.
4.1.2 Client Requests

After RaptorXML+XBRL Server has been started as a service, its functionality can be accessed by any HTTP client which can:

- use the HTTP methods GET, PUT, POST, and DELETE
- set the Content-Type header field

An easy-to-use HTTP client

There are a number of web clients available for download from the Internet. An easy-to-use and reliable web client we found was Mozilla's RESTClient, which can be added as a Firefox plugin. It's easy to install, supports the HTTP methods required by RaptorXML, and provides sufficiently good JSON syntax coloring. If you have no previous experience with HTTP clients, you might want to try RESTClient. Note, however, that installation and usage of RESTClient is at your own risk.

A typical client request would consist of a series of steps as shown in the diagram below.
The important points about each step are noted below. Key terms are in bold.

1. An HTTP POST method is used to make a request, with the body of the request being in JSON format. The request could be for any functionality of RaptorXML+XBRL Server. For example, the request could be for a validation, or for an XSLT transformation. The commands, arguments, and options used in the request are the same as those used on the command line. The request is posted to: http://localhost:8087/v1/queue, assuming localhost:8087 is the address of RaptorXML+XBRL Server (the initial address of the server). Such a request is termed a RaptorXML+XBRL Server job.

2. If the request is received and accepted for processing by RaptorXML+XBRL Server, a result document containing the results of the server action will be created after the job has been processed. The URI of this result document (the Result-Doc-URI in the...
3. The client sends a request for the result document (using the result document URI) in a GET method to the server. If processing of the job has not yet started or has not yet been completed at the time the request is received, the server returns a status of Running. The GET request must be repeated till such time that job processing has been completed and the result document has been created.

4. RaptorXML+XBRL Server returns the result document in JSON format. The result document might contain the URIs of error or output documents produced by RaptorXML+XBRL Server processing the original request. Error logs are returned, for example, if a validation returned errors. Primary output documents, such as the result of an XSLT transformation, are returned if an output-producing job is completed successfully.

5. The client sends the URIs of the output documents received in Step 4 via an HTTP GET method to the server. Each request is sent in a separate GET method.

6. RaptorXML+XBRL Server returns the requested documents in response to the GET requests made in Step 5.

7. The client can delete unwanted documents on the server that were generated as a result of a job request. This is done by submitting, in an HTTP DELETE method, the URI of the result document in question. All files on disk related to that job are deleted. This includes the result document file, any temporary files, and error and output document files. This step is useful for freeing up space on the server's hard disk.

The details of each step are described in the sub-sections of this section.

### 4.1.2.1 Initiating Jobs with POST

This section:

- Sending the request
- JSON syntax for POST requests
- Uploading files with the POST request
- Uploading ZIP archives

**Sending the request**

A RaptorXML+XBRL Server job is initiated with the HTTP POST method.

<table>
<thead>
<tr>
<th>HTTP Method</th>
<th>URI</th>
<th>Content-Type</th>
<th>Body</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST</td>
<td><a href="http://localhost:8087/v1/queue/">http://localhost:8087/v1/queue/</a></td>
<td>application/json</td>
<td>JSON</td>
</tr>
</tbody>
</table>

Note the following points:
- The URI above has a server address that uses the settings of the initial configuration.
- The URI has a /v1/queue/ path, which must be present in the URI. It can be considered to be an abstract folder in memory into which the job is placed.
- The correct version number /vN is the one that the server returns (and not necessarily the one in this documentation). The number that the server returns is the version number of the current HTTP interface. Previous version numbers indicate older versions of the HTTP interface, which are still supported for backward compatibility.
- The header must contain the field: Content-Type: application/json. However, if you wish to upload files within the body of the POST request, then the message header must have its content type set to multipart/form-data (i.e. Content-Type: multipart/form-data). See the section Uploading files with the POST request for details.
- The body of the request must be in JSON format.
- Files to be processed must be on the server. So files must either be copied to the server before a request is made, or be uploaded along with the POST request. In this case the message header must have its content type set to multipart/form-data. See the section Uploading files with the POST request below for details.

To check the well-formedness of an XML file, the request in JSON format would look something like this:

```
{
   "command": "wfxml", "args": [ "file:///c:/Test/Report.xml" ]
}
```

Valid commands, and their arguments and options, are as documented in the Command Line section.

### JSON syntax for HTTP POST requests

```
{
   "command": "Command-Name",
   "options": {"opt1": "opt1-value", "opt2": "opt2-value"},
   "args"   : ["file:///c:/filename1", "file:///c:/filename2"]
}
```

- All black text is fixed and must be included. This includes all braces, double quotes, colons, commas, and square brackets. Whitespace can be normalized.
- Blue italics are placeholders and stand for command names, options and option values, and argument values. Refer to the command line section for a description of the commands.
- The command and args keys are mandatory. The options key is optional. Some options keys have default values; so, of these options, only those for which the default values need to be changed need be specified.
- All strings must be enclosed in double quotes. Boolean values and numbers must not have quotes. So: {"error-limit": "unlimited"} and {"error-limit": 1} is correct
usage.

- Notice that file URIs—rather than file paths—are recommended and that they use forward slashes. Windows file paths, if used, take backslashes. Furthermore, Windows file-path backslashes must be escaped in JSON (with backslash escapes; so "c:\dir \filename"). Note that file URIs and file paths are strings and, therefore, must be in quotes.

Here is an example with options. Notice that some options (like `input` or `xslt-version`) take a straight option value, while others (like `param`) take a key-value pair as their value, and therefore require a different syntax.

```json
{
   "command": "xslt",
   "args": [
      "file:///C:/Work/Test.xslt"
   ],
   "options": {
      "input": "file:///C:/Work/Test.xml",
      "xslt-version": 1,
      "param": {
         "key": "myTestParam",
         "value": "SomeParamValue"
      },
      "output": "file:///C:/temp/out2.xml"
   }
}
```

The example below shows a third type of option: that of an array of values (as for the `xsd` option below). In this case, the syntax to be used is that of a JSON Array.

```json
{
   "command": "xsi",
   "args": [
      "file:///C:/Work/Test.xml"
   ],
   "options": {
      "xsd": ["file:///C:/Work/File1.xsd", "file:///C:/Work/File2.xsd"]
   }
}
```

**Uploading files with the POST request**

Files to be processed can be uploaded within the body of the POST request. In this case, the POST request must be made as follows.

**Request header**

In the request header, set `Content-Type: multipart/form-data` and specify any arbitrary string
as the boundary. Here is an example header:

**Content-Type:** multipart/form-data; boundary=---PartBoundary

The purpose of the boundary is to set the boundaries of the different form-data parts in the request body (see below).

**Request body: Message part**
The body of the request has the following form-data parts, separated by the boundary string specified in the request header (see above):

- **Mandatory form-data parts:** `msg`, which specifies the processing action requested, and `args`, which contains the files to be uploaded as the argument/s of the command specified in the `msg` form-data part. *See the listing below.*
- **Optional form-data part:** A form-data part name `additional-files`, which contains files referenced from files in the `msg` or `args` form-data parts. Additionally form-data parts named after an option of the command can also contain files to be uploaded.

**Note:** All uploaded files are created in a single virtual directory.

See [Example-1 (with Callouts): Validate XML](#) for a detailed explanation of the code, and [Example-2: Using a Catalog to Find the Schema](#).

### Testing with CURL

You can use a third-party data-transfer application such as CURL ([http://curl.haxx.se/](http://curl.haxx.se/)) to test the POST request. CURL provides a helpful trace option that generates and lists the part boundaries of the requests. This will save you the task of manually creating the part boundaries. How you can use CURL is described in the section, *Testing with CURL.*

### Uploading ZIP archives

ZIP archives can also be uploaded, and files within a ZIP can be referenced by using the `additional-files` scheme. For example:

```java
additional-files:///mybigarchive.zip%7Czip/biginstance.xml
```

**Note:** The `|zip/` part needs to be URI-escaped as `%7Czip/` in order to conform to the URI RFC since the pipe `|` symbol is not directly allowed. The use of glob patterns (`*` and `?`) is also allowed. So you can use something like this to validate all XML files within the ZIP archive:

```json
{"command": "xsi", "args": ["additional-files:///mybigarchive.zip%7Czip/*\.xml"], "options": {...}}
```
See Example-3: Using ZIP Archives for a listing of example code.

**Example-1 (with Callouts): Validate XML**

Given below is a listing of the body of a POST request. It has numbered callouts that are explained below. The command submitted in the listing request would have the following CLI equivalent:

```
raptorxmlxbri xsi First.xml Second.xml --xsd=Demo.xsd
```

The request is for the validation of two XML files according to a schema. The body of the request would look something like this, assuming that ---PartBoundary has been specified in the header as the boundary string (see Request Header above).

```
-----PartBoundary
Content-Disposition: form-data; name="msg"
Content-Type: application/json

{"command": "xsi", "options": {}, "args": []}

-----PartBoundary
Content-Disposition: attachment; filename="First.xml"; name="args"
Content-Type: application/octet-stream

<?xml version="1.0" encoding="UTF-8"?>
<test xsi:noNamespaceSchemaLocation="Demo.xsd" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">42</test>

-----PartBoundary
Content-Disposition: attachment; filename="Second.xml"; name="args"
Content-Type: application/octet-stream

<?xml version="1.0" encoding="UTF-8"?>
<test xsi:noNamespaceSchemaLocation="Demo.xsd" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">35</test>

-----PartBoundary
Content-Disposition: attachment; filename="Demo.xsd"; name="additional-files"
Content-Type: application/octet-stream

<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
  elementFormDefault="qualified" attributeFormDefault="unqualified">
  <xs:element name="test" type="xs:int"/>
</xs:schema>

-----PartBoundary--
```
The name of the main form-data part boundaries are declared in the request header. The part boundary separator must be a unique string that will not occur anywhere in the embedded documents. It is prefixed with two dashes and is used to separate the multiple parts. The first form-data part in this example is msg. Note that the content type is application/json.

This is the standard syntax for HTTP POST requests. If args contains a reference to a file and if additional files are uploaded, both sets of files will be passed to the server.

The first member of the args array is a file attachment called First.xml.

The text of the file First.xml. It contains a reference to a schema called Demo.xsd, which will also be uploaded—in the additional-files form-data part.

The second member of the args array is an attachment called Second.xml.

The text of the file Second.xml. It too contains a reference to the schema Demo.xsd. See callout 7.

The first additional files part contains the Demo.xsd attachment metadata.

The text of the file Demo.xsd.

The second additional files part, and the additional-files form-data part. Note that the last part boundary separator is both prefixed and postfixed with two dashes.

Example-2: Using a Catalog to Find the Schema

In this example, a catalog file is used to find the XML schema that is referenced by the XML files to be validated.

-----PartBoundary
Content-Disposition: form-data; name="msg"
Content-Type: application/json

{"command": "xsi", "args": ["additional-files:///First.xml", "additional-files:///Second.xml"], "options": {"user-catalog": "additional-files:///catalog.xml"}}

-----PartBoundary
Content-Disposition: attachment; filename="First.xml"; name="additional-files"
Content-Type: application/octet-stream

<?xml version="1.0" encoding="UTF-8"?>
<test xsi:noNamespaceSchemaLocation="http://example.com/Demo.xsd"
xmns:xsi="http://www.w3.org/2001/XMLSchema-instance">42</test>

-----PartBoundary
Content-Disposition: attachment; filename="Second.xml"; name="additional-files"
Content-Type: application/octet-stream

<?xml version="1.0" encoding="UTF-8"?>
Example-3: Using ZIP Archives

ZIP archives can also be uploaded, and files within a ZIP can be referenced by using the `additional-files` scheme. For example:

```
additional-files://mybigarchive.zip%7Czip/biginstance.xml
```

**Note:** The `|zip/` part needs to be URI-escaped as `%7Czip/` in order to conform to the URI RFC since the pipe `|` symbol is not directly allowed. The use of glob patterns (`*` and `?`) is also allowed. So you can use something like this to validate all XML files within the ZIP archive:

```
{"command": "xsi", "args": ["additional-files:///mybigarchive.zip%7Czip/*.*", "options": {...}]}
```

**Note:** 'Content-Disposition: form-data' is also valid, in addition to 'Content-Disposition: attachment'. Since several tools generate form-data as content-disposition, the value form-data is accepted as valid.

Example: Validating all XML files in a ZIP archive

In this example, it is assumed that all schema references are relative paths and that all schemas are contained within the zip.
Content-Type: application/json

{"command": "xsi", "args": ["additional-files:///Demo.zip%7Czip/*.xml"], "options": {}}

-----PartBoundary
Content-Disposition: attachment; filename="Demo.zip"; name="additional-files"
Content-Type: application/octet-stream

Binary content of Demo.zip archive

-----PartBoundary--

Example: Validating XML files in a ZIP archive containing references to external schemas

In this example, the XML files in a ZIP archive are validated using references to an external schema, which is provided in a second ZIP archive.

-----PartBoundary
Content-Disposition: form-data; name="msg"
Content-Type: application/json

{"command": "xsi", "args": ["additional-files:///Instances.zip%7Czip/*.xml"], "options": ["user-catalog": "additional-files:///Schemas.zip%7Czip/catalog.xml"]}

-----PartBoundary
Content-Disposition: attachment; filename="Instances.zip"; name="additional-files"
Content-Type: application/octet-stream

Binary content of Instances.zip archive

-----PartBoundary
Content-Disposition: attachment; filename="Schemas.zip"; name="additional-files"
Content-Type: application/octet-stream

Binary content of Schemas.zip archive

-----PartBoundary--

Testing with CURL

The third-party application CURL (http://curl.haxx.se/) is a command line utility that you can use to test the POST request. CURL provides a very useful trace option that generates and lists the part boundaries of requests, which you can use directly in your requests or as a reference.

Given below is a sample test scenario in which an XML file is validated against an XML Schema. We assume the following:
- the commands below are executed from the folder in which the files to be submitted for validation are located; (this enables us to write simple relative paths to these files). If you have installed Altova's XMLSpy application, the files used in this example can be found in the application's Examples folder, which is located by default at: C:\Users\<username>\Documents\Altova\XMLSpy2019\Examples
- RaptorXML+XBRL Server is running locally on port 8087

For more information about the CURL command line options, see the CURL Help.

**Call CURL with the validation command on Windows**

[input: powershell]
```
\path\to\curl.exe -F 'msg={"command": "xsi", "args": ["additional-files:///PurchaseOrder.zip%7Czip/ipo.xml"] , "options":{}};type=application/json' -F "additional-files=@PurchaseOrder.zip;type=application/octet-stream" http://localhost:8087/v1/queue
```

**Note:** In powershell, if quotes occur within quotes, different types of quotes (single/double) must be used.

[input: cmd]
```
\path\to\curl.exe -F "msg={"command": "xsi", "args": ["additional-files:///PurchaseOrder.zip%7Czip/ipo.xml"] , "options":{}};type=application/json" -F "additional-files=@PurchaseOrder.zip;type=application/octet-stream" http://localhost:8087/v1/queue
```

[output]
```
{"jobid": "058F9E97-CB95-43EF-AC0A-496CD3AC43A3", "result": "/v1/results/058F9E97-CB95-43EF-AC0A-496CD3AC43A3"}
```

**Use the URL of "result" to fetch the result**

[input]
```
\path\to\curl.exe http://localhost:8087/v1/results/058F9E97-CB95-43EF-AC0A-496CD3AC43A3
```

[output]
```
{"jobid": "058F9E97-CB95-43EF-AC0A-496CD3AC43A3", "state": "OK", "error": {} , "jobs": [{"file": "additional-files:///PurchaseOrder.zip%7Czip/ipo.xml", "jobid": "D4B91CB0-CF03-4D29-B563-B6506E123A06", "output": {} , "state": "OK", "error": {}}]}
```

**CURL’s trace option**

CURL has a trace option (`--trace-ascii`), which traces the HTTP traffic sent to and from the server. The option is very useful since it lists the part boundaries that are required for initiating jobs with POST. You can use the information in the trace, either directly or as a reference, to create the part boundaries. The listing below shows the trace obtained by running the command given above.
Trace listing

== Info: Trying ::1...

Call CURL with the well-formed-check command on Linux

```
/path/to/curl -F 'msg={"command": "wxml", "args":[]};type=application/json' -F "args=@ipo.xml;type=application/octet-stream" http://localhost:8087/v1/queue
```

```
/path/to/curl -F 'msg={"command": "wxml", "args":["additional-files://ipo.zip%7Czip/ipo.xml"]};type=application/json' -F "additional-files=@ipo.zip;type=application/octet-stream" http://localhost:8087/v1/queue
```

4.1.2.2 Server Response to POST Request

**This section:**

- **Overview of possible server responses**
- **Response: Request failed, no response from server**
- **Response: Request communicated, but job rejected by server**
- **Response: Job executed (with positive or negative result)**

When a **POST** request is made successfully to the server, the job is placed in the server queue. A **201 Created** message and a result document URI are returned. The job will be processed at the earliest. In the meanwhile, if the **result document is requested**, a "**status": "Running"** message is returned if the job has not been completed; the client should try again at a later time. A **Dispatched state** indicates that the job is in the server queue but has not yet bee started.

The result of the job (for example, a validation request) may be negative (validation failed) or positive (validation successful). In either case a **201 Created** message is returned and a result document is generated. It is also possible that the **POST request was not communicated to the server (Request failed)**, or the request was communicated but the job was rejected by the server (**Request communicated, but job rejected**). The various possible outcomes are shown in the diagram below.
The possible outcomes to the client's POST request are as follows:

**Request failed, no response from server**

When requests cannot be made successfully to the server, the most common errors are those listed below:

<table>
<thead>
<tr>
<th>Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>404 Not Found</td>
<td>The correct path is: <a href="http://localhost:8087/v1/queue/">http://localhost:8087/v1/queue/</a></td>
</tr>
<tr>
<td>405 Method Not Allowed</td>
<td>Specified method is invalid for this resource. Use the POST method.</td>
</tr>
<tr>
<td>415 Unsupported Media Type</td>
<td>The message header should be Content-Type:application/json.</td>
</tr>
</tbody>
</table>

**Request communicated, but job rejected by server**

When requests are made successfully to the server, the server could reject them for the following reasons:

<table>
<thead>
<tr>
<th>Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>400 Bad Request (bad cmd)</td>
<td>The RaptorXML command is incorrect.</td>
</tr>
<tr>
<td>Code</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>400 Bad Request (json error)</td>
<td>The request body has a JSON syntax error.</td>
</tr>
<tr>
<td>404 File Not Found</td>
<td>Check file URI (or filepath) syntax of all files named in the command.</td>
</tr>
</tbody>
</table>

Job executed (with positive or negative result)

When a job (for example, a validation job) is executed, its result can be positive (OK) or negative (Failed). For example, the result of a validation job is positive (OK) when the document to be validated is valid, negative (Failed) if the document is invalid.

In both cases, the job is executed, but with different results. A 201 Created message is returned in both cases as soon as the job is successfully placed in the queue. Also, in both cases a result document URI is returned to the HTTP client that made the request. (The result document itself might not yet have been created if processing of the job has not yet started or completed.) After the result document has been created, it can be fetched with an HTTP GET request. In addition to the result document, other documents may be generated also, as follows:

- **Job executed with result 'Failed':** An error log is created in three formats: text, long XML, and short XML. The URIs of these three documents are sent in the result document (which is in JSON format). The URIs can be used in an HTTP GET request to fetch the error documents.

- **Job executed with result 'OK':** The job is processed successfully and output documents—such as the output produced by an XSLT transformation—are created. If output files have been generated, their URIs are sent in the JSON-format result document. The URIs can then be used in an HTTP GET request to fetch the output documents. Note that not all jobs will have output files; for example, a validation job. Also a job can finish with a state of 'OK', but there might have been warnings and/or other messages that were written to error files. In this case, error file URIs are also sent in the result document (that is, in addition to output documents).

See [Getting the Result Document](#) and [Getting Error/Output Documents](#) for a description of these documents and how to access them.

### 4.1.2.3 Getting the Result Document

This section:

- The Result Document URI
- Fetching the Result Document
  - Result Document containing URIs of error documents
  - Result Document containing URIs of output documents
  - Result Document containing no URI
- Accessing error and output documents listed in the Result Document

The Result Document URI

A result document will be created every time a job is created, no matter whether the result of a job (for example, a validation) is positive (document valid) or negative (document invalid). In both cases a 201 Created message is returned. This message will be in JSON format and will contain
a relative URI of the result document. The JSON fragment will look something like this:

```json
{
  "result": "/v1/results/E6C4262D-8ADB-49CB-8693-990DF79EABEB",
  "jobid": "E6C4262D-8ADB-49CB-8693-990DF79EABEB"
}
```

The `result` object contains the relative URI of the result document. The URI is relative to the server address. For example, if the server address is `http://localhost:8087/` (the initial configuration address), then the expanded URI of the result document specified in the listing above will be:

```
http://localhost:8087/v1/results/E6C4262D-8ADB-49CB-8693-990DF79EABEB
```

**Note:** The correct version number `/vN` is the one that the server returns (and is not necessarily the one in this documentation). The number that the server returns is the version number of the current HTTP interface. Previous version numbers indicate older versions of the HTTP interface, which, however, are still supported for backward compatibility.

**Fetching the Result Document**

To get the result document submit the document's expanded URI (see above), in an HTTP GET request. The result document is returned and could be one of the generic types described below.

**Note:** When a job is successfully placed in the server queue, the server returns the URI of the result document. If the client requests the result before the job has been started (it is still in the queue), a "status": "Dispatched" message will be returned. If the job has been started but not completed (say, because it is a large job), a "status": "Running" message will be returned. In these two situations, the client should wait for some time before making a fresh request for the result document.

**Note:** The example documents below all assume restricted client access. So error documents, message documents, and output documents are all assumed to be saved in the relevant job directory on the server. The URIs for them in the result document are therefore all relative URIs. None is a file URI (which would be the kind of URI generated in cases of unrestricted client access). For the details of these URIs, see the section Getting Error/Message/Output Documents.

**Result document containing URIs of error documents**

If the requested job finished with a state of *Failed*, then the job returned a negative result. For example, a validation job returned a document-invalid result. The errors encountered while executing the job are stored in error logs, created in three file formats: (i) text, (ii) long-XML (detailed error log), and (iii) short-XML (less-detailed error log). See the JSON listing below.

```json
{}
"jobid": "6B4EE31B-FAC9-4834-B50A-582FABF47B58",
"state": "Failed",
"error":
{
  "text": "/v1/results/6B4EE31B-FAC9-4834-B50A-582FABF47B58/error/error.txt",
  "longxml": "/v1/results/6B4EE31B-FAC9-4834-B50A-582FABF47B58/error/
```
Note the following:

- Jobs have sub-jobs.
- Errors at sub-job level propagate up to the top-level job. The state of the top-level job will be OK only if all of its sub-jobs have a state of OK.
- Each job or sub-job has its own error log.
- Error logs include warning logs. So, even though a job finishes with a state of OK, it might have URIs of error files.
- The URIs of the error files are relative to the server address (see above).

**Result document containing URIs of output documents**

If the requested job finished with a state of OK, then the job returned a positive result. For example, a validation job returned a document-valid result. If the job produced an output document— for example, the result of an XSLT transformation—then the URI of the output document is returned. See the JSON listing below.

```json
{
    "jobid": "5E47A3E9-D229-42F9-83B4-CC11F8366466",
    "state": "OK",
    "error": {
    }
}
```

Jobs have sub-jobs.
Note the following:

- The output file is created in the output folder of the job. You can use its relative URI to access the file.
- The URIs of the output files are relative to the server address (see above).
- The output-mapping item maps the output document in the job directory on the server to the file location specified by the client in the job request. Notice that only output documents specified by the client in the job request have a mapping; job-related files generated by the server (such as error files) have no mapping.
- Alternatively, it is possible to retrieve all the generated result documents for a specific job as a zip archive using the URL "/v1/results/JOBID/output/zip". This feature is not available in unrestricted filesystem mode. Please note that the zip archive will contain mangled file names, which need to be mapped back to the actual names using the output-mapping object.

**Result document containing no URI**

If the requested job finished with a state of OK, then the job returned a positive result. For example, a validation job returned a document-valid result. Some jobs—such as a validation or well-formed-test—produce no output document. If a job of this type finishes with a state of OK, then the result document will have neither the URI of an output document nor the URI of an error log. See the JSON listing below.

```json
{
  "jobid": "3FC8B90E-A2E5-427B-B9E9-27CB7BB6B405",
  "state": "OK",
  "error": {}
}
```

```json
"jobs": [
{
  "file": "file:///c:/Test/SimpleExample.xml",
  "jobid": "532F14A9-F9F8-4FED-BCDA-16A17A848FEA",
  "output": {}
},
{
  "state": "OK",
  "error": {}
}
]
```
Note the following:

- Both the output and error components of the sub-job in the listing above are empty.
- A job could finish with a state of OK but still contain warnings or other messages, which are logged in error files. In such cases, the result document will contain URIs of error files even though the job finished with a state of OK.

Accessing error and output documents listed in the Result Document

Error and output documents can be accessed with HTTP GET requests. These are described in the next section, Getting Error/Output Documents.

### 4.1.2.4 Getting Error/Message/Output Documents

A result document can contain the file URIs or relative URIs of error documents, message documents (such as logs), and/or output documents. (There are some situations in which a result document might not contain any URI.) The various kinds of URIs are described below.

To access these documents via HTTP, do the following:

1. **Expand the relative URI** of the file in the result document to its absolute URI
2. **Use the expanded URI in an HTTP GET request** to access the file

#### URIs (in the result document) of error/message/output documents

The result document contains URIs of error, message, and/or output documents. Error and message documents are job-related documents that are generated by the server; they are always saved in the job directory on the server. Output documents (such as the output of XSLT transformations) can be saved to one of the following locations:

- To any file location accessible to the server. For output files to be saved to any location, the server must be configured to allow the client unrestricted access (the default setting).
- To the job directory on the server. The server is configured to restrict client access.

If a client specifies that an output file be created, the location to which the output file is saved will be determined by the server.unrestricted-filesystem-access option of the server configuration file.

- If access is unrestricted, the file will be saved to the location specified by the client and the URI returned for the document will be a file URI.
- If access is restricted, the file will be saved to the job directory and its URI will be a relative URI. Additionally, there will be a mapping of this relative URI to the file URL specified by the client. (See the listing of Result document containing URIs of output documents.)

In summary, therefore, the following kinds of URIs will be encountered:

- **File URI of error/message documents**
  
  These documents are saved in the job directory on the server. File URIs will have this form:
  
  `file://<output-root-dir>/JOBID/message.doc`
File URI of output documents
These documents are saved at any location. File URIs will have this form:
file:///<path-to-file>/output.doc

HTTP URI of error/messaging/output documents
These documents are saved in the job directory on the server. URIs are relative to the server address and must be expanded to the full HTTP URI. The relative will have this form:
/vN/results/JOBID/error/error.txt for error documents
/vN/results/JOBID/output/verbose.log for message documents
/vN/results/JOBID/output/1 for output documents

In the case of output documents, output mappings are given (see example listing). These mappings map each output document URI in the result document to the corresponding document in the client request.

Expand the relative URI
Expand the relative URI in the result document to an absolute HTTP URI by prefixing the relative URI with the server address. For example, if the server address is:
http://localhost:8087/ (the initial configuration address)
and the relative URI of an error file in the result document is:
/v1/results/20008201-219F-4790-BB59-C091C276FED2/error/error.txt
then the expanded absolute address will be

For more related information, see the sections: Configuring the Server and Getting the Result Document.

Use an HTTP GET request to access the file
Use the expanded URI in an HTTP GET request to obtain the required file. RaptorXML+XBRL Server returns the requested document.

4.1.2.5 Freeing Server Resources after Processing
RaptorXML+XBRL Server keeps the result document file, temporary files, and error and output document files related to a processed job on hard disk. These files can be deleted in one of two ways:

- **By providing the URI of the result document** with the HTTP DELETE method. This deletes all files related to the job indicated by the submitted result-document URI, including error and output documents.
- **Manual deletion of individual files on the server by an administrator.**

The structure of the URI to use with the HTTP DELETE method is as shown below. Notice that the full URI consists of the server address plus the relative URI of the result document.
HTTP Method | URI
---|---
DELETE | http://localhost:8087/v1/result/D405A84A-AB96-482A-96E7-4399885FAB0F

To locate the output directory of a job on disk, construct the URI as follows:

\(<server.output-root-dir>\) [see server configuration file] + [jobid]

**Note:** Since a large number of error and output document files can be created, it is advisable to monitor hard disk usage and schedule deletions according to your environment and requirements.
4.2 COM/.NET API

RaptorXML+XBRL Server is licensed on the machine on which it is installed. The .NET interface is built as a wrapper around the COM interface. The COM and .NET interfaces of RaptorXML+XBRL Server use a single API: the COM/.NET API of RaptorXML+XBRL Server (object reference here).

You can use RaptorXML+XBRL Server with:

- Scripting languages, such as JavaScript, via the COM interface
- Programming languages, such as C#, via the .NET interface
4.2.1 COM Interface

RaptorXML+XBRL Server is automatically registered as a COM server object when RaptorXML +XBRL Server is installed. So it can be invoked from within applications and scripting languages that have programming support for COM calls. If you wish to change the location of the RaptorXML +XBRL Server installation package, it is best to de-install RaptorXML+XBRL Server and then re-install it at the required location. In this way the necessary de-registration and registration are carried out by the installer process.

Check the success of the registration

If the registration was successful, the Registry will contain the RaptorXML.Server classes. These classes will typically be found under HKEY_LOCAL_MACHINE\SOFTWARE\Classes.

Code examples

- A VBScript example showing how the RaptorXML API can be used via its COM interface is listed in the following topic.
- An example file corresponding to this listing is available in the examples/API folder of the RaptorXML application folder.
4.2.2 COM Example: VBScript

The VBScript example below is structured into the following parts:

- Set up and initialize the RaptorXML COM object
- Validate an XML file
- Perform an XSLT transformation, return the result as a string
- Process an XQuery document, save the result in a file
- Set up the execution sequence of the script and its entry point

' The RaptorXML COM object
dim objRaptor

' Initialize the RaptorXML COM object
sub Init
    objRaptor = Null
    On Error Resume Next
    ' Try to load the 32-bit COM object; do not throw exceptions if object is not found
    Set objRaptor = WScript.GetObject( "", "RaptorXML.Server" )
    On Error Goto 0
    if ( IsNull( objRaptor ) ) then
        ' Try to load the 64-bit object (exception will be thrown if not found)
        Set objRaptor = WScript.GetObject( "", "RaptorXML_x64.Server" )
    end if
    ' Configure the server: error reporting, HTTP server name and port (IPv6 localhost in this example)
    objRaptor.ErrorLimit = 1
    objRaptor.ReportOptionalWarnings = true
    objRaptor.ServerName = "::1"
    objRaptor.ServerPort = 8087
end sub

' Validate one file
sub ValidateXML
    ' Get a validator instance from the Server object
dim objXMLValidator
    Set objXMLValidator = objRaptor.GetXMLValidator()

    ' Configure input data
    objXMLValidator.InputFileName = "MyXMLFile.xml"

    ' Validate; in case of invalid file report the problem returned by RaptorXML
    if ( objXMLValidator.IsValid() ) then
        MsgBox( "Input string is valid" )
    else
        MsgBox( objXMLValidator.LastErrorMessage )
    end if
end sub
' Perform a transformation; return the result as a string
sub RunXSLT
    ' Get an XSLT engine instance from the Server object
    dim objXSLT
    set objXSLT = objRaptor.GetXSLT

    ' Configure input data
    objXSLT.InputXMLFileName = "MyXMLFile.xml"
    objXSLT.XSLFileName = "MyTransformation.xsl"

    ' Run the transformation; in case of success the result will be returned,
    ' in case of errors the engine returns an error listing
    MsgBox( objXSLT.ExecuteAndGetResultAsString() )
end sub

' Execute an XQuery; save the result in a file
sub RunXQuery
    ' Get an XQuery engine instance from the Server object
    dim objXQ
    set objXQ = objRaptor.GetXQuery()

    ' Configure input data
    objXQ.InputXMLFileName = "MyXMLFile.xml"
    objXQ.XQueryFileName = "MyQuery.xq"

    ' Configure serialization (optional - for fine-tuning the result's
    ' format)
    objXQ.OutputEncoding = "UTF8"
    objXQ.OutputIndent = true
    objXQ.OutputMethod = "xml"
    objXQ.OutputOmitXMLDeclaration = false

    ' Run the query; the result will be serialized to the given path
    call objXQ.Execute( "MyQueryResult.xml" )
end sub

' Perform all sample functions
sub main
    Init
    ValidateXML
    RunXSLT
    RunXQuery
end sub

' Script entry point; run the main function
main
4.2.3 .NET Interface

The .NET interface is built as a wrapper around the RaptorXML+XBRL Server COM interface. It is provided as a primary interop assembly signed by Altova; it uses the namespace Altova.RaptorXMLServer.

Adding the RaptorXML DLL as a reference to a Visual Studio .NET project

In order to use RaptorXML+XBRL Server in your .NET project, add a reference to the RaptorXML DLL (Altova.RaptorXMLServer.dll) in your project. Your RaptorXML+XBRL Server installation contains a signed DLL file, named Altova.RaptorXMLServer.dll. This DLL file will automatically be added to the global assembly cache (GAC) when RaptorXML+XBRL Server is installed using the RaptorXML+XBRL Server installer. The GAC is typically in the folder: C:\WINDOWS\assembly.

To add the RaptorXML DLL as a reference in a .NET project, do the following:

1. With the .NET project open, click Project | Add Reference. The Add Reference dialog (screenshot below) pops up.

![Add Reference dialog](screenshot)

2. In the Browse tab, go to the folder: \<RaptorXML application folder>\bin, select the RaptorXML DLL Altova.RaptorXMLServer.dll, and click OK.
3. Select the command View | Object Browser to see the objects of the RaptorXML API.

Once the Altova.RaptorXMLServer.dll is available to the .NET interface and RaptorXML has been registered as a COM server object, RaptorXML functionality will be available in your .NET project.
Note: RaptorXML will automatically be registered as a COM server object during installation. There is no need for a manual registration.

Note: If you receive an access error, check that permissions are correctly set. Go to Component Services and give permissions to the same account that runs the application pool containing RaptorXML.

Code examples
A [C# example](#) and a [Visual Basic .NET example](#) showing how the RaptorXML API can be used via its .NET interface are listed in the following topics. The files corresponding to these listings are available in the examples/API folder of the RaptorXML application folder.
4.2.4 .NET Example: C#

The C# example below does the following:

- Set up and initialize the RaptorXML .NET object
- Validate an XML file
- Perform an XSLT transformation, return the result as a string
- Process an XQuery document, save the result in a file
- Set up the execution sequence of the code and its entry point

```csharp
using System;
using System.Text;
using Altova.RaptorXMLServer;

namespace RaptorXMLRunner
{
    class Program
    {
        // The RaptorXML Server .NET object
        static ServerClass objRaptorXMLServer;

        // Initialize the RaptorXML Server .NET object
        static void Init()
        {
            // Allocate a RaptorXML object
            objRaptorXMLServer = new ServerClass();

            // Configure the server: error reporting, HTTP server name and port
            // (IPv6 localhost in this example)
            objRaptorXMLServer.ErrorLimit = 1;
            objRaptorXMLServer.ReportOptionalWarnings = true;
            objRaptorXMLServer.ServerName = ::1
            objRaptorXMLServer.ServerPort = 8087
        }

        // Validate one file
        static void ValidateXML()
        {
            // Get a validator engine instance from the Server object
            XMLValidator objXMLValidator = objRaptorXMLServer.GetXMLValidator();

            // Configure input data
            objXMLValidator.InputFileName = "MyXMLFile.xml";

            // Validate; in case of invalid file,
            // report the problem returned by RaptorXML
            if ( objXMLValidator.IsValid() )
```
```csharp
Console.WriteLine( "Input string is valid" );
else
    Console.WriteLine( objXMLValidator.LastErrorMessage );

// Perform an XSLT transformation, and
// return the result as a string
static void RunXSLT()
{
    // Get an XSLT engine instance from the Server object
    XSLT objXSLT = objRaptorXMLServer.GetXSLT();

    // Configure input data
    objXSLT.InputXMLFileName = "MyXMLFile.xml";
    objXSLT.XSLFileName = "MyTransformation.xsl";

    // Run the transformation.
    // In case of success, the result is returned.
    // In case of errors, an error listing
    Console.WriteLine( objXSLT.ExecuteAndGetResultAsString() );
}

// Execute an XQuery, save the result in a file
static void RunXQuery()
{
    // Get an XQuery engine instance from the Server object
    XQuery objXQuery = objRaptorXMLServer.GetXQuery();

    // Configure input data
    objXQuery.InputXMLFileName = exampleFolder + "simple.xml";
    objXQuery.XQueryFileName = exampleFolder + "CopyInput.xq";

    // Configure serialization (optional, for better formatting)
    objXQuery.OutputEncoding = "UTF8";
    objXQuery.OutputIndent = true;
    objXQuery.OutputMethod = "xml";
    objXQuery.OutputOmitXMLDeclaration = false;

    // Run the query; result serialized to given path
    objXQuery.Execute( "MyQueryResult.xml" );
}

static void Main(string[] args)
{
    // additional code here
}
```
try
{
    // Entry point. Perform all functions
    Init();
    ValidateXML();
    RunXSLT();
    RunXQuery();
}
catch (System.Exception ex)
{
    Console.WriteLine( ex.Message );
    Console.WriteLine( ex.ToString() );
}
}
4.2.5 .NET Example: Visual Basic .NET

The Visual Basic example below does the following:

- Set up and initialize the RaptorXML .NET object
- Validate an XML file
- Perform an XSLT transformation, return the result as a string
- Process an XQuery document, save the result in a file
- Set up the execution sequence of the code and its entry point

Option Explicit On
Imports Altova.RaptorXMLServer

Module RaptorXMLRunner

' The RaptorXML .NET object
Dim objRaptor As Server

' Initialize the RaptorXML .NET object
Sub Init()

' Allocate a RaptorXML object
objRaptor = New Server()

' Configure the server: error reporting, HTTP server name and port (IPv6 localhost in this example)
objRaptor.ErrorLimit = 1
objRaptor.ReportOptionalWarnings = True
objRaptor.ServerName = "::1"
objRaptor.ServerPort = 8087
End Sub

' Validate one file
Sub ValidateXML()

' Get a validator instance from the RaptorXML object
Dim objXMLValidator As XMLValidator
objXMLValidator = objRaptor.GetXMLValidator()

' Configure input data
objXMLValidator.InputFileName = "MyXMLFile.xml"

' Validate; in case of invalid file report the problem returned by RaptorXML
If (objXMLValidator.IsValid()) Then
    Console.WriteLine("Input string is valid")
Else
    Console.WriteLine(objXMLValidator.LastErrorMessage)
End If
End Sub
' Perform a transformation; return the result as a string
Sub RunXSLT()

' Get an XSLT engine instance from the Server object
Dim objXSLT As XSLT
objXSLT = objRaptor.GetXSLT()

' Configure input data
objXSLT.InputXMLFileName = "MyXMLFile.xml"
objXSLT.XSLFileName = "MyTransformation.xsl"

' Run the transformation; in case of success the result will be returned,
in case of errors the engine returns an error listing
Console.WriteLine(objXSLT.ExecuteAndGetResultAsString())
End Sub

' Execute an XQuery; save the result in a file
Sub RunXQuery()

' Get an XQuery engine instance from the Server object
Dim objXQ As XQuery
objXQ = objRaptor.GetXQuery()

' Configure input data
objXQ.InputXMLFileName = "MyXMLFile.xml"
objXQ.XQueryFileName = "MyQuery.xq"

' Configure serialization (optional - for fine-tuning the result's formatting)
objXQ.OutputEncoding = "UTF8"
objXQ.OutputIndent = true
objXQ.OutputMethod = "xml"
objXQ.OutputOmitXMLDeclaration = false

' Run the query; the result will be serialized to the given path
objXQ.Execute( "MyQueryResult.xml" )
End Sub

Sub Main()
' Entry point; perform all sample functions
Init()
ValidateXML()
RunXSLT()
RunXQuery()
End Sub

End Module
4.3 Java API

The RaptorXML+XBRL Server API can be accessed from Java code. To access RaptorXML+XBRL Server from Java code, the libraries listed below must be listed in the classpath. These libraries are installed in the bin folder of the installation folder.

- **RaptorXMLServer.jar**: The library that communicates with the RaptorXML server using HTTP requests
- **RaptorXMLServer_JavaDoc.zip**: A Javadoc file containing help documentation for the Java API

**Note:** In order to use the Java API, the Jar file must be on the Java Classpath. You may copy the Jar file to any location if this fits your project setup better than referencing it from the installed location.
4.3.1 Overview of the Interface

The Java API is packaged in the com.altova.raptorxml package. The RaptorXML class provides an entry-point method called getFactory(), which returns RaptorXMLFactory objects. So, a RaptorXMLFactory instance can be created with the call: RaptorXML.getFactory().

The RaptorXMLFactory interface provides methods for getting engine objects for validation and other processing functionality (such as XSLT transformation).

RaptorXMLFactory

The public RaptorXMLFactory interface is described by the following listing:

```java
public interface RaptorXMLFactory {
    public XMLValidator getXMLValidator();
    public XBRL getXBRL();
    public XMLDSig getXQuery();
    public XQuery getXQuery();
    public XSLT getXSLT();
    public void setServerName(String name) throws RaptorXMLException;
    public void setServerPath(String path) throws RaptorXMLException;
    public void setServerPort(int port) throws RaptorXMLException;
    public void setServerName(String name);
    public void setServerPath(String path);
    public void setServerPort(int port);
    public void setGlobalCatalog(String catalog);
    public void setUserCatalog(String catalog);
    public void setGlobalResourcesFile(String file);
    public void setGlobalResourceConfig(String config);
    public void setErrorFormat(RaptorXMLException format);
    public void setErrorLimit(int limit);
    public void setReportOptionalWarnings(boolean report);
}
```

For more details, see the descriptions of RaptorXMLFactory and the respective Java methods. Also see the Example Java Project.
4.3.2 Example Java Project

The Java code listing below shows how basic functionality can be accessed. It is structured into the following parts:

- Locate the examples folder, and create a RaptorXML COM object instance
- Validate an XML file
- Perform an XSLT transformation, return the result as a string
- Process an XQuery document, return the result as a string
- Run the project

This basic functionality is included in the files in the examples/API folder of the RaptorXML+XBRL Server application folder.

```java
public class RunRaptorXML {
    // Locate samples installed with the product
    // (will be two levels higher from examples/API/Java)
    // REMARK: You might need to modify this path
    static final String strExamplesFolder = System.getProperty("user.dir") + "/../../";

    static com.altova.raptorxml.RaptorXMLFactory rxml;

    static void ValidateXML() throws com.altova.raptorxml.RaptorXMLException {
        com.altova.raptorxml.XMLValidator xmlValidator = rxml.getXMLValidator();
        System.out.println("RaptorXML Java - XML validation");
        xmlValidator.setInputFromText("<!DOCTYPE root [
        <!ELEMENT root (#PCDATA)>
        ]> <root>simple input document</root>" );
        if (xmlValidator.isWellFormed())
            System.out.println("The input string is well-formed");
        else
            System.out.println("Input string is not well-formed: "+
            xmlValidator.getLastErrorMessage());
        if (xmlValidator.isValid())
            System.out.println("The input string is valid");
        else
            System.out.println("Input string is not valid: "+
            xmlValidator.getLastErrorMessage());
    }

    static void RunXSLT() throws com.altova.raptorxml.RaptorXMLException {
        System.out.println("RaptorXML Java - XSL Transformation");
    }
}
```
```java
com.altova.raptorxml.XSLT xsltEngine = rxml.getXSLT();
xsltEngine.setInputXMLFileName( strExamplesFolder + "simple.xml" );
xsltEngine.setXSLFileName( strExamplesFolder + "transform.xsl" );
String result = xsltEngine.executeAndGetResultAsString();
if( result == null )
    System.out.println( "Transformation failed: " +
xsltEngine.getLastErrorMessage() );
else
    System.out.println( "Result is " + result );
}

static void RunXQuery() throws com.altova.raptorxml.RaptorXMLException
{
    System.out.println("RaptorXML Java - XQuery execution");
    com.altova.raptorxml.XQuery xqEngine = rxml.getXQuery();
xqEngine.setInputXMLFileName( strExamplesFolder + "simple.xml" );
xqEngine.setXQueryFileName( strExamplesFolder + "CopyInput.xq" );
System result = xqEngine.executeAndGetResultAsString();
if( result == null )
    System.out.println( "Execution failed: " +
xqEngine.getLastErrorMessage() );
else
    System.out.println( "Result is " + result );
}

public static void main(String[] args)
{
    try
    {
        rxml = com.altova.raptorxml.RaptorXML.getFactory();
rxml.setErrorLimit( 3 );
        ValidateXML();
        RunXSLT();
        RunXQuery();
    }
    catch( com.altova.raptorxml.RaptorXMLException e )
    {
        e.printStackTrace();
    }
}
```
4.4 Server API Reference

This section describes the RaptorXML+XBRL Server API: its object model and the details of its interfaces and enumerations. The API description applies to both the COM/.NET and Java interfaces. While the structure of the API is the same for both interfaces, the names of methods and properties are different. For this reason, each method, property, and enumeration is described with a separate signature for COM/.NET and Java.

The starting point for using the functionality of RaptorXML+XBRL Server is the `IServer` interface (COM/.NET) or `RaptorXMLFactory` class (Java).
4.4.1 Interfaces/Classes

The starting point for using the functionality of RaptorXML is the **IServer** interface (COM/.NET) or **RaptorXMLFactory** class (Java). This object contains the objects that provide the RaptorXML functionality: XML validation, XBRL validation, XQuery document and XML Signature processing, and XSLT transformations.

The hierarchy of the object model is shown below, and the interfaces are described in detail in the corresponding sections. The methods and properties of each interface are described in the section for that interface.

**IServer (COM/.NET) / RaptorXMLFactory (Java)**

| -- IXBRL (COM/.NET) / XBRL (Java) |
| -- IXMLDSig (COM/.NET) / XMLDSig (Java) |
| -- IXMLValidator (COM/.NET) / XMLValidator (Java) |
| -- IXSLT (COM/.NET) / XSLT (Java) |
| -- IXQuery (COM/.NET) / XQuery (Java) |

### 4.4.1.1 IServer/RaptorXMLFactory

Use the **IServer/RaptorXMLFactory** interface to access the RaptorXML engine that you want. Note that the name of the interface in the COM/.NET API is different than that of the interface in the Java API:

- In COM/.NET: **IServer**
- In Java: **RaptorXMLFactory**

The methods and properties of **IServer/RaptorXMLFactory** are described in this section.

#### Java API entry-point method

The Java API is packaged in the `com.altova.raptorxml` package. The **RaptorXML** class provides an entry-point method called `getFactory()`, which returns **RaptorXMLFactory** objects. So, a **RaptorXMLFactory** instance can be created with the call: `RaptorXML.getFactory()`.

### Methods

The methods of the **IServer** (COM/.NET) and **RaptorXMLFactory** (Java) interfaces return an instance of the respective RaptorXML engine or class: XBRL, XMLDSig, XML Validator, XSLT, and XQuery.

<table>
<thead>

<td>getXMLValidator</td>
</tr>
</tbody>
</table>
### GetXBRL

Returns an instance of the XBRL Engine.

**COM and .NET**

*Signature: IXBRL GetXBRL()*

**Java**

*Signature: public XBRL getXBRL()*

### GetXMLDSig (for XML Signatures)

Returns an instance of the XML Signature interface/class (XMLDSig).

**COM and .NET**

*Signature: IXMLDSig GetXMLDSig()*

**Java**

*Signature: public XMLDSig getXMLDSig()*

### GetXMLValidator

Returns an instance of the XML Validator Engine.

**COM and .NET**

*Signature: IXMLValidator GetXMLValidator()*

**Java**

*Signature: public XMLValidator getXMLValidator()*
**GetXQuery**

Returns an instance of the XQuery Engine.

**COM and .NET**

*Signature: **IXQuery** GetXQuery()*

**Java**

*Signature: **public** XQuery getXQuery()*

**GetXSLT**

Returns an instance of the XSLT Engine.

**COM and .NET**

*Signature: **IXSLT** GetXSLT()*

**Java**

*Signature: **public** XSLT getXSLT()*

**Properties**

The properties of the **IServer (COM/.NET)** and **RaptorXMLFactory (Java)** interfaces are described in this section.

</tbody>
</table>

**APIMajorVersion**

Returns the major version of the API as an integer. The API major version can be different from the product's major version if the API is connected to another server.

**COM and .NET**

*Signature:* `int APIMajorVersion()`

**Java**

*Signature:* `public int getAPIMajorVersion()`

**APIMinorVersion**

Returns the minor version of the API as an integer. The API minor version can be different from the product's minor version if the API is connected to another server.

**COM and .NET**

*Signature:* `int APIMinorVersion()`

**Java**

*Signature:* `public int getAPIMinorVersion()`
**APIServicePackVersion**

Returns the service pack version of the API as an integer. The service pack version of the API can be different from the product's service pack version if the API is connected to another server.

**COM and .NET**

*Signature:* `int APIServicePackVersion()`

**Java**

*Signature:* `public int getAPIServicePackVersion()`

---

**ErrorFormat**

Sets the RaptorXML error format to one of the `ENUMErrorFormat` literals (Text, ShortXML, LongXML).

**COM and .NET**

*Signature:* `ErrorFormat(ENUMErrorFormat format)`

**Java**

*Signature:* `public void setErrorFormat(ENUMErrorFormat format)`

---

**ErrorLimit**

Sets the RaptorXML validation error limit. The `limit` parameter is of type `int` (Java), `uint` (COM/.NET), and specifies the number of errors to be reported before execution is halted. Use `-1` to set `limit` to be unlimited (that is, all errors will be reported). The default value is `100`.

**COM and .NET**

*Signature:* `ErrorLimit(uint limit)`

**Java**

*Signature:* `public int setErrorLimit(int limit)`

---

**GlobalCatalog**

Sets the location, as a URL, of the main (entry-point) catalog file. The supplied string must be an absolute URL that gives the exact location of the main catalog file to use.
**COM and .NET**

*Signature:* `GlobalCatalog(string catalog)`

**Java**

*Signature:* `public void setGlobalCatalog(string catalog)`

**GlobalResourceConfig**

Sets the active configuration of the global resource. The `config` parameter is of type `String`, and specifies the name of the configuration used by the active global resource.

**COM and .NET**

*Signature:* `GlobalResourceConfig(string config)`

**Java**

*Signature:* `public void setGlobalResourceConfig(string config)`

**GlobalResourcesFile**

Sets the location, as a URL, of the Global Resources XML File. The supplied string must be an absolute URL that gives the exact location of the Global Resources XML File.

**COM and .NET**

*Signature:* `GlobalResourcesFile(string url)`

**Java**

*Signature:* `public void setGlobalResourcesFile(string url)`

**Is64Bit**

Checks if the application is a 64-bit executable. Returns boolean `true` if the application is 64 bit, `false` if it is not. **Example:** For Altova RaptorXML+XBRL Server 2019r2sp1(x64), returns `true`. If an error occurs, a `RaptorXMLException` is raised.

**COM and .NET**
**Signature:** boolean Is64Bit()

Java

**Signature:** public boolean is64Bit()

**MajorVersion**

Returns the major version of the product as an integer. *Example:* For Altova RaptorXML+XBRL Server 2018r2sp1(x64), returns 20 (the difference between the major version (2018) and the initial year 1998). If an error occurs, a `RaptorXMLException` is raised.

**COM and .NET**

**Signature:** int MajorVersion()

Java

**Signature:** public int getMajorVersion()

**MinorVersion**

Returns the minor version of the product as an integer. *Example:* For Altova RaptorXML+XBRL Server 2019r2sp1(x64), returns 2 (from the minor version number r2). If an error occurs, a `RaptorXMLException` is raised.

**COM and .NET**

**Signature:** int MinorVersion()

Java

**Signature:** public int getMinorVersion()

**ProductName**

Returns the name of the product as a string. *Example:* For Altova RaptorXML+XBRL Server 2019r2sp1(x64), returns Altova RaptorXML+XBRL Server. If an error occurs, a `RaptorXMLException` is raised.

**COM and .NET**

**Signature:** string ProductName()
Java

Signature: public string getProductName()

ProductNameAndVersion

Returns the product name, major version, minor version, and service pack version of the product as a string. Example: For Altova RaptorXML+XBRL Server 2019r2sp1(x64), returns Altova RaptorXML+XBRL Server 2019r2sp1(x64). If an error occurs, a RaptorXMLException is raised.

COM and .NET

Signature: string ProductNameAndVersion()

Java

Signature: public string getProductNameAndVersion()

ReportOptionalWarnings

Enables/disables the reporting of warnings. A value of true enables warnings; false disables them.

COM and .NET

Signature: ReportOptionalWarnings(boolean report)

Java

Signature: public void setReportOptionalWarnings(boolean report)

ServerName

Sets the name of the HTTP server through which the connection to RaptorXML+XBRL Server is made. The input parameter is a string that gives the name of the HTTP server. If an error occurs, a RaptorXMLException is raised.

COM and .NET

Signature: ServerName(string name)
Java

Signature: `public void setServerName(string name)`

**ServerPath**

Specifies, in the form of a URL, the path to the HTTP server.

COM and .NET

Signature: `ServerPath(string path)`

Java

Signature: `public void setServerPath(string path)`

**ServerPort**

Sets the port on the HTTP server via which the service is accessed. The port must be fixed and known so that HTTP requests can be correctly addressed to the service. The input parameter is an integer that specifies the access port on the HTTP server. If an error occurs, a `RaptorXMLException` is raised.

COM and .NET

Signature: `ServerPort(int port)`

Java

Signature: `public void setServerPort(int port)`

**ServicePackVersion**

Returns the service pack version of the product as an integer. Example: For RaptorXML+XBRL Server 2019r2sp1(x64), returns 1 (from the service pack version number sp1). If an error occurs, a `RaptorXMLException` is raised.

COM and .NET

Signature: `int ServicePackVersion()`
Java

Signature: `public int getServicePackVersion()`

UserCatalog

Sets the location, as a URL, of the custom user catalog file. The supplied string must be an absolute URL that gives the exact location of the custom catalog file to use.

COM and .NET

Signature: `UserCatalog(string userCatalog)`

Java

Signature: `public void setUserCatalog(string userCatalog)`

4.4.1.2 RaptorXMLException

Generates an exception that contains information about an error that occurs during processing. The `message` parameter provides information about the error.

COM and .NET

Signature: `RaptorXMLException(string message)`

Java

Signature: `public void RaptorXMLException(string message)`

4.4.1.3 XBRL

The `IXBRL/XBRL` interface/class provides methods to validate XBRL instance and taxonomy documents, as well as methods to evaluate formulas and generate XBRL tables. Validations results are boolean `true` or `false`. The interface also enables formula parameters to be passed through for formula evaluation. Formula assertions and formula output can also be read and be returned as strings. The properties of the interface define its parameters.

Note that the name of the interface in the COM/.NET API is different than that of the class in the Java API:

- In COM/.NET: `IXBRL`
- In Java: `XBRL`
**Note:** Where string inputs are to be interpreted as URLs, absolute paths should be used. If a relative path is used, a mechanism to resolve the relative path should be defined in the calling module.

**COM/.NET structures**
The following COM/.NET structure is defined.

```csharp
public struct XBRLParamValuePair
{
    String ParamType;
    String ParamValue;
};
```

**Java utility class**
The following Java utility class is defined.

```java
public class ParamValuePair
{
    public String paramType;
    public String paramValue;
    public ParamValuePair( String type, String value )
    {
        paramType = type;
        paramValue = value;
    }
};
```

**Methods**
The methods of the IXBRL interface (COM/.NET) and XBRL class (Java) are described in this section.

<table>

</tbody>
</table>
AddTableForProcessing

Limits assertion evaluation to the given assertion only. Call multiple times to specify more than one assertion. The supplied string holds the name of the assertion set. Use **none** for no assertion, and **all** for all assertions.

**COM and .NET**

*Signature:* `AddTableForProcessing(string assertion)`

**Java**

*Signature:* `public void addTableForProcessing(string assertion)`

AddTaxonomyPackage

ClearPythonScriptFiles

ClearPythonScriptFiles

ClearTaxonomyPackage

ClearTaxonomyPackage

IsValid

isValid

ReadFormulaAsssertions

readFormulaAsssertions

ReadFormulaOutput

readFormulaOutput

AddAssertionForProcessing

Limits assertion execution to the given assertion only. Call multiple times to specify more than one assertion set. The supplied string holds the name of the assertion set. Use **none** for processing no assertion set and **all** for processing all assertion sets.

**COM and .NET**

*Signature:* `AddAssertionForProcessing(string assertion)`

**Java**

*Signature:* `public void addAssertionForProcessing(string assertion)`

AddAssertionSetForProcessing

Limits assertion set execution to the given assertion set only. Call multiple times to specify more than one assertion set. The supplied string holds the name of the assertion set. Use **none** for processing no assertion set and **all** for processing all assertion sets.

**COM and .NET**

*Signature:* `AddAssertionSetForProcessing(string assertionSet)`

**Java**

*Signature:* `public void add AssertionSetForProcessing(string assertionSet)`
**Signature:** public void addAssertionSetForProcessing(string assertionSet)

**AddExternalDTS**

Specifies the URL of an external DTS (Discoverable Taxonomy Set) that will be used for XBRL evaluation.

**COM and .NET**

**Signature:** AddExternalDTS(string DTS)

**Java**

**Signature:** public void addExternalDTS(string DTS)

**AddFormulaArrayParameter**

Adds an array-parameter used in the formula evaluation process. All the arguments are strings:

- **type** is the default datatype of non-pair values inside array values; default is xs:string;
- **name** is the parameter's name;
- **values** is an array of value and datatype-value pairs.

For more information and code samples, see the section, [XBRL Formula Parameters](#).

**COM and .NET**

**Signature:** AddFormulaArrayParameter(string type, string name, object[] values)

**Java**

**Signature:** public void addFormulaArrayParameter(string type, string name, object[] values)

**AddFormulaForProcessing**

Limits formula execution to the given formula only. Call multiple times to specify more than one formula. The supplied string holds the name of the formula. Use `##none` for processing no formula and `##all` for processing all formulas.

**COM and .NET**

**Signature:** AddFormulaForProcessing(string formula)
Java

Signature: public void addFormulaForProcessing(string formula)

AddFormulaParameter

Adds a parameter used in the formula evaluation process. Each parameter must be specified in a separate call to the method. If this method is used, the namespace is passed to addFormulaParameterNamespace.

All the arguments are strings:

- **type** is a string that gives the parameter's datatype;
- **name** is the parameter's name;
- **value** is a string that gives the parameter's value;
- **namespace** is a string that gives the parameter's namespace; default is the empty string.

For more information and code samples, see the section, XBRL Formula Parameters.

COM and .NET

Signature: AddFormulaParameter(string type, string name, string value, string namespace)

Java

Signature: public void addFormulaParameter(string type, string name, string value, string namespace)

AddFormulaParameterNamespace

Defines a namespace used in the QNames of parameter names, types, or values. All the arguments are strings:

- **prefix** is the namespace-prefix of values passed to addFormulaArrayParameter;
- **uri** is the namespace URI to use.

For more information and code samples, see the section, XBRL Formula Parameters.

COM and .NET

Signature: AddFormulaParameterNamespace(string prefix, string uri)

Java

Signature: public void addFormulaParameterNamespace(string prefix, string uri)
AddIXBRLTransformationRegistryLimit

Limit the available Inline XBRL Transformation Registries to the specified version. The limit parameter is the version to which available Inline XBRL Registries are limited.

COM and .NET

*Signature:* `AddIXBRLTransformationRegistryLimit(string version)`

Java

*Signature:* `public void addIXBRLTransformationRegistryLimit(string version)`

AddPythonScriptFile

Specifies the Python script file that provides additional processing of the file submitted for validation. The supplied string must be an absolute URL of the Python script. The Python script will be processed with a Python package that is bundled with RaptorXML+XBRL Server. The bundled Python package is version 3.5.

COM and .NET

*Signature:* `AddPythonScriptFile(string filepath)`

Java

*Signature:* `public void addPythonScriptFile(string filepath)`

AddTableForProcessing

Limits table generation to the given table only. Call multiple times to specify more than one table. The supplied string holds the name of the table. Use `##none` for processing no table and `##all` for processing all tables.

COM and .NET

*Signature:* `AddTableForProcessing(string table)`

Java

*Signature:* `public void addTableForProcessing(string table)`
**AddTaxonomyPackage**  
Specifies the URL of a taxonomy package to use for XBRL evaluation.

**COM and .NET**

*Signature:* `AddTaxonomyPackage(string package)`

**Java**

*Signature:* `public void addTaxonomyPackage(string package)`

---

**ClearExternalDTS**  
Removes any external DTS list previously specified with `AddExternalDTS`.

**COM and .NET**

*Signature:* `ClearExternalDTS()`

**Java**

*Signature:* `public void clearExternalDTS()`

---

**ClearFormulaParameterList**  
Removes any formula parameter list previously specified with `AddFormulaParameter`.

**COM and .NET**

*Signature:* `ClearFormulaParameterList()`

**Java**

*Signature:* `public void clearFormulaParameterList()`

---

**ClearIXBRLTransformationRegistryLimit**  
Removes any limit specified for Inline XBRL Transformation Registries previously specified with `AddIXBRLTransformationRegistryLimit`.

**COM and .NET**
Signature: `ClearIXBRLTransformationRegistryLimit()`

Java

Signature: `public void clearIXBRLTransformationRegistryLimit()`

**ClearPythonScriptFiles**

Clears Python script files added with the `AddPythonScriptFile` method or `PythonScriptFile` property.

COM and .NET

Signature: `ClearPythonScriptFile()`

Java

Signature: `public void clearPythonScriptFile()`

**ClearTaxonomyPackage**

Removes any reference to a taxonomy package previously specified with `AddTaxonomyPackage`.

COM and .NET

Signature: `ClearTaxonomyPackage()`

Java

Signature: `public void clearTaxonomyPackage()`

**EvaluateFormula**

Returns the result of evaluating XBRL formulas in an XBRL instance file. The result is `true` on success, `false` on failure. If an error occurs, a `RaptorXMLException` is raised. Use the `LastErrorMessage` property to access additional information.

COM and .NET

Signature: `boolean EvaluateFormula()`

Java
**Signature:** public boolean evaluateFormula()

**GenerateTables**
Evaluates XBRL tables in an instance file. The result is true on success, false on failure. If an error occurs, a RaptorXMLException is raised. Use the LastErrorMessage property to access additional information.

**COM and .NET**

**Signature:** boolean GenerateTables()

**Java**

**Signature:** public boolean generateTables()

**IsValid**
The type of XBRL document to validate is specified by the type parameter, which takes an ENUMXBRLValidationType literal as its value. The result is true on success, false on failure. If an error occurs, a RaptorXMLException is raised. Use LastErrorMessage to access additional information.

**COM and .NET**

**Signature:** boolean IsValid(ENUMXBRLValidationType type)

**Java**

**Signature:** public boolean isValid(ENUMXBRLValidationType type)

**ReadFormulaAssertions**
Retrieves formula assertions from the file being evaluated, and returns a string containing the formula assertions.

**COM and .NET**

**Signature:** string ReadFormulaAssertions()

**Java**

**Signature:** public string readFormulaAssertions()
ReadFormulaOutput
Reads the output of the file's formula assertions, and returns a string containing the output.

COM and .NET

Signature: string ReadFormulaOutput()

Java

Signature: public string readFormulaOutput()

Properties
The properties of the IXBRL interface (COM/.NET) and XBRL class (Java) are described in this section.

ConceptLabelLinkrole
Specifies the preferred extended link role to use when rendering concept labels. The supplied string holds the preferred link role.

COM and .NET

Signature: ConceptLabelLinkrole(string labelLinkrole)

Java

Signature: public void setConceptLabelLinkrole(string labelLinkrole)

ConceptLabelRole
Specifies the preferred label role to use when rendering concept labels. The supplied string holds the preferred label role. Default is: http://www.xbrl.org/2008/role/label.

COM and .NET

Signature: ConceptLabelRole(string labelRole)

Java

Signature: public void setConceptLabelRole(string labelRole)
**DimensionExtensionEnabled**

Enables XBRL Dimension extension validation. Takes boolean `true` or `false`. A value of `true` enables support; `false` disables it. Default is `true`.

**COM and .NET**

*Signature:* `DimensionExtensionEnabled(boolean enable)`

**Java**

*Signature:* `public void setDimensionExtensionEnabled(boolean enable)`

**EvaluateReferencedParametersOnly**

If set to `false`, forces evaluation of all parameters even if they are not referenced by any formulas/ assertions/tables. Default is `true`.

**COM and .NET**

*Signature:* `EvaluateReferenceParametersOnly(boolean evaluate)`

**Java**

*Signature:* `public void setEvaluateReferenceParametersOnly(boolean evaluate)`

**ExtensibleEnumerationsEnabled**

Enables extensible enumerations. Takes boolean `true` or `false`. A value of `true` enables support; `false` disables it.

**COM and .NET**

*Signature:* `ExtensionEnumerationsEnabled(boolean enable)`

**Java**

*Signature:* `public void setExtensionEnumerationsEnabled(boolean enable)`
**FormulaAssertionsAsXML**

Enables XML formatting of the assertion file when RaptorXML+XBRL is run with assertions enabled. A value of `true` enables XML output; `false` generates JSON output. Default is `false`.

**COM and .NET**

*Signature:* `FormulaAssertionsAsXML(boolean enable)`

**Java**

*Signature:* `public void setFormulaAssertionsAsXML(boolean enable)`

**FormulaAssertionsOutput**

Specifies the location of the file containing the retrieved formula assertions. The `outputFile` argument is a string that holds the full path of the output file.

**COM and .NET**

*Signature:* `FormulaAssertionsOutput(string outputFile)`

**Java**

*Signature:* `public void setFormulaAssertionsOutput(string outputFile)`

**FormulaExtensionEnabled**

Enables XBRL formula extensions for validation. A value of `true` enables support; `false` disables it. Default is `true`.

**COM and .NET**

*Signature:* `FormulaExtensionEnabled(boolean enable)`

**Java**

*Signature:* `public void setFormulaExtensionEnabled(boolean enable)`

**FormulaOutput**

Sets the location of the file containing the output of formula evaluation. The supplied string holds the full path of the output file.
COM and .NET

*Signature:* `FormulaOutput(string file)`

Java

*Signature:* `public void setFormulaOutput(string file)`

**FormulaParameterFile**
Sets the location of the formula parameter file. The full path must be specified.

COM and .NET

*Signature:* `FormulaParameterFile(string file)`

Java

*Signature:* `public void setFormulaParameterFile(string file)`

**FormulaPreloadSchemas**
Defines whether XBRL formula schemas will be preloaded. A value of `true` preloads the schemas; `false` does not. The default value is `false`.

COM and .NET

*Signature:* `FormulaPreloadSchemas(boolean preload)`

Java

*Signature:* `public void setFormulaPreloadSchemas(boolean preload)`

**GenericLabelLinkrole**
Specifies the preferred extended link role to use when rendering generic labels. The supplied string holds the preferred link role.

COM and .NET

*Signature:* `GenericLabelLinkrole(string labelLinkrole)`
Java

Signature: public void setGenericLabelLinkrole(String labelLinkrole)

**GenericLabelRole**

Specifies the preferred label role to use when rendering generic labels. The supplied string holds the preferred label role. Default is: http://www.xbrl.org/2008/role/label.

COM and .NET

Signature: GenericLabelRole(String labelRole)

Java

Signature: public void setGenericLabelRole(String labelRole)

**InputFileArray**

Provides an array of URLs of the files to be used as input data. The array is an object containing the strings of the absolute URLs of each of the input files.

COM and .NET

Signature: InputFileArray(Object fileArray)

Java

Signature: public void setInputFileArray(Object fileArray)

**InputFileName**

Sets the location, as a URL, of the input data file to process. The supplied string must be an absolute URL that gives the location of the input file.

COM and .NET

Signature: InputFileName(String filepath)

Java

Signature: public void setInputFileName(String filepath)
InputFromText
Supplies a string that is the text content of the document to process.

COM and .NET
Signature: InputFromText(string doc)

Java
Signature: public void setInputFromText(string doc)

InputTextArray
Provides an array of the URLs of the text-files to be used as input data. The property supplies an object containing, as strings, the absolute URLs of each of the text files.

COM and .NET
Signature: InputTextArray(object textfileArray)

Java
Signature: public void setInputTextArray(object textfileArray)

IXBRLOutput
If specified, the generated XBRL output will be written to this path. The supplied string holds the absolute URL of the output location.

COM and .NET
Signature:IXBRLOutput(string outputFile)

Java
Signature: public void setIXBRLOutput(string outputFile)

IXBRLUriTransformationStrategy
Specifies how Inline XBRL URIs should be transformed in the generated XBRL document. The selected enumeration literal specifies the strategy to follow. The default enumeration is
eStrategyKeepRelative.

**COM and .NET**

*Signature:* `IXBRLUriTransformationStrategy(ENUMIXBRLUriStrategy strategy)`

**Java**

*Signature:* `public void setIXBRLUriTransformationStrategy(ENUMIXBRLUriStrategy strategy)`

**IXBRLValidateTarget**

Defines whether the IXBRL output will be validated. Takes boolean `true` or `false`.

**COM and .NET**

*Signature:* `IXBRLValidateTargetr(boolean validate)`

**Java**

*Signature:* `public void setIXBRLValidateTargetr(boolean validate)`

**IXBRLVersion**

Specifies the Inline XBRL version to use. Takes the `ENUMIXBRLVersion` literal that is specified.

**COM and .NET**

*Signature:* `IXBRLVersion(ENUMIXBRLVersion version)`

**Java**

*Signature:* `public void setIXBRLVersion(ENUMIXBRLVersion version)`

**LabelLang**

Specifies the preferred label language to use when rendering labels. The supplied string holds the preferred label language. Default is: `en`.

**COM and .NET**

*Signature:* `LabelLang(string lang)`
Java

*Signature:* `public void setLabelLang(string lang)`

**ParallelAssessment**

Enables or disables the use of parallel assessment. A value of `true` enables parallel assessment; `false` disables it. The default value is `false`.

COM and .NET

*Signature:* `ParallelAssessment(boolean enable)`

Java

*Signature:* `public void setParallelAssessment(boolean enable)`

**PreloadSchemas**

Defines whether XBRL 2.1 schemas will be pre-loaded. Takes boolean `true` or `false`. A value of `true` indicates preloads; `false` disables it. Default is `true`.

COM and .NET

*Signature:* `PreloadSchemas(boolean preload)`

Java

*Signature:* `public void setPreloadSchemas(boolean preload)`

**PreloadSchemasEnabled**

Defines whether XBRL 2.1 schemas will be pre-loaded. Takes boolean `true` or `false`. A value of `true` indicates preloads; `false` disables it. Default is `true`.

COM and .NET

*Signature:* `PreloadSchemasEnabled(boolean enable)`

Java

*Signature:* `public void setPreloadSchemasEnabled(boolean enable)`
PythonScriptFile

Specifies the Python script file that provides additional processing of the file submitted for validation. The supplied string must be an absolute URL of the Python script. The Python script will be processed with a Python package that is bundled with RaptorXML+XBRL Server. The bundled Python package is version 3.5.

COM and .NET

Signature: PythonScriptFile(string filepath)

Java

Signature: public void setPythonScriptFile(string filepath)

SchemaImports

Specifies how schema imports are to be handled based on the attribute values of the `$xs:import` elements. The kind of handling is specified by the `ENUMSchemaImports` literal that is submitted.

COM and .NET

Signature: SchemaImports(ENUMSchemaImports importOption)

Java

Signature: public void setSchemaImports(ENUMSchemaImports importOption)

SchemalocationHints

Specifies the mechanism to use to locate the schema. The mechanism is specified by the `ENUMLoadSchemalocation` literal that is selected.

COM and .NET

Signature: SchemalocationHints(ENUMSchemalocation hint)

Java

Signature: public void setSchemalocationHints(ENUMSchemalocation hint)
**SchemaMapping**

Sets what mapping to use in order to locate the schema. The mapping is specified by the `ENUMSchemaMapping` literal that is selected.

**COM and .NET**

*Signature:* `SchemaMapping(ENUMSchemaMapping mappingOption)`

**Java**

*Signature:* `public void setSchemaMapping(ENUMSchemaMapping mappingOption)`

**TableEliminateEmptyRows**

Enables the elimination of empty table rows/columns in HTML output only. A value of `true` enables support; `false` disables it.

**COM and .NET**

*Signature:* `TableEliminateEmptyRows(boolean enable)`

**Java**

*Signature:* `public void setTableEliminateEmptyRows(boolean enable)`

**TableExtensionEnabled**

Enables XBRL Table 1.0 extensions for validation. A value of `true` enables support; `false` disables it.

**COM and .NET**

*Signature:* `TableExtensionEnabled(boolean enable)`

**Java**

*Signature:* `public void setTableExtensionEnabled(boolean enable)`

**TableLinkbaseNamespace**

Enables the loading of table linkbases written with a previous draft specification. The `namespace` parameter specifies the table linkbase. Table linkbase validation, resolution, and layout is, however, always performed according to the Table Linkbase 1.0 Recommendation of 18 March...
2014. Use `##detect` to enable auto-detection.

The following values are recognized for the `namespace` parameter:

- `##detect`
- `http://xbrl.org/PWD/2013-05-17/table`
- `http://xbrl.org/PWD/2013-08-28/table`
- `http://xbrl.org/PR/2013-12-18/table`
- `http://xbrl.org/2014/table`

**COM and .NET**

*Signature:* `TableLinkbaseNamespace(string namespace)`

**Java**

*Signature:* `public void setTableLinkbaseNamespace(string namespace)`

**TableOutput**

Sets the location of the file containing the output of table generation. The supplied string holds the full path of the output file.

**COM and .NET**

*Signature:* `TableOutput(string outputFile)`

**Java**

*Signature:* `public void setTableOutput(string outputFile)`

**TableOutputFormat**

Sets the format of the table output file. The format will be a literal of `ENUMTableOutputFormat`.

**COM and .NET**

*Signature:* `TableOutputFormat(ENUMTableOutputFormat format)`

**Java**

*Signature:* `public void setTableOutputFormat(ENUMTableOutputFormat format)`
**TablePreloadSchemas**

Enables preloading of schemas of the XBRL Table 1.0 specification. A value of `true` enables support; `false` disables it. Default is `false`.

**COM and .NET**

*Signature:* `TablePreloadSchemas (boolean preload)`

**Java**

*Signature:* `public void setTablePreloadSchemas (boolean preload)`

---

**TaxonomyPackagesConfigFile**

Specifies the path to the `TaxonomyPackagesConfig.json` file, which is used to load XBRL taxonomy packages. The file's convenience is that it serves as a catalog of taxonomy packages. The structure of the JSON file is as in the example listing below. The value of the `uri` key gives the location of the package. The `active` key (of a set of packages) switches on usage of those packages.

```json
{"taxonomies":  {
    "EIOPA Solvency II XBRL Taxonomy 2.1.0":    {
        "packages": [
            "uri":"C:\test\XBRL\EIOPA_SolvencyII_XBRL_Taxonomy_2.1.0.zip"],
            "uri":"C:\test\XBRL\AdditionalTestPkg.zip"
        ],"active":true
    },
    "Test Taxonomy":    {
        "packages": [
            "uri":"C:\test\XBRL\test.zip"],"active":true
    }
}
```

**COM and .NET**

*Signature:* `TaxonomyPackagesConfigFile (string filepath)`

**Java**

*Signature:* `public void setTaxonomyPackagesConfigFile (string filepath)`

---

**TreatXBRLInconsistenciesAsErrors**

A value of `true` causes XBRL validation to fail if the file contains any inconsistencies as defined by the XBRL 2.1 specification. Takes boolean `true` or `false`. Default is `false`. When `false`, XBRL inconsistencies according to the XBRL 2.1 specification are not treated as errors.

**COM and .NET**
Signature: `TreatXBRLInconsistenciesAsErrors(boolean enable)`

Java

Signature: `public void setTreatXBRLInconsistenciesAsErrors(boolean enable)`

**UTREnabled**

If `true`, enables the XBRL Unit Registry 1.0 extension. Default is: `false`.

COM and .NET

Signature: `UTREnabled(boolean enable)`

Java

Signature: `public void setUTREnabled(boolean enable)`

**ValidateDTSOnly**

If set to `true`, the DTS is discovered by starting from the XBRL instance document. All referenced taxonomy schemas and linkbases are discovered and validated. The rest of the XBRL instance document is ignored. Default value is `false`.

COM and .NET

Signature: `ValidateDTSOnly(boolean dts)`

Java

Signature: `public void setValidateDTSOnly(boolean dts)`

**XincludeSupport**

Enables or disables the use of XInclude elements. A value of `true` enables XInclude support; `false` disables it. The default value is `false`.

COM and .NET

Signature: `XincludeSupport(boolean xinclude)`

Java
4.4.1.4 XMLDSig (for XML Signatures)

Methods of the IXMLDSig/XMLDSig interface/class can be used to sign XML documents, verify signed documents, update (with a new signature) previously signed documents that have been modified, and remove signatures.

Note that the name of the interface in the COM/.NET API is different than that of the class in the Java API:

- In COM/.NET: IXMLDSig
- In Java: XMLDSig

**Methods**

The methods of the IXMLDSig interface (COM/.NET) and XMLDSig class (Java) are described in this section.

**ExecuteRemove**

Removes the XML signature of the signed XML file, and saves the resulting unsigned document to an output location defined by `outputPath`, which is a string that provides the URL of the file location. The result is `true` on success, `false` on failure.

**COM and .NET**

*Signature:* `boolean ExecuteRemove(string outputPath)`

**Java**

*Signature:* `public boolean executeRemove(string outputPath)`

**ExecuteSign**

Signs the XML document according to the specified signing options (given in the `signatureType` and `canonicalizationMethod` parameters; see the `xmlsignature-sign CLI command for available values`). The output file is defined by `outputPath`, which is a string that provides the URL of the output file. The result is `true` on success, `false` on failure.

**COM and .NET**

*Signature:* `boolean ExecuteSign(string outputPath, string signatureType, string canonicalizationMethod)`
Java

Signature: `public boolean executeSign(String outputPath, String signatureType, String canonicalizationMethod)`

**ExecuteUpdate**

Updates the XML signature in the signed XML file. If the document has been modified, the updated XML signature will be different; otherwise, the updated signature will be the same as the previous signature. The output file is specified with `outputPath`, which is a string that provides the URL of the file with the updated signature. The result is `true` on success, `false` on failure.

Either (i) the **HMAC secret key** property or (ii) the **certificate-name** and **certificate-store** properties must be specified. If the certificate options are specified, then they must match those that were used to sign the XML document previously. (Note that the certificate-store option is currently not supported on Linux and macOS.)

**COM and .NET**

`Signature: boolean ExecuteUpdate(String outputPath)`

Java

Signature: `public boolean executeUpdate(String outputPath)`

**ExecuteVerify**

Returns the result of the signature verification: `true` if verification is successful, `false` otherwise.

**COM and .NET**

`Signature: boolean ExecuteVerify()`

Java

`Signature: public boolean executeVerify()`

**Properties**

The properties of the **IXMLDSig** interface (COM/.NET) and **XMLDSig** class (Java) are described in this section.
**AbsoluteReferenceUri**

Specifies whether the URI of the signed document is to be read as absolute (true) or relative (false). Default is false.

**COM and .NET**

*Signature:* `AbsoluteReferenceUri(boolean absoluteuri)`

**Java**

*Signature:* `public void setAbsoluteReferenceUri(boolean absoluteuri)`

**AppendKeyInfo**

Specifies whether to include the `KeyInfo` element in the signature or not. The default is false.

**COM and .NET**

*Signature:* `AppendKeyInfo(boolean include)`

**Java**

*Signature:* `public void setAppendKeyInfo(boolean include)`

**CertificateName**

The name of the certificate used for signing.

**Windows**

This is the **Subject** name of a certificate from the selected --certificate-store.

*Example to list the certificates (under PowerShell)*

```bash
% ls cert://CurrentUser/My
PSParentPath: Microsoft.PowerShell.Security\Certificate::CurrentUser\My
Thumbprint Subject
--------- -------
C9DF64BB0AAF5FA73474D78B7CCFFC37C95BFC6C CN=certificate1
... CN=...
```

*Example:* `--certificate-name==certificate1`

**Linux/MacOS**

`--certname` specifies the file name of a PEM encoded X.509v3 certificate with the private key. Such files usually have the extension .pem.
**Example:** --certificate-name=/path/to/certificate1.pem

**COM and .NET**

**Signature:** CertificateName(string name)

**Java**

**Signature:** public void setCertificateName(string name)

**CertificateStore**

The location where the certificate specified with `--certificate-name` is stored.

**Windows**

The name of a certificate store under `cert://CurrentUser`. The available certificate stores can be listed (under PowerShell) by using `% ls cert://CurrentUser/`. Certificates would then be listed as follows:

Name: TrustedPublisher
Name: ClientAuthIssuer
Name: Root
Name: UserDS
Name: CA
Name: ACRS
Name: REQUEST
Name: AuthRoot
Name: MSIEHistoryJournal
Name: TrustedPeople
Name: MyCertStore
Name: Local NonRemovable Certificates
Name: SmartCardRoot
Name: Trust
Name: Disallowed

**Example:** --certificate-store=MyCertStore

**Linux/MacOS**

The `--certstore` option is currently not supported.

**COM and .NET**

**Signature:** CertificateStore(string filelocation)

**Java**
**DigestMethod**

The algorithm that is used to compute the digest value over the input XML file. Available values are: `sha1|sha256|sha384|sha512|base64`.

**COM and .NET**

**Signature**: `DigestMethod(string algo)`

**Java**

**Signature**: `public void setDigestMethod(string algo)`

**HMACOutputLength**

Truncates the output of the HMAC algorithm to `length` bits. If specified, this value must be a multiple of 8, larger than 80, and larger than half of the underlying hash algorithm's output length.

**COM and .NET**

**Signature**: `HMACOutputLength(int length)`

**Java**

**Signature**: `public void setHMACOutputLength(int length)`

**HMACSecretKey**

The HMAC shared secret key; must have a minimum length of six characters.

**COM and .NET**

**Signature**: `HMACSecretKey(string key)`

**Java**

**Signature**: `public void setHMACSecretKey(string key)`
**InputXMLFileName**

Sets the location, as a URL, of the XML document to process. The supplied string must be an absolute URL that gives the exact location of the XML file.

**COM and .NET**

*Signature:* `InputXMLFileName(string filepath)`

**Java**

*Signature:* `public void setInputXMLFileName(string filepath)`

**LastErrorErrorMessage**

Retrieves a string that is the last error message from the RaptorXML engine.

**COM and .NET**

*Signature:* `string LastErrorMessage()`

**Java**

*Signature:* `public string getLastErrorMessage()`

**SignatureMethod**

Specifies the algorithm to use for generating the signature.

*When a certificate is used*  
If a certificate is specified, then `SignatureMethod` is optional and the value for this parameter is derived from the certificate. If specified, it must match the algorithm used by the certificate.  
*Example:* `rsa-sha256`.

*When --hmac-secret-key is used*  
When `HMACSecretKey` is used, then `SignatureMethod` is mandatory. The value must be one of the supported HMAC algorithms:

- `hmac-sha256`
- `hmac-sha386`
- `hmac-sha512`
- `hmac-sha1` *(discouraged by the specification)*

*Example:* `hmac-sha256`

**COM and .NET**
**Signature:** `SignatureMethod(string algo)`

Java

**Signature:** `public void setSignatureMethod(string algo)`

**Transforms**

Specifies the XML Signature transformations applied to the input document. The supported values are:

- `REC-xml-c14n-20010315` for Canonical XML 1.0 (omit comments)
- `xml-c14n11` for Canonical XML 1.1 (omit comments)
- `xml-exc-c14n#` for Exclusive XML Canonicalization 1.0 (omit comments)
- `REC-xml-c14n-20010315#WithComments` for Canonical XML 1.0 (with comments)
- `xml-c14n11#WithComments` for Canonical XML 1.1 (with comments)
- `xml-exc-c14n#WithComments` for Exclusive XML Canonicalization 1.0 (with comments)
- `base64`
- `strip-whitespaces` Altova extension

**COM and .NET**

**Signature:** `Transforms(string value)`

Java

**Signature:** `public void setTransforms(string value)`

**WriteDefaultAttributes**

Specifies whether to include default attribute values from the DTD in the signed document.

**COM and .NET**

**Signature:** `WriteDefaultAttributes(boolean write)`

Java

**Signature:** `public void setWriteDefaultAttributes(boolean write)`

### 4.4.5 XMLValidator

The `IXMLValidator/XMLValidator` interface/class provides methods to (i) validate various types of documents, (ii) check documents for well-formedness, and (iii) extract an Avro schema from an
Avro binary. You can also provide additional processing via a Python script.

Note that the name of the interface in the COM/.NET API is different than that of the class in the Java API:

- In COM/.NET: `IXMLValidator`
- In Java: `XMLValidator`

### Methods

The methods of the `IXMLValidator` interface (COM/.NET) and `XMLValidator` class (Java) are described in this section.

#### AddPythonScriptFile

Specifies the Python script file that provides additional processing of the file submitted for validation. The supplied string must be an absolute URL of the Python script. The Python script will be processed with a Python package that is bundled with RaptorXML+XBRL Server. The bundled Python package is version 3.5.

**COM and .NET**

*Signature:* `AddPythonScriptFile(string filepath)`

**Java**

*Signature:* `public void addPythonScriptFile(string filepath)`

#### ClearPythonScriptFile

Clears Python script files added with the `AddPythonScriptFile` method or `PythonScriptFile` property.

**COM and .NET**

*Signature:* `ClearPythonScriptFile()`

**Java**

*Signature:* `public void clearPythonScriptFile()`

#### ExtractAvroSchema

Extracts an Avro schema from a binary file. The `outputPath` parameter is an absolute URL that specifies the output location. The result is `true` on success, `false` on failure. If an error occurs,
a **RaptorXMLException** is raised. Use **LastErrorMessage** to access additional information.

**COM and .NET**

*Signature:* **ExtractAvroSchema**(string outputPath)

**Java**

*Signature:* **public void** addPythonScriptFile**(string outputPath)**

**isValid**

Returns the result of validating the XML document, schema document, or DTD document. The type of document to validate is specified by the **type** parameter, which takes an **ENUMValidationType** literal as its value. The result is **true** on success, **false** on failure. If an error occurs, a **RaptorXMLException** is raised. Use **LastErrorMessage** to access additional information.

**COM and .NET**

*Signature:* **boolean** IsValid**(ENUMValidationType type)**

**Java**

*Signature:* **public boolean** isValid**(ENUMValidationType type)**

**isWellFormed**

Returns the result of checking the XML document or DTD document for well-formedness. The type of document to check is specified by the **type** parameter, which takes an **ENUMWellformedCheckType** literal as its value. The result is **true** on success, **false** on failure. If an error occurs, a **RaptorXMLException** is raised. Use **LastErrorMessage** to access additional information.

**COM and .NET**

*Signature:* **boolean** isWellFormed**(ENUMWellformedCheckType type)**

**Java**

*Signature:* **public boolean** isWellFormed**(ENUMWellformedCheckType type)**
Properties

The properties of the `IXMLValidator` interface (COM/.NET) and `XMLValidator` class (Java) are described in this section.

AssessmentMode

Sets the assessment mode of the XML validation (Strict/Lax), which is given by an `ENUMAssessmentMode` literal.

**COM and .NET**

*Signature:* `AssessmentMode(ENUMAssessmentMode mode)`

**Java**

*Signature:* `public void setAssessmentMode(ENUMAssessmentMode mode)`

AvroSchemaFileName

Sets the location, as a URL, of the external Avro Schema to use. The supplied string must be an absolute URL that gives the exact location of the Avro Schema file.

**COM and .NET**

*Signature:* `AvroSchemaFileName(string url)`

**Java**

*Signature:* `public void setAvroSchemaFileName(string url)`

AvroSchemaFromText

Supplies a string that is the text content of the Avro Schema document to use.

**COM and .NET**

*Signature:* `AvroSchemaFromText(string avroschema)`

**Java**

*Signature:* `public void setAvroSchemaFromText(string avroschema)`
**DTDFilename**

Sets the location, as a URL, of the DTD document to use for validation. The supplied string must be an absolute URL that gives the exact location of the DTD document.

**COM and .NET**

*Signature:* `DTDFilename(string url)`

**Java**

*Signature:* `public void setDTDFilename(string url)`

**DTDFromText**

Supplies a string that is the text content of the DTD document to use for validation.

**COM and .NET**

*Signature:* `DTDFromText(string dtdtext)`

**Java**

*Signature:* `public void setDTDFromText(string dtdtext)`

**EnableNamespaces**

Enables namespace-aware processing. This is useful for checking the XML instance for errors due to incorrect namespaces. A value of true enables namespace-aware processing; false disables it. The default is false.

**COM and .NET**

*Signature:* `EnableNamespaces(boolean enableNS)`

**Java**

*Signature:* `public void setEnableNamespaces(boolean enableNS)`

**InputFileArray**

Provides an array of URLs of the files to be used as input data. The array is an object containing the strings of the absolute URLs of each of the input files.
COM and .NET

Signature: InputFileArray(object fileArray)

Java

Signature: public void setInputFileArray(object fileArray)

InputFileCollection

Supplies the collection of XML files that will be used as input data. The files are identified by their URLs. A collection of strings is submitted; each string is the absolute URL of an input XML file.

COM and .NET

Signature: InputFileCollection(collection? urlCollection)

Java

Signature: public void setInputFileCollection(collection? urlCollection)

InputFileName

Sets the location, as a URL, of the input data file to process. The supplied string must be an absolute URL that gives the location of the input file.

COM and .NET

Signature: InputFileName(string filepath)

Java

Signature: public void setInputFileName(string filepath)

InputFromText

Supplies a string that is the text content of the document to process.

COM and .NET

Signature: InputFromText(string doc)
Java

Signature: public void setInputFromText(string doc)

**InputTextArray**

Provides an array of the URLs of the text-files to be used as input data. The property supplies an object containing, as strings, the absolute URLs of each of the text files.

**COM and .NET**

Signature: InputTextArray(object textfileArray)

Java

Signature: public void setInputTextArray(object textfileArray)

**InputTextCollection**

Supplies the content of multiple XML files that will be used as input data. A collection of strings, each of which is the content of an input XML file.

**COM and .NET**

Signature: InputTextCollection(collection? textCollection)

Java

Signature: public void setInputTextCollection(collection? textCollection)

**InputXMLFileName**

Sets the location, as a URL, of the XML document to process. The supplied string must be an absolute URL that gives the exact location of the XML file.

**COM and .NET**

Signature: InputXMLFileName(string url)

Java

Signature: public void setInputXMLFileName(string url)
**InputXMLFromText**
Supplies a string that is the text content of the XML document to process.

**COM and .NET**

*Signature:* `InputXMLFromText(string xml)`

**Java**

*Signature:* `public void setInputXMLFromText(string xml)`

**Json5**
If set to `true`, enables JSON 5 support.

**COM and .NET**

*Signature:* `Json5(boolean json5)`

**Java**

*Signature:* `public void setJson5(boolean json5)`

**JSONSchemaFileName**
Sets the location, as a URL, of the JSON Schema file that will be used for JSON instance-document validation. The supplied string must be an absolute URL that gives the exact location of the JSON Schema file.

**COM and .NET**

*Signature:* `JSONSchemaFileName(string url)`

**Java**

*Signature:* `public void setJSONSchemaFileName(string url)`

**JSONSchemaFromText**
Supplies a string that is the text content of the JSON Schema document that will be used for validation of the JSON instance document.
COM and .NET

**Signature:** JSONSchemaFromText(`string jsonschema`)

Java

**Signature:** `public void setJSONSchemaFromText(string jsonschema)`

**LastErrorMessage**
Retrieves a string that is the last error message from the RaptorXML engine.

COM and .NET

**Signature:** `string LastErrorMessage()`

Java

**Signature:** `public string getLastErrorMessage()`

**ParallelAssessment**
Enables/disables parallel schema validity assessment.

COM and .NET

**Signature:** `ParallelAssessment(boolean enable)`

Java

**Signature:** `public void setParallelAssessment(boolean enable)`

**PythonScriptFile**
Specifies the Python script file that provides additional processing of the file submitted for validation. The supplied string must be an absolute URL of the Python script. The Python script will be processed with a Python package that is bundled with RaptorXML+XBRL Server. The bundled Python package is version 3.5.

COM and .NET

**Signature:** `PythonScriptFile(string filepath)`
Java

Signature: `public void setPythonScriptFile(string filepath)`

**SchemaFileArray**

Supplies the collection of XML Schema files that will be used as external XML Schemas. The files are identified by their URLs. The input is a collection of strings, each of which is the absolute URL of an XML Schema file.

**COM and .NET**

Signature: `SchemaFileArray(object urlArray)`

**Java**

Signature: `public void setSchemaFileArray(object urlArray)`

**SchemaFileName**

Sets the location, as a URL, of the XML Schema document to be used for validation. The supplied string must be an absolute URL that gives the exact location of the XML Schema file.

**COM and .NET**

Signature: `SchemaFileName(string filepath)`

**Java**

Signature: `public void setSchemaFileName(string filepath)`

**SchemaFromText**

Supplies a string that is the text content of the XML Schema document to use for validation of the XML instance document.

**COM and .NET**

Signature: `SchemaFileName(string xsdText)`

**Java**
**Signature:** public void setSchemaFileName(string xsdText)

**SchemaImports**

Specifies how schema imports are to be handled based on the attribute values of the `xs:import` elements. The kind of handling is specified by the `ENUMSchemaImports` literal that is submitted.

**COM and .NET**

**Signature:** SchemaImports(ENUMSchemaImports importOption)

**Java**

**Signature:** public void setSchemaImports(ENUMSchemaImports importOption)

**SchemalocationHints**

Specifies the mechanism to use to locate the schema. The mechanism is specified by the `ENUMLoadSchemalocation` literal that is selected.

**COM and .NET**

**Signature:** SchemalocationHints(ENUMSchemalocation hint)

**Java**

**Signature:** public void setSchemalocationHints(ENUMSchemalocation hint)

**SchemaMapping**

Sets what mapping to use in order to locate the schema. The mapping is specified by the `ENUMSchemaMapping` literal that is selected.

**COM and .NET**

**Signature:** SchemaMapping(ENUMSchemaMapping mappingOption)

**Java**

**Signature:** public void setSchemaMapping(ENUMSchemaMapping mappingOption)
**SchemaTextArray**

Supplies the content of multiple XML Schema files. The input is a collection of strings, each of which is the content of an XML Schema document.

**COM and .NET**

*Signature:* `SchemaTextArray(object schemaDocs)`

**Java**

*Signature:* `public void setSchemaTextArray(object schemaDocs)`

**Streaming**

Enables streaming validation. In streaming mode, data that is stored in memory is minimized and processing is faster. A value of `true` enables streaming; `false` disables it. Default is `true`.

**COM and .NET**

*Signature:* `Streaming(boolean enable)`

**Java**

*Signature:* `public void setStreaming(boolean enable)`

**XIncludeSupport**

Enables or disables the use of XInclude elements. A value of `true` enables XInclude support; `false` disables it. The default value is `false`.

**COM and .NET**

*Signature:* `XincludeSupport(boolean xinclude)`

**Java**

*Signature:* `public void setXincludeSupport(boolean xinclude)`

**XMLValidationMode**

Sets the XML validation mode, which is an enumeration literal of `ENUMXMLValidationMode` that determines whether to check validity or well-formedness.
COM and .NET

**Signature:** `XMLValidationMode(ENUMXMLValidationMode valMode)`

Java

**Signature:** `public void setXMLValidationMode(ENUMXMLValidationMode valMode)`

**XSDVersion**

Sets the XML Schema version against which the XML document will be validated. Value is an enumeration literal of `ENUMXSDVersion`.

COM and .NET

**Signature:** `XSDVersion(ENUMXSDVersion version)`

Java

**Signature:** `public void setXSDVersion(ENUMXSDVersion version)`

### 4.4.1.6 XQuery

The `IXQuery/XQuery` interface/class provides methods to (i) execute XQuery documents and XQuery updates, and (ii) validate XQuery-related documents. You can also provide data for the executions via external variables.

Note that the name of the interface in the COM/.NET API is different than that of the class in the Java API:

- In COM/.NET: `IXQuery`
- In Java: `XQuery`

#### Methods

The methods of the `IXQuery` interface (COM/.NET) and `XQuery` class (Java) are described in this section.

**AddExternalVariable**

Adds the name and value of a new external variable. Each external variable and its value is to be specified in a separate call to the method. Variables must be declared in the XQuery document (with an optional type declaration). If the variable value is a string, enclose the value in single
quotes. The name parameter holds the name of the variable, which is a QName, as a string. The value parameter holds the value of the variable as a string.

COM and .NET

Signature: AddExternalVariable(string name, string value)

Java

Signature: public void addExternalVariable(string name, string value)

ClearExternalVariableList

Clears the external variables list created by the AddExternalVariable method.

COM and .NET

Signature: ClearExternalVariableList()

Java

Signature: public void clearExternalVariableList()

Execute

Executes the XQuery transformation according to the XQuery version named in the EngineVersion property, and saves the result to the output file named in the outputFile parameter. The parameter is a string that provides the location (path and filename) of the output file. The result is true on success, false on failure. If an error occurs, a RaptorXMLException is raised. Use the LastErrorMessage property to access additional information.

COM and .NET

Signature: boolean Execute(string outputFile)

Java

Signature: public boolean execute(string outputFile)

ExecuteAndGetResultAsString

Executes the XQuery update according to the XQuery Update specification named in the EngineVersion property, and returns the result as a string. This method does not produce additional result files, such as charts or secondary results. It also does not hold binary results.
such as .docx OOXML files. If additional output files are needed, use the `Execute` method.

**COM and .NET**

*Signature:* `string ExecuteAndGetResultAsString()`

**Java**

*Signature:* `public string executeAndGetResultAsString()`

---

### ExecuteUpdate

Executes the XQuery update according to the XQuery Update specification named in the `XQueryUpdateVersion` property, and saves the result to the output file named in the `outputFile` parameter. The parameter is a string that provides the location (path and filename) of the output file. The result is `true` on success, `false` on failure. If an error occurs, a `RaptorXMLException` is raised. Use the `LastErrorMessage` property to access additional information.

**COM and .NET**

*Signature:* `boolean ExecuteUpdate(string outputFile)`

**Java**

*Signature:* `public boolean executeUpdate(string outputFile)`

---

### ExecuteUpdateAndGetResultAsString

Executes the XQuery update according to the XQuery Update specification named in the `XQueryUpdateVersion` property, and returns the result as a string. This method does not produce additional result files, such as charts or secondary results. It also does not hold binary results such as .docx OOXML files.

**COM and .NET**

*Signature:* `string ExecuteUpdateAndGetResultAsString()`

**Java**

*Signature:* `public string executeUpdateAndGetResultAsString()`
IsValid

Returns the result of validating the XQuery document according to the XQuery specification named in the EngineVersion property. The result is true on success, false on failure. If an error occurs, a RaptorXMLException is raised. Use the LastErrorMessage property to access additional information.

COM and .NET

Signature: boolean IsValid()

Java

Signature: public boolean isValid()

IsValidUpdate

Returns the result of validating the XQuery Update document according to the XQuery Update specification named in the XQueryUpdateVersion property. The result is true on success, false on failure. If an error occurs, a RaptorXMLException is raised. Use the LastErrorMessage property to access additional information.

COM and .NET

Signature: boolean IsValidUpdate()

Java

Signature: public boolean isValidUpdate()

Properties

The properties of the IXQuery interface (COM/.NET) and xQuery class (Java) are described in this section.

AdditionalOutputs

Returns the additional outputs of the last executed job.

COM and .NET

Signature: string AdditionalOutputs()
Java

Signature: public String getAdditionalOutputs()

ChartExtensionsEnabled

Enables or disables Altova’s chart extension functions. A value of true enables chart extensions; false disables them. Default value is true.

COM and .NET

Signature: ChartExtensionsEnabled(boolean enable)

Java

Signature: public void setChartExtensionsEnabled(boolean enable)

DotNetExtensionsEnabled

Enables or disables .NET extension functions. A value of true enables .NET extensions; false disables them. Default value is true.

COM and .NET

Signature: DotNetExtensionsEnabled(boolean enable)

Java

Signature: public void setDotNetExtensionsEnabled(boolean enable)

EngineVersion

Specifies the XQuery version to use. The property value is an ENUMXQueryVersion literal.

COM and .NET

Signature: EngineVersion(ENUMXQueryVersion version)

Java

Signature: public void setEngineVersion(ENUMXQueryVersion version)
**IndentCharacters**

Submits the character string that will be used as indentation in the output.

**COM and .NET**

*Signature:* `IndentCharacters(string indentChars)`

**Java**

*Signature:* `public void setIndentCharacters(string indentChars)`

**InputXMLFileName**

Sets the location, as a URL, of the XML document to process. The supplied string must be an absolute URL that gives the exact location of the XML file.

**COM and .NET**

*Signature:* `InputXMLFileName(string url)`

**Java**

*Signature:* `public void setInputXMLFileName(string url)`

**InputXMLFromText**

Supplies a string that is the text content of the XML document to process.

**COM and .NET**

*Signature:* `InputXMLFromText(string xml)`

**Java**

*Signature:* `public void setInputXMLFromText(string xml)`

**JavaBarcodeExtensionLocation**

Specifies the location of the barcode extension file. See the section on Altova's barcode extension functions for more information. The supplied string must be an absolute URL that gives the base location of the file to use.
COM and .NET

Signature: `JavaBarcodeExtensionLocation(string url)`

Java

Signature: `public void setJavaBarcodeExtensionLocation(string url)`

`JavaExtensionsEnabled` Enables or disables Java extension functions. A value of true enables Java extensions; false disables them. Default value is true.

COM and .NET

Signature: `JavaExtensionsEnabled(boolean enable)`

Java

Signature: `public void setJavaExtensionsEnabled(boolean enable)`

`KeepFormatting` Specifies whether the formatting of the original document should be kept (as far as possible) or not. A value of true keeps formatting; false does not keep formatting. Default value is true.

COM and .NET

Signature: `KeepFormatting(boolean keep)`

Java

Signature: `public void setKeepFormatting(boolean keep)`

`LastErrorMessage` Retrieves a string that is the last error message from the RaptorXML engine.

COM and .NET

Signature: `string LastErrorMessage()`
Java

Signature: `public string getLastErrorMessage()`

**LoadXMLWithPSVI**

Enables validation of input XML files and generates post-schema-validation info for them. A value of `true` enables XML validation and generates post-schema-validation info for the XML files; `false` disables validation. Default value is `true`.

**COM and .NET**

Signature: `LoadXMLWithPSVI(boolean enable)`

Java

Signature: `public void setLoadXMLWithPSVI(boolean enable)`

**MainOutput**

Returns the main output of the last executed job.

**COM and .NET**

Signature: `string MainOutput()`

Java

Signature: `public string getMainOutput()`

**OutputEncoding**

Sets the encoding for the result document. Use an official IANA encoding name, such as `UTF-8`, `UTF-16`, `US-ASCII`, `ISO-8859-1`, as a string.

**COM and .NET**

Signature: `OutputEncoding(string encoding)`

Java

Signature: `public void setOutputEncoding(string encoding)`
**OutputIndent**

Enables or disables indentation in the output document. A value of `true` enables indentation; `false` disables it.

**COM and .NET**

*Signature:* `OutputIndent(boolean outputIndent)`

**Java**

*Signature:* `public void setOutputIndent(boolean outputIndent)`

**OutputMethod**

Specifies the serialization of the output document. Valid values are: `xml|xhtml|html|text`. Default value is `xml`.

**COM and .NET**

*Signature:* `OutputMethod(string format)`

**Java**

*Signature:* `public void setOutputMethod(string format)`

**OutputOmitXMLDeclaration**

Enables/disables the inclusion of the XML declaration in the result document. A value of `true` omits the declaration; `false` includes it. Default value is `false`.

**COM and .NET**

*Signature:* `OutputOmitXMLDeclaration(boolean omitDeclaration)`

**Java**

*Signature:* `public void setOutputOmitXMLDeclaration(boolean omitDeclaration)`
UpdatedXMLWriteMode

Specifies how updates to the XML file are handled. The property value is an ENUMXQueryUpdatedXML literal.

COM and .NET

Signature: UpdateXMLWriteMode(ENUMXQueryUpdatedXML updateMode)

Java

Signature: public void setUpdateXMLWriteMode(ENUMXQueryUpdatedXML updateMode)

XIncludeSupport

Enables or disables the use of XInclude elements. A value of true enables XInclude support; false disables it. The default value is false.

COM and .NET

Signature: XIncludeSupport(boolean xinclude)

Java

Signature: public void setXIncludeSupport(boolean xinclude)

XMLValidationErrorsAsWarnings

Enables the treating of XML validation errors as warnings. Takes boolean true or false.

COM and .NET

Signature: XMLValidationErrorsAsWarnings(boolean enable)

Java

Signature: public void setXMLValidationErrorsAsWarnings(boolean enable)

XMLValidationMode

Sets the XML validation mode, which is an enumeration literal of ENUMXMLValidationMode that determines whether to check validity or well-formedness.
COM and .NET

*Signature:* `XMLValidationMode(ENUMXMLValidationMode valMode)`

Java

*Signature:* `public void setXMLValidationMode(ENUMXMLValidationMode valMode)`

**XQueryFileName**

Specifies the XQuery file to use. The supplied string must be an absolute URL that gives the location of the XQuery file to use.

COM and .NET

*Signature:* `XQueryFileName(string fileurl)`

Java

*Signature:* `public void setXQueryFileName(string fileurl)`

**XQueryFromText**

Supplies, as a text string, the contents of the XQuery document to use.

COM and .NET

*Signature:* `XQueryFromText(string xqtext)`

Java

*Signature:* `public void setXQueryFromText(string xqtext)`

**XQueryUpdateVersion**

Specifies the XQuery Update version to use. The property value is an `ENUMXQueryUpdateVersion` literal.

COM and .NET

*Signature:* `XQueryUpdateVersion(ENUMXQueryUpdateVersion version)`
Java

Signature: public void setXQueryUpdateVersion(ENUMXQueryUpdateVersion version)

XSDVersion

Sets the XML Schema version against which the XML document will be validated. Value is an enumeration literal of ENUMXSDVersion.

COM and .NET

Signature: XSDVersion(ENUMXSDVersion version)

Java

Signature: public void setXSDVersion(ENUMXSDVersion version)

4.4.1.7 XSLT

The IXSLT/XSLT interface/class provides methods to execute XSLT transformations and validate XSLT-related documents. You can also provide data for the transformation via external parameters.

Note that the name of the interface in the COM/.NET API is different than that of the class in the Java API:

- In COM/.NET: IXSLT
- In Java: XSLT

Methods

The methods of the IXSLT interface (COM/.NET) and XSLT class (Java) are described in this section.

AddExternalParameter

Adds the name and value of a new external parameter. Each external parameter and its value is to be specified in a separate call to the method. Parameters must be declared in the XSLT document. Since parameter values are XPath expressions, parameter values that are strings must be enclosed in single quotes. The name parameter holds the name of the variable, which is a QName, as a string. The value parameter holds the value of the variable as a string.

COM and .NET
**Signature:** `AddExternalParameter(string name, string value)`

Java

**Signature:** `public void addExternalParameter(string name, string value)`

**ClearExternalParameterList**
Clears the external parameters list created by the `AddExternalParameter` method.

COM and .NET

**Signature:** `ClearExternalParameterList()`

Java

**Signature:** `public void clearExternalParameterList()`

**Execute**
Executes the XSLT transformation according to the XSLT specification named in the `EngineVersion` property, and saves the result to the output file named in the `outputFile` parameter. If an error occurs, a `RaptorXMLException` is raised. Use the `LastErrorMessage` property to access additional information.

COM and .NET

**Signature:** `boolean Execute(string outputFile)`

Java

**Signature:** `public boolean execute(string outputFile)`

**ExecuteAndGetResultAsString**
Executes the XSLT transformation according to the XSLT specification named in the `EngineVersion` property, and returns the result as a string. This method does not produce additional result files, such as charts or secondary results. It also does not hold binary results such as .docx OOXML files. If additional output files are needed, use the `Execute` method. If an error occurs, a `RaptorXMLException` is raised. Use the `LastErrorMessage` property to access additional information.

COM and .NET
Signature: `string ExecuteAndGetResultAsString()`

Java

Signature: `public string executeAndGetResultAsString()`

**ExecuteAndGetResultAsStringWithBaseOutputURI**

Executes the XSLT transformation according to the XSLT specification named in the `EngineVersion` property, and returns the result as a string at the location defined by the base URI. The `baseURI` parameter is a string that provides a URI. This method does not produce additional result files, such as charts or secondary results. It also does not hold binary results such as .docx OOXML files. If additional output files are needed, use the `Execute` method. If an error occurs, a `RaptorXMLException` is raised. Use the `LastErrorMessage` property to access additional information.

**COM and .NET**

Signature: `string ExecuteAndGetResultAsStringWithBaseOutputURI(string baseURI)`

Java

Signature: `public string ExecuteAndGetResultAsStringWithBaseOutputURI(string baseURI)`

**IsValid**

Returns the result of validating the XSLT document according to the XSLT specification named in the `EngineVersion` property. The result is `true` on success, `false` on failure. If an error occurs, a `RaptorXMLException` is raised. Use the `LastErrorMessage` property to access additional information.

**COM and .NET**

Signature: `boolean IsValid()`

Java

Signature: `public boolean isValid()`

**Properties**

The properties of the `IXSLT` interface (COM/.NET) and `XSLT` class (Java) are described in this section.
**AdditionalOutputs**

Returns the additional outputs of the last executed job.

**COM and .NET**

*Signature:* `string AdditionalOutputs()`

**Java**

*Signature:* `public string getAdditionalOutputs()`

**ChartExtensionsEnabled**

Enables or disables Altova's chart extension functions. A value of `true` enables chart extensions; `false` disables them. Default value is `true`.

**COM and .NET**

*Signature:* `ChartExtensionsEnabled(boolean enable)`

**Java**

*Signature:* `public void setChartExtensionsEnabled(boolean enable)`

**DotNetExtensionsEnabled**

Enables or disables .NET extension functions. A value of `true` enables .NET extensions; `false` disables them. Default value is `true`.

**COM and .NET**

*Signature:* `DotNetExtensionsEnabled(boolean enable)`

**Java**

*Signature:* `public void setDotNetExtensionsEnabled(boolean enable)}`
**EngineVersion**

Specifies the XSLT version to use. The property value is an `ENUMXSLTVersion` literal.

**COM and .NET**

*Signature:* `EngineVersion(ENUMXSLTVersion version)`

**Java**

*Signature:* `public void setEngineVersion(ENUMXSLTVersion version)`

**IndentCharacters**

Submits the character string that will be used as indentation in the output.

**COM and .NET**

*Signature:* `IndentCharacters(string indentChars)`

**Java**

*Signature:* `public void setIndentCharacters(string indentChars)`

**InitialTemplateMode**

Sets the initial mode for XSLT processing. Templates with a mode value equal to the submitted string will be processed.

**COM and .NET**

*Signature:* `InitialTemplateMode(string mode)`

**Java**

*Signature:* `public void setInitialTemplateMode(string mode)`

**InputXMLFileName**

Sets the location, as a URL, of the XML document to process. The supplied string must be an absolute URL that gives the exact location of the XML file.

**COM and .NET**
Signature: InputXMLFileName(string url)

Java

Signature: public void setInputXMLFileName(string url)

InputXMLFromText
Supplies a string that is the text content of the XML document to process.

COM and .NET

Signature: InputXMLFromText(string xml)

Java

Signature: public void setInputXMLFromText(string xml)

JavaBarcodeExtensionLocation
Specifies the location of the barcode extension file. See the section on Altova's barcode extension functions for more information. The supplied string must be an absolute URL that gives the base location of the file to use.

COM and .NET

Signature: JavaBarcodeExtensionLocation(string url)

Java

Signature: public void setJavaBarcodeExtensionLocation(string url)

JavaExtensionsEnabled
Enables or disables Java extension functions. A value of true enables Java extensions; false disables them. Default value is true.

COM and .NET

Signature: JavaExtensionsEnabled(boolean enable)
Java

Signature: `public void setJavaExtensionsEnabled(boolean enable)`

LastErrorMessage
Retrieves a string that is the last error message from the RaptorXML engine.

COM and .NET

Signature: `string LastErrorMessage()`

Java

Signature: `public string getLastErrorMessage()`

LoadXMLWithPSVI
Enables validation of input XML files and generates post-schema-validation info for them. A value of `true` enables XML validation and generates post-schema-validation info for the XML files; `false` disables validation. Default value is `true`.

COM and .NET

Signature: `LoadXMLWithPSVI(boolean enable)`

Java

Signature: `public void setLoadXMLWithPSVI(boolean enable)`

MainOutput
Returns the main output of the last executed job.

COM and .NET

Signature: `string MainOutput()`

Java

Signature: `public string getMainOutput()`
**NamedTemplateEntryPoint**

Specifies the name, as a string, of the named template to use as an entry point for the transformation.

**COM and .NET**

*Signature:* `NamedTemplateEntryPoint(string template)`

**Java**

*Signature:* `public void setNamedTemplateEntryPoint(string template)`

**SchemaImports**

Specifies how schema imports are to be handled based on the attribute values of the `xs:import` elements. The kind of handling is specified by the `ENUMSchemaImports` literal that is submitted.

**COM and .NET**

*Signature:* `SchemaImports(ENUMSchemaImports importOption)`

**Java**

*Signature:* `public void setSchemaImports(ENUMSchemaImports importOption)`

**SchemalocationHints**

Specifies the mechanism to use to locate the schema. The mechanism is specified by the `ENUMLoadSchemalocation` literal that is selected.

**COM and .NET**

*Signature:* `SchemalocationHints(ENUMSchemalocation hint)`

**Java**

*Signature:* `public void setSchemalocationHints(ENUMSchemalocation hint)`

**SchemaMapping**

Sets what mapping to use in order to locate the schema. The mapping is specified by the `ENUMSchemaMapping` literal that is selected.
COM and .NET

**Signature:** `SchemaMapping (ENUMSchemaMapping mappingOption)`

Java

**Signature:** `public void setSchemaMapping (ENUMSchemaMapping mappingOption)`

**StreamingSerialization**

Enables streaming serialization. In streaming mode, data stored in memory is minimized and processing is faster. A value of `true` enables streaming serialization; `false` disables it.

COM and .NET

**Signature:** `StreamingSerialization (boolean enable)`

Java

**Signature:** `public void setStreamingSerialization (boolean enable)`

**XIncludeSupport**

Enables or disables the use of XInclude elements. A value of `true` enables XInclude support; `false` disables it. The default value is `false`.

COM and .NET

**Signature:** `XIncludeSupport (boolean xinclude)`

Java

**Signature:** `public void setXIncludeSupport (boolean xinclude)`

**XMLValidationErrorsAsWarnings**

Enables the treating of XML validation errors as warnings. Takes boolean `true` or `false`.

COM and .NET

**Signature:** `XMLValidationErrorsAsWarnings (boolean enable)`
Java

Signature: public void setXMLValidationErrorsAsWarnings(boolean enable)

**XMLValidationMode**

Sets the XML validation mode, which is an enumeration literal of ENUMXMLValidationMode that determines whether to check validity or well-formedness.

COM and .NET

Signature: XMLValidationMode(ENUMXMLValidationMode valMode)

Java

Signature: public void setXMLValidationMode(ENUMXMLValidationMode valMode)

**XSDVersion**

Sets the XML Schema version against which the XML document will be validated. Value is an enumeration literal of ENUMXSDVersion.

COM and .NET

Signature: XSDVersion(ENUMXSDVersion version)

Java

Signature: public void setXSDVersion(ENUMXSDVersion version)

**XSLFileName**

Specifies the XSLT file to use. The supplied string must be an absolute URL that gives the location of the XSLT file to use.

COM and .NET

Signature: XSLFileName(string fileurl)

Java

Signature: public void setXSLFileName(string fileurl)
XSLFromText

Supplies, as a text string, the contents of the XSLT document to use

COM and .NET

Signature: XSLFromText(string xsltext)

Java

Signature: public void setXSLFromText(string xsltext)
4.4.2 Enumerations

Enumerations of the COM/.NET and Java Server APIs are described in this section. Each description includes links to the methods or properties that use the enumeration.

- ENUMAssessmentMode
- ENUMErrorFormat
- ENUMIXBRLUrStrategy
- ENUMIXBRLVersion
- ENUMLoadSchemaLocation
- ENUMSchemaImports
- ENUMSchemaMapping
- ENUMTableOutputFormat
- ENUMValidationType
- ENUMWellformedCheckType
- ENUMXBRLValidationType
- ENUMXMLValidationMode
- ENUMXQueryUpdatedXML
- ENUMXQueryUpdateVersion
- ENUMXQueryVersion
- ENUMXSDVersion
- ENUMXSLTVersion

4.4.2.1 ENUMAssessmentMode

Defines the assessment mode of the XML Validator to be strict or lax:

- eAssessmentModeStrict: Sets the schema-validity assessment mode to Strict. This is the default value.
- eAssessmentModeLax: Sets the schema-validity assessment mode to Lax.

**COM and .NET**

<table>
<thead>
<tr>
<th>ENUMAssessmentMode</th>
</tr>
</thead>
<tbody>
<tr>
<td>eAssessmentModeStrict</td>
</tr>
<tr>
<td>eAssessmentModeLax</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXMLValidator</td>
<td>AssessmentMode</td>
</tr>
</tbody>
</table>

**Java**

```java
public enum ENUMAssessmentMode {
    eAssessmentModeLax,
    eAssessmentModeStrict
}
```
4.4.2.2 ENUMErrorFormat

Specifies the format of the error output:

- **eFormatText**: Sets the error output format to **Text**. The default value.
- **eFormatShortXML**: Sets the error output format to **ShortXML**. This format is an abbreviated form of the **LongXML** format.
- **eFormatLongXML**: Sets the error output format to **LongXML**. This format provides the most detail of all three output formats.

### COM and .NET

<table>
<thead>
<tr>
<th>ENUM</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eFormatText</td>
<td>0</td>
</tr>
<tr>
<td>eFormatShortXML</td>
<td>1</td>
</tr>
<tr>
<td>eFormatLongXML</td>
<td>2</td>
</tr>
</tbody>
</table>

**Used by**

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IServer</td>
<td>ErrorFormat</td>
</tr>
</tbody>
</table>

### Java

```java
public enum ENUMErrorFormat {
    eFormatText,
    eFormatShortXML,
    eFormatLongXML
}
```

**Used by**

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>RaptorXMLFactory</td>
<td>setErrorFormat</td>
</tr>
</tbody>
</table>

4.4.2.3 ENUMIXBRLUriStrategy

Specifies how URIs in the Inline XBRL should be written to the generated XBRL document:

- **eStrategyNone**: Copies the URI verbatim to the target document.
- **eStrategyMakeAbsolute**: Makes any relative URIs absolute by resolving against the in-scope base URI at the respective element in the input document.
- **eStrategyMakeRelative**: If possible, makes any absolute and relative URIs relative to the output document (otherwise writes the resolved absolute URI).
- **eStrategyKeepRelative**: If possible, makes only the relative URIs relative to the output document (and copies any absolute URI).

**COM and .NET**

<table>
<thead>
<tr>
<th>eStrategyNone</th>
<th>= 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>eStrategyMakeAbsolute</td>
<td>= 1</td>
</tr>
<tr>
<td>eStrategyMakeRelative</td>
<td>= 2</td>
</tr>
<tr>
<td>eStrategyKeepRelative</td>
<td>= 3</td>
</tr>
</tbody>
</table>

**Used by**

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXBRL</td>
<td>IXBRLUriStrategy</td>
</tr>
</tbody>
</table>

**Java**

```java
public enum ENUMIXBRLUriStrategy {
    eStrategyNone,
    eStrategyMakeAbsolute,
    eStrategyMakeRelative,
    eStrategyKeepRelative
}
```

**Used by**

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XBRL</td>
<td>setIXBRLUriTransformationStrategy</td>
</tr>
</tbody>
</table>

### 4.4.2.4 ENUMIXBRLVersion

Specifies which version of the Inline XBRL specification to use: [Inline XBRL 1.0](https://www.xbrl.org/standard/inline-xbrl) or [Inline XBRL 1.1](https://www.xbrl.org/standard/inline-xbrl).

- **eIXBRLVersion10**: Specifies that the Inline XBRL 1.0 specification be used.
- **eIXBRLVersion11**: Specifies that the Inline XBRL 1.1 specification be used.
- **eIXBRLVersionDetect**: Enables auto-detection of the version from the submitted Inline XBRL document.

**COM and .NET**

<table>
<thead>
<tr>
<th>eIXBRLVersion10</th>
<th>= 0ót</th>
</tr>
</thead>
<tbody>
<tr>
<td>eIXBRLVersion11</td>
<td>= 1</td>
</tr>
<tr>
<td>eIXBRLVersionDetect</td>
<td>= 2</td>
</tr>
</tbody>
</table>

**Used by**

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXBRL</td>
<td>IXBRLVersion</td>
</tr>
</tbody>
</table>

**Java**

```java
public enum ENUMIXBRLVersion {
    eVersion10,
    eVersion11,
    eVersionDetect
}
```

**Used by**

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XBRL</td>
<td>setIXBRLVersion</td>
</tr>
</tbody>
</table>

### 4.4.2.5 ENUMLoadSchemalocation

Indicates how the schema's location should be determined. The selection is based on the schema location attribute of the XML or XBRL instance document. This attribute could be `xsi:schemaLocation` or `xsi:noNamespaceSchemaLocation`.

- **eSHLoadBySchemalocation**: uses the URL of the schema location attribute in the XML or XBRL instance document. This enumeration literal is the default value.
- **eSHLoadByNamespace**: uses the namespace part of `xsi:schemaLocation` and an empty string in the case of `xsi:noNamespaceSchemaLocation` to locate the schema via a catalog mapping.
- **eSHLoadCombiningBoth**: If either the namespace URL or schema location URL has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of `ENUMSchemaMapping` decides which mapping is used. If neither the namespace nor schema location has a catalog mapping, the schema location URL is used.
- **eSHLoadIgnore**: The `xsi:schemaLocation` and `xsi:noNamespaceSchemaLocation` attributes are both ignored.

**COM and .NET**

| eSHLoadBySchemalocation | = 0 |
| eSHLoadByNamespace      | = 1 |
| eSHLoadCombiningBoth    | = 2 |
| eSHLoadIgnore           | = 3 |

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXBRL</td>
<td>SchemalocationHints</td>
</tr>
<tr>
<td>IXMLValidator</td>
<td>SchemalocationHints</td>
</tr>
<tr>
<td>IXSLT</td>
<td>SchemalocationHints</td>
</tr>
</tbody>
</table>

Java

```java
public enum ENUMLoadSchemalocation {
    eSHLoadBySchemalocation,
    eSHLoadByNamespace,
    eSHLoadCombiningBoth,
    eSHLoadIgnore
}
```

Used by

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XBRL</td>
<td>setSchemalocationHints</td>
</tr>
<tr>
<td>XMLValidator</td>
<td>setSchemalocationHints</td>
</tr>
<tr>
<td>XSLT</td>
<td>setSchemalocationHints</td>
</tr>
</tbody>
</table>

4.4.2.6 ENUMSchemalImports

Defines the behavior of the schema’s `xs:import` elements, each of which has an optional `namespace` attribute and an optional `schemaLocation` attribute.

- **eSILoadBySchemalocation** uses the value of the `schemaLocation` attribute to locate the schema, taking account of catalog mappings. If the `namespace` attribute is present, the namespace is imported (licensed).
- **eSILoadPreferringSchemalocation**: If the `schemaLocation` attribute is present, it is used, taking account of catalog mappings. If no `schemaLocation` attribute is present, then the value of the `namespace` attribute is used via a catalog mapping. This enumeration literal is the default value.
- **eSILoadByNamespace** uses the value of the `namespace` attribute to locate the schema via a catalog mapping.
- **eSILoadCombiningBoth**: If either the `namespace` URL or `schemaLocation` URL has a catalog mapping, then the catalog mapping is used. If both have catalog mappings, then the value of `ENUMSchemaMapping` decides which mapping is used. If neither the `namespace` nor `schemaLocation` URL has a catalog mapping, the `schemaLocation` URL is used.
- **eSILicenseNamespaceOnly**: The namespace is imported. No schema document is imported.

COM and .NET
<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eSILoadBySchemalocation</td>
<td>0</td>
</tr>
<tr>
<td>eSILoadPreferringSchemalocation</td>
<td>1</td>
</tr>
<tr>
<td>eSILoadByNamespace</td>
<td>2</td>

<td>SchemaImports</td>
</tr>
<tr>
<td>XMLValidator</td>
<td>SchemaImports</td>
</tr>
<tr>
<td>XSLT</td>
<td>SchemaImports</td>
</tr>
</tbody>
</table>

**Java**

```java
public enum ENUMSchemaImports {
    eSILoadBySchemalocation,
    eSILoadPreferringSchemalocation,
    eSILoadByNamespace,
    eSICombiningBoth,
    eSILicenseNamespaceOnly
}
```

**Used by**

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XBRL</td>
<td>setSchemaImports</td>
</tr>
<tr>
<td>XMLValidator</td>
<td>setSchemaImports</td>
</tr>
<tr>
<td>XSLT</td>
<td>setSchemaImports</td>
</tr>
</tbody>
</table>

### 4.4.2.7 ENUMSchemaMapping

Specifies which of two catalog mappings is preferred: namespaces or schema-location URLs. This enumeration is useful for disambiguating `ENUMLoadSchemalocation` and `ENUMSchemaImports`.

- `eSMPreferNamespace`: Selects the namespace.
- `eSMPreferSchemalocation`: Selects the schema location. This is the default value.

**COM and .NET**

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eSMPreferSchemalocation</td>
<td>0</td>
</tr>
<tr>
<td>eSMPreferNamespace</td>
<td>1</td>
</tr>
</tbody>
</table>

**Used by**
### Interface and Property

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXBRL</td>
<td>SchemaMapping</td>
</tr>
<tr>
<td>XMLValidator</td>
<td>SchemaMapping</td>
</tr>
<tr>
<td>XSLT</td>
<td>SchemaMapping</td>
</tr>
</tbody>
</table>

### Java

```java
public enum ENUMSchemaMapping {
    eSMPreferSchemalocation,  // eSMPreferNamespace
}
```

#### Used by

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>

<tbody>
<tr>
<td>XBRL</td>
<td>setSchemaMapping</td>
</tr>
<tr>
<td>XMLValidator</td>
<td>setSchemaMapping</td>
</tr>
<tr>
<td>XSLT</td>
<td>setSchemaMapping</td>
</tr>
</tbody>
</table>

### ENUMTableOutputFormat

Specifies the output format of the document containing the generated XBRL tables.

- **eFormatXML**: The output document with the generated tables is in XML format.
- **eFormatHTML**: The output document with the generated tables is in HTML format.

#### COM and .NET

<table>
<thead>
<tr>
<th>ENUMTableOutputFormat</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eFormatXML</td>
<td>0</td>
</tr>
<tr>
<td>eFormatHTML</td>
<td>1</td>
</tr>
</tbody>
</table>

#### Used by

<tbody>
<tr>
<td>IXBRL</td>
<td>TableOutputFormat</td>
</tr>
</tbody>
</table>

### Java

```java
public enum ENUMTableOutputFormat {
    eFormatXML,  // eFormatHTML
}
```

#### Used by

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
</table>
4.4.2.9 ENUMValidationType

Specifies what validation to carry out and, in the case of XML documents, whether validation is against a DTD or XSD.

- **eValidateAny**: The document type (for example, XML or XSD) is detected, and validation is set automatically for that document type.
- **eValidateXMLWithDTD**: Specifies validation of an XML document against a DTD.
- **eValidateXMLWithXSD**: Specifies validation of an XML document against an XSD (XML Schema).
- **eValidateDTD**: Specifies validation of a DTD document.
- **eValidateXSD**: Specifies validation of an XSD (W3C XMLSchema) document.
- **eValidateJSON**: Specifies validation of a JSON instance document.
- **eValidateJSONSchema**: Specifies validation of a JSON Schema document according to JSON Schema v4.
- **eValidateAvro**: Specifies validation of an Avro binary file. The Avro data in the binary file is validated against the Avro Schema contained in the binary file.
- **eValidateAvroSchema**: Specifies validation of an Avro schema against the Avro schema specification.
- **eValidateAvroJSON**: Specifies validation of a JSON-serialized Avro data file against an Avro schema.

**COM and .NET**

<table>
<thead>
<tr>
<th>ENUM</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eValidateAny</td>
<td>0</td>
</tr>
<tr>
<td>eValidateXMLWithDTD</td>
<td>1</td>
</tr>
<tr>
<td>eValidateXMLWithXSD</td>
<td>2</td>
</tr>
<tr>
<td>eValidateDTD</td>
<td>3</td>
</tr>
<tr>
<td>eValidateXSD</td>
<td>4</td>
</tr>
<tr>
<td>eValidateJSON</td>
<td>5</td>
</tr>
<tr>
<td>eValidateJSONSchema</td>
<td>6</td>
</tr>
<tr>
<td>eValidateAvro</td>
<td>7</td>
</tr>
<tr>
<td>eValidateAvroSchema</td>
<td>8</td>
</tr>
<tr>
<td>eValidateAvroJSON</td>
<td>9</td>
</tr>
</tbody>
</table>

*Used by*

<table>
<thead>
<tr>
<th>Interface</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXMLValidator</td>
<td>IsValid</td>
</tr>
</tbody>
</table>
Java

```java
public enum ENUMValidationType {
    eValidateAny,
    eValidateXMLWithDTD,
    eValidateXMLWithXSD,
    eValidateDTD,
    eValidateXSD,
    eValidateJSON,
    eValidateJSONSchema,
    eValidateAvro,
    eValidateAvroSchema,
    eValidateAvroJSON
}
```

**Used by**

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLValidator</td>
<td>isValid</td>
</tr>
</tbody>
</table>

4.4.2.10 ENUMWellformedCheckType

Specifies the type of well-formed check to make (for XML, DTD, or JSON).

- `eWellformedAny`: The document type is detected, and the type of check is set automatically.
- `eWellformedXML`: Checks an XML document for well-formedness.
- `eWellformedDTD`: Checks a DTD document for well-formedness.
- `eWellformedJSON`: Checks a JSON document for well-formedness.

COM and .NET

```plaintext
eWellformedAny  = 0
eWellformedXML  = 1
eWellformedDTD  = 2
eWellformedJSON = 3
```

**Used by**

<table>
<thead>
<tr>
<th>Interface</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXMLValidator</td>
<td>isWellFormed</td>
</tr>
</tbody>
</table>

Java

```java
public enum ENUMWellformedCheckType {
    eWellformedAny
}
```
Used by

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLValidator</td>
<td>isWellFormed</td>
</tr>
</tbody>
</table>

4.4.2.11 ENUMXBRLValidationType

Specifies the type of XBRL validation to carry out: document to validate (for example, an XBRL instance, XBRL taxonomy, etc).

- **eValidateXBRLAny**: The document type is detected automatically, and the type of validation is set automatically according to the document type.
- **eValidateXBRLInstance**: Sets the validation type to Instance. Validates an XBRL instance document (.xbrl file extension).
- **eValidateXBRLTaxonomy**: Sets the validation type to Taxonomy. Validates an XBRL taxonomy (.xsd file extension).
- **eValidateInline**: Sets the validation type to Inline. Validates an Inline XBRL (iXBRL) document against the [Inline XBRL 1.0 or Inline XBRL 1.1 specification](https://www.xbrl.org/standards/inline-xbrl).
- **eValidateTaxonomyPackage**: Sets the validation type to TaxonomyPackage. Validates an XBRL taxonomy package according to the [Taxonomy 1.0 Packages specification](https://www.xbrl.org/standards/taxonomy-1.0).
- **eValidate(XBRL)VersioningReport**: Sets the validation type to XBRLVersion. Validates an XBRL versioning report (an XBRL Versioning document) according to the XBRL Versioning 1.0 specification. Note that this enumeration literal in Java does not contain XBRL. See below for exact COM/.NET and Java literals, respectively.

**Names in COM/.NET are different than in Java**

Note that not only is the name of the enumeration different (ENUMXBRLValidationType and ENUMXValidationType). Some enumeration values are also different. The differently named values (by their COM.NET names) are: eValidateXBRLAny, eValidateXBRLInstance, eValidateXBRLTaxonomy, eValidateXBRLVersioningReport.

See the Java section below for the corresponding Java names.

**COM and .NET**

<table>
<thead>
<tr>
<th>eValidateXBRLAny</th>
<th>= 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>eValidateXBRLInstance</td>
<td>= 1</td>
</tr>
<tr>
<td>eValidateXBRLTaxonomy</td>
<td>= 2</td>
</tr>
<tr>
<td>eValidateInline</td>
<td>= 3</td>
</tr>
<tr>
<td>eValidateTaxonomyPackage</td>
<td>= 4</td>
</tr>
<tr>
<td>eValidateXBRLVersioningReport</td>
<td>= 5</td>
</tr>
</tbody>
</table>
4.4.2.12 ENUMXMLValidationMode

Specifies the type of XML validation to perform (validation or well-formedness check).

- eProcessingModeWF: Sets the XML processing mode to wellformed. This is the default value.
- eProcessingModeValid: Sets the XML processing mode to validation.
- eProcessingModeID: Internal, not for use.

### COM and .NET

<table>
<thead>
<tr>
<th>ENUMXMLValidationMode</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eXMLValidationModeWF</td>
<td>0</td>
</tr>
<tr>
<td>eXMLValidationModeID</td>
<td>1</td>
</tr>
<tr>
<td>eXMLValidationModeValid</td>
<td>2</td>
</tr>
</tbody>
</table>

**Used by**

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLValidator</td>
<td>setXMLValidationMode</td>
</tr>
<tr>
<td>XQuery</td>
<td>setXMLValidationMode</td>
</tr>
<tr>
<td>XSLT</td>
<td>setXMLValidationMode</td>
</tr>
</tbody>
</table>

4.4.2.13 ENUMXQueryUpdatedXML

Specifies how XQuery updates are handled.

- **eUpdatedDiscard**: Updates are discarded and not written to file.
- **eUpdatedWriteback**: Updates are written to the input XML file specified with `InputXMLFileName`.
- **eUpdatedAsMainResult**: Updates are written to the location specified by the `outputFile` parameter of `ExecuteUpdate`.

COM and .NET

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>eUpdatedDiscard</td>
<td>1</td>
</tr>
<tr>
<td>eUpdatedWriteback</td>
<td>2</td>
</tr>
<tr>
<td>eUpdatedAsMainResult</td>
<td>3</td>
</tr>
</tbody>
</table>

Used by

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXQuery</td>
<td>UpdatedXMLWriteMode</td>
</tr>
</tbody>
</table>

Java

```java
public enum ENUMXQueryUpdatedXML {
    eUpdatedDiscard,
    eUpdatedWriteback,
    eUpdatedAsMainResult
}
```

Used by

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XQuery</td>
<td>setUpdatedXMLWriteMode</td>
</tr>
</tbody>
</table>
4.4.2.14 ENUMXQueryUpdateVersion

Sets the XQuery Update version to be used for processing.

- `eXQueryUpdateVersion10`: Sets the XQuery Update version to XQuery Update 1.0.

**Note:** The Java enumeration literal is differently named than the COM/.NET literal. See below.

**COM and .NET**

```
enum eXQueryUpdateVersion { 1
}
```

**Used by**

<table>
<thead>
<tr>
<th>Interface</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>IXQuery</td>
<td>XQueryUpdateVersion</td>
</tr>
</tbody>
</table>

**Java**

```java
public enum ENUMXQueryUpdateVersion { 
  eVersion10
}
```

**Used by**

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XQuery</td>
<td>setXQueryUpdateVersion</td>
</tr>
</tbody>
</table>

4.4.2.15 ENUMXQueryVersion

Sets the XQuery version to be used for processing (execution or validation).

- `eXQueryVersion10`: Sets the XQuery version to XQuery 1.0.
- `eXQueryVersion30`: Sets the XQuery version to XQuery 3.0. The default value.
- `eXQueryVersion31`: Sets the XQuery version to XQuery 3.1.

**Note:** The Java enumeration literals are differently named than the COM/.NET literals. See below.

**COM and .NET**

```
enum eXQueryVersion { 1, 3, 31
```

<table>
<thead>
<tr>
<th>ENUMXQueryUpdateVersion</th>
<th>COM and .NET</th>
<th>Java</th>
</tr>
</thead>
<tbody>
<tr>
<td>eXQueryUpdateVersion10</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>eXQueryVersion10</td>
<td></td>
<td></td>
</tr>
<tr>
<td>eXQueryVersion30</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td>eXQueryVersion31</td>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>
4.4.2.16 ENUMXSDVersion

Specifies the XML Schema version to use for validation.

- **eXSDVersionAuto**: The XML Schema version is detected automatically from the XSD document's `vc:minVersion` attribute. If this attribute's value is 1.1, then the document is considered to be XSD 1.1. If the attribute has any other value, or if no value exists, then the document is considered to be XSD 1.0.
- **eXSDVersion10**: Sets the XML Schema version for validation to XML Schema 1.0.
- **eXSDVersion11**: Sets the XML Schema version for validation to XML Schema 1.1.

### COM and .NET

<table>
<thead>
<tr>
<th>ENUMXSDVersion</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>eXSDVersionAuto</td>
<td>0</td>
</tr>
<tr>
<td>eXSDVersion10</td>
<td>1</td>
</tr>
<tr>

<td>XQuery</td>
<td>setXSDVersion</td>
</tr>
<tr>
<td>XSLT</td>
<td>setXSDVersion</td>
</tr>
</tbody>
</table>

---

### 4.4.2.17 ENUMXSLTVersions

Sets the XSLT version to be used for processing (validation or XSLT transformation).

- **eVersion10**: Sets the XSLT version to XSLT 1.0.
- **eVersion20**: Sets the XSLT version to XSLT 2.0.
- **eVersion30**: Sets the XSLT version to XSLT 3.0.

#### COM and .NET

<table>
<thead>
<tr>
<th>ENUMXSLTVersions</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSLT</td>
<td>setEngineVersion</td>
</tr>
</tbody>
</table>
5 Engine APIs: Python and .NET

RaptorXML+XBRL Server provides two engine APIs:

- a Python wheel file (.whl), which is the Python Engine API: `raptorxml<versiondetails>.whl`
- a .NET DLL file (.dll), which is the .NET Engine API: `raptorxmlxbralipi.dll`

These two engine APIs provide the RaptorXML+XBRL Server functionality as separate packages that are standalone and independent from RaptorXML+XBRL Server (see figure below). Each package must be installed on the user's machine before it can be imported as a Python module or integrated into a custom .NET application. Because all processing is performed locally on the user's machine, the Python and .NET engine APIs provide detailed access to the data models of any valid XML and XBRL instances, XSD schemas and XBRL taxonomies. The APIs expose a rich set of methods to iterate over the content of XBRL instances or allow to retrieve specific bits of information from XBRL taxonomies with a few lines of code.

Note the following points about the Engine APIs:

- After you install RaptorXML+XBRL Server, both engine APIs will be located in the `bin` folder of the RaptorXML+XBRL Server installation folder.
- The engine APIs provide additional advanced processing via more versatile objects in their APIs.
- In order to use an engine API, a licensed version of RaptorXML+XBRL Server must be installed on the machine on which the Python program or .NET application is executed (see Usage below).

Usage

You can create a Python program or .NET application as follows:
**Python program**
A Python program can access RaptorXML functionality by using Python API objects (see here). When the Python program is executed, it will use the RaptorXML library that has been installed in your Python environment when you install the Python wheel. Note that the Python wheel is compatible with Python version 3.5 only.

**.NET application**
A .NET application can access RaptorXML functionality by using .NET API objects (see here). When the .NET application is executed, it will use the RaptorXML that is contained in the .NET API DLL.

**Licensing**
In order to use an engine API, a licensed version of RaptorXML+XBRL Server must be installed on the machine on which the Python program or .NET application is executed. See the section Licensing for more detailed information.
5.1 Licensing

In order for an API package to run on a client machine, that machine will have to be licensed as a RaptorXML+XBRL Server client. Licensing consists of two steps:

1. Registering the machine as a RaptorXML+XBRL Server client with Altova LicenseServer.
2. Assigning a RaptorXML+XBRL Server license from LicenseServer to that machine.

If you plan to use the API package from a given machine, then two possible situations arise:

- If the client machine is already running a licensed installation of RaptorXML+XBRL Server, then the API package can be run without you needing to take any additional steps. This is because the machine is already licensed to run RaptorXML+XBRL Server. Consequently, use of the API package on this machine is covered by the license assigned to RaptorXML+XBRL Server on that machine.
- If RaptorXML+XBRL Server is not installed on the client machine and you do not want to install RaptorXML+XBRL Server on that machine for whatever reason. In this case, you can still register the machine as a RaptorXML+XBRL Server client and assign it a RaptorXML+XBRL Server license. How to do this is described below.

To register a machine (on which RaptorXML+XBRL Server is not installed) as a RaptorXML+XBRL Server client, use the command line application `registerlicense.exe`, which is located in the application's `bin` folder:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>Program Files\Altova\RaptorXMLXBRLServer2019\bin</td>
</tr>
<tr>
<td>Linux</td>
<td>/opt/Altova/RaptorXMLXBRLServer2019/bin</td>
</tr>
<tr>
<td>Mac</td>
<td>/usr/local/Altova/RaptorXMLXBRLServer2019/bin</td>
</tr>
</tbody>
</table>

On the command line run the command:

```
registerlicense <LicenseServer>
```

where `<LicenseServer>` is the IP address or host name of the LicenseServer machine.

This command will register the machine as a RaptorXML+XBRL Server client with Altova LicenseServer. For information about how to assign a RaptorXML+XBRL Server license to the machine and for more information about licensing, see the Altova LicenseServer documentation.

**Deploying on Linux**

To deploy the `registerlicense` application with your Python wheel package, the shared libraries that are listed below need to be present in a sibling `lib` directory. The shared libraries can be copied from your Raptor installation folder:

```
/opt/Altova/RaptorXMLServerRaptorXMLXBRLServer2019/lib
```

- `libcrypto.so.1.0.0`
- `libssl.so.1.0.0`
- `libstdc++.so.6`
• libtbb.so.2
5.2 Python API

The RaptorXML Python API enables data in XML documents, XML Schema documents, XBRL instance documents, and XBRL taxonomy documents to be accessed and manipulated in Python scripts. Some typical use cases of the Python API include:

- implement custom validation rules and error messages
- export content from XML and XBRL documents to a database
- export content from XML and XBRL documents to custom data formats
- interactively navigate and query the data model of XML and XBRL documents within a Python shell or Jupyter notebook (http://jupyter.org/)

The Python APIs

The Python APIs (for XML, XSD and XBRL) provide access to the meta-information, structural information, and data contained in XML, XSD, and XBRL instance and taxonomy documents. As a result, Python scripts can be created that make use of the APIs to access and process document information. For example, a Python script can be passed to RaptorXML+XBRL Server that writes data from an XML or XBRL instance document to a database or to a CSV file.

Example scripts for Raptor's Python APIs are available at: https://github.com/altova

The Python APIs are described in their API references:

- Python API v1 Reference
- Python API v2 Reference

Note: Raptor's Python API v1 is deprecated. Please use Python API v2.

RaptorXML+XBRL Server package for Python

In your installation of RaptorXML+XBRL Server, you will also find a Python package in wheel format. You can use Python's pip command to install this package as a module of your Python installation. After the RaptorXMLXBRL module has been installed, you can use the module's functions within your code. In this way, RaptorXMLXBRL's functionality can be used easily in any Python program you write, together with other third-party Python libraries, such as graphics libraries.

For information about how to use RaptorXML+XBRL Server's Python package, see the section RaptorXML+XBRL Server as a Python Package.

Note: The Python wheel is compatible with Python version 3.5 only.

Python scripts

A user-created Python script is submitted with the --script parameter of the following commands:

- valxml-withxsd (xsi)
- valxsd (xsd)
- valxbrltaxonomy (dts)
- valxbrl (xbrl)
These commands invoking Python scripts can be used both on the Command Line Interface (CLI) and via the HTTP Interface. The usage of Python scripts with the Python APIs of RaptorXML+XBRL Server are described at: https://github.com/altova.

Making Python scripts safe
When a Python script is specified in a command via HTTP to RaptorXML+XBRL Server, the script will only work if it is located in the trusted directory. The script is executed from the trusted directory. Specifying a Python script from any other directory will result in an error. The trusted directory is specified in the server.script-root-dir setting of the server configuration file, and a trusted directory must be specified if you wish to use Python scripts. Make sure that all Python scripts to be used are saved in this directory.

Though all output generated by the server for HTTP job requests is written to the job output directory (which is a sub-directory of the output-root-directory), this limitation does not apply to Python scripts, which can write to any location. The server administrator must review the Python scripts in the trusted directory for potential vulnerability issues.
5.2.1 Python API Versions

RaptorXML+XBRL Server supports multiple Python API versions. Any previous Python API version is also supported by the current version of RaptorXML+XBRL Server. The Python API version is selected by the `--script-api-version=MAJOR_VERSION` command line flag. The default of the `MAJOR_VERSION` argument is always the current version. A new RaptorXML+XBRL Server Python API `MAJOR_VERSION` is introduced when incompatible changes or major enhancements are introduced. Users of the API do not need to upgrade their existing scripts when a new major version is released.

It is recommended that:

- You use the `--script-api-version=MAJOR_VERSION` flag to invoke utility scripts from the RaptorXML+XBRL Server command-line (or Web-API). This ensures that scripts still work as expected after RaptorXML+XBRL Server updates—even if a new API `MAJOR_VERSION` has been released.
- You use the latest version of the API for new projects, even though previous versions will be supported by future RaptorXML+XBRL Server releases.

The Python API versions listed below are currently available. The documentation of the different APIs are available online at the locations given below.

**Example files**

For examples of scripts that use Raptor's Python APIs, go to [https://github.com/altova](https://github.com/altova).

**Python API version 1**

Introduced with RaptorXML+XBRL Server v2014

<table>
<thead>
<tr>
<th>Command line flag:</th>
<th><code>--script-api-version=1</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Documentation:</td>
<td><a href="https://github.com/altova">Python API Version 1 Reference</a></td>
</tr>
</tbody>
</table>

This is the original RaptorXML+XBRL Server Python API. It covers support to access the internal model of RaptorXML+XBRL Server for:

- XML 1.0 and XML 1.1 (API module `xml`)
- XMLSchema 1.0 and XMLSchema 1.1 (API module `xsd`)
- XBRL 2.1 (API module `xbrl`)

The API can be used through callback functions which are implemented in a Python script file.

- `on_xsi_valid`
- `on_xsd_valid`
- `on_dts_valid`
- `on_xbrl_valid`

A script is specified with the `--script` option on the command line. The callback functions are invoked only if the validation succeeds. Details about the callback functions and the API are...
described in the RaptorXML+XBRL Server Python API version 1 reference.

**Note:** Raptor's **Python API v1 is deprecated**. Please use Python API v2.

**Python API version 2**

Introduced with RaptorXML+XBRL Server v2015r3. The latest API version is **2.7.0**.

<table>

</tr>
<tr>
<td></td>
<td>--script-api-version=2.7.0</td>
<td>v2019r3</td>
</tr>
</tbody>
</table>

**Documentation:** [Python API Version 2 Reference](#)

This API version introduces over 300 new classes and reorganizes the modules from the RaptorXML+XBRL Server Python API version 1 in such a way that frequently used information (for example, PSVI data) can be accessed more simply and related APIs are grouped logically together (for example, xbrl.taxonomy, xbrl.formula, xbrl.table). In this version, the callback functions are invoked not only if validation succeeds, but also if validation fails. To reflect this behavior, the name of the callback functions are changed to:

- on_xsi_finished
- on_xsd_finished
- on_dts_finished
- on_xbrl_finished

To enable modularization, RaptorXML+XBRL Server now supports multiple `--script` options. The callbacks implemented in these Python script files are executed in the order specified on the command line.
5.2.2 RaptorXML+XBRL Server as a Python Package

Starting with RaptorXML+XBRL Server 2017, the Python API is available as a native Python wheel package for **Python 3.5**. The Python wheel package can be installed as an extension module into your favored Python 3.5 distribution (for example, from python.org). Some Python 3 distributions (for example, from jupyter.org, anaconda.org and SciPy.org) include a wide range of extension modules for big data, mathematics, science, engineering and graphics. These modules now become available to RaptorXML+XBRL Server without the need to build these modules specifically for RaptorXML+XBRL Server. Otherwise, the wheel package works the same way as the RaptorXMLXBRL-python.exe application that is included with RaptorXML+XBRL Server.

**Note:** The Python wheel package is a native Python 3.5 extension module and is compatible with Python version 3.5.

**Note:** The Python wheel package does not include the Python API v1.

**Note:** If you update your version of RaptorXML+XBRL Server, make sure to update the Python wheel package in your Python environment.

The information required to correctly install the RaptorXML+XBRL Server package is given in the sections below:

- Name of wheel file
- Location of wheel file
- Installing a wheel with pip
- The root catalog file
- The JSON config file

For information about how to use RaptorXML+XBRL Server's Python API, see the Python API Reference and examples. Also see example scripts that use Raptor's Python API at https://github.com/altova.

Name of wheel file

Wheel files are named according to the following pattern:

```python
raptorxmlserver-{version}(-{build tag})?-{python tag}-{abi tag}-{platform tag}.whl
```

**Examples:**

- raptorxmlserver-2.6.0-cp35-cp35m-win_amd64.whl
- raptorxmlserver-2.6.0-cp35-cp35m-win_amd64.whl

Location of wheel file

A wheel file is packaged with your installation of RaptorXML+XBRL Server. It is located in the application's `bin` folder:

<table>
<thead>
<tr>
<th>Windows</th>
<th>Program Files\Altova\RaptorXMLXBRLServer2019\bin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>/opt/Altova/RaptorXMLXBRLServer2019/bin</td>
</tr>
</tbody>
</table>
Installing a wheel with pip

To install the RaptorXML+XBRL Server package as a Python module, use the **pip** command:

```
pip install <wheel-file>.whl
python -m pip install <wheel-file>.whl
```

If you have installed Python 3.5 or later from python.org, then **pip** will already be installed. Otherwise, you will need to install **pip** first. For more information, see [https://docs.python.org/3/installing/](https://docs.python.org/3/installing/).

The root catalog file

The RaptorXMLXBRL module for Python must be able to locate `RootCatalog.xml`, the root catalog file that is stored in your RaptorXML+XBRL Server installation folder. This is so that the RaptorXMLXBRL module can use the catalog to correctly locate the various resources, such as schemas and other specifications, that the module references in order to carry out functions such as validations and transformations. The RaptorXMLXBRL module will automatically locate `RootCatalog.xml` if the catalog's location has not been changed subsequent to the installation of RaptorXML+XBRL Server.

In case you move or modify your RaptorXML+XBRL Server environment, or if you move `RootCatalog.xml` from its original installed location, then you can specify the catalog's location by means of environment variables and the **RaptorXMLXBRL module's JSON Config File**. See the list below for the various ways in which you can do this. The RaptorXMLXBRL module determines the location of `RootCatalog.xml` by looking up the following resources in the order given.

<table>
<thead>
<tr>
<th></th>
<th>Environment variable</th>
<th>Create with a value that is the path to <code>RootCatalog.xml</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALTOVA_RAPTORXML_PYTHON_CATALOGPATH</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>HKLM Registry: SOFTWARE\Altova\RaptorXML +XBRLServer\Installation_v2019_x64 \Setup\CatalogPath</td>
<td>Registry key is added by RaptorXML +XBRL Server installer. Value is the path to <code>RootCatalog.xml</code>. <strong>Windows only</strong></td>
</tr>
<tr>
<td>3</td>
<td>Location: /opt/Altova/ RaptorXMLXBRLServer2019/etc/ RootCatalog.xml</td>
<td><strong>Linux only</strong></td>
</tr>
<tr>
<td>4</td>
<td>Location: /usr/local/Altova/ RaptorXMLXBRLServer2019/etc/ RootCatalog.xml</td>
<td><strong>Mac only</strong></td>
</tr>
<tr>
<td>5</td>
<td>Environment variable ALTOVA_RAPTORXML_PYTHON_CONFIG</td>
<td>Create with a value that is the path to the <strong>JSON config file</strong>.</td>
</tr>
<tr>
<td>6</td>
<td>Location: .altova/raptorxml-python.config</td>
<td><strong>The JSON config file</strong> in the current working directory</td>
</tr>
<tr>
<td>7</td>
<td>Location: ~/.config/altova/raptorxml-python.config</td>
<td><strong>The JSON config file</strong> in the user's home directory</td>
</tr>
</tbody>
</table>

---

© 2019 Altova GmbH

Altova RaptorXML+XBRL Server 2019

Mac /usr/local/Altova/RaptorXMLXBRLServer2019/bin
The JSON config file

You can create a JSON config file for the RaptorXMLXBRLServer module. This file will be used by options 5 to 8 in the table above to locate the root catalog file. The JSON config file must contain a map with a "CatalogPath" key that has a value which is the path to the root catalog file.

Listing of JSON config file

```json
{
    "CatalogPath": "/path/to/RootCatalog.xml"
}
```
5.3 .NET Framework API

The .NET Framework API of RaptorXML+XBRL Server enables you to integrate the RaptorXML engine in applications written in C# and other .NET languages.

It is implemented as a .NET assembly and puts the RaptorXML engine directly inside an application or a .NET-framework-based extension mechanism like VSTO (Visual Studio Tools for Office). The API provides fine-grained access to validate documents and to query their internal data model from RaptorXML+XBRL Server.

Reference and resources

- **Example code**: The example code is hosted at https://github.com/altova/RaptorXML-Examples.
6  Additional Information

This section contains the following additional information:

- Exit Codes
- Schema Location Hints
- XBRL Formula Parameters
## 6.1 Exit Codes

The following exit codes are available:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Validation successful</td>
</tr>
<tr>
<td>1</td>
<td>Validation failed with error / Process interrupted by Ctrl+C/Break/terminal closed / License expired during execution</td>
</tr>
<tr>
<td>11</td>
<td>RaptorXML could not start; the reason is given in the log file</td>
</tr>
<tr>
<td>22</td>
<td>Could not load root catalog / Could not load list file</td>
</tr>
<tr>
<td>64</td>
<td>Invalid command/options</td>
</tr>
<tr>
<td>77</td>
<td>Failed to acquire license during startup</td>
</tr>
<tr>
<td>128+n</td>
<td>RaptorXML terminated because of signal number n. All exit codes above 128 indicate termination as a result of a received external signal or an internally triggered signal. For example, if the exit code is 134, then the signal number is 134-128=6 (the number of SIGABRT).</td>
</tr>
</tbody>
</table>
6.2 Schema Location Hints

Instance documents can use hints to indicate the schema location. Two attributes are used for hints:

- `xsi:schemaLocation` for schema documents with target namespaces. The attribute's value is a pair of items, the first of which is a namespace, the second is a URL that locates a schema document. The namespace name must match the target namespace of the schema document.

  ```xml
  <document xmlns="http://www.altova.com/schemas/test03"
            xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xsi:schemaLocation="http://www.altova.com/schemas/test03 Test.xsd">
  </document>
  ```

- `xsi:noNamespaceSchemaLocation` for schema documents without target namespaces. The attribute's value is the schema document's URL. The referenced schema document must have no target namespace.

  ```xml
  <document xmlns="http://www.altova.com/schemas/test03"
            xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xsi:noNamespaceSchemaLocation="Test.xsd">
  </document>
  ```

The `--schemalocation-hints` option specifies how these two attributes are to be used as hints, especially how the `schemaLocation` attribute information is to be handled (see the option's description above). Note that RaptorXML+XBRL Server considers the namespace part of the `xsi:noNamespaceSchemaLocation` value to be the empty string.

Schema location hints can also be given in an import statement of an XML Schema document.

  ```xml
  <import namespace="someNS" schemaLocation="someURL">
  </import>
  ```

In the import statement, too, hints can be given via a namespace that can be mapped to a schema in a catalog file, or directly as a URL in the `schemaLocation` attribute. The `--schema-imports` option (for XBRL and XSD/XML) specifies how the schema location is to be selected.
6.3 XBRL Formula Parameters

This section contains the following topics:

- **Formula Parameter Formats**, which gives examples of the XML and JSON formats of XBRL formula parameters.
- **Using Formula Parameters** contains listings in Java, VB.NET, C#, VBScript, and JScript that show formula parameters can be used using objects from the Java and COM/.NET API libraries.
6.3.1 Formula Parameter Formats

Formula parameters can be given in XML format or JSON format.

**XML format**

The listing below shows formula parameters in XML format.

```xml
<?xml version="1.0" encoding="utf-8"?>
<options:formula-parameters
  xmlns:options="http://www.altova.com/schemas/altova/raptorxml/options"
  xmlns:p="http://xbrl.org/formula/conformance/paramstuff"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.altova.com/schemas/altova/raptorxml/options
  http://www.altova.com/schemas/altova/raptorxml/options.xsd">

  <options:parameter name="p1">
    <options:value type="xs:string">hello world from new xml (without namespace)</value>
  </options:parameter>

  <options:parameter name="ns1:p1" type="xs:string" value="hello world from new xml"/>

</options:formula-parameters>
```

Note the following points:

- The @type attribute is optional and defaults to xs:string.
- Multiple <options:value> child elements can be specified in order to assign an XPath sequence to a parameter.
- @value and <options:value> cannot be used at the same time.

**JSON format**

The listing below shows formula parameters in JSON format.

```json
{
  "formula-parameters": [
    {
      "name": "p1",
      "values": [
        {
          "type": "xs:string",
          "value": "hello world from json new (without namespace)"
        }
      ]
    },
    {
      "name": "ns1:p1",
      "values": [
        {
          "type": "xs:string",
          "value": "hello world from json new"
        }
      ]
    }
  ]
}
```
Note the following points:

- The **type** key is optional and defaults to `xs:string`.
- The `xs` key is optional and defaults to `http://www.w3.org/2001/XMLSchema`.
- The type in the parameter map is used if a value is specified directly as a JSON string.
- Other ways of writing are currently also supported:

```json
{
    "name": "p2",
    "type": "xs:string",
    "value": "hello world from json new (without namespace)"
},
{
    "name": "p3",
    "type": "xs:int",
    "values": ["1", "2"]
},
{
    "name": "p4",
    "type": "xs: int",
    "values": ["1", {"type": "xs:string", "value": "abc"}, "2"]
}
```
6.3.2 Using Formula Parameters

The example listings below shows how XBRL formula parameters can be used in various programming languages. For more information, see the description of the Server API's XBRL interface.

Java

```java
RaptorXMLFactory rxml = RaptorXML.getFactory();
XBRL xbrl = rxml.getXBRL();

xbrl.addFormulaParameter( "ns1:string", "ns1:Param1", "ns1:theqname" );
xbrl.addFormulaParameterNamespace( "ns1", "www.www.www" );

// The parameter is an array of dates
xbrl.addFormulaArrayParameter( "", "startDates", new Object[]{ new FormulaParam( "xs:date", "2010-01-01" ), new FormulaParam( "xs:date", "2012-01-01" ) } );

// The parameter is an array of figs
xbrl.addFormulaArrayParameter( "ns1:figs", "startFigs", new Object[]{ "fig1", "fig2", "fig3" } );

// The parameter is an array of figs, dates and raisins (rather wild example)
xbrl.addFormulaArrayParameter( "ns1:figs", "startDryFruit", new Object[]{ "fig1", "fig2", new FormulaParam( "xs:date", "2010-01-01" ), new FormulaParam( "ns1:raisin", "dried grape" ), "fig3" } );
```

VB.NET

```vbnet
Dim objRaptor As New Server()
Dim objXBRL As XBRL
objXBRL = objRaptor.GetXBRL()

objXBRL.AddFormulaParameter("ns1:string", "ns1:Param1", "ns1:theqname")
objXBRL.AddFormulaParameterNamespace("ns1", "www.www.www")

' The parameter is an array of dates

' The parameter is an array of figs
objXBRL.AddFormulaArrayParameter("ns1:figs", "startFigs", {"fig1", "fig2", "fig3"})

' The parameter is an array of figs, dates and raisins (rather wild example)
objXBRL.AddFormulaArrayParameter("ns1:figs", "startDryFruit", {"fig1", "fig2", "fig3"})
```
"fig2", New XBRLFormulaParam With {.ParamType = "xs:date", .ParamValue = "2010-01-01"}, New XBRLFormulaParam With {.ParamType = "ns1:raisin", .ParamValue = "dried grape"}, "fig3")

C#

Server app = new Server();
XBR objXBRL = app.GetXBRL();

objXBRL.AddFormulaParameter("ns1:string", "ns1:Param1", "ns1:theqname");
objXBRL.AddFormulaParameterNamespace("ns1", "www.www.www");

//The parameter is an array of dates
objXBRL.AddFormulaArrayParameter("", "startDates", new object[] {new XBRLFormulaParam { ParamType = "xs:date", ParamValue = "2010-01-01"}, new XBRLFormulaParam {ParamType = "xs:date", ParamValue = "2012-01-01"}});

//The parameter is an array of figs
objXBRL.AddFormulaArrayParameter("ns1:figs", "startFigs", new object[] {"fig1", "fig2", "fig3"});

//The parameter is an array of figs, dates and raisins (rather wild example)
objXBRL.AddFormulaArrayParameter("ns1:figs", "startDryFruit", new object[] {"fig1", "fig2", new XBRLFormulaParam { ParamType = "xs:date", ParamValue = "2010-01-01" }, new XBRLFormulaParam { ParamType = "ns1:raisin", ParamValue = "dried grape" }, "fig3" });

VBScript

Since the Raptor type library cannot be loaded by scripting languages, and because the type XBRLFormulaParameters doesn't exist, the VBScript user, instead of using XBRLFormulaParam objects, must declare a class in his/her program. The class must have two public properties, ParamName and ParamValue (just as the XBRLFormulaParam has). The class should have a constructor that takes the type and value, since this simplifies usage; otherwise the object needs to be created and have its members set). For more information, see the description of the Server API's XBRL interface.

Class MyPair
Public ParamType
Public ParamValue
Public Default Function Init( inType, inValue )
    ParamType = inType
    ParamValue = inValue
    set Init = Me
End Function
End Class
Sub Main
    Dim objRaptor
    Set objRaptor = WScript.GetObject( "" , "RaptorXML.Server" )
    Dim objXBRL
    Set objXBRL = objRaptor.GetXBRL

    Call objXBRL.AddFormulaParameter("ns1:string", "ns1:Param1", "ns1:theqname")
    Call objXBRL.AddFormulaParameterNamespace("ns1", "www.www.www")

    'The parameter is an array of dates
    Call objXBRL.AddFormulaArrayParameter("", "startDates", Array( ( New MyPair)( "xs:date", "2010-01-01"), ( New MyPair)( "xs:date", "2012-01-01")) )

    'The parameter is an array of figs
    Call objXBRL.AddFormulaArrayParameter("ns1:figs", "startFigs", Array("fig1", "fig2", "fig3") )

    'The parameter is an array of figs, dates and raisins (rather wild example)
    Call objXBRL.AddFormulaArrayParameter("ns1:figs", "startDryFruit", Array("fig1", "fig2", ( New MyPair)( "xs:date", "2010-01-01"), ( New MyPair)( "ns1:raisin", "dried grape"), "fig3") )
End Sub

Call Main

JScript

Since the Raptor type library cannot be loaded by scripting languages, and because the type XBRLFormulaParameters doesn't exist, the JScript user, instead of using XBRL.FormulaParam objects, must declare function-classes in his/her program that holds the type-value pair. Names of members must be ParamType and ParamValue. For more information, see the description of the Server API's XBRL interface.

function FormulaParam( inType, inValue)
{
    this.ParamType = inType;
    this.ParamValue = inValue;
}

function main()
{
    var objRaptor = new ActiveXObject( "RaptorXML.Server" );
    var objXBRL = objRaptor.GetXBRL();

    objXBRL.addFormulaParameter( "ns1:string", "ns1:Param1", "ns1:theqname" );
objXBRL.addFormulaParameter( "xs:string", "Param1", "bla", "www.www.www" );

// The parameter is an array of dates
objXBRL.addFormulaArrayParameter("", "startDates", [new FormulaParam("xs:date", "2010-01-01"), new FormulaParam("xs:date", "2012-01-01")]);

// The parameter is an array of figs
objXBRL.addFormulaArrayParameter("ns1:figs", "startFigs", ["fig1", "fig2", "fig3"]);

// The parameter is an array of figs, dates and raisins (rather wild example)
objXBRL.addFormulaArrayParameter("ns1:figs", "startDryFruit", ["fig1", "fig2", new FormulaParam("xs:date", "2010-01-01"), new FormulaParam("ns1:raisin", "dried grape"), "fig3"]);

main()
7 Engine Information

This section contains information about the XSLT and XQuery engines contained in RaptorXML +XBRL Server. This information mostly concerns engine behavior in situations where the specifications leave the decision regarding behavior up to the implementation. This section also contains information about Altova extension functions for XPath/XQuery.
7.1 XSLT and XQuery Engine Information

The XSLT and XQuery engines of RaptorXML+XBRL Server follow the W3C specifications closely and are therefore stricter than previous Altova engines—such as those in previous versions of XMLSpy and those of AltovaXML, the predecessor of RaptorXML. As a result, minor errors that were ignored by previous engines are now flagged as errors by RaptorXML+XBRL Server.

For example:

- It is a type error (err:XPTY0018) if the result of a path operator contains both nodes and non-nodes.
- It is a type error (err:XPTY0019) if $E_1$ in a path expression $E_1/E_2$ does not evaluate to a sequence of nodes.

If you encounter this kind of error, modify either the XSLT/XQuery document or the instance document as appropriate.

This section describes implementation-specific features of the engines, organized by specification:

- XSLT 1.0
- XSLT 2.0
- XSLT 3.0
- XQuery 1.0
- XQuery 3.1
7.1.1 **XSLT 1.0**

The XSLT 1.0 Engine of RaptorXML+XBRL Server conforms to the World Wide Web Consortium's (W3C's) *XSLT 1.0 Recommendation of 16 November 1999* and *XPath 1.0 Recommendation of 16 November 1999*. Note the following information about the implementation.

**Notes about the implementation**

When the *method* attribute of *xsl:output* is set to HTML, or if HTML output is selected by default, then special characters in the XML or XSLT file are inserted in the HTML document as HTML character references in the output. For instance, the character U+00A0 (the hexadecimal character reference for a non-breaking space) is inserted in the HTML code either as a character reference (``&#160;`` or ``&#xA0;``) or as an entity reference, ``&nbsp;``.
7.1.2 XSLT 2.0

This section:

- Engine conformance
- Backward compatibility
- Namespaces
- Schema awareness
- Implementation-specific behavior

Conformance

Backwards Compatibility
The XSLT 2.0 engine is backwards compatible. The only time the backwards compatibility of the XSLT 2.0 engine comes into effect is when using the XSLT 2.0 engine (CLI parameter --xslt=2) to process an XSLT 1.0 stylesheet. Note that there could be differences in the outputs produced by the XSLT 1.0 Engine and the backwards-compatible XSLT 2.0 engine.

Namespaces
Your XSLT 2.0 stylesheet should declare the following namespaces in order for you to be able to use the type constructors and functions available in XSLT 2.0. The prefixes given below are conventionally used; you could use alternative prefixes if you wish.

<table>
<thead>
<tr>
<th>Namespace Name</th>
<th>Prefix</th>
<th>Namespace URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML Schema types</td>
<td>xs:</td>
<td><a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a></td>
</tr>
<tr>
<td>XPath 2.0 functions</td>
<td>fn:</td>
<td><a href="http://www.w3.org/2005/xpath-functions">http://www.w3.org/2005/xpath-functions</a></td>
</tr>
</tbody>
</table>

Typically, these namespaces will be declared on the xsl:stylesheet or xsl:transform element, as shown in the following listing:

```xml
<xsl:stylesheet version="2.0"
   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:fn="http://www.w3.org/2005/xpath-functions"
   ...
</xsl:stylesheet>
```

The following points should be noted:

- The XSLT 2.0 engine uses the XPath 2.0 and XQuery 1.0 Functions namespace (listed in the table above) as its default functions namespace. So you can use XPath 2.0 and XSLT 2.0 functions in your stylesheet without any prefix. If you declare the XPath 2.0 Functions namespace in your stylesheet with a prefix, then you can additionally use the prefix assigned in the declaration.
- When using type constructors and types from the XML Schema namespace, the prefix
used in the namespace declaration must be used when calling the type constructor (for example, xs:date).

- Some XPath 2.0 functions have the same name as XML Schema datatypes. For example, for the XPath functions fn:string and fn:boolean there exist XML Schema datatypes with the same local names: xs:string and xs:boolean. So if you were to use the XPath expression string('Hello'), the expression evaluates as fn:string('Hello')—not as xs:string('Hello').

**Schema-awareness**

The XSLT 2.0 engine is schema-aware. So you can use user-defined schema types and the xsl:validate instruction.

**Implementation-specific behavior**

Given below is a description of how the XSLT 2.0 engine handles implementation-specific aspects of the behavior of certain XSLT 2.0 functions.

**xsl:result-document**

Additionally supported encodings are (the Altova-specific): x-base16tobinary and x-base64tobinary.

**function-available**

The function tests for the availability of in-scope functions (XSLT, XPath, and extension functions).

**unparsed-text**

The href attribute accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the file:// protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64.

**unparsed-text-available**

The href attribute accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the file:// protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64.

**Note:** The following encoding values, which were implemented in earlier versions of RaptorXML's predecessor product, AltovaXML, are now deprecated: base16tobinary, base64tobinary, binarytobase16 and binarytobase64.
7.1.3  XSLT 3.0

The XSLT 3.0 engine has the same implementation-specific characteristics as the XSLT 2.0 engine. Additionally, it includes support for a number of new XSLT 3.0 features: XPath/XQuery 3.1 functions and operators, and the XPath 3.1 specification.

Note: The optional streaming feature is not supported currently. The entire document will be loaded into memory regardless of the value of the streamable attribute, and will be processed if enough memory is available. In 64-bit apps this should not be a problem. If memory does turn out to be an issue, a solution would be to add more memory to the system.
7.1.4  XQuery 1.0

This section:

- Engine conformance
- Schema awareness
- Encoding
- Namespaces
- XML source and validation
- Static and dynamic type checking
- Library modules
- External functions
- Collations
- Precision of numeric data
- XQuery instructions support

Conformance
The XQuery 1.0 Engine of RaptorXML+XBRL Server conforms to the World Wide Web Consortium's (W3C's) XQuery 1.0 Recommendation of 14 December 2010. The XQuery standard gives implementations discretion about how to implement many features. Given below is a list explaining how the XQuery 1.0 Engine implements these features.

Schema awareness
The XQuery 1.0 Engine is schema-aware.

Encoding
The UTF-8 and UTF-16 character encodings are supported.

Namespaces
The following namespace URIs and their associated bindings are pre-defined.

<table>
<thead>
<tr>
<th>Namespace Name</th>
<th>Prefix</th>
<th>Namespace URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML Schema types</td>
<td>xs:</td>
<td><a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a></td>
</tr>
<tr>
<td>Schema instance</td>
<td>xsi:</td>
<td><a href="http://www.w3.org/2001/XMLSchema-instance">http://www.w3.org/2001/XMLSchema-instance</a></td>
</tr>
<tr>
<td>Built-in functions</td>
<td>fn:</td>
<td><a href="http://www.w3.org/2005/xpath-functions">http://www.w3.org/2005/xpath-functions</a></td>
</tr>
<tr>
<td>Local functions</td>
<td>local:</td>
<td><a href="http://www.w3.org/2005/xquery-local-functions">http://www.w3.org/2005/xquery-local-functions</a></td>
</tr>
</tbody>
</table>

The following points should be noted:

- The XQuery 1.0 Engine recognizes the prefixes listed above as being bound to the corresponding namespaces.
- Since the built-in functions namespace listed above is the default functions namespace in XQuery, the fn: prefix does not need to be used when built-in functions are invoked (for example, string("Hello") will call the fn:string function). However, the prefix fn: can be used to call a built-in function without having to declare the namespace in the query.
You can change the default functions namespace by declaring the `default function namespace expression` in the query prolog.

When using types from the XML Schema namespace, the prefix `xs:` may be used without having to explicitly declare the namespaces and bind these prefixes to them in the query prolog. (Example: `xs:date` and `xs:yearMonthDuration`.) If you wish to use some other prefix for the XML Schema namespace, this must be explicitly declared in the query prolog. (Example: `declare namespace alt = "http://www.w3.org/2001/XMLSchema"; alt:date("2004-10-04")`.)

Note that the `untypedAtomic`, `dayTimeDuration`, and `yearMonthDuration` datatypes have been moved, with the CRs of 23 January 2007, from the XPath Datatypes namespace to the XML Schema namespace, so: `xs:yearMonthDuration`.

If namespaces for functions, type constructors, node tests, etc are wrongly assigned, an error is reported. Note, however, that some functions have the same name as schema datatypes, e.g. `fn:string` and `fn:boolean`. (Both `xs:string` and `xs:boolean` are defined.) The namespace prefix determines whether the function or type constructor is used.

**XML source document and validation**

XML documents used in executing an XQuery document with the XQuery 1.0 Engine must be well-formed. However, they do not need to be valid according to an XML Schema. If the file is not valid, the invalid file is loaded without schema information. If the XML file is associated with an external schema and is valid according to it, then post-schema validation information is generated for the XML data and will be used for query evaluation.

**Static and dynamic type checking**

The static analysis phase checks aspects of the query such as syntax, whether external references (e.g. for modules) exist, whether invoked functions and variables are defined, and so on. If an error is detected in the static analysis phase, it is reported and the execution is stopped.

Dynamic type checking is carried out at run-time, when the query is actually executed. If a type is incompatible with the requirement of an operation, an error is reported. For example, the expression `xs:string("1") + 1` returns an error because the addition operation cannot be carried out on an operand of type `xs:string`.

**Library Modules**

Library modules store functions and variables so they can be reused. The XQuery 1.0 Engine supports modules that are stored in a single external XQuery file. Such a module file must contain a `module declaration` in its prolog, which associates a target namespace. Here is an example module:

```xquery
module namespace libns="urn:module-library";
declare variable $libns:company := "Altova";
declare function libns:webaddress() { "http://www.altova.com" };
```

All functions and variables declared in the module belong to the namespace associated with the module. The module is used by importing it into an XQuery file with the `import module` statement in the query prolog. The `import module` statement only imports functions and variables declared directly in the library module file. As follows:
import module namespace modlib = "urn:module-library" at "modulefilename.xq";

if ($modlib:company = "Altova")
then  modlib:webaddress()
else  error("No match found.")

External functions
External functions are not supported, i.e. in those expressions using the external keyword, as in:

declare function hoo($param as xs:integer) as xs:string external;

Collations
The default collation is the Unicode-codepoint collation, which compares strings on the basis of their Unicode codepoint. Other supported collations are the ICU collations listed here. To use a specific collation, supply its URI as given in the list of supported collations. Any string comparisons, including for the fn:max and fn:min functions, will be made according to the specified collation. If the collation option is not specified, the default Unicode-codepoint collation is used.

Precision of numeric types

- The xs:integer datatype is arbitrary-precision, i.e. it can represent any number of digits.
- The xs:decimal datatype has a limit of 20 digits after the decimal point.
- The xs:float and xs:double datatypes have limited-precision of 15 digits.

XQuery Instructions Support
ThePragma instruction is not supported. If encountered, it is ignored and the fallback expression is evaluated.
7.1.5 **XQuery 3.1**

The XQuery 3.1 Engine of RaptorXML+XBRL Server conforms to the World Wide Web Consortium's (W3C's) [XQuery 3.1 Recommendation of 21 March 2017](https://www.w3.org/TR/xquery31/) and includes support for XPath and XQuery Functions 3.1. The XQuery 3.1 specification is a superset of the 3.0 specification. The XQuery 3.1 engine therefore supports XQuery 3.0 features.

Implementation-specific characteristics are the same as for [XQuery 1.0](https://www.w3.org/TR/xquery11/).
7.2 XSLT and XPath/XQuery Functions

This section lists Altova extension functions and other extension functions that can be used in XPath and/or XQuery expressions. Altova extension functions can be used with Altova’s XSLT and XQuery engines, and provide functionality additional to that available in the function libraries defined in the W3C standards.

General points

The following general points should be noted:

- Functions from the core function libraries defined in the W3C specifications can be called without a prefix. That's because the XSLT and XQuery engines read non-prefixed functions as belonging to a default functions namespace which is that specified in the XPath/XQuery functions specifications [http://www.w3.org/2005/xpath-functions](http://www.w3.org/2005/xpath-functions). If this namespace is explicitly declared in an XSLT or XQuery document, the prefix used in the namespace declaration can also optionally be used on function names.
- In general, if a function expects a sequence of one item as an argument, and a sequence of more than one item is submitted, then an error is returned.
- All string comparisons are done using the Unicode codepoint collation.
- Results that are QNames are serialized in the form [prefix:]localname.

Precision of xs:decimal

The precision refers to the number of digits in the number, and a minimum of 18 digits is required by the specification. For division operations that produce a result of type xs:decimal, the precision is 19 digits after the decimal point with no rounding.

Implicit timezone

When two date, time, or dateTime values need to be compared, the timezone of the values being compared need to be known. When the timezone is not explicitly given in such a value, the implicit timezone is used. The implicit timezone is taken from the system clock, and its value can be checked with the implicit-timezone() function.

Collations

The default collation is the Unicode codepoint collation, which compares strings on the basis of their Unicode codepoint. The engine uses the Unicode Collation Algorithm. Other supported collations are the ICU collations listed below; to use one of these, supply its URI as given in the table below. Any string comparisons, including for the max and min functions, will be made according to the specified collation. If the collation option is not specified, the default Unicode-codepoint collation is used.

<table>
<thead>
<tr>
<th>Language</th>
<th>URIs</th>

<td>da: Danish</td>
<td>da_DK</td>
</tr>
<tr>
<td>de: German</td>
<td>de_AT, de_BE, de_CH, de_DE, de_LI, de_LU</td>
</tr>
</tbody>
</table>
### Namespace axis

The namespace axis is deprecated in XPath 2.0. Use of the namespace axis is, however, supported. To access namespace information with XPath 2.0 mechanisms, use the `in-scope-prefixes()`, `namespace-uri()` and `namespace-uri-for-prefix()` functions.

7.2.1 Altova Extension Functions

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

Functions defined in the W3C’s XPath/XQuery Functions specifications can be used in: (i) XPath expressions in an XSLT context, and (ii) in XQuery expressions in an XQuery document. In this documentation we indicate the functions that can be used in the former context (XPath in XSLT) with an XP symbol and call them XPath functions; those functions that can be used in the latter (XQuery) context are indicated with an XQ symbol; they work as XQuery functions. The W3C’s XSLT specifications—not XPath/XQuery Functions specifications—also define functions that can be used in XPath expressions in XSLT documents. These functions are marked with an XSLT symbol and are called XSLT functions. The XPath/XQuery and XSLT versions in which a function can be used are indicated in the description of the function (see symbols below). Functions from the XPath/XQuery and XSLT function libraries are listed without a prefix. Extension functions from other libraries, such as Altova extension functions, are listed with a prefix.

<table>
<thead>
<tr>
<th>XPath functions (used in XPath expressions in XSLT):</th>
<th>XP1 XP2 XP3.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSLT functions (used in XPath expressions in XSLT):</td>
<td>XSLT1 XSLT2 XSLT3</td>
</tr>
<tr>
<td>XQuery functions (used in XQuery expressions in XQuery):</td>
<td>XQ1 XQ3.1</td>
</tr>
</tbody>
</table>

**XSLT functions**

XSLT functions can only be used in XPath expressions in an XSLT context (similarly to XSLT 2.0’s current-group() or key() functions). These functions are not intended for, and will not work in, a non-XSLT context (for instance, in an XQuery context). Note that XSLT functions for XBRL can be used only with editions of Altova products that have XBRL support.

**XPath/XQuery functions**

XPath/XQuery functions can be used both in XPath expressions in XSLT contexts as well as in XQuery expressions:

- Date/Time
- Geolocation
- Image-related
- Numeric
- Sequence
- String
- Miscellaneous
Chart functions (Enterprise and Server Editions only)
Altova extension functions for charts are supported only in the Enterprise and Server Editions of Altova products and enable charts to be generated from XML data.

Barcode functions
Altova's barcode extension functions enable barcodes to be generated and placed in output generated via XSLT stylesheets.

7.2.1.1 XSLT Functions

XSLT extension functions can be used in XPath expressions in an XSLT context. They will not work in a non-XSLT context (for instance, in an XQuery context).

Note about naming of functions and language applicability
Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

<table>

<th>XP1 XP2 XP3.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSLT functions (used in XPath expressions in XSLT):</td>
<td>XSLT1 XSLT2 XSLT3</td>
</tr>
<tr>
<td>XQuery functions (used in XQuery expressions in XQuery):</td>
<td>XQ1 XQ3.1</td>
</tr>
</tbody>
</table>

Standard functions

- distinct-nodes [altova:]

  `altova:distinct-nodes(node(*)*) as node()*`  
  Takes a set of one or more nodes as its input and returns the same set minus nodes with duplicate values. The comparison is done using the XPath/XQuery function `fn:deep-equal`.  
  **Examples**
  - `altova:distinct-nodes(country)` returns all child `country` nodes less those having duplicate values.

- evaluate [altova:]

  `altova:evaluate(XPathExpression as xs:string[, ValueOf$p1, ... ValueOf$pN])`  
  Takes an XPath expression, passed as a string, as its mandatory argument. It returns the output of the evaluated expression. For example: `altova:evaluate(//Name[1]')` returns the contents of the first `Name` element in the document. Note that the expression `//Name[1]` is passed as a string by enclosing it in single quotes.
The `altova:evaluate` function can optionally take additional arguments. These arguments are the values of in-scope variables that have the names \( p_1, p_2, p_3, \ldots p_N \). Note the following points about usage: (i) The variables must be defined with names of the form \( p_X \), where \( X \) is an integer; (ii) the `altova:evaluate` function's arguments (see signature above), from the second argument onwards, provide the values of the variables, with the sequence of the arguments corresponding to the numerically ordered sequence of variables: \( p_1 \) to \( p_N \); The second argument will be the value of the variable \( p_1 \), the third argument that of the variable \( p_2 \), and so on; (iii) The variable values must be of type `item*`.

**Example**

```xml
<xsl:variable name="xpath" select="'${p3}, ${p2}, ${p1}'" />
<xsl:value-of select="altova:evaluate($xpath, 10, 20, 'hi')" />

outputs "hi 20 10"
```

In the listing above, notice the following:

- The second argument of the `altova:evaluate` expression is the value assigned to the variable \( p_1 \), the third argument that assigned to the variable \( p_2 \), and so on.
- Notice that the fourth argument of the function is a string value, indicated by its being enclosed in quotes.
- The `select` attribute of the `xs:string` element supplies the XPath expression. Since this expression must be of type `xs:string`, it is enclosed in single quotes.

**Examples to further illustrate the use of variables**

- `<xsl:variable name="xpath" select="'$p1'" />
  <xsl:value-of select="altova:evaluate($xpath, //Name[1])" />
  Outputs value of the first Name element.

- `<xsl:variable name="xpath" select="'$p1'" />
  <xsl:value-of select="altova:evaluate($xpath, '//Name[1]')" />
  Outputs "//Name[1]"

The `altova:evaluate()` extension function is useful in situations where an XPath expression in the XSLT stylesheet contains one or more parts that must be evaluated dynamically. For example, consider a situation in which a user enters his request for the sorting criterion and this criterion is stored in the attribute `UserReq/@sortkey`. In the stylesheet, you could then have the expression: `<xsl:sort select="altova:evaluate(../UserReq/@sortkey)" order="ascending"/>`. The `altova:evaluate()` function reads the `sortkey` attribute of the `UserReq` child element of the parent of the context node. Say the value of the `sortkey` attribute is `Price`, then `Price` is returned by the `altova:evaluate()` function and becomes the value of the `select` attribute: `<xsl:sort select="'Price'" order="ascending"/>`. If this sort instruction occurs within the context of an element called `Order`, then the `Order` elements will be sorted according to the values of their `Price` children. Alternatively, if the value of `@sortkey` were, say, `Date`, then the `Order` elements would be sorted according to the values of their `Date` children. So the sort criterion for `Order` is selected from the `sortkey` attribute at runtime. This could not have been achieved with an expression like: `<xsl:sort select="../UserReq/@sortkey""/>`
In the case shown above, the sort criterion would be the `sortkey` attribute itself, not `Price` or `Date` (or any other current content of `sortkey`).

**Note:** The static context includes namespaces, types, and functions—but not variables—from the calling environment. The base URI and default namespace are inherited.

More examples

- Static variables: `<xsl:value-of select="$i3, $i2, $i1" />
  Outputs the values of three variables.

- Dynamic XPath expression with dynamic variables:
  `<xsl:variable name="xpath" select="/p3, $p2, $p1" />
  `<xsl:value-of select="altova:evaluate($xpath, 10, 20, 30)" />
  Outputs "30 20 10"

- Dynamic XPath expression with no dynamic variable:
  `<xsl:variable name="xpath" select="/p3, $p2, $p1" />
  `<xsl:value-of select="altova:evaluate($xpath)" />
  Outputs error: No variable defined for $p3.

**encode-for-rtf [altova:]**

```
altova:encode-for-rtf(input as xs:string, preserveallwhitespace as xs:boolean, preservenewlines as xs:boolean) as xs:string
```

Converts the input string into code for RTF. Whitespace and new lines will be preserved according to the boolean value specified for their respective arguments.

XBRL functions

Altova XBRL functions can be used only with editions of Altova products that have XBRL support.

**xbrl-footnotes [altova:]**

```
altova:xbrl-footnotes(node()) as node()*
```

Takes a node as its input argument and returns the set of XBRL footnote nodes referenced by the input node.

**xbrl-labels [altova:]**

```
altova:xbrl-labels(xs:QName, xs:string) as node()*
```

Takes two input arguments: a node name and the taxonomy file location containing the node. The function returns the XBRL label nodes associated with the input node.
7.2.1.2 XPath/XQuery Functions: Date and Time

Altova’s date/time extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data held as XML Schema’s various date and time datatypes. The functions in this section can be used with Altova’s XPath 3.0 and XQuery 3.0 engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

.Grouped by functionality

- Add a duration to xs:dateTime and return xs:dateTime
- Add a duration to xs:date and return xs:date
- Add a duration to xs:time and return xs:time
- Format and retrieve durations
- Remove timezone from functions that generate current date/time
- Return days, hours, minutes, and seconds from durations
- Return weekday as integer from date
- Return week number as integer from date
- Build date, time, or duration type from lexical components of each type
- Construct date, dateTime, or time type from string input
- Age-related functions

.Grouped alphabetically

altova:add-days-to-date
altova:add-days-to-dateTime
altova:add-hours-to-dateTime
altova:add-hours-to-time
altova:add-minutes-to-dateTime
altova:add-minutes-to-time
altova:add-months-to-date
altova:add-months-to-dateTime
altova:add-seconds-to-dateTime
altova:add-seconds-to-time
altova:add-years-to-date
altova:add-years-to-dateTime
altova:age
altova:age-details
Add a duration to xs:dateTime [XP3.1 XQ3.1]

These functions add a duration to xs:dateTime and return xs:dateTime. The xs:dateTime type has a format of CCYY-MM-DDThh:mm:ss.sss. This is a concatenation of the xs:date and xs:time formats separated by the letter T. A timezone suffix +01:00 (for example) is optional.

**add-years-to-dateTime [altova:]**

```
altova:add-years-to-dateTime(DateTime as xs:dateTime, Years as xs:integer) as xs:dateTime
```

Adds a duration in years to an xs:dateTime (see examples below). The second argument is the number of years to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

**Examples**

- `altova:add-years-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10)` returns 2024-01-15T14:00:00
- `altova:add-years-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -4)` returns 2010-01-15T14:00:00

**add-months-to-dateTime [altova:]**

```
altova:add-months-to-dateTime(DateTime as xs:dateTime, Months as xs:integer) as xs:dateTime
```

Adds a duration in months to an xs:dateTime (see examples below). The second argument is the number of months to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.
Examples

- `altova:add-months-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10)` returns `2011-11-15T14:00:00`
- `altova:add-months-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -2)` returns `2013-11-15T14:00:00`

### add-days-to-dateTime [altova:]

```xml
altova:add-days-to-dateTime(Date|Time as xs:dateTime, Days as xs:integer) as xs:dateTime
```

Adds a duration in days to an `xs:dateTime` (see examples below). The second argument is the number of days to be added to the `xs:dateTime` supplied as the first argument. The result is of type `xs:dateTime`.

#### Examples

- `altova:add-days-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10)` returns `2014-01-25T14:00:00`
- `altova:add-days-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -8)` returns `2014-01-07T14:00:00`

### add-hours-to-dateTime [altova:]

```xml
altova:add-hours-to-dateTime(Date|Time as xs:dateTime, Hours as xs:integer) as xs:dateTime
```

Adds a duration in hours to an `xs:dateTime` (see examples below). The second argument is the number of hours to be added to the `xs:dateTime` supplied as the first argument. The result is of type `xs:dateTime`.

#### Examples

- `altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T13:00:00"), 10)` returns `2014-01-15T23:00:00`
- `altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T13:00:00"), -8)` returns `2014-01-15T05:00:00`

### add-minutes-to-dateTime [altova:]

```xml
altova:add-minutes-to-dateTime(Date|Time as xs:dateTime, Minutes as xs:integer) as xs:dateTime
```

Adds a duration in minutes to an `xs:dateTime` (see examples below). The second argument is the number of minutes to be added to the `xs:dateTime` supplied as the first argument. The result is of type `xs:dateTime`.

#### Examples

- `altova:add-minutes-to-dateTime(xs:dateTime("2014-01-15T14:10:00"), -5)` returns `2014-01-15T14:05:00`

### add-seconds-to-dateTime [altova:]

```xml
```

Add a duration in seconds to an `xs:dateTime` (see examples below). The second argument is the number of seconds to be added to the `xs:dateTime` supplied as the first argument. The result is of type `xs:dateTime`.

#### Examples

- `altova:add-seconds-to-dateTime(xs:dateTime("2014-01-15T14:10:00"), 100)` returns `2014-01-15T14:10:100:00`
- `altova:add-seconds-to-dateTime(xs:dateTime("2014-01-15T14:10:00"), -5)` returns `2014-01-15T14:10:05:00`
altova:add-seconds-to-dateTime(DateTime as xs:dateTime, Seconds as xs:integer) as xs:dateTime XP3.1 XQ3.1

Adds a duration in seconds to an xs:dateTime (see examples below). The second argument is the number of seconds to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

Examples

- altova:add-seconds-to-dateTime(xs:dateTime("2014-01-15T14:00:10"), 20) returns 2014-01-15T14:00:30
- altova:add-seconds-to-dateTime(xs:dateTime("2014-01-15T14:00:10"), -5) returns 2014-01-15T14:00:05

Add a duration to xs:date XP3.1 XQ3.1

These functions add a duration to xs:date and return xs:date. The xs:date type has a format of CCYY-MM-DD.

- add-years-to-date [altova:]
  altova:add-years-to-date(Date as xs:date, Years as xs:integer) as xs:date XP3.1 XQ3.1
  Adds a duration in years to a date. The second argument is the number of years to be added to the xs:date supplied as the first argument. The result is of type xs:date.
  Examples
  - altova:add-years-to-date(xs:date("2014-01-15"), 10) returns 2024-01-15
  - altova:add-years-to-date(xs:date("2014-01-15"), -4) returns 2010-01-15

- add-months-to-date [altova:]
  altova:add-months-to-date(Date as xs:date, Months as xs:integer) as xs:date XP3.1 XQ3.1
  Adds a duration in months to a date. The second argument is the number of months to be added to the xs:date supplied as the first argument. The result is of type xs:date.
  Examples

- add-days-to-date [altova:]
  altova:add-days-to-date(Date as xs:date, Days as xs:integer) as xs:date XP3.1 XQ3.1
  Adds a duration in days to a date. The second argument is the number of days to be added to the xs:date supplied as the first argument. The result is of type xs:date.
  Examples
Format and retrieve durations

These functions add a duration to `xs:date` and return `xs:date`. The `xs:date` type has a format of CCYY-MM-DD.

- **format-duration [altova:]**
  
  ```xml
  altova:format-duration(Duration as xs:duration, Picture as xs:string) as xs:string
  ```

  Formats a duration, which is submitted as the first argument, according to a picture string submitted as the second argument. The output is a text string formatted according to the picture string.

  **Examples**
  
  - `altova:format-duration(xs:duration("P2DT2H53M11.7S"), "Days:[D01] Hours:[H01] Minutes:[m01] Seconds:[s01] Fractions:[f0]")` returns "Days:02 Hours:02 Minutes:53 Seconds:11 Fractions:7"
  
  - `altova:format-duration(xs:duration("P3M2DT2H53M11.7S"), "Months:[M01] Days:[D01] Hours:[H01] Minutes:[m01]")` returns "Months:03 Days:02 Hours:02 Minutes:53"

- **parse-duration [altova:]**
  
  ```xml
  altova:parse-duration(InputString as xs:string, Picture as xs:string) as xs:duration
  ```

  Takes a patterned string as the first argument, and a picture string as the second argument. The input string is parsed on the basis of the picture string, and an `xs:duration` is returned.

  **Examples**
  
  - `altova:parse-duration("Days:02 Hours:02 Minutes:53 Seconds:11 Fractions:7"), "Days:[D01] Hours:[H01] Minutes:[m01] Fractions:[f0]")` returns "P2DT2H53M11.7S"
  

Add a duration to xs:time

These functions add a duration to `xs:time` and return `xs:time`. The `xs:time` type has a lexical form of hh:mm:ss.sss. An optional time zone may be suffixed. The letter Z indicates Coordinated Universal Time (UTC). All other time zones are represented by their difference from UTC in the format +hh:mm, or -hh:mm. If no time zone value is present, it is considered unknown; it is not assumed to be UTC.

- **add-hours-to-time [altova:]**

[ Top ]
altova:add-hours-to-time(Time as xs:time, Hours as xs:integer) as xs:time

XP3.1 XQ3.1

Adds a duration in hours to a time. The second argument is the number of hours to be added to the xs:time supplied as the first argument. The result is of type xs:time.

Examples

- `altova:add-hours-to-time(xs:time("11:00:00"), 10)` returns 21:00:00
- `altova:add-hours-to-time(xs:time("11:00:00"), -7)` returns 04:00:00

add-minutes-to-time [altova:]

altova:add-minutes-to-time(Time as xs:time, Minutes as xs:integer) as xs:time

XP3.1 XQ3.1

Adds a duration in minutes to a time. The second argument is the number of minutes to be added to the xs:time supplied as the first argument. The result is of type xs:time.

Examples

- `altova:add-minutes-to-time(xs:time("14:10:00"), 45)` returns 14:55:00
- `altova:add-minutes-to-time(xs:time("14:10:00"), -5)` returns 14:05:00

add-seconds-to-time [altova:]

altova:add-seconds-to-time(Time as xs:time, Minutes as xs:integer) as xs:time

XP3.1 XQ3.1

Adds a duration in seconds to a time. The second argument is the number of seconds to be added to the xs:time supplied as the first argument. The result is of type xs:time. The Seconds component can be in the range of 0 to 59.999.

Examples

- `altova:add-seconds-to-time(xs:time("14:00:00"), 20)` returns 14:00:20
- `altova:add-seconds-to-time(xs:time("14:00:00"), 20.895)` returns 14:00:20.895

Remove the timezone part from date/time datatypes

XP3.1 XQ3.1

These functions remove the timezone from the current xs:dateTime, xs:date, or xs:time values, respectively. Note that the difference between xs:dateTime and xs:dateTimeStamp is that in the case of the latter the timezone part is required (while it is optional in the case of the former). So the format of an xs:dateTimeStamp value is: CCYY-MM-DDThh:mm:ss.sss±hh:mm or CCYY-MM-DDThh:mm:ss.sssZ. If the date and time is read from the system clock as xs:dateTimeStamp, the current-dateTime-no-TZ() function can be used to remove the timezone if so required.

current-date-no-TZ [altova:]

altova:current-date-no-TZ() as xs:date

XP3.1 XQ3.1

This function takes no argument. It removes the timezone part of current-date() (which is the current date according to the system clock) and returns an xs:date value.

Examples
If the current date is 2014-01-15+01:00:

- `<altova:current-date-no-TZ>()` returns 2014-01-15

**current-dateTime-no-TZ [altova:]**

```xml
<altova:current-dateTime-no-TZ() as xs:dateTime> XP3.1 XQ3.1
```
This function takes no argument. It removes the timezone part of `current-dateTime()` (which is the current date-and-time according to the system clock) and returns an xs:dateTime value.

**Examples**

If the current dateTime is 2014-01-15T14:00:00+01:00:

- `<altova:current-dateTime-no-TZ>()` returns 2014-01-15T14:00:00

**current-time-no-TZ [altova:]**

```xml
<altova:current-time-no-TZ() as xs:time> XP3.1 XQ3.1
```
This function takes no argument. It removes the timezone part of `current-time()` (which is the current time according to the system clock) and returns an xs:time value.

**Examples**

If the current time is 14:00:00+01:00:

- `<altova:current-time-no-TZ>()` returns 14:00:00

**date-no-TZ [altova:]**

```xml
<altova:date-no-TZ(InputDate as xs:date) as xs:date> XP3.1 XQ3.1
```
This function takes an xs:date argument, removes the timezone part from it, and returns an xs:date value. Note that the date is not modified.

**Examples**

- `<altova:date-no-TZ(xs:date("2014-01-15+01:00"))>` returns 2014-01-15

**dateTime-no-TZ [altova:]**

```xml
<altova:dateTime-no-TZ(InputDateTime as xs:dateTime) as xs:dateTime> XP3.1 XQ3.1
```
This function takes an xs:dateTime argument, removes the timezone part from it, and returns an xs:dateTime value. Note that neither the date nor the time is modified.

**Examples**

- `<altova:dateTime-no-TZ(xs:dateTime("2014-01-15T14:00:00+01:00"))>` returns 2014-01-15T14:00:00

**time-no-TZ [altova:]**

```xml
<altova:time-no-TZ(InputTime as xs:time) as xs:time> XP3.1 XQ3.1
```
This function takes an `xs:time` argument, removes the timezone part from it, and returns an `xs:time` value. Note that the time is not modified.

**Examples**

- `altova:time-no-TZ(xs:time("14:00:00+01:00"))` returns `14:00:00`

---

**Return the number of days, hours, minutes, seconds from durations**

These functions return the number of days in a month, and the number of hours, minutes, and seconds, respectively, from durations.

### days-in-month [altova:]

```
altova:days-in-month(Year as xs:integer, Month as xs:integer) as xs:integer
```

Returns the number of days in the specified month. The month is specified by means of the `Year` and `Month` arguments.

**Examples**

- `altova:days-in-month(2018, 10)` returns `31`
- `altova:days-in-month(2018, 2)` returns `28`
- `altova:days-in-month(2020, 2)` returns `29`

### hours-from-dayTimeDuration-accumulated

```
altova:hours-from-dayTimeDuration-accumulated(DayAndTime as xs:duration) as xs:integer
```

Returns the total number of hours in the duration submitted by the `DayAndTime` argument (which is of type `xs:duration`). The hours in the `Day` and `Time` components are added together to give a result that is an integer. A new hour is counted for a full 60 minutes. Negative durations result in a negative hour value.

**Examples**

- `altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5D"))` returns `120`, which is the total number of hours in 5 days.
- `altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H"))` returns `122`, which is the total number of hours in 5 days plus 2 hours.
- `altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H60M"))` returns `123`, which is the total number of hours in 5 days plus 2 hours and 60 mins.
- `altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H119M"))` returns `123`, which is the total number of hours in 5 days plus 2 hours and 119 mins.
- `altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H120M"))` returns `124`, which is the total number of hours in 5 days plus 2 hours and 120 mins.
- `altova:hours-from-dayTimeDuration-accumulated(xs:duration("-P5DT2H"))` returns `122`
minutes-from-dayTimeDuration-accumulated

```xml
   xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="minutes-from-dayTimeDuration-accumulated">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="DayAndTime" type="xs:duration"/>
      </xs:sequence>
      <xs:attribute name="as" type="xs:string"/>
    </xs:complexType>
    <xs:simpleType name="minutes-from-dayTimeDuration-accumulated">
      <xs:restriction base="xs:integer">
        <xs:minInclusive value="-86400"/>
        <xs:maxInclusive value="86400"/>
      </xs:restriction>
    </xs:simpleType>
  </xs:element>
</xs:schema>
```

Returns the total number of minutes in the duration submitted by the DayAndTime argument (which is of type `xs:duration`). The minutes in the Day and Time components are added together to give a result that is an integer. Negative durations result in a negative minute value.

**Examples**

- `altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT60M"))` returns 60
- `altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT1H"))` returns 60, which is the total number of minutes in 1 hour.
- `altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT1H40M"))` returns 100
- `altova:minutes-from-dayTimeDuration-accumulated(xs:duration("P1D"))` returns 1440, which is the total number of minutes in 1 day.
- `altova:minutes-from-dayTimeDuration-accumulated(xs:duration("-P1DT60M"))` returns -1500

seconds-from-dayTimeDuration-accumulated

```xml
   xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="seconds-from-dayTimeDuration-accumulated">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="DayAndTime" type="xs:duration"/>
      </xs:sequence>
      <xs:attribute name="as" type="xs:string"/>
    </xs:complexType>
    <xs:simpleType name="seconds-from-dayTimeDuration-accumulated">
      <xs:restriction base="xs:integer">
        <xs:minInclusive value="-86400"/>
        <xs:maxInclusive value="86400"/>
      </xs:restriction>
    </xs:simpleType>
  </xs:element>
</xs:schema>
```

Returns the total number of seconds in the duration submitted by the DayAndTime argument (which is of type `xs:duration`). The seconds in the Day and Time components are added together to give a result that is an integer. Negative durations result in a negative seconds value.

**Examples**

- `altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT1M"))` returns 60, which is the total number of seconds in 1 minute.
- `altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT1H"))` returns 3600, which is the total number of seconds in 1 hour.
- `altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT1H2M"))` returns 3720
- `altova:seconds-from-dayTimeDuration-accumulated(xs:duration("P1D"))` returns 86400, which is the total number of seconds in 1 day.
- `altova:seconds-from-dayTimeDuration-accumulated(xs:duration("-P1DT1M"))` returns -86460

Return the weekday from xs:dateTime or xs:date

These functions return the weekday (as an integer) from `xs:dateTime` or `xs:date`. The days of the week are numbered (using the American format) from 1 to 7, with Sunday=1. In the European format, the week starts with Monday (=1). The American format, where Sunday=1, can be set by using the integer 0 where an integer is accepted to indicate the format.
altova:weekday-from-dateTime(DateTime as xs:dateTime) as xs:integer  
XP3.1 
XQ3.1
Takes a date-with-time as its single argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with Sunday=1. If the European format is required (where Monday=1), use the other signature of this function (see next signature below).

Examples
- altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00")) returns 2, which would indicate a Monday.

altova:weekday-from-dateTime(DateTime as xs:dateTime, Format as xs:integer) as xs:integer  
XP3.1 
XQ3.1
Takes a date-with-time as its first argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with Monday=1. If the second (integer) argument is 0, then the weekdays are numbered 1 to 7 starting with Sunday=1. If the second argument is an integer other than 0, then Monday=1. If there is no second argument, the function is read as having the other signature of this function (see previous signature).

Examples
- altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00"), 1) returns 1, which would indicate a Monday
- altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00"), 4) returns 1, which would indicate a Monday
- altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00"), 0) returns 2, which would indicate a Monday.

weekday-from-date [altova:]

altova:weekday-from-date(Date as xs:date) as xs:integer  
XP3.1 
XQ3.1
Takes a date as its single argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with Sunday=1. If the European format is required (where Monday=1), use the other signature of this function (see next signature below).

Examples
- altova:weekday-from-date(xs:date("2014-02-03+01:00")) returns 2, which would indicate a Monday

altova:weekday-from-date(Date as xs:date, Format as xs:integer) as xs:integer  
XP3.1 
XQ3.1
Takes a date as its first argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with Monday=1. If the second (Format) argument is 0, then the weekdays are numbered 1 to 7 starting with Sunday=1. If the second argument is an integer other than 0, then Monday=1. If there is no second argument, the function is read as having the other signature of this function (see previous signature).

Examples
- altova:weekday-from-date(xs:date("2014-02-03"), 1) returns 1, which would indicate a Monday
- altova:weekday-from-date(xs:date("2014-02-03"), 4) returns 1, which would indicate a Monday
- altova:weekday-from-date(xs:date("2014-02-03"), 0) returns 2, which would
indicate a Monday.

Return the week number from xs:dateTime or xs:date

These functions return the week number (as an integer) from xs:dateTime or xs:date. Week-numbering is available in the US, ISO/European, and Islamic calendar formats. Week-numbering is different in these calendar formats because the week is considered to start on different days (on Sunday in the US format, Monday in the ISO/European format, and Saturday in the Islamic format).

**weeknumber-from-date [altova:]**

```
altova:weeknumber-from-date(Date as xs:date, Calendar as xs:integer) as xs:integer
```

Returns the week number of the submitted date argument as an integer. The second argument (Calendar) specifies the calendar system to follow. Supported Calendar values are:

- 0 = US calendar (week starts Sunday)
- 1 = ISO standard, European calendar (week starts Monday)
- 2 = Islamic calendar (week starts Saturday)

Default is 0.

**Examples**

- `altova:weeknumber-from-date(xs:date("2014-03-23"), 0)` returns 13
- `altova:weeknumber-from-date(xs:date("2014-03-23"), 1)` returns 12
- `altova:weeknumber-from-date(xs:date("2014-03-23"), 2)` returns 13
- `altova:weeknumber-from-date(xs:date("2014-03-23"))` returns 13

The day of the date in the examples above (2014-03-23) is Sunday. So the US and Islamic calendars are one week ahead of the European calendar on this day.

**weeknumber-from-dateTime [altova:]**

```
altova:weeknumber-from-dateTime(DateTime as xs:dateTime, Calendar as xs:integer) as xs:integer
```

Returns the week number of the submitted dateTime argument as an integer. The second argument (Calendar) specifies the calendar system to follow. Supported Calendar values are:

- 0 = US calendar (week starts Sunday)
- 1 = ISO standard, European calendar (week starts Monday)
- 2 = Islamic calendar (week starts Saturday)

Default is 0.
Examples

- `altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"), 0)` returns 13
- `altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"), 1)` returns 12
- `altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"), 2)` returns 13
- `altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"))` returns 13

The day of the dateTime in the examples above (2014-03-23T00:00:00) is Sunday. So the US and Islamic calendars are one week ahead of the European calendar on this day.

Build date, time, and duration datatypes from their lexical components

The functions take the lexical components of the `xs:date`, `xs:time`, or `xs:duration` datatype as input arguments and combine them to build the respective datatype.

### build-date [altova:]

```
altova:build-date(Year as xs:integer, Month as xs:integer, Date as xs:integer) as xs:date
```

The first, second, and third arguments are, respectively, the year, month, and date. They are combined to build a value of `xs:date` type. The values of the integers must be within the correct range of that particular date part. For example, the second argument (for the month part) should not be greater than 12.

#### Examples

- `altova:build-date(2014, 2, 03)` returns 2014-02-03

### build-time [altova:]

```
altova:build-time(Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer) as xs:time
```

The first, second, and third arguments are, respectively, the hour (0 to 23), minutes (0 to 59), and seconds (0 to 59) values. They are combined to build a value of `xs:time` type. The values of the integers must be within the correct range of that particular time part. For example, the second (Minutes) argument should not be greater than 59. To add a timezone part to the value, use the other signature of this function (see next signature).

#### Examples

- `altova:build-time(23, 4, 57)` returns 23:04:57
- `altova:build-time(Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer, TimeZone as xs:string) as xs:time`
of the value. The four arguments are combined to build a value of `xs:time` type. The values of the integers must be within the correct range of that particular time part. For example, the second (Minutes) argument should not be greater than 59.

**Examples**

- `altova:build-time(23, 4, 57, '+1')` returns `23:04:57+01:00`

**build-duration [altova:]**

`altova:build-duration(Years as xs:integer, Months as xs:integer)` as `xs:yearMonthDuration` XP3.1 XQ3.1

Takes two arguments to build a value of type `xs:yearMonthDuration`. The first argument provides the `Years` part of the duration value, while the second argument provides the `Months` part. If the second (`Months`) argument is greater than or equal to 12, then the integer is divided by 12; the quotient is added to the first argument to provide the `Years` part of the duration value while the remainder (of the division) provides the `Months` part. To build a duration of type `xs:dayTimeDuration`, see the next signature.

**Examples**

- `altova:build-duration(2, 10)` returns `P2Y10M`
- `altova:build-duration(14, 27)` returns `P16Y3M`
- `altova:build-duration(2, 24)` returns `P4Y`

`altova:build-duration(Days as xs:integer, Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer)` as `xs:dayTimeDuration` XP3.1 XQ3.1

Takes four arguments and combines them to build a value of type `xs:dayTimeDuration`. The first argument provides the `Days` part of the duration value, the second, third, and fourth arguments provide, respectively, the `Hours`, `Minutes`, and `Seconds` parts of the duration value. Each of the three Time arguments is converted to an equivalent value in terms of the next higher unit and the result is used for calculation of the total duration value. For example, 72 seconds is converted to `1M+12S` (1 minute and 12 seconds), and this value is used for calculation of the total duration value. To build a duration of type `xs:yearMonthDuration`, see the previous signature.

**Examples**

- `altova:build-duration(2, 10, 3, 56)` returns `P2DT10H3M56S`
- `altova:build-duration(1, 0, 100, 0)` returns `P1DT1H40M`
- `altova:build-duration(1, 0, 0, 3600)` returns `P1DT1H`

**Construct date, dateTime, and time datatypes from string input** XP2 XQ1 XP3.1 XQ3.1

These functions take strings as arguments and construct `xs:date`, `xs:dateTime`, or `xs:time` datatypes. The string is analyzed for components of the datatype based on a submitted pattern argument.

**parse-date [altova:]**

`altova:parse-date(Date as xs:string, DatePattern as xs:string)` as `xs:date` XP2 XQ1 XP3.1 XQ3.1

Returns the input string `Date` as an `xs:date` value. The second argument `DatePattern`
specifies the pattern (sequence of components) of the input string. DatePattern is described with the component specifiers listed below and with component separators that can be any character. See the examples below.

| D | Date |
| M | Month |
| Y | Year |

The pattern in DatePattern must match the pattern in Date. Since the output is of type xs:date, the output will always have the lexical format YYYY-MM-DD.

**Examples**

- `altova:parse-date(xs:string("09-12-2014"), "[D]-[M]-[Y]")` returns 2014-12-09
- `altova:parse-date(xs:string("09-12-2014"), "[M]-[D]-[Y]")` returns 2014-09-12
- `altova:parse-date("06/03/2014", "/\/[D]/\/[Y]")` returns 2014-06-03
- `altova:parse-date("06 03 2014", "/\/[D]/\/[Y]")` returns 2014-06-03
- `altova:parse-date("6 3 2014", "/\/[D]/\/[Y]")` returns 2014-06-03

**parse-dateTime [altova:]**

```
altova:parse-dateTime(DateTime as xs:string, DateTimePattern as xs:string) as xs:dateTime
```

Returns the input string DateTime as an xs:dateTime value. The second argument DateTimePattern specifies the pattern (sequence of components) of the input string. DateTimePattern is described with the component specifiers listed below and with component separators that can be any character. See the examples below.

| D | Date |
| M | Month |
| Y | Year |
| H | Hour |
| m | minutes |
| s | seconds |

The pattern in DateTimePattern must match the pattern in DateTime. Since the output is of type xs:dateTime, the output will always have the lexical format YYYY-MM-DDTHH:mm:ss.

**Examples**

- `altova:parse-dateTime(xs:string("09-12-2014 13:56:24"), "[M]-[D]-[Y] [H]:[m]:[s]")` returns 2014-09-12T13:56:24
- `altova:parse-dateTime("time=13:56:24; date=09-12-2014", "time=[H]:[m]:[s]; date=[D]-[M]-[Y]")` returns 2014-09-12T13:56:24

**parse-time [altova:]**

```
altova:parse-time(Time as xs:string, TimePattern as xs:string) as xs:time
```

© 2019 Altova GmbH
Returns the input string **Time** as an **xs:time** value. The second argument **TimePattern** specifies the pattern (sequence of components) of the input string. **TimePattern** is described with the component specifiers listed below and with component separators that can be any character. See the examples below.

- **H** Hour
- **m** minutes
- **s** seconds

The pattern in **TimePattern** must match the pattern in **Time**. Since the output is of type **xs:time**, the output will always have the lexical format **HH:mm:ss**.

**Examples**

- `altova:parse-time("13-56-24", "[H]-[m]")` returns 13:56:00
- `altova:parse-time("time=13h56m24s", "time=[H]h[m]m[s]s")` returns 13:56:24
- `altova:parse-time("time=24s56m13h", "time=[s]s[m]m[H]h")` returns 13:56:24

### Age-related functions

These functions return the age as calculated (i) between one input argument date and the current date, or (ii) between two input argument dates. The `altova:age` function returns the age in terms of years, the `altova:age-details` function returns the age as a sequence of three integers giving the years, months, and days of the age.

#### `altova:age(StartDate as xs:date) as xs:integer`  
XP3.1 XQ3.1

Returns an integer that is the age in years of some object, counting from a start-date submitted as the argument and ending with the current date (taken from the system clock). If the input argument is a date anything greater than or equal to one year in the future, the return value will be negative.

**Examples**

If the current date is 2014-01-15:

- `altova:age(xs:date("2013-01-15"))` returns 1
- `altova:age(xs:date("2013-01-16"))` returns 0
- `altova:age(xs:date("2015-01-15"))` returns -1
- `altova:age(xs:date("2015-01-14"))` returns 0

#### `altova:age(StartDate as xs:date, EndDate as xs:date) as xs:integer`  
XP3.1 XQ3.1

Returns an integer that is the age in years of some object, counting from a start-date that is submitted as the first argument up to an end-date that is the second argument. The return value will be negative if the first argument is one year or more later than the second argument.
Examples

If the current date is 2014-01-15:

- `altova:age(xs:date("2000-01-15"), xs:date("2010-01-15"))` returns 10
- `altova:age(xs:date("2000-01-15"), current-date())` returns 14 if the current date is 2014-01-15
- `altova:age(xs:date("2014-01-15"), xs:date("2010-01-15"))` returns -4

age-details [altova:]

`altova:age-details(InputDate as xs:date) as (xs:integer)*`  
XP3.1 XQ3.1

Returns three integers that are, respectively, the years, months, and days between the date that is submitted as the argument and the current date (taken from the system clock). The sum of the returned `years+months+days` together gives the total time difference between the two dates (the input date and the current date). The input date may have a value earlier or later than the current date, but whether the input date is earlier or later is not indicated by the sign of the return values; the return values are always positive.

Examples

If the current date is 2014-01-15:

- `altova:age-details(xs:date("2014-01-16"))` returns (0 0 1)
- `altova:age-details(xs:date("2014-01-14"))` returns (0 0 1)
- `altova:age-details(xs:date("2013-01-16"))` returns (1 0 1)
- `altova:age-details(current-date())` returns (0 0 0)

`altova:age-details(Date-1 as xs:date, Date-2 as xs:date) as (xs:integer)*`  
XP3.1 XQ3.1

Returns three integers that are, respectively, the years, months, and days between the two argument dates. The sum of the returned `years+months+days` together gives the total time difference between the two input dates; it does not matter whether the earlier or later of the two dates is submitted as the first argument. The return values do not indicate whether the input date occurs earlier or later than the current date. Return values are always positive.

Examples

- `altova:age-details(xs:date("2014-01-16"), xs:date("2014-01-15"))` returns (0 0 1)
- `altova:age-details(xs:date("2014-01-15"), xs:date("2014-01-16"))` returns (0 0 1)

7.2.1.3 XPath/XQuery Functions: Geolocation

The following geolocation XPath/XQuery extension functions are supported in the current version of RaptorXML+XBRL Server and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability
Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

| XPath functions (used in XPath expressions in XSLT): | XP1 XP2 XP3.1 |
| XSLT functions (used in XPath expressions in XSLT): | XSLT1 XSLT2 XSLT3 |
| XQuery functions (used in XQuery expressions in XQuery): | XQ1 XQ3.1 |

**format-geolocation [altova:]**

\[
\text{altova:format-geolocation}(\text{Latitude as xs:decimal}, \text{Longitude as xs:decimal}, \text{GeolocationOutputStringFormat as xs:integer}) \text{ as xs:string} \text{ XP3.1 XQ3.1}
\]

Takes the latitude and longitude as the first two arguments, and outputs the geolocation as a string. The third argument, GeolocationOutputStringFormat, is the format of the geolocation output string; it uses integer values from 1 to 4 to identify the output string format (see 'Geolocation output string formats' below). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** The image-exif-data function and the Exif metadata's attributes can be used to supply the input strings.

**Examples**

- \[\text{altova:format-geolocation}(33.33, -22.22, 4) \text{ returns the xs:string } "33.33-22.22"\]
- \[\text{altova:format-geolocation}(33.33, -22.22, 2) \text{ returns the xs:string } "33.33N, 22.22W"\]
- \[\text{altova:format-geolocation}(-33.33, 22.22, 2) \text{ returns the xs:string } "33.33S, 22.22E"\]
- \[\text{altova:format-geolocation}(33.33, -22.22, 1) \text{ returns the xs:string } "33°19'48.00"S, 22°13'12.00"E"\]

**Geolocation output string formats:**

The supplied latitude and longitude is formatted in one of the output formats given below. The desired format is identified by its integer ID (1 to 4). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

<table>
<thead>
<tr>
<th>1</th>
</tr>
</thead>
</table>

| Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W) |
| \(\text{D}^\circ\text{M}'\text{S}.\text{SS}"\text{N/S} \quad \text{D}^\circ\text{M}'\text{S}.\text{SS}"\text{E/W} \) |
| Example: \(33^\circ55'11.11"\text{N} \quad 22^\circ44'66.66"\text{W}\) |
### Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute `Geolocation` from standard Exif metadata tags. `Geolocation` is a concatenation of four Exif tags: `GPSLatitude`, `GPSLatitudeRef`, `GPSLongitude`, `GPSLongitudeRef`, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitude Ref</th>
<th>GPSLongitude</th>
<th>GPSLongitude Ref</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33.51</td>
<td>S</td>
<td>151.13</td>
<td>E</td>
<td>33°51′21.91″S 151°13′11.73″E</td>
</tr>
</tbody>
</table>

#### parse-geolocation [altova:]

```xquery
altova:parse-geolocation(GeolocationInputString as xs:string) as xs:decimal+
XM3.1 XQ3.1
```

Parses the supplied `GeolocationInputString` argument and returns the geolocation's latitude and longitude (in that order) as a sequence two `xs:decimal` items. The formats in which the geolocation input string can be supplied are listed below.

**Note:** The `image-exif-data` function and the Exif metadata's `@Geolocation` attribute can be used to supply the geolocation input string (see example below).

#### Examples

- `altova:parse-geolocation("33.33  -22.22")` returns the sequence of two `xs:decimals` (`33.33, 22.22`)
- `altova:parse-geolocation("48°51′29.6″N  24°17′40.2″E")` returns the sequence of two `xs:decimals` (`48.8582222222222, 24.2945`)
- `altova:parse-geolocation("48°51′29.6″N  24°17′40.2″E")` returns the
sequence of two `xs:decimals` (48.8582222222222, 24.2945)

**Geolocation input string formats:**

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (`''`) while unit indicators that are escaped are highlighted in blue (`""`).

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, W/E)**

  ```
  D°M'S.SS"N/S  D°M'S.SS"W/E
  Example: 33°55'11"N  22°44'55.25"W
  ```

- **Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/W) is optional**

  ```
  +/-D°M'S.SS"  +/-D°M'S.SS"
  Example: 33°55'11"N  22°44'55.25"W
  ```

- **Degrees, decimal minutes, with suffixed orientation (N/S, W/E)**

  ```
  D°M.MM'N/S  D°M.MM'W/E
  Example: 33°55.55'N  22°44.44'W
  ```

- **Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/W) is optional**

  ```
  +/-D°M.MM'  +/-D°M.MM'
  Example: +33°55.55'N  22°44.44'W
  ```

- **Decimal degrees, with suffixed orientation (N/S, W/E)**

  ```
  D.DDN/S  D.DDW/E
  Example: 33.33N  22.22W
  ```

- **Decimal degrees, with prefixed sign (+/-); the plus sign for (N/W) is optional**

  ```
  +/-D.DD  +/-D.DD
  Example: 33.33  -22.22
  ```

**Examples of format-combinations:**

```
33.33N  -22°44'55.25"
33.33  22°44'55.25"W
33.33  22.45
```

**Altova Exif Attribute: Geolocation**

The Altova XPath/XQuery Engine generates the custom attribute `Geolocation` from
standard Exif metadata tags. **Geolocation** is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>33°51'21.91&quot;S 151°13'11.73&quot;E</td>
</tr>
</tbody>
</table>

**geolocation-distance-km [altova:]**

```xquery
altova:geolocation-distance-km(GeolocationInputString-1 as xs:string, GeolocationInputString-2 as xs:string) as xs:decimal
```

Calculates the distance between two geolocations in kilometers. The formats in which the geolocation input string can be supplied are listed below. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** The **image-exif-data** function and the Exif metadata's **@Geolocation** attribute can be used to supply geolocation input strings.

**Examples**

- `altova:geolocation-distance-km("33.33 -22.22", "48°51'29.6"N 24°17'40.2"W")` returns the `xs:decimal 4183.08132372392`

**Geolocation input string formats:**

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow ("), while unit indicators that are escaped are highlighted in blue ("').

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, W/E)**
  
  ```xquery```
  ```
  D°M'S.SS"N/S D°M'S.SS"W/E
  ```
  ```xquery```
  
  **Example:** `33°55'11.11"N 22°44'55.25"W`

- **Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/W) is optional**

  ```xquery```
  ```
  +/-D°M'S.SS" +/-D°M'S.SS"
  ```
  ```xquery```
  
  **Example:** `33°55'11.11"  -22°44'55.25"W`
• **Degrees, decimal minutes, with suffixed orientation** (N/S, W/E)
  
  \[D^\circ M.'M.'' N/S D^\circ M.'M.'' W/E\]
  
  *Example*: 33°55.55'N 22°44.44'W

• **Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/W) is optional**
  
  \[\pm D^\circ M.'M.'' \pm D^\circ M.'M.''\]
  
  *Example*: +33°55.55' -22°44.44'

• **Decimal degrees, with suffixed orientation** (N/S, W/E)
  
  \[D.DD N/S D.DD W/E\]
  
  *Example*: 33.33N 22.22W

• **Decimal degrees, with prefixed sign (+/-); the plus sign for (N/W) is optional**
  
  \[\pm D.DD \pm D.DD\]
  
  *Example*: 33.33  -22.22

*Examples of format-combinations:*
- 33°51'21.91"S
- 151°13'11.73"E
- 33 22°44'55.25"W
- 22.45

**Altova Exif Attribute: Geolocation**

The Altova XPath/XQuery Engine generates the custom attribute `Geolocation` from standard Exif metadata tags. `Geolocation` is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>33°51'21.91&quot;S 151°13'11.73&quot;E</td>
</tr>
</tbody>
</table>

**geolocation-distance-mi [altova:]**

`altova:geolocation-distance-mi(GeolocationInputString-1 as xs:string, GeolocationInputString-2 as xs:string) as xs:decimal` XP3.1 XQ3.1

Calculates the distance between two geolocations in miles. The formats in which a geolocation input string can be supplied are listed below. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

*Note*: The `image-exif-data` function and the Exif metadata’s `@Geolocation` attribute can be used to supply geolocation input strings.

**Examples**

- `altova:geolocation-distance-mi("33.33 -22.22", "48°51'29.6"N 24°17'40.2"E")` returns the `xs:decimal` 2599.40652340653
**Geolocation input string formats:**

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to −90 (N to S). Longitude values range from +180 to −180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (”) while unit indicators that are escaped are highlighted in blue (“’”).

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, W/E)**
  \[D°M'S.SS"N/S\]
  \[D°M'S.SS"W/E\]
  **Example:** 33°55'11.11"N  22°44'55.25"W

- **Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/W) is optional**
  \[+/−D°M'S.SS"\]
  \[+/−D°M'S.SS"\]
  **Example:** 33°55'11.11"  -22°44'55.25"

- **Degrees, decimal minutes, with suffixed orientation (N/S, W/E)**
  \[D°M.MM'N/S\]
  \[D°M.MM'W/E\]
  **Example:** 33°55.55'N  22°44.44'W

- **Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/W) is optional**
  \[+/−D°M.MM'\]
  \[+/−D°M.MM'\]
  **Example:** +33°55.55'  -22°44.44'

- **Decimal degrees, with suffixed orientation (N/S, W/E)**
  \[D.DDN/S\]
  \[D.DDW/E\]
  **Example:** 33.33N  22.22W

- **Decimal degrees, with prefixed sign (+/-); the plus sign for (N/W) is optional**
  \[+/−D.DD\]
  \[+/−D.DD\]
  **Example:** 33.33  -22.22

**Examples of format-combinations:**

- 33.33N  -22°44'55.25"
- 33.33  22°44'55.25"W
- 33.33  22.45

**Altova Exif Attribute: Geolocation**

The Altova XPath/XQuery Engine generates the custom attribute `Geolocation` from standard Exif metadata tags. `Geolocation` is a concatenation of four Exif tags: `GPSLatitude`, `GPSLatitudeRef`, `GPSLongitude`, `GPSLongitudeRef`, with units added (see table below).
### geolocation-within-polygon [altова]

```xml
    altova:geolocation-within-polygon(Geolocation as xs:string, ((PolygonPoint as xs:string)+)) as xs:boolean  XP3.1 XQ3.1
```

Determines whether Geolocation (the first argument) is within the polygonal area described by the PolygonPoint arguments. If the PolygonPoint arguments do not form a closed figure (formed when the first point and the last point are the same), then the first point is implicitly added as the last point in order to close the figure. All the arguments (Geolocation and PolygonPoint+) are given by geolocation input strings (formats listed below). If the Geolocation argument is within the polygonal area, then the function returns `true()`; otherwise it returns `false()`. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** The `image-exif-data` function and the Exif metadata's `@Geolocation` attribute can be used to supply geolocation input strings.

**Examples**

- `altova:geolocation-within-polygon("33 -22", ("58 -32", "-78 -55", "48°51'29.6" N 24°17'40.2" W))`) returns `true()`

**Geolocation input string formats:**

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow ("), while unit indicators that are escaped are highlighted in blue ("’").

- Degrees, minutes, decimal seconds, with suffixed orientation (N/S, W/E)
  ```
  D°M’S.SS”N/S  D°M’S.SS”W/E
  ```

**Example:** $33^\circ55'11.11"N \ 22^\circ44'55.25"W$

- Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/W) is optional
  
  $+/-D^\circ M'S.SS"$ $+/-D^\circ M'S.SS"$
  
  **Example:** $33^\circ55'11.11" \ -22^\circ44'55.25"$

- Degrees, decimal minutes, with suffixed orientation (N/S, W/E)
  
  $D^\circ M.MM'N/S \ D^\circ M.MM'W/E$
  
  **Example:** $33^\circ55.55'N \ 22^\circ44.44'W$

- Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/W) is optional
  
  $+/-D^\circ M.MM'$ $+/-D^\circ M.MM'$
  
  **Example:** $+33^\circ55.55' \ -22^\circ44.44'$

- Decimal degrees, with suffixed orientation (N/S, W/E)
  
  $D.DDN/S \ D.DD W/E$
  
  **Example:** $33.33N \ 22.22W$

- Decimal degrees, with prefixed sign (+/-); the plus sign for (N/W) is optional
  
  $+/-D.DD$ $+/-D.DD$
  
  **Example:** $33.33 \ -22.22$

**Examples of format-combinations:**

- $33.33N \ -22^\circ44'55.25"$
- $33.33 \ 22^\circ44'55.25"W$
- $33.33 \ 22.45$

**Altova Exif Attribute: Geolocation**

The Altova XPath/XQuery Engine generates the custom attribute **Geolocation** from standard Exif metadata tags. **Geolocation** is a concatenation of four Exif tags: `GPSLatitude`, `GPSLatitudeRef`, `GPSLongitude`, `GPSLongitudeRef`, with units added *(see table below)*.

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>$33^\circ51'21.91&quot;S \ 151^\circ13'11.73&quot;E$</td>
</tr>
</tbody>
</table>

**geolocation-within-rectangle [altova:]**

```
altova:geolocation-within-rectangle(Geolocation as xs:string, RectCorner-1 as xs:string, RectCorner-2 as xs:string) as xs:boolean XP3.1 XQ3.1
```

Determines whether **Geolocation** (the first argument) is within the rectangle defined by the second and third arguments, **RectCorner-1** and **RectCorner-2**, which specify opposite corners of the rectangle. All the arguments (**Geolocation**, **RectCorner-1** and **RectCorner-2**,
2) are given by geolocation input strings (formats listed below). If the `Geolocation` argument is within the rectangle, then the function returns `true()`; otherwise it returns `false()`.

Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** The `image-exif-data` function and the Exif metadata's `@Geolocation` attribute can be used to supply geolocation input strings.

**Examples**

- `altova:geolocation-within-rectangle("33 -22", "58 -32", "-48 24")` returns `true()`
- `altova:geolocation-within-rectangle("33 -22", "58 -32", "48 24")` returns `false()`
- `altova:geolocation-within-rectangle("33 -22", "58 -32", "48°51'29.6"S 24°17'40.2"W")` returns `true()`

**Geolocation input string formats:**

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (""), while unit indicators that are escaped are highlighted in blue (""").

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, W/E)**
  
  \[ D°M'S.SS"N/S \quad D°M'S.SS"W/E \]

  **Example:** 33°55'11.11"N  22°44'55.25"W

- **Degrees, minutes, decimal seconds, with prefixed sign (+/−); the plus sign for (N/W) is optional**
  
  \[ +/-D°M'S.SS" \quad +/-D°M'S.SS" \]

  **Example:** 33°55'11.11"  -22°44'55.25"

- **Degrees, decimal minutes, with suffixed orientation (N/S, W/E)**
  
  \[ D°M.MM'N/S \quad D°M.MM'W/E \]

  **Example:** 33°55.55'N  22°44.44'W

- **Degrees, decimal minutes, with prefixed sign (+/−); the plus sign for (N/W) is optional**
  
  \[ +/-D°M.MM' \quad +/-D°M.MM' \]

  **Example:** +33°55.55'  -22°44.44'

- **Decimal degrees, with suffixed orientation (N/S, W/E)**
  
  \[ D.DDN/S \quad D.DDW/E \]
Example: 33.33N 22.22W

- Decimal degrees, with prefixed sign (+/-); the plus sign for (N/W) is optional
  +/-D.DD  +/-D.DD
  Example: 33.33  -22.22

Examples of format-combinations:
33.33N -22°44'55.25"
33.33  22°44'55.25"W
33.33  22.45

Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitude Ref</th>
<th>GPSLongitude</th>
<th>GPSLongitude Ref</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51</td>
<td>S</td>
<td>151 13</td>
<td>E</td>
<td>33°51'21.91&quot;S 151°</td>
</tr>
<tr>
<td>21.91</td>
<td></td>
<td>11.73</td>
<td></td>
<td>13'11.73&quot;E</td>
</tr>
</tbody>
</table>

[ Top ]

7.2.1.4 XPath/XQuery Functions: Image-Related

The following image-related XPath/XQuery extension functions are supported in the current version of RaptorXML+XBRL Server and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

<table>
<thead>
<tr>
<th>Functions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XP1, XP2, XP3.1</td>
<td>XPath functions (used in XPath expressions in XSLT):</td>
</tr>
<tr>
<td>XSLT1, XSLT2, XSLT3</td>
<td>XSLT functions (used in XPath expressions in XSLT):</td>
</tr>
<tr>
<td>XQ1, XQ3.1</td>
<td>XQuery functions (used in XQuery expressions in XQuery):</td>
</tr>
</tbody>
</table>
suggested-image-file-extension [altova:]

```xml
altova:suggested-image-file-extension(Base64String as string) as string?
```

XP3.1 XQ3.1

Takes the Base64 encoding of an image file as its argument and returns the file extension of the image as recorded in the Base64-encoding of the image. The returned value is a suggestion based on the image type information available in the encoding. If this information is not available, then an empty string is returned. This function is useful if you wish to save a Base64 image as a file and wish to dynamically retrieve an appropriate file extension.

**Examples**

- `altova:suggested-image-file-extension(/MyImages/MobilePhone/Image20141130.01)` returns 'jpg'
- `altova:suggested-image-file-extension($XML1/Staff/Person/@photo)` returns ''

In the examples above, the nodes supplied as the argument of the function are assumed to contain a Base64-encoded image. The first example retrieves jpg as the file's type and extension. In the second example, the submitted Base64 encoding does not provide usable file extension information.

image-exif-data [altova:]

```xml
altova:image-exif-data(Base64BinaryString as string) as element? XP3.1 XQ3.1
```

Takes a Base64-encoded JPEG image as its argument and returns an element called Exif that contains the Exif metadata of the image. The Exif metadata is created as attribute-value pairs of the Exif element. The attribute names are the Exif data tags found in the Base64 encoding. The list of Exif-specification tags is given below. If a vendor-specific tag is present in the Exif data, this tag and its value will also be returned as an attribute-value pair.

Additional to the standard Exif metadata tags (see list below), Altova-specific attribute-value pairs are also generated. These Altova Exif attributes are listed below.

**Examples**

- To access any one attribute, use the function like this:
  ```xml
  image-exif-data(/MyImages/Image20141130.01)/@GPSLatitude
  image-exif-data(/MyImages/Image20141130.01)/@Geolocation
  ```
- To access all the attributes, use the function like this:
  ```xml
  image-exif-data(/MyImages/Image20141130.01)/@*
  ```
- To access the names of all the attributes, use the following expression:
  ```xml
  for $i in image-exif-data(/MyImages/Image20141130.01)/@* return name($i)
  ```

This is useful to find out the names of the attributes returned by the function.

**Altova Exif Attribute: Geolocation**

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).
Altova XPath/XQuery Functions

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLongitude</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>151 13 11.73</td>
<td>33°51'21.91&quot;S 151° 13'11.73&quot;E</td>
</tr>
</tbody>
</table>

The Altova XPath/XQuery Engine generates the custom attribute OrientationDegree from the Exif metadata tag Orientation.

OrientationDegree translates the standard Exif tag Orientation from an integer value (1, 8, 3, or 6) to the respective degree values of each (0, 90, 180, 270), as shown in the figure below. Note that there are no translations of the Orientation values of 2, 4, 5, 7. (These orientations are obtained by flipping image 1 across its vertical center axis to get the image with a value of 2, and then rotating this image in 90-degree jumps clockwise to get the values of 7, 4, and 5, respectively).

Altova’s numeric extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova’s XPath 3.0 and XQuery 3.0 engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

**Auto-numbering functions**

- generate-auto-number [altova:]

  \[
  \text{altova:generate-auto-number}(ID \text{ as } \text{xsl:string}, \text{StartsWith} \text{ as } \text{xsl:double, Increment} \text{ as } \text{xsl:double, ResetOnChange} \text{ as } \text{xsl:string}) \text{ as } \text{xsl:integer}
  \]

  Generates a number each time the function is called. The first number, which is generated the first time the function is called, is specified by the StartsWith argument. Each subsequent call to the function generates a new number, this number being incremented over the previously generated number by the value specified in the Increment argument. In effect, the altova:generate-auto-number function creates a counter having a name specified by the ID argument, with this counter being incremented each time the function is called. If the value of the ResetOnChange argument changes from that of the previous function call, then the value of the number to be generated is reset to the StartsWith value. Auto-numbering can also be reset by using the altova:reset-auto-number function.

**Examples**

- \[
  \text{altova:generate-auto-number}("ChapterNumber", 1, 1, "SomeString") \]

  will
return one number each time the function is called, starting with 1, and incrementing by 1 with each call to the function. As long as the fourth argument remains "SomeString" in each subsequent call, the incrementing will continue. When the value of the fourth argument changes, the counter (called ChapterNumber) will reset to 1. The value of ChapterNumber can also be reset by a call to the altova:reset-auto-number function, like this: altova:reset-auto-number("ChapterNumber").

**reset-auto-number [altova:]**

`altova:reset-auto-number(ID as xs:string)`  
This function resets the number of the auto-numbering counter named in the ID argument. The number is reset to the number specified by the StartsWith argument of the altova:generate-auto-number function that created the counter named in the ID argument.

**Examples**

- `altova:reset-auto-number("ChapterNumber")` resets the number of the auto-numbering counter named ChapterNumber that was created by the altova:generate-auto-number function. The number is reset to the value of the StartsWith argument of the altova:generate-auto-number function that created ChapterNumber.

**Numeric functions**

**hex-string-to-integer [altova:]**

`altova:hex-string-to-integer(HexString as xs:string) as xs:integer`  
Takes a string argument that is the Base-16 equivalent of an integer in the decimal system (Base-10), and returns the decimal integer.

**Examples**

- `altova:hex-string-to-integer('1')` returns 1
- `altova:hex-string-to-integer('9')` returns 9
- `altova:hex-string-to-integer('A')` returns 10
- `altova:hex-string-to-integer('B')` returns 11
- `altova:hex-string-to-integer('F')` returns 15
- `altova:hex-string-to-integer('G')` returns an error
- `altova:hex-string-to-integer('10')` returns 16
- `altova:hex-string-to-integer('01')` returns 1
- `altova:hex-string-to-integer('20')` returns 32
- `altova:hex-string-to-integer('21')` returns 33
- `altova:hex-string-to-integer('5A')` returns 90
- `altova:hex-string-to-integer('USA')` returns an error

**integer-to-hex-string [altova:]**

`altova:integer-to-hex-string(Integer as xs:integer) as xs:string`  
Takes an integer argument and returns its Base-16 equivalent as a string.
**Examples**

- `altova:integer-to-hex-string(1)` returns '1'
- `altova:integer-to-hex-string(9)` returns '9'
- `altova:integer-to-hex-string(10)` returns 'A'
- `altova:integer-to-hex-string(11)` returns 'B'
- `altova:integer-to-hex-string(15)` returns 'F'
- `altova:integer-to-hex-string(16)` returns '10'
- `altova:integer-to-hex-string(15)` returns 'F'
- `altova:integer-to-hex-string(32)` returns '20'
- `altova:integer-to-hex-string(33)` returns '21'
- `altova:integer-to-hex-string(90)` returns '5A'

**Number-formatting functions**

**generate-auto-number [altova:]**

```xml
altova:generate-auto-number(ID as xs:string, StartsWith as xs:double, Increment as xs:double, ResetOnChange as xs:string) as xs:integer
```

Generates a number each time the function is called. The first number, which is generated the first time the function is called, is specified by the `StartsWith` argument. Each subsequent call to the function generates a new number, this number being incremented over the previously generated number by the value specified in the `Increment` argument. In effect, the `altova:generate-auto-number` function creates a counter having a name specified by the `ID` argument, with this counter being incremented each time the function is called. If the value of the `ResetOnChange` argument changes from that of the previous function call, then the value of the number to be generated is reset to the `StartsWith` value. Auto-numbering can also be reset by using the `altova:reset-auto-number` function.

**Examples**

- `altova:generate-auto-number("ChapterNumber", 1, 1, "SomeString")` will return one number each time the function is called, starting with 1, and incrementing by 1 with each call to the function. As long as the fourth argument remains "SomeString" in each subsequent call, the incrementing will continue. When the value of the fourth argument changes, the counter (called `ChapterNumber`) will reset to 1. The value of `ChapterNumber` can also be reset by a call to the `altova:reset-auto-number` function, like this: `altova:reset-auto-number("ChapterNumber")`.

### 7.2.1.6 XPath/XQuery Functions: Sequence

Altova's sequence extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova's [XPath 3.0](http://www.xml.org/ xpath) and [XQuery 3.0](https://www.w3.org/2001/XMLSchema-instance) engines. They are available in XPath/XQuery contexts.

**Note about naming of functions and language applicability**
Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):

- XP1
- XP2
- XP3.1

XSLT functions (used in XPath expressions in XSLT):

- XSLT1
- XSLT2
- XSLT3

XQuery functions (used in XQuery expressions in XQuery):

- XQ1
- XQ3.1

---

**attributes [altova:]**

```xml
altova:attributes(AttributeName as xs:string) as attribute()*
```

Returns all attributes that have a local name which is the same as the name supplied in the input argument, AttributeName. The search is case-sensitive and conducted along the attribute:: axis. This means that the context node must be the parent element node.

**Examples**

- `altova:attributes("MyAttribute")` returns `MyAttribute()`*

```xml
altova:attributes(AttributeName as xs:string, SearchOptions as xs:string) as attribute()*
```

Returns all attributes that have a local name which is the same as the name supplied in the input argument, AttributeName. The search is case-sensitive and conducted along the attribute:: axis. The context node must be the parent element node. The second argument is a string containing option flags. Available flags are:

- `r` = switches to a regular-expression search; AttributeName must then be a regular-expression search string;
- `f` = If this option is specified, then AttributeName provides a full match; otherwise AttributeName need only partially match an attribute name to return that attribute. For example: if `f` is not specified, then MyAtt will return MyAttribute;
- `i` = switches to a case-insensitive search;
- `p` = includes the namespace prefix in the search; AttributeName should then contain the namespace prefix, for example: altova:MyAttribute.

The flags can be written in any order. Invalid flags will generate errors. One or more flags can be omitted. The empty string is allowed, and will produce the same effect as the function having only one argument (previous signature). However, an empty sequence is not allowed as the second argument.

**Examples**

- `altova:attributes("MyAttribute", "rfip")` returns `MyAttribute()`*
- `altova:attributes("MyAttribute", "pri")` returns `MyAttribute()`*
- `altova:attributes("MyAtt", "rip")` returns `MyAttribute()`*
- `altova:attributes("MyAttributes", "rfip")` returns no match
- `altova:attributes("MyAttribute", ")" returns `MyAttribute()`*
- `altova:attributes("MyAttribute", "Rip")` returns an unrecognized-flag error.
- `altova:attributes("MyAttribute", )` returns a missing-second-argument error.
 elements [altova:]

\[\text{altova:elements}(\text{ElementName as xs:string}) \text{ as element()\*} \text{ XP3.1 XQ3.1}\]

Returns all elements that have a local name which is the same as the name supplied in the input argument, ElementName. The search is case-sensitive and conducted along the child:: axis. The context node must be the parent node of the element/s being searched for.

Examples

- \[\text{altova:elements} ("MyElement") \text{ returns MyElement()\*}\]

\[\text{altova:elements}(\text{ElementName as xs:string}, \text{SearchOptions as xs:string}) \text{ as element()\*} \text{ XP3.1 XQ3.1}\]

Returns all elements that have a local name which is the same as the name supplied in the input argument, ElementName. The search is case-sensitive and conducted along the child:: axis. The context node must be the parent node of the element/s being searched for. The second argument is a string containing option flags. Available flags are:

- r = switches to a regular-expression search; ElementName must then be a regular-expression search string;
- f = if this option is specified, then ElementName provides a full match; otherwise ElementName need only partially match an element name to return that element. For example: if f is not specified, then MyElem will return MyElement;
- i = switches to a case-insensitive search;
- p = includes the namespace prefix in the search; ElementName should then contain the namespace prefix, for example: altova:MyElement.

The flags can be written in any order. Invalid flags will generate errors. One or more flags can be omitted. The empty string is allowed, and will produce the same effect as the function having only one argument (previous signature). However, an empty sequence is not allowed.

Examples

- \[\text{altova:elements} ("MyElement", "rip") \text{ returns MyElement()\*}\]
- \[\text{altova:elements} ("MyElement", "pri") \text{ returns MyElement()\*}\]
- \[\text{altova:elements} ("MyElement", ") \text{ returns MyElement()\*}\]
- \[\text{altova:attributes} ("MyElem", "rip") \text{ returns MyElement()\*}\]
- \[\text{altova:attributes} ("MyElements", "rfip") \text{ returns no match}\]
- \[\text{altova:elements} ("MyElement", "Rip") \text{ returns an unrecognized-flag error.}\]
- \[\text{altova:elements} ("MyElement", ) \text{ returns a missing-second-argument error.}\]

find-first [altova:]

\[\text{altova:find-first}((\text{Sequence as item()\*}), (\text{Condition( Sequence-Item as xs:boolean)) as item()?} \text{ XP3.1 XQ3.1}\]

This function takes two arguments. The first argument is a sequence of one or more items of any datatype. The second argument, Condition, is a reference to an XPath function that takes one argument (has an arity of 1) and returns a boolean. Each item of Sequence is submitted, in turn, to the function referenced in Condition. (Remember: This function takes a single argument.) The first Sequence item that causes the function in Condition to evaluate to true() is returned as the result of altova:find-first, and the iteration stops.

Examples
- \texttt{altova:find-first((5 \text{ to } 10, \text{ function($a) } \{ $a \text{ mod } 2 = 0 \}) \text{ returns xs:integer } 6)
}

The \texttt{Condition} argument references the XPath 3.0 inline function, \texttt{function()}, which declares an inline function named \$a and then defines it. Each item in the \texttt{Sequence} argument of \texttt{altova:find-first} is passed, in turn, to \$a as its input value. The input value is tested on the condition in the function definition (\$a mod 2 = 0). The first input value to satisfy this condition is returned as the result of \texttt{altova:find-first} (in this case 6).

- \texttt{altova:find-first((1 \text{ to } 10), (\text{ function($a) } \{ $a+3=7 \}) \text{ returns xs:integer } 4)
}

\textit{Further examples}

If the file \texttt{C:\Temp\Customers.xml} exists:

- \texttt{altova:find-first( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1) \text{ returns xs:string } C:\Temp\Customers.xml)
}

If the file \texttt{C:\Temp\Customers.xml} does not exist, and \texttt{http://www.altova.com/index.html} exists:

}

If the file \texttt{C:\Temp\Customers.xml} does not exist, and \texttt{http://www.altova.com/index.html} also does not exist:

- \texttt{altova:find-first( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1) \text{ returns no result}
}

\textit{Notes about the examples given above}

- The XPath 3.0 function, \texttt{doc-available}, takes a single string argument, which is used as a URI, and returns \texttt{true} if a document node is found at the submitted URI. (The document at the submitted URI must therefore be an XML document.)
- The \texttt{doc-available} function can be used for \texttt{Condition}, the second argument of \texttt{altova:find-first}, because it takes only one argument (arity=1), because it takes an \texttt{item()} as input (a string which is used as a URI), and returns a boolean value.
- Notice that the \texttt{doc-available} function is only referenced, not called. The \#1 suffix that is attached to it indicates a function with an arity of 1. In its entirety \texttt{doc-available#1} simply means: \textit{Use the \texttt{doc-available()} function that has \texttt{arity=1}, passing to it as its single argument, in turn, each of the items in the first sequence. As a result, each of the two strings will be passed to \texttt{doc-available()}, which uses the string as a URI and tests whether a document node exists at the URI. If one does, the \texttt{doc-available()} evaluates to \texttt{true()} and that string is returned as the result of the \texttt{altova:find-first} function. Note about the \texttt{doc-available()} function: Relative paths are resolved relative to the the current base URI, which is}
by default the URI of the XML document from which the function is loaded.

find-first-combination [altova:]

\[
\text{find-first-combination}((\text{Seq-01 as item()^*}), (\text{Seq-02 as item()^*}), \\
(\text{Condition( Seq-01-Item, Seq-02-Item as xs:boolean)}) \text{ as item()^*}) \quad \text{XP3.1 XQ3.1}
\]

This function takes three arguments:

- The first two arguments, Seq-01 and Seq-02, are sequences of one or more items of any datatype.
- The third argument, Condition, is a reference to an XPath function that takes two arguments (has an arity of 2) and returns a boolean.

The items of Seq-01 and Seq-02 are passed in ordered pairs (one item from each sequence making up a pair) as the arguments of the function in Condition. The pairs are ordered as follows.

If Seq-01 = X1, X2, X3 ... Xn
And Seq-02 = Y1, Y2, Y3 ... Yn
Then (X1 Y1), (X1 Y2), (X1 Y3) ... (X1 Yn), (X2 Y1), (X2 Y2) ... (Xn Yn)

The first ordered pair that causes the Condition function to evaluate to true() is returned as the result of find-first-combination. Note that: (i) If the Condition function iterates through the submitted argument pairs and does not once evaluate to true(), then find-first-combination will always be a pair of items (of any datatype) or no item at all.

Examples

- \text{find-first-combination}(11 \text{ to } 20, 21 \text{ to } 30, \text{function($a, $b) {a +$b = 32}}) \text{ returns the sequence of xs:integers } \{11, 21\}
- \text{find-first-combination}(11 \text{ to } 20, 21 \text{ to } 30, \text{function($a, $b) {a +$b = 33}}) \text{ returns the sequence of xs:integers } \{11, 22\}
- \text{find-first-combination}(11 \text{ to } 20, 21 \text{ to } 30, \text{function($a, $b) {a +$b = 34}}) \text{ returns the sequence of xs:integers } \{11, 23\}

find-first-pair [altova:]

\[
\text{find-first-pair}((\text{Seq-01 as item()^*}), (\text{Seq-02 as item()^*}), \\
(\text{Condition( Seq-01-Item, Seq-02-Item as xs:boolean)}) \text{ as item()^*}) \quad \text{XP3.1 XQ3.1}
\]

This function takes three arguments:

- The first two arguments, Seq-01 and Seq-02, are sequences of one or more items of any datatype.
- The third argument, Condition, is a reference to an XPath function that takes two arguments (has an arity of 2) and returns a boolean.

The items of Seq-01 and Seq-02 are passed in ordered pairs as the arguments of the function in Condition. The pairs are ordered as follows.

If Seq-01 = X1, X2, X3 ... Xn
And \( \text{Seq-02} = Y_1, Y_2, Y_3 \ldots Y_n \)
Then \((X_1 Y_1), (X_2 Y_2), (X_3 Y_3) \ldots (X_n Y_n)\)

The first ordered pair that causes the \text{Condition} function to evaluate to \text{true()} is returned as the result of \text{altova:find-first-pair}. Note that: (i) If the \text{Condition} function iterates through the submitted argument pairs and does not once evaluate to \text{true()}, then \text{altova:find-first-pair} returns \text{No results}; (ii) The result of \text{altova:find-first-pair} will always be a pair of items (of any datatype) or no item at all.

\textbf{Examples}

• \text{altova:find-first-pair}(11 to 20, 21 to 30, function($a$, $b$) {$a$+$b$ = 32}) returns the sequence of \text{xm:integers} \((11, 21)\)
• \text{altova:find-first-pair}(11 to 20, 21 to 30, function($a$, $b$) {$a$+$b$ = 33}) returns \text{No results}

Notice from the two examples above that the ordering of the pairs is: \((11, 21)\) \((12, 22)\) \((13, 23)\)\ldots\((20, 30)\). This is why the second example returns \text{No results} (because no ordered pair gives a sum of 33).

\textbf{find-first-pair-pos [altova]}

\text{altova:find-first-pair-pos}((\text{Seq-01} as item())*, (\text{Seq-02} as item())*, (\text{Condition} (\text{Seq-01-Item}, \text{Seq-02-Item} as \text{xs:boolean}) as \text{xs:integer})) as \text{xs:integer} \ XP3.1 \ XQ3.1

This function takes three arguments:

• The first two arguments, \text{Seq-01} and \text{Seq-02}, are sequences of one or more items of any datatype.
• The third argument, \text{Condition}, is a reference to an XPath function that takes two arguments (has an arity of 2) and returns a boolean.

The items of \text{Seq-01} and \text{Seq-02} are passed in ordered pairs as the arguments of the function in \text{Condition}. The pairs are ordered as follows.

If \( \text{Seq-01} = X_1, X_2, X_3 \ldots X_n \)
And \( \text{Seq-02} = Y_1, Y_2, Y_3 \ldots Y_n \)
Then \((X_1 Y_1), (X_2 Y_2), (X_3 Y_3) \ldots (X_n Y_n)\)

The index position of the first ordered pair that causes the \text{Condition} function to evaluate to \text{true()} is returned as the result of \text{altova:find-first-pair-pos}. Note that if the \text{Condition} function iterates through the submitted argument pairs and does not once evaluate to \text{true()}, then \text{altova:find-first-pair-pos} returns \text{No results}.

\textbf{Examples}

• \text{altova:find-first-pair-pos}(11 to 20, 21 to 30, function($a$, $b$) {$a$+$b$ = 32}) returns 1
• \text{altova:find-first-pair-pos}(11 to 20, 21 to 30, function($a$, $b$) {$a$+$b$ = 33}) returns \text{No results}

Notice from the two examples above that the ordering of the pairs is: \((11, 21)\) \((12, 22)\) \((13, 23)\)\ldots\((20, 30)\). In the first example, the first pair causes the \text{Condition} function to evaluate to \text{true()}.
function to evaluate to true(), and so its index position in the sequence, 1, is returned. The second example returns No results because no pair gives a sum of 33.

**find-first-pos [altova:]**

\[
\text{altova:find-first-pos((Sequence as item()), (Condition( Sequence-Item as xs:boolean)) as xs:integer})
\]

XP3.1 XQ3.1

This function takes two arguments. The first argument is a sequence of one or more items of any datatype. The second argument, Condition, is a reference to an XPath function that takes one argument (has an arity of 1) and returns a boolean. Each item of sequence is submitted, in turn, to the function referenced in Condition. (Remember: This function takes a single argument.) The first Sequence item that causes the function in Condition to evaluate to true() has its index position in Sequence returned as the result of altova:find-first-pos, and the iteration stops.

**Examples**

- \[
\text{altova:find-first-pos([5 to 10], function($a) {$a mod 2 = 0})}
\] returns
  \[
  \text{xs:integer 2}
  \]

  The Condition argument references the XPath 3.0 inline function, function(), which declares an inline function named $a and then defines it. Each item in the Sequence argument of altova:find-first-pos is passed, in turn, to $a as its input value. The input value is tested on the condition in the function definition ($a mod 2 = 0). The index position in the sequence of the first input value to satisfy this condition is returned as the result of altova:find-first-pos (in this case 2, since 6, the first value (in the sequence) to satisfy the condition, is at index position 2 in the sequence).

- \[
\text{altova:find-first-pos([2 to 10], (function($a) {$a+3=7})})
\] returns
  \[
  \text{xs:integer 3}
  \]

**Further examples**

If the file C:\Temp\Customers.xml exists:

- \[
\text{altova:find-first-pos( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1))}
\] returns 1

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html exists:

- \[
\text{altova:find-first-pos( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1))}
\] returns 2

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html also does not exist:

- \[
\text{altova:find-first-pos( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1))}
\] returns no result

**Notes about the examples given above**
The XPath 3.0 function, `doc-available`, takes a single string argument, which is used as a URI, and returns `true` if a document node is found at the submitted URI. (The document at the submitted URI must therefore be an XML document.)

The `doc-available` function can be used for `condition`, the second argument of `altova:find-first-pos`, because it takes only one argument (arity=1), because it takes an `item()` as input (a string which is used as a URI), and returns a boolean value.

Notice that the `doc-available` function is only referenced, not called. The #1 suffix that is attached to it indicates a function with an arity of 1. In its entirety `doc-available#1` simply means: Use the `doc-available()` function that has arity=1, passing to it as its single argument, in turn, each of the items in the first sequence. As a result, each of the two strings will be passed to `doc-available()`, which uses the string as a URI and tests whether a document node exists at the URI. If one does, the `doc-available()` function evaluates to `true()` and the index position of that string in the sequence is returned as the result of the `altova:find-first-pos` function. Note about the `doc-available()` function: Relative paths are resolved relative to the the current base URI, which is by default the URI of the XML document from which the function is loaded.

---

altova:for-each-attribute-pair (Seq1 as element()?, Seq2 as element()?, Function as function()) as item()*

The first two arguments identify two elements, the attributes of which are used to build attribute pairs, where one attribute of a pair is obtained from the first element and the other attribute is obtained from the second element. Attribute pairs are selected on the basis of having the same name, and the pairs are ordered alphabetically (on their names) into a set. If, for one attribute no corresponding attribute on the other element exists, then the pair is "disjoint", meaning that it consists of one member only. The function item (third argument `Function`) is applied separately to each pair in the sequence of pairs (joint and disjoint), resulting in an output that is a sequence of items.

Examples

- `altova:for-each-attribute-pair(/Example/Test-A, /Example/Test-B, function($a, $b){$a+$b})` returns ...

  (2, 4, 6) if
  `<Test-A att1="1" att2="2" att3="3" />`
  `<Test-B att1="1" att2="2" att3="3" />`

  (2, 4, 6) if
  `<Test-A att2="2" att1="1" att3="3" />`
  `<Test-B att3="3" att2="2" att1="1" />`

  (2, 6) if
  `<Test-A att4="4" att1="1" att3="3" />`
  `<Test-B att3="3" att2="2" att1="1" />`

  Note: The result (2, 6) is obtained by way of the following action: (1+1, ()+2, 3+3, 4+()). If one of the operands is the empty sequence, as in the case of items 2
and 4, then the result of the addition is an empty sequence.

- `altova:for-each-attribute-pair` HACKING: returns ...

```
(11, 22, 33) if
<Test-A att1="1" att2="2" att3="3" />
<Test-B att1="1" att2="2" att3="3" />

(11, 2, 33, 4) if
<Test-A att4="4" att1="1" att3="3" />
<Test-B att3="3" att2="2" att1="1" />
```

**for-each-combination [altova:]**

```
altova:for-each-combination(FirstSequence as item()* , SecondSequence as item()*, Function($i,$j){$i || $j}) as item()* XP3.1 XQ3.1
```

The items of the two sequences in the first two arguments are combined so that each item of the first sequence is combined, in order, once with each item of the second sequence. The function given as the third argument is applied to each combination in the resulting sequence, resulting in an output that is a sequence of items (see example).

**Examples**

- `altova:for-each-combination` HACKING: returns ...

```
( 'a1', 'a2', 'a3', 'b1', 'b2', 'b3', 'c1', 'c2', 'c3')
```

**for-each-matching-attribute-pair [altova:]**

```
altova:for-each-matching-attribute-pair(Seq1 as element()?, Seq2 as element()?, Function as function()) as item()* XP3.1 XQ3.1
```

The first two arguments identify two elements, the attributes of which are used to build attribute pairs, where one attribute of a pair is obtained from the first element and the other attribute is obtained from the second element. Attribute pairs are selected on the basis of having the same name, and the pairs are ordered alphabetically (on their names) into a set. If, for one attribute no corresponding attribute on the other element exists, then no pair is built. The function item (third argument `Function`) is applied separately to each pair in the sequence of pairs, resulting in an output that is a sequence of items.

**Examples**

- `altova:for-each-matching-attribute-pair` HACKING: returns ...

```
(2, 4, 6) if
<Test-A att1="1" att2="2" att3="3" />
<Test-B att1="1" att2="2" att3="3" />

(2, 4, 6) if
<Test-A att2="2" att1="1" att3="3" />
<Test-B att3="3" att2="2" att1="1" />
```
XSLT and XPath/XQuery Functions

7.2.1.7 XPath/XQuery Functions: String

Altova's string extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova's XPath 3.0 and XQuery 3.0 engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

<table>

</table>

(2, 6) if

```xml
<Test-A att4="4" att1="1" att3="3" />
<Test-B att3="3" att2="2" att3="1" />
```

- `altova:for-each-matching-attribute-pair(/Example/Test-A, /Example/Test-B, concat#2) returns ...

(11, 22, 33) if

```xml
<Test-A att1="1" att2="2" att3="3" />
<Test-B att1="1" att2="2" att3="3" />
```

(11, 33) if

```xml
<Test-A att4="4" att1="1" att3="3" />
<Test-B att3="3" att2="2" att1="1" />
```

▼ substitute-empty [altova:]

```xml
altova:substitute-empty(FirstSequence as item()*, SecondSequence as item())
```

as item() XP3.1 XQ3.1

If FirstSequence is empty, returns SecondSequence. If FirstSequence is not empty, returns FirstSequence.

Examples

- `altova:substitute-empty( (1,2,3), (4,5,6) ) returns (1,2,3)`
- `altova:substitute-empty( (), (4,5,6) ) returns (4,5,6)`
### camel-case [altova:]

**Function:**

```
altova:camel-case(InputString as xs:string) as xs:string  XP3.1 XQ3.1
```

**Description:**
Returns the input string `InputString` in CamelCase. The string is analyzed using the regular expression `\s` (which is a shortcut for the whitespace character). The first non-whitespace character after a whitespace or sequence of consecutive whitespaces is capitalized. The first character in the output string is capitalized.

**Examples**
- `altova:camel-case("max")` returns `Max`
- `altova:camel-case("max max")` returns `Max Max`
- `altova:camel-case("file01.xml")` returns `File01.xml`
- `altova:camel-case("file01.xml file02.xml")` returns `File01.xml File02.xml`
- `altova:camel-case("file01.xml file02.xml")` returns `File01.xml File02.xml`
- `altova:camel-case("file01.xml -file02.xml")` returns `File01.xml -file02.xml`

**Function:**

```
altova:camel-case(InputString as xs:string, SplitChars as xs:string, IsRegex as xs:boolean) as xs:string  XP3.1 XQ3.1
```

**Description:**
Converts the input string `InputString` to camel case by using `SplitChars` to determine the character/s that trigger the next capitalization. `SplitChars` is used as a regular expression when `IsRegex = true()`, or as plain characters when `IsRegex = false()`. The first character in the output string is capitalized.

**Examples**
- `altova:camel-case("setname getname", "set|get", true())` returns `setName getName`
- `altova:camel-case("altova\documents\testcases", ",", false())` returns `Altova\Documents\Testcases`

### char [altova:]

**Function:**

```
altova:char(Position as xs:integer) as xs:string  XP3.1 XQ3.1
```

**Description:**
Returns a string containing the character at the position specified by the `Position` argument, in the string obtained by converting the value of the context item to `xs:string`. The result string will be empty if no character exists at the index submitted by the `Position` argument.

**Examples**
- If the context item is `1234ABCD`:
  - `altova:char(2)` returns `2`
  - `altova:char(5)` returns `A`
  - `altova:char(9)` returns the empty string.
  - `altova:char(-2)` returns the empty string.

**Function:**

```
altova:char(InputString as xs:string, Position as xs:integer) as xs:string  XP3.1 XQ3.1
```

**Description:**
Returns a string containing the character at the position specified by the `Position` argument, in the string submitted as the `InputString` argument. The result string will be
empty if no character exists at the index submitted by the Position argument.

**Examples**

- `altova:char("2014-01-15", 5)` returns `-`
- `altova:char("USA", 1)` returns `U`
- `altova:char("USA", 10)` returns the empty string.
- `altova:char("USA", -2)` returns the empty string.

**create-hash-from-string**

Generates a hash string from InputString by using the hashing algorithm specified by the HashAlgo argument. The following hashing algorithms may be specified (in upper or lower case): `MD5`, `SHA-1`, `SHA-224`, `SHA-256`, `SHA-384`, `SHA-512`. If the second argument is not specified (see the first signature above), then the `SHA-256` hashing algorithm is used.

**Examples**

- `altova:create-hash-from-string('abc')` returns a hash string generated by using the `SHA-256` hashing algorithm.
- `altova:create-hash-from-string('abc', 'md5')` returns a hash string generated by using the `MD5` hashing algorithm.
- `altova:create-hash-from-string('abc', 'MD5')` returns a hash string generated by using the `MD5` hashing algorithm.

**first-chars**

Returns a string containing the first X-Number of characters of the string obtained by converting the value of the context item to `xs:string`.

**Examples**

If the context item is `1234ABCD`:

- `altova:first-chars(2)` returns `12`
- `altova:first-chars(5)` returns `1234A`
- `altova:first-chars(9)` returns `1234ABCD`

**format-string**

Returns a string containing the first X-Number of characters of the string submitted as the InputString argument.

**Examples**

- `altova:first-chars("2014-01-15", 5)` returns `2014-`
- `altova:first-chars("USA", 1)` returns `U`
The input string (first argument) contains positional parameters (%1, %2, etc). Each parameter is replaced by the string item that is located at the corresponding position in the format sequence (submitted as the second argument). So the first item in the format sequence replaces the positional parameter %1, the second item replaces %2, and so on. The function returns this formatted string that contains the replacements. If no string exists for a positional parameter, then the positional parameter itself is returned. This happens when the index of a positional parameter is greater than the number of items in the format sequence.

**Examples**

- `altova:format-string('Hello %1, %2, %3', ('Jane', 'John', 'Joe'))` returns "Hello Jane, John, Joe"
- `altova:format-string('Hello %1, %2, %3', ('Jane', 'John', 'Joe', 'Tom'))` returns "Hello Jane, John, Joe"
- `altova:format-string('Hello %1, %2, %4', ('Jane', 'John', 'Joe', 'Tom'))` returns "Hello Jane, John, Tom"
- `altova:format-string('Hello %1, %2, %4', ('Jane', 'John', 'Joe'))` returns "Hello Jane, John, %4"

**last-chars [altova]**

`altova:last-chars(X-Number as xs:integer) as xs:string` XP3.1 XQ3.1

Returns a string containing the last X-Number of characters of the string obtained by converting the value of the context item to `xs:string`.

**Examples**

If the context item is 1234ABCD:

- `altova:last-chars(2)` returns CD
- `altova:last-chars(5)` returns 4ABCD
- `altova:last-chars(9)` returns 1234ABCD

`altova:last-chars(InputString as xs:string, X-Number as xs:integer) as xs:string` XP3.1 XQ3.1

Returns a string containing the last X-Number of characters of the string submitted as the `InputString` argument.

**Examples**

- `altova:last-chars("2014-01-15", 5)` returns 01-15
- `altova:last-chars("USA", 10)` returns USA

**pad-string-left [altova]**

`altova:pad-string-left(StringToPad as xs:string, StringLength as xs:integer, PadCharacter as xs:string) as xs:string` XP3.1 XQ3.1

The PadCharacter argument is a single character. It is padded to the left of the string to increase the number of characters in StringToPad so that this number equals the integer value of the StringLength argument. The StringLength argument can have any integer value (positive or negative), but padding will occur only if the value of StringLength is greater than the number of characters in StringToPad. If StringToPad has more characters than
the value of `StringLength`, then `StringToPad` is left unchanged.

**Examples**

- `altova:pad-string-left('AP', 1, 'Z')` returns `AP`
- `altova:pad-string-left('AP', 2, 'Z')` returns `AP`
- `altova:pad-string-left('AP', 3, 'Z')` returns `ZAP`
- `altova:pad-string-left('AP', 4, 'Z')` returns `ZZAP`
- `altova:pad-string-left('AP', -3, 'Z')` returns `AP`
- `altova:pad-string-left('AP', 3, 'YZ')` returns a pad-character-too-long error

**pad-string-right [altova:]**

```
altova:pad-string-right(StringToPad as xs:string, StringLength as xs:integer, PadCharacter as xs:string) as xs:string
```

The `PadCharacter` argument is a single character. It is padded to the right of the string to increase the number of characters in `StringToPad` so that this number equals the integer value of the `StringLength` argument. The `StringLength` argument can have any integer value (positive or negative), but padding will occur only if the value of `StringLength` is greater than the number of characters in `StringToPad`. If `StringToPad` has more characters than the value of `StringLength`, then `StringToPad` is left unchanged.

**Examples**

- `altova:pad-string-right('AP', 1, 'Z')` returns `AP`
- `altova:pad-string-right('AP', 2, 'Z')` returns `AP`
- `altova:pad-string-right('AP', 3, 'Z')` returns `APZ`
- `altova:pad-string-right('AP', 4, 'Z')` returns `APZZ`
- `altova:pad-string-right('AP', -3, 'Z')` returns `AP`
- `altova:pad-string-right('AP', 3, 'YZ')` returns a pad-character-too-long error

**repeat-string [altova:]**

```
altova:repeat-string(InputString as xs:string, Repeats as xs:integer) as xs:string
```

Generates a string that is composed of the first `InputString` argument repeated `Repeats` number of times.

**Examples**

- `altova:repeat-string("Altova #", 3)` returns "Altova #Altova #Altova #"

**substring-after-last [altova:]**

```
altova:substring-after-last(MainString as xs:string, CheckString as xs:string) as xs:string
```

If `CheckString` is found in `MainString`, then the substring that occurs after `CheckString` in `MainString` is returned. If `CheckString` is not found in `MainString`, then the empty string is returned. If `CheckString` is an empty string, then `MainString` is returned in its entirety. If there is more than one occurrence of `CheckString` in `MainString`, then the substring after the last occurrence of `CheckString` is returned.

**Examples**

- `altova:substring-after-last('ABCDEFGH', 'B')` returns 'CDEFGH'
• altova:substring-after-last('ABCDEFGH', 'BC') returns 'DEFGH'
• altova:substring-after-last('ABCDEFGH', 'BD') returns ''
• altova:substring-after-last('ABCDEFGH', 'Z') returns ''
• altova:substring-after-last('ABCDEFGH', '') returns 'ABCDEFGH'
• altova:substring-after-last('ABCD-ABCD', 'B') returns 'CD'
• altova:substring-after-last('ABCD-ABCD-ABCD', 'BCD') returns ''

• altova:substring-before-last('ABCDEFGH', 'BC') returns 'A'
• altova:substring-before-last('ABCDEFGH', 'BD') returns ''
• altova:substring-before-last('ABCDEFGH', 'Z') returns ''
• altova:substring-before-last('ABCDEFGH', '') returns ''
• altova:substring-before-last('ABCD-ABCD', 'B') returns 'ABCD-A'

• altova:substring-before-last('ABCD-ABCD-ABCD', 'BCD') returns ''

• altova:substring-pos('Altova', 'to') returns 3
• altova:substring-pos('Altova', 'tov') returns 3
• altova:substring-pos('Altova', 'tv') returns 0
• altova:substring-pos('AltovaAltova', 'to') returns 3

• altova:substring-pos(StringToCheck as xs:string, StringToFind as xs:string, Integer as xs:integer) as xs:integer

Returns the character position of the first occurrence of StringToFind in the string StringToCheck. The character position is returned as an integer. The first character of StringToCheck has the position 1. If StringToFind does not occur within StringToCheck, the integer 0 is returned. To check for the second or a later occurrence of StringToCheck, use the next signature of this function.

• altova:substring-pos('Altova', 'to') returns 3
• altova:substring-pos('Altova', 'tov') returns 3
• altova:substring-pos('Altova', 'tv') returns 0
• altova:substring-pos('AltovaAltova', 'to') returns 3

• altova:substring-pos(StringToCheck as xs:string, StringToFind as xs:string, Integer as xs:integer) as xs:integer

Returns the character position of StringToFind in the string, StringToCheck. The search for StringToFind starts from the character position given by the Integer argument; the character substring before this position is not searched. The returned integer, however, is the position of the found string within the entire string, StringToCheck. This signature is useful for finding the second or a later position of a string that occurs multiple times with the
StringToCheck. If StringToFind does not occur within StringToCheck, the integer 0 is returned.

**Examples**

- altova:substring-pos('Altova', 'to', 1) returns 3
- altova:substring-pos('Altova', 'to', 3) returns 3
- altova:substring-pos('Altova', 'to', 4) returns 0
- altova:substring-pos('Altova-Altova', 'to', 0) returns 3
- altova:substring-pos('Altova-Altova', 'to', 4) returns 10

**trim-string [altova:]**

```xml
altova:trim-string(InputString as xs:string) as xs:string XP3.1 XQ3.1
```

This function takes an xs:string argument, removes any leading and trailing whitespace, and returns a "trimmed" xs:string.

**Examples**

- altova:trim-string("    Hello World   ") returns "Hello World"
- altova:trim-string("Hello World   ") returns "Hello World"
- altova:trim-string("    Hello World") returns "Hello World"
- altova:trim-string("Hello World") returns "Hello World"
- altova:trim-string("Hello   World") returns "Hello   World"

**trim-string-left [altova:]**

```xml
altova:trim-string-left(InputString as xs:string) as xs:string XP3.1 XQ3.1
```

This function takes an xs:string argument, removes any leading whitespace, and returns a left-trimmed xs:string.

**Examples**

- altova:trim-string-left("    Hello World   ") returns "Hello World    
- altova:trim-string-left("Hello World   ") returns "Hello World   
- altova:trim-string-left("    Hello World") returns "Hello World    
- altova:trim-string-left("Hello World") returns "Hello World"
- altova:trim-string-left("Hello   World") returns "Hello   World"

**trim-string-right [altova:]**

```xml
altova:trim-string-right(InputString as xs:string) as xs:string XP3.1 XQ3.1
```

This function takes an xs:string argument, removes any trailing whitespace, and returns a right-trimmed xs:string.

**Examples**

- altova:trim-string-right("    Hello World   ") returns "Hello World  
- altova:trim-string-right("Hello World   ") returns "Hello World"
- altova:trim-string-right("    Hello World") returns "Hello World  
- altova:trim-string-right("Hello World") returns "Hello World"
- altova:trim-string-right("Hello   World") returns "Hello   World"
7.2.1.8 XPath/XQuery Functions: Miscellaneous

The following general purpose XPath/XQuery extension functions are supported in the current version of RaptorXML+XBRL Server and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

<table>
<thead>
<tr>
<th>XPath functions (used in XPath expressions in XSLT):</th>
<th>XP1</th>
<th>XP2</th>
<th>XP3.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSLT functions (used in XPath expressions in XSLT):</td>
<td>XSLT1</td>
<td>XSLT2</td>
<td>XSLT3</td>
</tr>
<tr>
<td>XQuery functions (used in XQuery expressions in XQuery):</td>
<td>XQ1</td>
<td>XQ3.1</td>
<td></td>
</tr>
</tbody>
</table>

get-temp-folder [altova:]

altova:get-temp-folder() as xs:string  

This function takes no argument. It returns the path to the temporary folder of the current user.

Examples

- altova:get-temp-folder() would return, on a Windows machine, something like C:\Users\<UserName>\AppData\Local\Temp\ as an xs:string.

generate-guid [altova:]

altova:generate-guid() as xs:string  

Generates a unique string GUID string.

Examples

- altova:generate-guid() returns (for example) 85F971DA-17F3-4E4E-994E-99137873ACCD

high-res-timer [altova:]

altova:high-res-timer() as xs:double  

Returns a system high-resolution timer value in seconds. A high-resolution timer, when present on a system, enables high precision time measurements when these are required (for example, in animations and for determining precise code-execution time). This function provides the resolution of the system’s high-res timer.

Examples
• **altova:high-res-timer()** returns something like '1.16766146154566E6'

**parse-html [altova:]**

```xml
altova:parse-html(HTMLText as xs:string) as node() XP3.1 XQ3.1
```

The **HTMLText** argument is a string that contains the text of an HTML document. The function creates an HTML tree from the string. The submitted string may or may not contain the HTML element. In either case, the root element of the tree is an element named **HTML**. It is best to make sure that the HTML code in the submitted string is valid HTML.

**Examples**

• **altova:parse-html("<html><head/><body><h1>Header</h1></body></html>")**
  
creates an HTML tree from the submitted string

**sleep[altova:]**

```xml
altova:sleep(Millisecs as xs:integer) as empty-sequence() XP2 XQ1 XP3.1 XQ3.1
```

Suspends execution of the current operation for the number of milliseconds given by the **Millisecs** argument.

**Examples**

• **altova:sleep(1000)** suspends execution of the current operation for 1000 milliseconds.

---

### 7.2.1.9 Chart Functions

The chart functions listed below enable you to create, generate, and save charts as images. They are supported in the current version of your Altova product in the manner described below. However, note that in future versions of your product, support for one or more of these functions might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

The chart functions are **XPath functions** (not XSLT functions), and organized into two groups:

- Functions for generating and saving charts
- Functions for creating charts

**Note:** Chart functions are supported only in **Altova’s Server products** and the **Enterprise Editions of Altova products**.

**Note:** Supported image formats for charts in server editions are jpg, png, and bmp. The best option is png because it is lossless and compressed. In Enterprise editions, the supported formats are jpg, png, bmp, and gif.
Functions for generating and saving charts
These functions take the chart object (obtained with the chart creation functions) and either generate an image or save an image to file

\texttt{altova:generate-chart-image} ($\texttt{chart}$, $\texttt{width}$, $\texttt{height}$, $\texttt{encoding}$) as atomic

where

- $\texttt{chart}$ is the chart extension item obtained with the \texttt{altova:create-chart} function
- $\texttt{width}$ and $\texttt{height}$ must be specified with a length unit
- $\texttt{encoding}$ may be binarytobase64 or binarytobase16

The function returns the chart image in the specified encoding.

\texttt{altova:generate-chart-image} ($\texttt{chart}$, $\texttt{width}$, $\texttt{height}$, $\texttt{encoding}$, $\texttt{imagetype}$) as atomic

where

- $\texttt{chart}$ is the chart extension item obtained with the \texttt{altova:create-chart} function
- $\texttt{width}$ and $\texttt{height}$ must be specified with a length unit
- $\texttt{encoding}$ may be base64Binary or hexBinary
- $\texttt{imagetype}$ may be one of the following image formats: png, gif, bmp, jpg, jpeg. Note that gif is not supported on server products. \textit{Also see note at top of page.}

The function returns the chart image in the specified encoding and image format.

\texttt{altova:save-chart-image} ($\texttt{chart}$, $\texttt{filename}$, $\texttt{width}$, $\texttt{height}$) as empty() \textit{(Windows only)}

where

- $\texttt{chart}$ is the chart extension item obtained with the \texttt{altova:create-chart} function
- $\texttt{filename}$ is the path to and name of the file to which the chart image is to be saved
- $\texttt{width}$ and $\texttt{height}$ must be specified with a length unit

The function saves the chart image to the file specified in $\texttt{filename}$.

\texttt{altova:save-chart-image} ($\texttt{chart}$, $\texttt{filename}$, $\texttt{width}$, $\texttt{height}$, $\texttt{imagetype}$) as empty() \textit{(Windows only)}

where

- $\texttt{chart}$ is the chart extension item obtained with the \texttt{altova:create-chart} function
- $\texttt{filename}$ is the path to and name of the file to which the chart image is to be saved
- $\texttt{width}$ and $\texttt{height}$ must be specified with a length unit
- $\texttt{imagetype}$ may be one of the following image formats: png, gif, bmp, jpg, jpeg. Note that gif is not supported on server products. \textit{Also see note at top of page.}
The function saves the chart image to the file specified in `$filename` in the image format specified.

**Functions for creating charts**
The following functions are used to create charts.

`altova:create-chart($chart-config, $chart-data-series*)` as chart extension item

where

- `$chart-config` is the chart-config extension item obtained with the `altova:create-chart-config` function or via the `altova:create-chart-config-from-xml` function
- `$chart-data-series` is the chart-data-series extension item obtained with the `altova:create-chart-data-series` function or `altova:create-chart-data-series-from-rows` function

The function returns a chart extension item, which is created from the data supplied via the arguments.

`altova:create-chart-config($type-name, $title)` as chart-config extension item

where

- `$type-name` specifies the type of chart to be created: Pie, Pie3d, BarChart, BarChart3d, BarChart3dGrouped, LineChart, ValueLineChart, RoundGauge, BarGauge
- `$title` is the name of the chart

The function returns a chart-config extension item containing the configuration information of the chart.

`altova:create-chart-config-from-xml($xml-struct)` as chart-config extension item

where

- `$xml-struct` is the XML structure containing the configuration information of the chart

The function returns a chart-config extension item containing the configuration information of the chart. This information is supplied in an XML data fragment.

`altova:create-chart-data-series($series-name?, $x-values*, $y-values*)` as chart-data-series extension item

where

- `$series-name` specifies the name of the series
- `$x-values` gives the list of X-Axis values
- `$y-values` gives the list of Y-Axis values
The function returns a chart-data-series extension item containing the data for building the chart: that is, the names of the series and the Axes data.

```xquery
altova:create-chart-data-row(x, y1, y2, y3, ...) as chart-data-x-Ny-row extension item

where

- x is the value of the X-Axis column of the chart data row
- yN are the values of the Y-Axis columns

The function returns a chart-data-x-Ny-row extension item, which contains the data for the X-Axis column and Y-Axis columns of a single series.
```

```xquery
altova:create-chart-data-series-from-rows($series-names as xs:string*, $row*) as chart-data-series extension item

where

- $series-name is the name of the series to be created
- $row is the chart-data-x-Ny-row extension item that is to be created as a series

The function returns a chart-data-series extension item, which contains the data for the X-Axis and Y-Axes of the series.
```

```xquery
altova:create-chart-layer($chart-config, $chart-data-series*) as chart-layer extension item

where

- $chart-config is the chart-config extension item obtained with the altova:create-chart-config function or or via the altova:create-chart-config-from-xml function
- $chart-data-series is the chart-data-series extension item obtained with the altova:create-chart-data-series function or altova:create-chart-data-series-from-rows function

The function returns a chart-layer extension item, which contains chart-layer data.
```

```xquery
altova:create-multi-layer-chart($chart-config, $chart-data-series*, $chart-layer*)

where

- $chart-config is the chart-config extension item obtained with the altova:create-chart-config function or or via the altova:create-chart-config-from-xml function
- $chart-data-series is the chart-data-series extension item obtained with the altova:create-chart-data-series function or altova:create-chart-data-series-from-rows function
- $chart-layer is the chart-layer extension item obtained with the altova:create-chart-layer function
```
The function returns a multi-layer-chart item.

\texttt{altova:create-multi-layer-chart}($\text{chart-config}$, $\text{chart-data-series}^*$, $\text{chart-layer}^*$, \text{x:boolean} $\text{mergecategoryvalues}$)

where

- $\text{chart-config}$ is the chart-config extension item obtained with the \texttt{altova:create-chart-config} function or or via the \texttt{altova:create-chart-config-from-xml} function
- $\text{chart-data-series}$ is the chart-data-series extension item obtained with the \texttt{altova:create-chart-data-series} function or \texttt{altova:create-chart-data-series-from-rows} function
- $\text{chart-layer}$ is the chart-layer extension item obtained with the \texttt{altova:create-chart-layer} function

The function returns a multi-layer-chart item.

**Chart Data XML Structure**

Given below is the XML structure of chart data, how it might appear for the Altova extension functions for charts. This affects the appearance of the specific chart. Not all elements are used for all chart kinds, e.g. the \texttt{<Pie>} element is ignored for bar charts.

**Note:** Chart functions are supported only in the Enterprise and Server Editions of Altova products.

\texttt{<chart-config>}

Example: Chart Functions

The example XSLT document below shows how Altova extension functions for charts can be used. Given further below are an XML document and a screenshot of the output image generated when the XML document is processed with the XSLT document using the XSLT 2.0 or 3.0 Engine.

Note: Chart functions are supported only in the Enterprise and Server Editions of Altova products.

Note: For more information about how chart data tables are created, see the documentation of Altova’s XMLSpy and StyleVision products.

XSLT document

This XSLT document (listing below) uses Altova chart extension functions to generate a pie chart. It can be used to process the XML document listed further below.
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"

7.2.1.10 Barcode Functions

The XSLT Engine uses third-party Java libraries to create barcodes. Given below are the classes and the public methods used. The classes are packaged in AltovaBarcodeExtension.jar, which is located in the folder <ProgramFilesFolder>\Altova\Common2019\jar.

The Java libraries used are in sub-folders of the folder <ProgramFilesFolder>\Altova\Common2019\jar:

- barcode4j\barcode4j.jar (Website: http://barcode4j.sourceforge.net/)
- zxing\core.jar (Website: http://code.google.com/p/zxing/)

The license files are also located in the respective folders.
Java virtual machine

In order to be able to use the barcode functions, a Java virtual machine must be available on your machine. The path to the machine is found as noted below.

- If you are using an Altova desktop product, the Altova application attempts to detect the path to the Java virtual machine automatically, by reading (in this order): (i) the Windows registry, and (ii) the JAVA_HOME environment variable. You can also add a custom path in the Options dialog of the application; this entry will take priority over any other Java VM path detected automatically.
- If you are running an Altova server product on a Windows machine, the path to the Java virtual machine will be read first from the Windows registry; if this is not successful the JAVA_HOME environment variable will be used.
- If you are running an Altova server product on a Linux or macOS machine, then make sure that the path to the Java virtual machine is stored in the JAVA_HOME environment variable. The path must point to the jvm.dll file in the \bin\server or \bin\client directory.

The com.altova.extensions.barcode package

The package, com.altova.extensions.barcode, is used to generate most of the barcode types.

The following classes are used:

```java
global public class BarcodeWrapper
    static BarcodeWrapper newInstance( String name, String msg, int dpi, int orientation, BarcodePropertyWrapper[] arrProperties )
dochead begin
    double getHeightPlusQuiet()
    double getWidthPlusQuiet()
    org.w3c.dom.Document generateBarcodeSVG()
dochead end
byte[] generateBarcodePNG()
dochead begin
String generateBarcodePngAsHexString()
dochead end

global public class BarcodePropertyWrapper Used to store the barcode properties that will be dynamically set later
    BarcodePropertyWrapper( String methodName, String propertyValue )
dochead begin
    BarcodePropertyWrapper( String methodName, Integer propertyValue )
docdochead end
    BarcodePropertyWrapper( String methodName, Double propertyValue )
dochead begin
    BarcodePropertyWrapper( String methodName, Boolean propertyValue )
docdochead end
    BarcodePropertyWrapper( String methodName, Character propertyValue )
dochead begin
String getMethodName()
dochead end
Object getPropertyValue()
dochead end

global public class AltovaBarcodeClassResolver Registers the class
    com.altova.extensions.barcode.proxy.zxing.QRCodeBean for the qrcode bean, additionally to the classes registered by the org.krysalis.barcode4j.DefaultBarcodeClassResolver.
```

The com.altova.extensions.barcode.proxy.zxing package

The package, com.altova.extensions.barcode.proxy.zxing, is used to generate the QRCODE barcode type.
The following classes are used:

**class** **QRCodeBean**

- *Extends* `org.krysalis.barcode4j.impl.AbstractBarcodeBean`
- *Creates an* `AbstractBarcodeBean` *interface for* `com.google.zxing.qrcode.encoder`

  ```java
  void generateBarcode(CanvasProvider canvasImp, String msg)
  void setQRErrorCorrectionLevel(QRCodeErrorCorrectionLevel level)
  BarcodeDimension calcDimensions(String msg)
  double getVerticalQuietZone()
  double getBarWidth()
  ```

**class **QRCodeErrorCorrectionLevel**  *Error correction level for the*  **QRCode**

  ```java
  static QRCodeErrorCorrectionLevel byName(String name)
  ```

  "L" = ~7% correction
  "M" = ~15% correction
  "H" = ~25% correction
  "Q" = ~30% correction

**XSLT example**

Given below is an XSLT example showing how barcode functions are used in an XSLT stylesheet.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
xmlns:xs="http://www.w3.org/2001/XMLSchema"
xmlns:fn="http://www.w3.org/2005/xpath-functions"
xmlns:altova="http://www.altova.com"
xmlns:altovaext="http://www.altova.com/xslt-extensions"
xmlns:altovaext-barcode="java:com.altova.extensions.barcode.BarcodeWrapper"
  <xsl:output method="html" encoding="UTF-8" indent="yes"/>
  <xsl:template match="/">
    <html>
      <head><title/></head>
      <body>
        <img alt="barcode" src="{altovaext:get-temp-folder()}barcode.png"/>
      </body>
    </html>
  </xsl:template>
</xsl:stylesheet>
```
</xsl:stylesheet>
7.2.2 Miscellaneous Extension Functions

There are several ready-made functions in programming languages such as Java and C# that are not available as XQuery/XPath functions or as XSLT functions. A good example would be the math functions available in Java, such as \( \sin() \) and \( \cos() \). If these functions were available to the designers of XSLT stylesheets and XQuery queries, it would increase the application area of stylesheets and queries and greatly simplify the tasks of stylesheet creators. The XSLT and XQuery engines used in a number of Altova products support the use of extension functions in Java and .NET, as well as MSXSL scripts for XSLT. They also support XBRL functions for XSLT. This section describes how to use extension functions and MSXSL scripts in your XSLT stylesheets and XQuery documents. The available extension functions are organized into the following sections:

- Java Extension Functions
- .NET Extension Functions
- XBRL functions for XSLT
- MSXSL Scripts for XSLT

The two main issues considered in the descriptions are: (i) how functions in the respective libraries are called; and (ii) what rules are followed for converting arguments in a function call to the required input format of the function, and what rules are followed for the return conversion (function result to XSLT/XQuery data object).

Requirements

For extension functions support, a Java Runtime Environment (for access to Java functions) and .NET Framework 2.0 (minimum, for access to .NET functions) must be installed on the machine running the XSLT transformation or XQuery execution, or must be accessible for the transformations.

7.2.2.1 Java Extension Functions

A Java extension function can be used within an XPath or XQuery expression to invoke a Java constructor or call a Java method (static or instance).

A field in a Java class is considered to be a method without any argument. A field can be static or instance. How to access fields is described in the respective sub-sections, static and instance.

This section is organized into the following sub-sections:

- Java: Constructors
- Java: Static Methods and Static Fields
- Java: Instance Methods and Instance Fields
- Datatypes: XPath/XQuery to Java
- Datatypes: Java to XPath/XQuery

Note the following

- If you are using an Altova desktop product, the Altova application attempts to detect the path to the Java virtual machine automatically, by reading (in this order): (i) the Windows registry, and (ii) the JAVA_HOME environment variable. You can also add a custom path in the Options dialog of the application; this entry will take priority over any other Java VM
If you are running an Altova server product on a Windows machine, the path to the Java virtual machine will be read first from the Windows registry; if this is not successful the 
JAVA_HOME environment variable will be used.
If you are running an Altova server product on a Linux or macOS machine, then make sure that the path to the Java virtual machine is stored in the 
JAVA_HOME environment variable. The path must point to the jvm.dll file in the \bin\server or \bin\client directory.

Form of the extension function
The extension function in the XPath/XQuery expression must have the form prefix:fname().

- The prefix: part identifies the extension function as a Java function. It does so by associating the extension function with an in-scope namespace declaration, the URI of which must begin with java: (see below for examples). The namespace declaration should identify a Java class, for example: xmlns:myns="java:java.lang.Math". However, it could also simply be: xmlns:myns="java" (without a colon), with the identification of the Java class being left to the fname() part of the extension function.
- The fname() part identifies the Java method being called, and supplies the arguments for the method (see below for examples). However, if the namespace URI identified by the prefix: part does not identify a Java class (see preceding point), then the Java class should be identified in the fname() part, before the class and separated from the class by a period (see the second XSLT example below).

Note: The class being called must be on the classpath of the machine.

XSLT example
Here are two examples of how a static method can be called. In the first example, the class name (java.lang.Math) is included in the namespace URI and, therefore, must not be in the fname() part. In the second example, the prefix: part supplies the prefix java: while the fname() part identifies the class as well as the method.

```xml
  select="jMath:cos(3.14)" />
<xsl:value-of xmlns:jmath="java"
  select="jmath:java.lang.Math.cos(3.14)" />
```

The method named in the extension function (cos() in the example above) must match the name of a public static method in the named Java class (java.lang.Math in the example above).

XQuery example
Here is an XQuery example similar to the XSLT example above:

```xml
<cosine xmlns:jMath="java:java.lang.Math">
  {jMath:cos(3.14)}
</cosine>
```
User-defined Java classes

If you have created your own Java classes, methods in these classes are called differently according to: (i) whether the classes are accessed via a JAR file or a class file, and (ii) whether these files (JAR or class) are located in the current directory (the same directory as the XSLT or XQuery document) or not. How to locate these files is described in the sections User-Defined Class Files and User-Defined Jar Files. Note that paths to class files not in the current directory and to all JAR files must be specified.

User-Defined Class Files

If access is via a class file, then there are two possibilities:

- The class file is in a package. The XSLT or XQuery file is in the same folder as the Java package. (See example below.)
- The class file is not packaged. The XSLT or XQuery file is in the same folder as the class file. (See example below.)
- The class file is in a package. The XSLT or XQuery file is at some random location. (See example below.)
- The class file is not packaged. The XSLT or XQuery file is at some random location. (See example below.)

Consider the case where the class file is not packaged and is in the same folder as the XSLT or XQuery document. In this case, since all classes in the folder are found, the file location does not need to be specified. The syntax to identify a class is:

```
java:classname
```

where

- `java:` indicates that a user-defined Java function is being called; (Java classes in the current directory will be loaded by default)
- `classname` is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call.

Class file packaged, XSLT/XQuery file in same folder as Java package

The example below calls the `getVehicleType()` method of the `Car` class of the `com.altova.extfunc` package. The `com.altova.extfunc` package is in the folder `JavaProject`. The XSLT file is also in the folder `JavaProject`.

```
xsl:stylesheet version="2.0"
xmns:xsl="http://www.w3.org/1999/XSL/Transform"
xmns:xs="http://www.w3.org/2001/XMLSchema"
xmns:fn="http://www.w3.org/2005/xpath-functions"
xmns:car="java:com.altova.extfunc.Car" >
<xsl:output exclude-result-prefixes="fn car xsl fo xs"/>
<xsl:template match="/">
```
Class file referenced, XSLT/XQuery file in same folder as class file

The example below calls the `getVehicleType()` method of the `Car` class. Let us say that: (i) the `Car` class file is in the following folder: `JavaProject/com/altova/extfunc`, and (ii) that this folder is the current folder in the example below. The XSLT file is also in the folder `JavaProject/com/altova/extfunc`.

```xml
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:car="java:Car">
<xsl:output exclude-result-prefixes="fn car xsl fo xs"/>

<xsl:template match="/">
    <a>
        <xsl:value-of select="car:getVehicleType()"/>
    </a>
</xsl:template>
</xsl:stylesheet>
```

Class file packaged, XSLT/XQuery file at any location

The example below calls the `getCarColor()` method of the `Car` class of the `com.altova.extfunc` package. The `com.altova.extfunc` package is in the folder `JavaProject`. The XSLT file is at any location. In this case, the location of the package must be specified within the URI as a query string. The syntax is:

```
java:classname[?path=uri-of-package]
```

where:

- `java:` indicates that a user-defined Java function is being called
- `uri-of-package` is the URI of the Java package
- `classname` is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call. The example below shows how to access a class file that is located in another directory than the current directory.

```xml
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
```
Class file referenced, XSLT/XQuery file at any location

The example below calls the `getCarColor()` method of the `Car` class. Let us say that the `Car` class file is in the folder `C:/JavaProject/com/altova/extfunc`, and the XSLT file is at any location. The location of the class file must then be specified within the namespace URI as a query string. The syntax is:

```
java:classname[?path=<uri-of-classfile>]
```

where

- `java:` indicates that a user-defined Java function is being called
- `uri-of-classfile` is the URI of the folder containing the class file
- `classname` is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call. The example below shows how to access a class file that is located in another directory than the current directory.

```xml
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:car="java:Car?path=file:///C:/JavaProject/com/altova/extfunc" >

    <xsl:output exclude-result-prefixes="fn car xsl xs"/>

    <xsl:template match="/">
        <xsl:variable name="myCar" select="car:new('red')" />
        <a><xsl:value-of select="car:getCarColor($myCar)"/></a>
    </xsl:template>

</xsl:stylesheet>
```

Note: When a path is supplied via the extension function, the path is added to the ClassLoader.
User-Defined Jar Files

If access is via a JAR file, the URI of the JAR file must be specified using the following syntax:

```xml
xmlns:classNS="java:classname?path=jar:uri-of-jarfile!/
```

The method is then called by using the prefix of the namespace URI that identifies the class:

```xml
classNS:method()
```

In the above:
- `java:` indicates that a Java function is being called
- `classname` is the name of the user-defined class
- `?` is the separator between the classname and the path
- `path=jar:` indicates that a path to a JAR file is being given
- `uri-of-jarfile` is the URI of the jar file
- `!/` is the end delimiter of the path
- `classNS:method()` is the call to the method

Alternatively, the classname can be given with the method call. Here are two examples of the syntax:

```xml
xmlns:ns1="java:docx.layout.pages?path=jar:file:///c:/projects/docs/docx.jar!/
ns1:main()

xmlns:ns2="java?path=jar:file:///c:/projects/docs/docx.jar!/"
ns2:docx.layout.pages.main()
```

Here is a complete XSLT example that uses a JAR file to call a Java extension function:

```xml
<xsl:stylesheet version="2.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:fn="http://www.w3.org/2005/xpath-functions"
  xmlns:car="java?path=jar:file:///C:/test/Car1.jar!/" >
  <xsl:output exclude-result-prefixes="fn car xsl xs"/>

  <xsl:template match="/"
    <xsl:variable name="myCar" select="car:Car1.new('red')" />
    <a><xsl:value-of select="car:Car1.getCarColor($myCar)" /></a>
  </xsl:template>

  <xsl:template match="car"/>
</xsl:stylesheet>
```

**Note:** When a path is supplied via the extension function, the path is added to the ClassLoader.
Java: Constructors

An extension function can be used to call a Java constructor. All constructors are called with the pseudo-function `new()`.

If the result of a Java constructor call can be implicitly converted to XPath/XQuery datatypes, then the Java extension function will return a sequence that is an XPath/XQuery datatype. If the result of a Java constructor call cannot be converted to a suitable XPath/XQuery datatype, then the constructor creates a wrapped Java object with a type that is the name of the class returning that Java object. For example, if a constructor for the class `java.util.Date` is called `(java.util.Date.new())`, then an object having a type `java.util.Date` is returned. The lexical format of the returned object may not match the lexical format of an XPath datatype and the value would therefore need to be converted to the lexical format of the required XPath datatype and then to the required XPath datatype.

There are two things that can be done with a Java object created by a constructor:

- It can be assigned to a variable:
  ```xml
  <xsl:variable name="currentdate" select="date:new()"
  xmlns:date="java:java.util.Date" />
  ```
- It can be passed to an extension function (see Instance Method and Instance Fields):
  ```xml
  <xsl:value-of select="date:toString(date:new())"
  xmlns:date="java:java.util.Date" />
  ```

Java: Static Methods and Static Fields

A static method is called directly by its Java name and by supplying the arguments for the method. Static fields (methods that take no arguments), such as the constant-value fields \( e \) and \( \pi \), are accessed without specifying any argument.

XSLT examples

Here are some examples of how static methods and fields can be called:

```xml
  select="jMath:cos(3.14)" />

  select="jMath:cos( jMath:PI() )" />

  select="jMath:E() * jMath:cos(3.14)" />
```

Notice that the extension functions above have the form `prefix:fname()`. The prefix in all three cases is `jMath:`, which is associated with the namespace URI `java:java.lang.Math`. The namespace URI must begin with `java:`. In the examples above it is extended to contain the class name (`java.lang.Math`) and the function name (`cos(3.14)`).
In the examples above, the class name has been included in the namespace URI. If it were not contained in the namespace URI, then it would have to be included in the $fname() part of the extension function. For example:

```xml
<xsl:value-of xmlns:java="java:"
  select="java:java.lang.Math.cos(3.14)" />
```

**XQuery example**

A similar example in XQuery would be:

```xml
<cosine xmlns:jMath="java:java.lang.Math">
  {jMath:cos(3.14)}
</cosine>
```

### Java: Instance Methods and Instance Fields

An instance method has a Java object passed to it as the first argument of the method call. Such a Java object typically would be created by using an extension function (for example a constructor call) or a stylesheet parameter/variable. An XSLT example of this kind would be:

```xml
<xsl:stylesheet version="1.0" exclude-result-prefixes="date"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:date="java:java.util.Date"
  xmlns:jlang="java:java.lang">
  <xsl:param name="CurrentDate" select="date:new()"/>
  <xsl:template match="/">
    <enrollment institution-id="Altova School"
      date="{date:toString($CurrentDate)}"
      type="{jlang:Object.toString(jlang:Object.getClass( date:new() ))}"
    />
  </xsl:template>
</xsl:stylesheet>
```

In the example above, the value of the node `enrollment/@type` is created as follows:

1. An object is created with a constructor for the class `java.util.Date` (with the `date:new()` constructor).
2. This Java object is passed as the argument of the `jlang.Object.getClass` method.
3. The object obtained by the `getClass` method is passed as the argument to the `jlang.Object.toString` method.

The result (the value of `@type`) will be a string having the value: `java.util.Date`.

An instance field is theoretically different from an instance method in that it is not a Java object per se that is passed as an argument to the instance field. Instead, a parameter or variable is passed as the argument. However, the parameter/variable may itself contain the value returned by a Java object. For example, the parameter `CurrentDate` takes the value returned by a constructor for the class `java.util.Date`. This value is then passed as an argument to the instance method `date:toString` in order to supply the value of `/enrollment/@date`. 
Datatypes: XPath/XQuery to Java

When a Java function is called from within an XPath/XQuery expression, the datatype of the function's arguments is important in determining which of multiple Java classes having the same name is called.

In Java, the following rules are followed:

- If there is more than one Java method with the same name, but each has a different number of arguments than the other/s, then the Java method that best matches the number of arguments in the function call is selected.
- The XPath/XQuery string, number, and boolean datatypes (see list below) are implicitly converted to a corresponding Java datatype. If the supplied XPath/XQuery type can be converted to more than one Java type (for example, \texttt{xs:integer}), then that Java type is selected which is declared for the selected method. For example, if the Java method being called is \texttt{fx(decimal)} and the supplied XPath/XQuery datatype is \texttt{xs:integer}, then \texttt{xs:integer} will be converted to Java's \texttt{decimal} datatype.

The table below lists the implicit conversions of XPath/XQuery string, number, and boolean types to Java datatypes.

<table>
<thead>
<tr>
<th>Datatype</th>
<th>Java Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{xs:string}</td>
<td>\texttt{java.lang.String}</td>
</tr>
<tr>
<td>\texttt{xs:boolean}</td>
<td>\texttt{boolean} (primitive), \texttt{java.lang.Boolean}</td>
</tr>
<tr>
<td>\texttt{xs:integer}</td>
<td>\texttt{int}, \texttt{long}, \texttt{short}, \texttt{byte}, \texttt{float}, \texttt{double}, and the wrapper classes of these, such as \texttt{java.lang.Integer}</td>
</tr>
<tr>
<td>\texttt{xs:float}</td>
<td>\texttt{float} (primitive), \texttt{java.lang.Float}, \texttt{double} (primitive)</td>
</tr>
<tr>
<td>\texttt{xs:double}</td>
<td>\texttt{double} (primitive), \texttt{java.lang.Double}</td>
</tr>
<tr>
<td>\texttt{xs:decimal}</td>
<td>\texttt{float} (primitive), \texttt{java.lang.Float}, \texttt{double} (primitive), \texttt{java.lang.Double}</td>
</tr>
</tbody>
</table>

Subtypes of the XML Schema datatypes listed above (and which are used in XPath and XQuery) will also be converted to the Java type/s corresponding to that subtype's ancestor type.

In some cases, it might not be possible to select the correct Java method based on the supplied information. For example, consider the following case.

- The supplied argument is an \texttt{xs:untypedAtomic} value of 10 and it is intended for the method \texttt{mymethod(float)}.
- However, there is another method in the class which takes an argument of another datatype: \texttt{mymethod(double)}.
- Since the method names are the same and the supplied type (\texttt{xs:untypedAtomic}) could be converted correctly to either \texttt{float} or \texttt{double}, it is possible that \texttt{xs:untypedAtomic} is converted to \texttt{double} instead of \texttt{float}.
- Consequently the method selected will not be the required method and might not produce the expected result. To work around this, you can create a user-defined method with a different name and use this method.
Types that are not covered in the list above (for example `xs:date`) will not be converted and will generate an error. However, note that in some cases, it might be possible to create the required Java type by using a Java constructor.

**Datatypes: Java to XPath/XQuery**

When a Java method returns a value, the datatype of the value is a string, numeric or boolean type, then it is converted to the corresponding XPath/XQuery type. For example, Java's `java.lang.Boolean` and `boolean` datatypes are converted to `xsd:boolean`.

One-dimensional arrays returned by functions are expanded to a sequence. Multi-dimensional arrays will not be converted, and should therefore be wrapped.

When a wrapped Java object or a datatype other than string, numeric or boolean is returned, you can ensure conversion to the required XPath/XQuery type by first using a Java method (e.g. `toString`) to convert the Java object to a string. In XPath/XQuery, the string can be modified to fit the lexical representation of the required type and then converted to the required type (for example, by using the `cast as` expression).

### 7.2.2 .NET Extension Functions

If you are working on the .NET platform on a Windows machine, you can use extension functions written in any of the .NET languages (for example, C#). A .NET extension function can be used within an XPath or XQuery expression to invoke a constructor, property, or method (static or instance) within a .NET class.

A property of a .NET class is called using the syntax `get_PropertyName()`.

This section is organized into the following sub-sections:

- **.NET: Constructors**
- **.NET: Static Methods and Static Fields**
- **.NET: Instance Methods and Instance Fields**
- **Datatypes: XPath/XQuery to .NET**
- **Datatypes: .NET to XPath/XQuery**

**Form of the extension function**

The extension function in the XPath/XQuery expression must have the form `prefix:fname()`. 

- The `prefix:` part is associated with a URI that identifies the .NET class being addressed.
- The `fname()` part identifies the constructor, property, or method (static or instance) within the .NET class, and supplies any argument/s, if required.
- The URI must begin with `clitype:` (which identifies the function as being a .NET extension function).
- The `prefix:fname()` form of the extension function can be used with system classes and with classes in a loaded assembly. However, if a class needs to be loaded, additional parameters containing the required information will have to be supplied.
## Parameters

To load an assembly, the following parameters are used:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asm</td>
<td>The name of the assembly to be loaded.</td>
</tr>
<tr>
<td>ver</td>
<td>The version number (maximum of four integers separated by periods).</td>
</tr>
<tr>
<td>sn</td>
<td>The key token of the assembly’s strong name (16 hex digits).</td>
</tr>
<tr>
<td>from</td>
<td>A URI that gives the location of the assembly (DLL) to be loaded. If the URI is relative, it is relative to the XSLT or XQuery document. If this parameter is present, any other parameter is ignored.</td>
</tr>
<tr>
<td>partialname</td>
<td>The partial name of the assembly. It is supplied to <code>Assembly.LoadWith.PartialName()</code>, which will attempt to load the assembly. If <code>partialname</code> is present, any other parameter is ignored.</td>
</tr>
<tr>
<td>loc</td>
<td>The locale, for example, en-US. The default is neutral.</td>
</tr>
</tbody>
</table>

If the assembly is to be loaded from a DLL, use the `from` parameter and omit the `sn` parameter. If the assembly is to be loaded from the Global Assembly Cache (GAC), use the `sn` parameter and omit the `from` parameter.

A question mark must be inserted before the first parameter, and parameters must be separated by a semi-colon. The parameter name gives its value with an equals sign (see example below).

### Examples of namespace declarations

An example of a namespace declaration in XSLT that identifies the system class `System.Environment`:

```xml
xmlns:myns="clitype:System.Environment"
```

An example of a namespace declaration in XSLT that identifies the class to be loaded as `Trade.Forward.Scrip`:

```xml
xmlns:myns="clitype:Trade.Forward.Scrip?asm=forward;version=10.6.2.1"
```

An example of a namespace declaration in XQuery that identifies the system class `MyManagedDLL.testClass`. Two cases are distinguished:

1. When the assembly is loaded from the GAC:
   ```xml
   declare namespace cs="clitype:MyManagedDLL.testClass?asm=MyManagedDLL;ver=1.2.3.4;loc=neutral;sn=b9f091b72dccfba8";
   ```

2. When the assembly is loaded from the DLL (complete and partial references below):
   ```xml
   declare namespace cs="clitype:MyManagedDLL.testClass?from=file:///C:/Altova/Projects/extFunctions/MyManagedDLL.dll;
   declare namespace cs="clitype:MyManagedDLL.testClass?from=MyManagedDLL.dll;
   ```
**XSLT example**

Here is a complete XSLT example that calls functions in system class `System.Math`:

```
<xsl:stylesheet version="2.0"
   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:fn="http://www.w3.org/2005/xpath-functions">
<xsl:output method="xml" omit-xml-declaration="yes" />
<xsl:template match="/">
  <math xmlns:math="clitype: System.Math">
    <sqrt><xsl:value-of select="math:Sqrt(9)" /></sqrt>
    <pi><xsl:value-of select="math:PI()" /></pi>
    <e><xsl:value-of select="math:E()" /></e>
    <pow><xsl:value-of select="math:Pow(math:PI(), math:E())" /></pow>
  </math>
</xsl:template>
</xsl:stylesheet>
```

The namespace declaration on the element `math` associates the prefix `math:` with the URI `clitype: System.Math`. The `clitype:` beginning of the URI indicates that what follows identifies either a system class or a loaded class. The `math:` prefix in the XPath expressions associates the extension functions with the URI (and, by extension, the class) `System.Math`. The extension functions identify methods in the class `System.Math` and supply arguments where required.

**XQuery example**

Here is an XQuery example fragment similar to the XSLT example above:

```
<math xmlns:math="clitype: System.Math">
  {math:Sqrt(9)}
</math>
```

As with the XSLT example above, the namespace declaration identifies the .NET class, in this case a system class. The XQuery expression identifies the method to be called and supplies the argument.

**.NET: Constructors**

An extension function can be used to call a .NET constructor. All constructors are called with the pseudo-function `new()`. If there is more than one constructor for a class, then the constructor that most closely matches the number of arguments supplied is selected. If no constructor is deemed to match the supplied argument/s, then a 'No constructor found' error is returned.

Constructors that return XPath/XQuery datatypes

If the result of a .NET constructor call can be implicitly converted to XPath/XQuery datatypes, then the .NET extension function will return a sequence that is an XPath/XQuery datatype.
Constructors that return .NET objects

If the result of a .NET constructor call cannot be converted to a suitable XPath/XQuery datatype, then the constructor creates a wrapped .NET object with a type that is the name of the class returning that object. For example, if a constructor for the class System.DateTime is called (with System.DateTime.new()), then an object having a type System.DateTime is returned.

The lexical format of the returned object may not match the lexical format of a required XPath datatype. In such cases, the returned value would need to be: (i) converted to the lexical format of the required XPath datatype; and (ii) cast to the required XPath datatype.

There are three things that can be done with a .NET object created by a constructor:

- It can be used within a variable:
  `<xsl:variable name="currentdate" select="date:new(2008, 4, 29)" xmlns:clitype="System.DateTime" />`

- It can be passed to an extension function (see Instance Method and Instance Fields):
  `<xsl:value-of select="date:ToString(date:new(2008, 4, 29))" xmlns:clitype="System.DateTime" />`

- It can be converted to a string, number, or boolean:
  `<xsl:value-of select="xs:integer(data:get_Month(date:new(2008, 4, 29)))" xmlns:clitype="System.DateTime" />`

.NET: Static Methods and Static Fields

A static method is called directly by its name and by supplying the arguments for the method. The name used in the call must exactly match a public static method in the class specified. If the method name and the number of arguments that were given in the function call matches more than one method in a class, then the types of the supplied arguments are evaluated for the best match. If a match cannot be found unambiguously, an error is reported.

Note: A field in a .NET class is considered to be a method without any argument. A property is called using the syntax `get_PropertyName()`.

Examples

An XSLT example showing a call to a method with one argument (System.Math.Sin(arg)):

An XSLT example showing a call to a field (considered a method with no argument) (System.Double.MaxValue()):

An XSLT example showing a call to a property (syntax is `get_PropertyName()`) (System.String()):
  `<xsl:value-of select="string:get_Length('my string')" xmlns:string="clitype:System.String"/>"
An XQuery example showing a call to a method with one argument (`System.Math.Sin(arg)`):

```xml
<sin xmlns:math="clitype:System.Math">
    { math:Sin(30) }
</sin>
```

### .NET: Instance Methods and Instance Fields

An instance method has a .NET object passed to it as the first argument of the method call. This .NET object typically would be created by using an extension function (for example a constructor call) or a stylesheet parameter/variable. An XSLT example of this kind would be:

```xml
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions">
    <xsl:output method="xml" omit-xml-declaration="yes"/>
    <xsl:template match="/">
        <xsl:variable name="releasedate" select="date:new(2008, 4, 29)"
            xmlns:date="clitype:System.DateTime"/>
        <doc>
            <date>
                <xsl:value-of select="date:ToString(date:new(2008, 4, 29))"
                    xmlns:date="clitype:System.DateTime"/>
            </date>
            <date>
                <xsl:value-of select="date:ToString($releasedate)"
                    xmlns:date="clitype:System.DateTime"/>
            </date>
        </doc>
    </xsl:template>
</xsl:stylesheet>
```

In the example above, a `System.DateTime` constructor (`new(2008, 4, 29)`) is used to create a .NET object of type `System.DateTime`. This object is created twice, once as the value of the variable `releasedate`, a second time as the first and only argument of the `System.DateTime.ToString()` method. The instance method `System.DateTime.ToString()` is called twice, both times with the `System.DateTime` constructor (`new(2008, 4, 29)`) as its first and only argument. In one of these instances, the variable `releasedate` is used to get the .NET object.

**Instance methods and instance fields**

The difference between an instance method and an instance field is theoretical. In an instance method, a .NET object is directly passed as an argument; in an instance field, a parameter or variable is passed instead—though the parameter or variable may itself contain a .NET object. For example, in the example above, the variable `releasedate` contains a .NET object, and it is this variable that is passed as the argument of `ToString()` in the second `date` element constructor. Therefore, the `ToString()` instance in the first `date` element is an instance method while the second is considered to be an instance field. The result produced in both instances, however, is the same.
Datatypes: XPath/XQuery to .NET

When a .NET extension function is used within an XPath/XQuery expression, the datatypes of the function's arguments are important for determining which one of multiple .NET methods having the same name is called.

In .NET, the following rules are followed:

- If there is more than one method with the same name in a class, then the methods available for selection are reduced to those that have the same number of arguments as the function call.
- The XPath/XQuery string, number, and boolean datatypes (see list below) are implicitly converted to a corresponding .NET datatype. If the supplied XPath/XQuery type can be converted to more than one .NET type (for example, xs:integer), then that .NET type is selected which is declared for the selected method. For example, if the .NET method being called is fx(double) and the supplied XPath/XQuery datatype is xs:integer, then xs:integer will be converted to .NET's double datatype.

The table below lists the implicit conversions of XPath/XQuery string, number, and boolean types to .NET datatypes.

<table>
<thead>
<tr>
<th>XPath/XQuery Datatype</th>
<th>.NET Datatypes</th>
</tr>
</thead>
<tbody>
<tr>
<td>xs:string</td>
<td>StringValue, string</td>
</tr>
<tr>
<td>xs:boolean</td>
<td>BooleanValue, bool</td>
</tr>
<tr>
<td>xs:integer</td>
<td>IntegerValue, decimal, long, integer, short, byte, double, float</td>
</tr>
<tr>
<td>xs:float</td>
<td>FloatValue, float, double</td>
</tr>
<tr>
<td>xs:double</td>
<td>DoubleValue, double</td>
</tr>
<tr>
<td>xs:decimal</td>
<td>DecimalValue, decimal, double, float</td>
</tr>
</tbody>
</table>

Subtypes of the XML Schema datatypes listed above (and which are used in XPath and XQuery) will also be converted to the .NET type/s corresponding to that subtype's ancestor type.

In some cases, it might not be possible to select the correct .NET method based on the supplied information. For example, consider the following case.

- The supplied argument is an xs:untypedAtomic value of 10 and it is intended for the method mymethod(float).
- However, there is another method in the class which takes an argument of another datatype: mymethod(double).
- Since the method names are the same and the supplied type (xs:untypedAtomic) could be converted correctly to either float or double, it is possible that xs:untypedAtomic is converted to double instead of float.
- Consequently the method selected will not be the required method and might not produce the expected result. To work around this, you can create a user-defined method with a different name and use this method.
Types that are not covered in the list above (for example `xs:date`) will not be converted and will generate an error.

**Datatypes: .NET to XPath/XQuery**

When a .NET method returns a value and the datatype of the value is a string, numeric or boolean type, then it is converted to the corresponding XPath/XQuery type. For example, .NET’s `decimal` datatype is converted to `xsd:decimal`.

When a .NET object or a datatype other than string, numeric or boolean is returned, you can ensure conversion to the required XPath/XQuery type by first using a .NET method (for example `System.DateTime.ToString()`) to convert the .NET object to a string. In XPath/XQuery, the string can be modified to fit the lexical representation of the required type and then converted to the required type (for example, by using the `cast as` expression).

### 7.2.2.3 XBRL Functions for XSLT

Functions defined in the [XBRL function registry](http://www.xbrl.org/functionregistry/functionregistry.xml) can be called from within an XSLT context for transforming XBRL instance documents. These XBRL functions are defined in one of two namespaces:

- `http://www.xbrl.org/2008/function/instance` (usually used with the `xfi:` prefix)
- `http://www.xbrl.org/2010/function/formula` (usually used with the `xff:` prefix)

So the XBRL function `xfi:context`, for example, expands to `http://www.xbrl.org/2008/function/instance:context` (assuming this namespace has been bound to the `xfi:` prefix).

For a complete list of the functions, go to [http://www.xbrl.org/functionregistry/functionregistry.xml](http://www.xbrl.org/functionregistry/functionregistry.xml).

### 7.2.2.4 MSXSL Scripts for XSLT

The `<msxsl:script>` element contains user-defined functions and variables that can be called from within XPath expressions in the XSLT stylesheet. The `<msxsl:script>` is a top-level element, that is, it must be a child element of `<xsl:stylesheet>` or `<xsl:transform>`.

The `<msxsl:script>` element must be in the namespace `urn:schemas-microsoft-com:xslt` (see example below).

**Scripting language and namespace**

The scripting language used within the block is specified in the `<msxsl:script>` element's `language` attribute and the namespace to be used for function calls from XPath expressions is identified with the `implements-prefix` attribute (see below).

```xml
<msxsl:script language="scripting-language" implements-prefix="user-namespace-prefix">
  function-1 or variable-1
</msxsl:script>
```
function-n or variable-n

The `<msxsl:script>` element interacts with the Windows Scripting Runtime, so only languages that are installed on your machine may be used within the `<msxsl:script>` element. The .NET Framework 2.0 platform or higher must be installed for MSXSL scripts to be used. Consequently, the .NET scripting languages can be used within the `<msxsl:script>` element.

The `language` attribute accepts the same values as the `language` attribute on the HTML `<script>` element. If the `language` attribute is not specified, then Microsoft JScript is assumed as the default.

The `implements-prefix` attribute takes a value that is a prefix of a declared in-scope namespace. This namespace typically will be a user namespace that has been reserved for a function library. All functions and variables defined within the `<msxsl:script>` element will be in the namespace identified by the prefix specified in the `implements-prefix` attribute. When a function is called from within an XPath expression, the fully qualified function name must be in the same namespace as the function definition.

Example
Here is an example of a complete XSLT stylesheet that uses a function defined within a `<msxsl:script>` element.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:msxsl="urn:schemas-microsoft-com:xslt"
    xmlns:user="http://mycompany.com/mynamespace">

    <msxsl:script language="VBScript" implements-prefix="user">
        <![CDATA[
            ' Input: A currency value: the wholesale price
            ' Returns: The retail price: the input value plus 20% margin,
            ' rounded to the nearest cent
            dim a as integer = 13
            Function AddMargin(WholesalePrice) as integer
                AddMargin = WholesalePrice * 1.2 + a
            End Function
        ]]>}
    </msxsl:script>

    <xsl:template match="/">
        <html>
            <body>
                <p>
                    <b>Total Retail Price = <xsl:value-of select="user:AddMargin(50)"/>
                </b><br/>
                <b>Total Wholesale Price = <xsl:value-of select="50"/>
            </p>
        </body>
    </xsl:template>
</xsl:stylesheet>
```
Datatypes
The values of parameters passed into and out of the script block are limited to XPath datatypes. This restriction does not apply to data passed among functions and variables within the script block.

Assemblies
An assembly can be imported into the script by using the `<msxsl:assembly>` element. The assembly is identified via a name or a URI. The assembly is imported when the stylesheet is compiled. Here is a simple representation of how the `<msxsl:assembly>` element is to be used.

```
<msxsl:script>
  <msxsl:assembly name="myAssembly.assemblyName" />
  <msxsl:assembly href="pathToAssembly" />
...
</msxsl:script>
```

The assembly name can be a full name, such as:

"system.Math, Version=3.1.4500.1 Culture=neutral PublicKeyToken=a46b3f648229c514"

or a short name, such as "myAssembly.Draw".

Namespaces
Namespaces can be declared with the `<msxsl:using>` element. This enables assembly classes to be written in the script without their namespaces, thus saving you some tedious typing. Here is how the `<msxsl:using>` element is used so as to declare namespaces.

```
<msxsl:script>
  <msxsl:using namespace="myAssemblyNS.NamespaceName" />
...
</msxsl:script>
```

The value of the `namespace` attribute is the name of the namespace.
