3.1	Creati	ng and Setting Up a New SPS	67
3.2	Inserti	ng Dynamic Content (from XML Source)	72
3.3	Inserting Static Content		

3.4	Forma	atting the Content	84
3.5	Using	90	
3.6	Using	94	
3.7	Using	Global Templates and Rest-of-Contents	101
3.8	That's	lt!	105
4	Usag	ge Overview	106
4.1	SPS a	and Sources	107
4.2	Creati	ng the Design	109
4.3	XSLT	and XPath Versions	110
4.4	Interne	et Explorer Compatibility	111
4.5		and Authentic View	
4.6	Synch	ronizing StyleVision and Authentic	115
4.7	Gener	ated Files	116
4.8	Projec	cts in StyleVision	119
4.9	Catalogs in StyleVision		124
	4.9.1	How Catalogs Work	124
	4.9.2	Catalog Structure in StyleVision	125
	4.9.3	Customizing Your Catalogs	126
	4.9.4	Variables for Windows System Locations	128
5	SPS	Content	130
5.1	Inserti	ng XML Content as Text	131
	5.1.1	Inserting Content with a Predefined Format	
	5.1.2	Adding Elements in Authentic View	134
	5.1.3	Rest-of-Contents	136
5.2	Inserti	ng MS Word Content	138
5.3	Inserti	ng MS Excel Content	141
5.4	User-l	Defined Templates	143
5.5	User-l	Defined Elements, XML Text Blocks	146
	5.5.1	User-Defined Elements	146
	5.5.2	User-Defined XML Text Blocks	147
56	Tables		149

	5.6.1	Static Tables	151
	5.6.2	Dynamic Tables	153
	5.6.3	Conditional Processing in Tables	158
	5.6.4	Tables in Design View	158
	5.6.5	Table Formatting	160
	5.6.6	Row and Column Display	165
	5.6.7	CALS/HTML Tables	166
5.7	Lists		171
	5.7.1	Static Lists	171
	5.7.2	Dynamic Lists	173
5.8	Graphi	ics	176
	5.8.1	Images: URIs and Inline Data	176
	5.8.2	Image Types and Output	178
	5.8.3	Example: ATemplate for Images	181
5.9	Charts	3	182
	5.9.1	Chart Basics	184
	5.9.2	Chart Settings: Quick Reference	187
	5.9.3	Chart Settings and Appearance	192
	5.9.4	Chart Data Selection: Simple	221
	5.9.5	Chart Data Selection: Flexible	225
	5.9.6	Example: Pie Charts	232
	5.9.7	Example: Bar Charts	237
	5.9.8	Example: Line Charts	243
	5.9.9	Example: Value Line Charts	246
	5.9.10	Example: Area Charts	249
	5.9.11	Example: Candlestick Charts	254
	5.9.12	Example: Gauge Charts	259
	5.9.13	Example: Overlay Charts	261
5.10	Form (Controls	265
	5.10.1	Input Fields, Multiline Input Fields	266
	5.10.2	Check Boxes	266
	5.10.3	Combo Boxes	268
	5.10.4	Radio Buttons, Buttons	271
5.11	Links		273
5.12	Barcoo	des	274

5.13	Layout Modules		278
	5.13.1	Layout Containers	278
	5.13.2	Layout Boxes	281
	5.13.3	Lines	285
5.14	The Ch	nange-To Feature	288
6	SPS	Structure	291
6.1	Schem	na Sources	293
	6.1.1	DTDs and XML Schemas	294
	6.1.2	DB Schemas	300
	6.1.3	XBRL Taxonomy	301
	6.1.4	User-Defined Schemas	306
	6.1.5	Multiple Schema Sources	308
	6.1.6	Schema Manager	311
6.2	Mergin	g XML Data from Multiple Sources	327
6.3	Modula	ar SPSs	330
	6.3.1	Available Module Objects	331
	6.3.2	Creating a Modular SPS	334
	6.3.3	Example: An Address Book	338
6.4	Templa	ates and Design Fragments	344
	6.4.1	Main Template	344
	6.4.2	Global Templates	345
	6.4.3	User-Defined Templates	349
	6.4.4	Variable Templates	352
	6.4.5	Node-Template Operations	352
	6.4.6	Design Fragments	356
6.5	XSLT ⁻	Templates	
6.6	Multiple	e Document Output	362
	6.6.1	Inserting a New Document Template	363
	6.6.2	New Document Templates and Design Structure	364
	6.6.3	URLs of New Document Templates	364
	6.6.4	Preview Files and Output Document Files	366
	6.6.5	Document Properties and Styles	369

7	Adv	anced Features	370
7.1	Auto-0	Auto-Calculations	
	7.1.1	Editing and Moving Auto-Calculations	371
	7.1.2	Updating Nodes with Auto-Calculations	374
	7.1.3	Auto-Calculations Based on Updated Nodes	376
	7.1.4	Example: An Invoice	377
7.2	Condi	itions	381
	7.2.1	Setting Up the Conditions	381
	7.2.2	Editing Conditions	384
	7.2.3	Output-Based Conditions	385
	7.2.4	Conditions and Auto-Calculations	386
7.3	Condi	itional Presence	387
7.4	Group	ping	389
	7.4.1	Example: Group-By (Persons.sps)	391
	7.4.2	Example: Group-By (Scores.sps)	393
7.5	Sortin	ng	397
	7.5.1	The Sorting Mechanism	397
	7.5.2	Example: Sorting on Multiple Sort-Keys	399
7.6	Paran	neters and Variables	403
	7.6.1	User-Declared Parameters	403
	7.6.2	Parameters for Design Fragments	405
	7.6.3	SPS Parameters for Sources	407
	7.6.4	Variables	408
	7.6.5	Editable Variables in Authentic	410
7.7	Table	of Contents, Referencing, Bookmarks	413
	7.7.1	Bookmarking Items for TOC Inclusion	416
	7.7.2	Creating the TOC Template	423
	7.7.3	Example: Simple TOC	428
	7.7.4	Example: Hierarchical and Sequential TOCs	432
	7.7.5	Auto-Numbering in the Document Body	435
	7.7.6	Cross-referencing	
	7.7.7	Bookmarks and Hyperlinks	440
7.8	Example: Multiple Languages 4		

8	Pres	sentation and Output	450
8.1	Prede	451	
8.2	Outpu	ıt Escaping	453
8.3	Value	Value Formatting (Formatting Numeric Datatypes)	
	8.3.1	The Value Formatting Mechanism	455
	8.3.2	Value Formatting Syntax	458
8.4	Worki	ng with CSS Styles	465
	8.4.1	External Stylesheets	466
	8.4.2	Global Styles	470
	8.4.3	Local Styles	472
	8.4.4	Setting Style Values	474
	8.4.5	Style Properties Via XPath	476
	8.4.6	Composite Styles	479
8.5	Text-S	Styling Flexibility in Authentic	483
	8.5.1	Composite Styles	483
	8.5.2	RichEdit	485
	8.5.3	Text State Icons	489
8.6	HTML	Document Properties	492
8.7	Desig	ning Print Output	494
	8.7.1	Document Sections	495
	8.7.2	Keeps and Breaks	509
	8.7.3	Footnotes	510
	8.7.4	PDF Fonts	511
	8.7.5	Pixel Resolution	514
	8.7.6	PDF Bookmarks	517
	8.7.7	PDF Attachments	521
	8.7.8	Watermarks	522
8.8	Fillabl	e PDF Forms	526
	8.8.1	Creating a Fillable PDF Form	528
	8.8.2	Form Controls	532
	8.8.3	Form Data	537

9	Addi	tional Functionality	541
9.1	Altova	542	
	9.1.1	Defining Global Resources	542
	9.1.2	Using Global Resources	553
9.2	Authen	tic Node Properties	559
9.3	Replac	e Parent Node OnClick With	561
9.4	Additio	nal Validation	564
9.5	Unpars	sed Entity URIs	566
9.6	New from	om XSLT, XSL-FO or FO File	568
9.7	User-D	Pefined XPath Functions	572
	9.7.1	Defining an XPath Function	574
	9.7.2	Reusing Functions to Locate Nodes	577
	9.7.3	Parameters in XPath Functions	578
9.8	Working with Dates		587
	9.8.1	Using the Date-Picker	588
	9.8.2	Formatting Dates	589
9.9	Using 9	593	
	9.9.1	Defining JavaScript Functions	594
	9.9.2	Assigning Functions as Event Handlers	595
	9.9.3	External JavaScript Files	596
9.10	HTML	lmport	598
	9.10.1	Creating New SPS via HTML Import	598
	9.10.2	Creating the Schema and SPS Design	600
	9.10.3	Creating Tables and Lists as Elements/Attributes	602
	9.10.4	Generating Output	604
9.11	XML S	gnatures	605
	9.11.1	XML Signature Configuration	607
	9.11.2	XML Signature Settings	608
	9.11.3	Signing the Authentic XML Document	611
	9.11.4	Signature Verification in Authentic	612
	9.11.5	XML Document Validity	614
	9.11.6	Working with Certificates	
9.12	ASPX Interface for Web Applications		

	9.12.1	Example: Localhost on Windows 7	620
9.13	PXF File: Container for SPS and Related Files		622
	9.13.1	Creating a PXF File	622
	9.13.2	Editing a PXF File	625
	9.13.3	Deploying a PXF File	626
10	Datal	bases	628
10.1	DBs ar	nd StyleVision	631
10.2	Conne	ct to a Data Source	633
	10.2.1	Start Database Connection Wizard	634
	10.2.2	Database Drivers Overview	636
	10.2.3	ADO Connection	640
	10.2.4	ADO.NET Connection	645
	10.2.5	JDBC Connection	651
	10.2.6	ODBC Connection	654
	10.2.7	SQLite Connection	657
	10.2.8	Native Connections	659
	10.2.9	Global Resources	660
	10.2.10	Database Connection Examples	660
10.3	DB Da	ta Selection	696
	10.3.1	Non-XML Databases	696
	10.3.2	XML Databases	703
10.4	The DE	3 Schema and DB XML files	707
10.5	DB Filt	ers: Filtering DB Data	710
10.6	SPS D	esign Features for DB	715
10.7	Genera	ating Output Files	719
10.8	Query	Database	721
	10.8.1	Data Sources	722
	10.8.2	Browser Pane: Viewing the DB Objects	725
	10.8.3	Query Pane: Description and Features	729
	10.8.4	Query Pane: Working with Queries	731
	10.8.5	Results and Messages	732

11	XBRL	_	735
11.1	Taxonomy Manager		737
	11.1.1	Run Taxonomy Manager	740
	11.1.2	Status Categories	743
	11.1.3	Patch or Install a Taxonomy	745
	11.1.4	Uninstall a Taxonomy, Reset	746
	11.1.5	Command Line Interface (CLI)	747
11.2	Creatin	g an XBRL SPS File	754
11.3	Taxono	omy Structure	757
11.4	Taxono	omy Source Properties	760
11.5		Templates	
	11.5.1	Types of Template	
	11.5.2	Context	765
	11.5.3	Concept	766
	11.5.4	Item	766
	11.5.5	Concept QName	767
	11.5.6	Periods	767
	11.5.7	ldentifiers	768
	11.5.8	Units and Unitrefs	769
	11.5.9	Dimensions	771
	11.5.10	Non-XDT Segments and Scenarios	772
	11.5.11	Footnote	
	11.5.12	XML Node	775
11.6	Open, Closed, and Classic Modes		776
	11.6.1	Concept Properties	
	11.6.2	Period Properties	778
	11.6.3	Identifier Properties	779
	11.6.4	Unit Properties	
	11.6.5	Explicit Dimension Properties	
	11.6.6	Typed Dimension Properties	
	11.6.7	Non-XDT Segment/Scenario Properties	
11.7		Tables	
11.8		Table Wizard	704

	11.8.1	XBRL Table Structure	795
	11.8.2	XBRL Table Options	800
	11.8.3	Component Properties	802
11.9	US-GA	AP Table Wizard	811

Introduction 19

1 Introduction

Altova StyleVision 2025 Enterprise Edition is an application for graphically designing and editing StyleVision Power Stylesheets, available in 64-bit and 32-bit versions. StyleVision® runs on Windows 10, Windows 11, and Windows Server 2016 or newer. Some functionality of StyleVision and Altova MissionKit can be integrated with applications of the Microsoft Office suite (MS Access, MS Excel, MS Word), version 2007 or newer.

A StyleVision Power Stylesheet (SPS) can be used for the following purposes:

- To control a graphical WYSIWYG view of XML documents in Authentic View, which is an XML document editor available in the following Altova products: Altova XMLSpy, Altova StyleVision, Altova Authentic Desktop, and Altova Authentic Browser. It enables you to easily create electronic forms based on XML documents.
- To enable the editing of **databases (DBs) via Authentic View** and to generate database reports in HTML, RTF, PDF, Text, and Word 2007-and-higher format.
- To generate XSLT stylesheets based on the SPS design. (XSLT 1.0, XSLT 2.0, and XSLT 3.0 are supported.) The XSLT stylesheets can be used outside StyleVision to transform XML documents into outputs such as HTML, RTF (Rich Text Format, used by word processing applications such as MS Word), XSL-FO (used to generate PDF and PostScript files), and Word 2007-and-higher.
- To generate, directly from within StyleVision, **HTML**, **RTF**, **XSL-FO**, **PDF**, **Text**, **and Word 2007-and-higher output** from an XML document. In the case of DB-based SPSs, StyleVision can additionally generate, for each SPS, an XML Schema based on the DB and an XML instance document that adheres to this schema and contains data from the DB.

Last updated: 17 March 2025

1.1 Product Features

The main product features of StyleVision are listed below:

General product features

Given below is a list of the main high-level features of StyleVision.

- Enterprise and Professional editions are each available as separate 64-bit and 32-bit applications.
- StyleVision functionality can be called via StyleVision Server.
- StyleVision functionality can be <u>integrated in external applications</u> and StyleVision an integrated in <u>Visual Studio</u> and <u>Eclipse</u> and <u>Eclipse</u> 305.

Sources

SPS designs can be based on XML Schemas and DTDs. A design uses other source files, such as XML and CSS files. The following additional features concerning sources are supported:

- Altova Global Resources (542) can be used to locate source files such as schema, XML, and CSS. The Global Resources mechanism enables faster and better development and testing by allowing developers to quickly change source data and to use the functionality of other Altova applications from within StyleVision.
- The SPS can use <u>multiple schemas</u> and/or a single <u>database (DB) source</u>, thus enabling the use of multiple XML document sources together with a DB source.
- XBRL taxonomies can be loaded and an SPS can be built based on the taxonomy.
- HTML documents can be converted to XML 598.

Interface

Given below are some general GUI features:

- <u>Multiple SPS designs</u> can be open simultaneously, with one being active at any given time. Each SPS design is shown in a separate tab.
- <u>Template filters</u> allow you to customize the display of the design document. With this feature you can disable the display of templates that are not currently being edited, thus increasing editing efficiency.
- <u>Hide Markup in Design View</u> 38: Markup tags in Design View can be hidden and collapsed, thus freeing up space in Design View.
- While designing the SPS, <u>Authentic View</u> ³⁸, <u>output views</u> ³⁹ and stylesheets can be displayed by clicking the respective tabs. This enables you to quickly preview the output and the XSLT code, and test Authentic View features.
- When an SPS is associated with an XML source document or source DB or source DB or source DB or source document can be edited directly in the Authentic View of StyleVision.

Databases

The following DB features are supported:

- DB reports can either be viewed in StyleVision or saved as HTML, RTF, PDF, and Word 2007-and-higher files.
- IBM DB2 databases (633), which contain XML columns, are supported.

A DB can be gueried 721 directly from StyleVision.

Output

Various output formats are supported depending upon the edition that has been installed. The following output-related features are supported:

- XSLT versions 1.0, 2.0, and 3.0 are supported.
- In the Enterprise and Professional Editions, <u>multiple output formats</u> (HTML, RTF, PDF, Text, and Word 2007-and-higher) are generated from a single SPS design.
- Conditions can be set on SPS components to <u>process them differently for different outputs</u> ³⁸⁵. With this level of granularity, different outputs can be flexibly structured to take in the requirements of that particular output.
- Both XSLT files and output files 116 can be generated and saved 118, either directly from within the GUI or via StyleVision Server.
- Altova has developed a special <u>PXF File format</u> that enables an SPS file to be saved together with related source and data files. This enables entire SPS projects to be transported rather than just the SPS file.
- ASPX Interface for Web Applications 619: With this feature, HTML web pages can be quickly updated. StyleVision generates, from an SPS, all the files necessary for an ASPX application. When the web page (a .aspx file) is refreshed, the source data (including any updates) is dynamically transformed via XSLT to the web page.

SPS design features

Given below is a list of the main StyleVision features specific to designing the SPS.

- The SPS can contain <u>static text</u> (131), which you enter in the SPS, and <u>dynamic text</u> (131), which is selected from the <u>source document/s</u> (293).
- <u>Dynamic content</u> is inserted in the design by dragging-and-dropping nodes from the <u>schema</u> <u>sources</u>. Design Elements (paragraphs, lists, images, etc) can also be inserted first, and an XML node from the schema tree can be assigned to the Design Element afterwards.
- <u>Dynamic content</u> (31) can be inserted as text, or in the form of a <u>data-entry device</u> (such as an <u>input field</u> (such
- An XBRL Table Wizard can automatically generate a dynamic SPS table according to your input.
- The <u>structure of the design (291)</u> is specified and controlled in a single <u>main template (301)</u>. This structure can be modified by optional templates for individual elements—known as <u>global templates</u> (344) because they can be applied globally for that element.
- Global templates (345) can also be created for individual datatypes, thus enabling processing to be handled also on the basis of types.
- <u>Multiple Document Output</u> 302: The output generated by the SPS can be designed to be split into multiple documents. In the design, New Document templates are created and content placed in them. Each New Document template generates a separate document in the output.
- <u>User-Defined Templates</u> ¹⁴³: A template can be generated for a sequence of items by an XPath expression you specify. These items may be atomic values or nodes. An XPath expression enables the selection of nodes to be more specific, allowing conditions and filters to be used for the selection.
- <u>User-Defined Elements</u> 146: This feature is intended to enable presentation language elements (such as HTML, XSLT, and XSL-FO) to be freely inserted at any location in the design.
- <u>User-Defined XML Text Blocks</u> 146: XML Text blocks can be freely inserted at any location in the design, and these blocks will be created at that location in the generated XSLT stylesheet.

Design Fragments enable the modularization and re-use of templates within an SPS, and also across multiple SPSs (see modular SPS) (see modular SPSs (see modular SPS) (see modular

- SPS modules (330) can be added to other SPS modules, thus making objects defined in one SPS module available to other modules. This enables re-use of module objects across multiple SPSs and makes maintenance easier.
- XSLT Templates 330: XSLT files can be imported into the generated stylesheets. If a node in the XML instance document is matched to a template in the imported XSLT file and no other template takes precedence over the imported template, then the imported template will be used. Additionally, named templates in the imported XSLT file can be called from within the design.
- New from XSLT 633: An SPS can be created from an XSLT-for-HTML or an XSLT-for-FO. Template structure and styling in the XSLT will be created in the SPS. You can then modify the SPS components and add content and formatting to the SPS.
- <u>User-Defined XPath Functions</u> The user can define XPath functions which can be used anywhere in the document where XPath functions may be used.
- Charts 182: This SPS design element provides a graphical representation of data in the source XML document. It is set up by specifying a sequence of items for each axis of the chart. StyleVision then automatically generates the chart in the various output formats.
- XBRL Charts: ⁸¹⁷ Data from XBRL instance files can be represented as charts in the various output formats.
- <u>Document Sections</u>
 (495): Documents can be divided into sections, with each section having its own properties, such as page layout properties. This enables different parts of a document to be presented differently.
- <u>Layout Containers</u> 278: A Layout Container is a block in which Design Elements can be laid out and absolutely positioned within the block.
- <u>Blueprints</u> Within a Layout Container an image of a form can be used as an underlay blueprint for the design. With the help of a blueprint, an existing design can be reproduced accurately.
- A common feature of XML documents is the repeating data structure. For example, an office department typically has several employees. The data for each employee would be stored in a data structure which is repeated for each employee. In the SPS, the <u>processing for each such data structure</u> is defined once and applied to each relevant node in turn (the employee node in our example).
- Multiple tables of contents 413 can be inserted in XSLT 2.0 and 3.0 SPSs.
- Repeating data structures can also be inserted as <u>dynamic tables</u> 149. This provides looping in a structured, table format, with each loop through the data structure producing a row (or, if required, a column) of the table.
- A repeating element can be <u>sorted on one or more sort-keys</u> you select, and the sorted element set is sent to the output (HTML, RTF, PDF, and Word 2007-and-higher).
- <u>Variables</u> 409: A variable can now be declared on a template and take a value that is specified with an XPath expression. Previously, the value of a variable was limited to the selection of the node on which it was created. Variables in the 2010 version allow any XPath expression to be specified as the value of the variable.
- Nodes can be <u>grouped</u> on the basis of common data content (for example, the common value of an attribute value) and their positions.
- The <u>conditional templates</u> (331) feature enables one of a set of templates to be processed according to what conditions in the XML document or system environment are fulfilled. This enables processing that is conditional on information contained in the source document or that cannot be known to the SPS document creator at the time of creation (for example, the date of processing). The available conditions are those that can be tested using XPath expressions.
- Auto-Calculations enable you to manipulate data from the source document/s and to display the result. This is useful, when you wish to perform calculations on numbers (for example, sum the prices in an invoice), manipulate strings (for example, change hyphens to slashes), generate content, etc. The available manipulations are those that can be effected using XPath expressions. Native Java and .NET functions can be used in the XPath expressions of Auto-Calculations.

• When data is edited in Authentic View, the result of <u>Auto-Calculations</u> (standard can also be passed to a node in the source document. This procedure is referred to as <u>updating the XML node</u> (with the value of the Auto-Calculation).

- Additional validation enables individual XML document nodes to be validated (additionally to schema validation) against an XPath expression defined for that node. In this way, Authentic View users can be alerted when the data they enter is invalid; a customized error message for the node can indicate the problem.
- <u>Barcodes</u> This new design component enables barcodes to be easily inserted in the design. Barcode images are generated on the fly and placed in the output documents.
- <u>Conditional presence</u> ³³⁷: Certain design components have a conditional presence property. A conditional design component will be created in the output only if the condition specified for it is fulfilled.
- Images 176 can be inserted in the design. The URI for the image can be static (entered in the SPS), or dynamic (taken from a node in the source document), or a combination of both static and dynamic parts.
- Images from inline data 149: Images can be generated from Base-16 and Base-64 encoded text in the XML document. Consequently, images can be stored directly in the source XML document as text. An SPS can now decode such text and render the image.
- Two types of <u>lists</u> ¹⁷¹ can be created: static and dynamic. In a <u>static list</u> ¹⁷¹, each list item is defined in the SPS. In a <u>dynamic list</u> ¹⁷³, a node is created as a list item; the values of all instances of that node are created as the items of the list.
- Static and dynamic links (and be inserted in the design. The target URI can be static (entered in the SPS), or dynamic (taken from a node in the source document), or a combination of both static and dynamic parts.
- Static bookmarks 440 can be inserted. These serve as anchors that can be linked to with a hyperlink.
- PDF Bookmarks ⁵¹⁷: A simpler mechanism to generate bookmarks in PDF output. In previous versions, the <u>Table of Contents</u> ⁴¹⁹ was used as the template for generating PDF bookmarks. While the TOC mechanism is a powerful one and is very useful for complex structures, the new PDF Bookmarks alternative simplifies the creation of non-complex bookmark tree structures.
- Parameters (403) can be declared globally for the entire SPS. A parameter is declared with a name and a string value, and can be used in XPath expressions in the SPS. The parameter value you declare is the default value. It can be overridden by a value passed via StyleVision Server.
- With the <u>Input Formatting</u> feature, the contents of numeric XML Schema datatype nodes can be formatted as required for Authentic View display and, in the case of some formats, optionally for output display. Input Formatting can also be used to format the result of an <u>Auto-Calculation</u> 371.
- <u>JavaScript functions</u> can be used in the SPS to provide user-defined functionality for Authentic View and HTML output.
- Authentic Scripting (88): Enables additional flexibility and interactivity in Authentic View.
- A number of <u>predefined HTML formats</u> are available via the GUI and can be applied to individual SPS components.
- A large number of CSS text formatting and layout properties can be applied to individual SPS components via the <u>Styles sidebar</u> 472.
- Additionally, CSS styles can be defined for HTML selectors at the global level of an SPS and in external CSS stylesheets. These style rules will be applied to Authentic View and HTML output, thus providing considerable formatting and layout flexibility.
- <u>Styles can also be assigned using XPath expressions</u> 476. This enables style property values to be selected from XML documents and to set property values conditionally.
- For paged output (typically RTF, PDF, and Word 2007-and-higher), a number of <u>page layout options</u> such as orientation, margins, page-numbering, and headers and footers, can be specified in the SPS.

1.2 Authentic View in Altova Products

Authentic View is a graphical XML document editor available in the following Altova products:

- * Altova XMLSpy
- * Altova Authentic Desktop
- * Altova Authentic Browser
- * Altova StyleVision

In StyleVision, Authentic View can be viewed in the Authentic eForm tab of the Main Window 33.

Introduction What Is an SPS? 25

1.3 What Is an SPS?

A StyleVision Power Stylesheet (or SPS) is an extended XSLT stylesheet which is used:

to control the display and entry of data in the <u>Authentic View</u> of XML documents and databases (DBs); and

• to specify the output design of an XML document transformation.

An SPS is saved with the file extension .sps.

Design of the SPS

An SPS is created graphically in StyleVision. It is based on a schema (DTD or XML Schema); if the SPS is to be used with a DB, it is based on an XML Schema generated automatically by StyleVision from the DB structure. The design of the SPS is flexible. It can contain dynamic and static content. The dynamic content of is the data in one or more XML documents or DBs. The static content or within components such as input fields, combo boxes, and tables. Additionally, dynamic content can be manipulated (using Auto-Calculations) and can be displayed if certain conditions in the source document are fulfilled. Different pieces of content can be placed at various and multiple locations in the SPS. Also, the SPS can contain various other components, such as images, hyperlinks, and JavaScript functions. Each component of the SPS can then be formatted for presentation as required.

The SPS and Authentic View

When a finished SPS is associated with an XML document or DB, that XML document or DB can be edited in Authentic View 28. Authentic View is an ideal solution for enabling the distributed and graphical editing of an XML document or DB. Multiple users can edit an XML document or DB in the graphical user interface presented by Authentic View. In StyleVision, as you design an SPS, you can preview and test the SPS (in the Authentic View tab for that SPS). For a detailed description of how SPSs work with Authentic View, see SPS and Authentic View 113.

The SPS and XSLT stylesheets

After you have completed designing the SPS, you can generate XSLT stylesheets based on the design you have created. StyleVision supports XSLT 1.0, XSLT 2.0 and XSLT 3.0, and from a single SPS, you can generate XSLT stylesheets for HTML, RTF, XSL-FO, Text, and Word 2007-and-higher output (*XSL-FO, Text, and Word 2007-and-higher in Enterprise edition only; RTF and Text in Enterprise and Professional Editions; in Basic Edition only HTML output is supported)*. The generated XSLT stylesheets can be used in external transformations to transform XML documents based on the same schema as the SPS from which the XSLT stylesheet was generated. For more information about procedures used with XSLT stylesheets, see the section Generated Files ¹¹⁶.

The SPS and output

You can also use StyleVision to directly generate output (*HTML*, *RTF*, *Text*, *XSL-FO*, *and PDF in Enterprise Edition*; *HTML and RTF in Professional Edition*; *and HTML in Basic Edition*). The tabs for Output Views display the output for the active SPS document directly in the StyleVision GUI. The required output can also be generated to file from within the GUI via the File | Save Generated Files command or via StyleVision Server.

26 Introduction What Is an SPS?

Authentic View in Altova Products

Authentic View is a graphical XML document editor available in the following Altova products:

- * Altova XMLSpy* Altova Authentic Desktop
- * Altova Authentic Browser
- * Altova StyleVision

1.4 Setting up StyleVision

Altova StyleVision runs on Windows 10, Windows 11. After downloading StyleVision from the <u>Altova website</u>, double-click the executable (.exe) file to run the setup program. The setup program will install StyleVision at the desired location. The Altova XSLT Engines (1.0 and 2.0) are built into StyleVision and are used for all internal transformations. You, therefore, do not need to install an XSLT Engine additionally to your StyleVision installation. The setup program will also install the Apache FOP processor (for the generation of PDF from XSL-FO) in the folder C:\ProgramData\Altova\SharedBetweenVersions.

You will, however, need to have the following components installed:

- Internet Explorer 5.5 or later, for Authentic View, HTML Preview and Design View. Internet Explorer 6.0 and later has better XML support and is recommended.
- Microsoft Word 2000 or later, for RTF Preview. Microsoft Word 2003 or later is recommended. For copy-paste from Word documents (and of content that can be pasted into Word documents, such as Excel tables and HTML page content) Word 2007+ is required
- Adobe Acrobat Reader, for PDF Preview (Acrobat Reader 6.0 or later is recommended).
- Microsoft Word 2007-and-higher or Microsoft's Word 2007-and-higher Viewer, for previewing Word 2007-and-higher output in the Word 2007-and-higher Preview tab. Microsoft Word 2003 with compatibility pack can be used for previewing Word 2007-and-higher output, but is sometimes unable to render Word 2007-and-higher files properly.

Note: In this documentation, we use the abbreviation **Word 2007+** to refer to Microsoft Word 2007 or higher versions of this program.

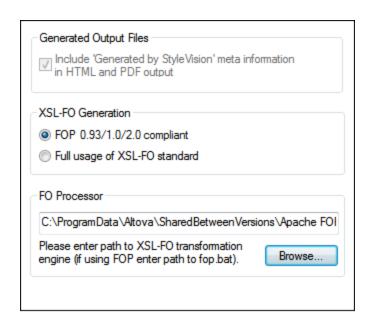

Note: If there is a problem with an embedded preview, StyleVision will attempt to open the preview document in an external application (usually MS Word or Adobe Reader). An error message about the embedded preview will appear in StyleVision. If the preview document is opened in an external application, you will need to close the external application before regenerating the temporary output document, otherwise you will get an error message saying the file is being used by another process. You should also close the external application before closing the SPS design, otherwise StyleVision will not be able to close the temporary output document due to the file lock placed on the document by the external application.

Note on FO processors

An FO processor is required to generate PDF output from an XSL-FO document. (During the StyleVision installation, FOP (the FO processor of the <u>Apache XML Project</u>) will be installed by default.

StyleVision can pass the XSL-FO document (generated by transforming the source document) to an FO processor of your choice. In the FO Processor input field of the Options dialog (<u>Tools | Options | XSL Options</u>) (*screenshot below*), enter the location of the file that starts the FO processor. The FO processor you select is used to generate the PDF Preview as well as the PDF files created via the <u>File | Save Generated Files</u> command.

Introduction

Unless you deselected the option to install the FOP processor of the <u>Apache XML Project</u>, it will have been installed in the folder C:\ProgramData\Altova\SharedBetweenVersions. If installed, the path to it will automatically have been entered in the FO Processor input field (see screenshot above). You can set the path to any FO processor you wish to use. Note, however, that the same path will be used by other Altova products that use FO processors and have settings to select the FO processor (XMLSpy and Authentic Desktop).

After you have installed the FO processor, you should set the XSL-FO compliance level in the Options dialog (Tools | Options | XSL-FO (1033)).

Note: Since conformance levels between any two FO processors can differ widely, and since the XSL-FO specification may be interpreted differently from processor to processor, the PDF produced by different processors from a single FO file could be different.

Note: When a large document is processed by FOP (Apache's FO processor), data in memory is discarded each time a new document section is processed. If you wish to reduce memory use, therefore, it is best to structure your document into multiple document sections 362.

JRE requirement for FOP

Note that FOP requires that a Java Runtime Environment (JRE) be installed on your machine (see the <u>Apache.org website</u> for more information). If you do not have JRE installed, you can install OpenJDK to provide the JRE requirement. Note that after installing the JRE, you must set the <u>JAVA_HOME</u> environment variable to correctly point to your JRE.

RaptorXML

RaptorXML 897 can be used to transform XML to the required output format.

Introduction Terminology 29

1.5 Terminology

This section lists terms used in the StyleVision GUI and in this documentation. Terms are organized into the groups listed below, and within each group, they are listed alphabetically.

Altova product-related terms

A list of terms that relate to Altova products.

Authentic View	An XML document editor view available in the following Altova products: Altova XMLSpy; Altova StyleVision; Altova Authentic Desktop; Altova Authentic Browser. For more details about Authentic View and Altova products, visit the <u>Altova website</u> .
SPS	The abbreviated form of StyleVision Power Stylesheet, it is used throughout this documentation to refer to the design document created in StyleVision and saved as a file with the .sps extension. For a detailed description, see What Is an SPS? .
Global resource	An alias for a set of files, a set of folders, or a set of databases. Each alias has a set of configurations and each configuration is mapped to a resource. In StyleVision, when a global resource is used, the resource can be changed by changing the active configuration in StyleVision.

General XML terms

Definitions of certain XML terms as used in this documentation.

schema	A schema (with lowercase 's') refers to any type of schema. Schemas supported by StyleVision are XML Schema (capitalized) and DTD.
XML Schema	In this documentation, XML Schema (<i>capitalized</i>) is used to refer to schemas that are compliant with the <u>W3C's XML Schema specification</u> . XML Schema is considered to be a subset of all <u>schemas</u> (<i>lowercased</i>).
URI and URL	In this documentation, the more general URI is used exclusively—even when the identifier has only a "locator" aspect, and even for identifiers that use the http scheme.

XSLT and XPath terms

There have been changes in terminology from XSLT 1.0 and XPath 1.0 to XSLT 2.0 and XPath 2.0. For example, what was the root node in XPath 1.0 is the <u>document node</u> in XPath 2.0. In this documentation, we use the newest, XSLT 3.0 and XPath 3.0, terminology.

absolute XPath	A path expression that starts at the root node of the tree containing the <u>context node</u> 29. In StyleVision, when entering path expressions in dialogs, the expression can be entered as ar absolute path if you check the Absolute XPath check box in the dialog. If this check box is unchecked, the path is relative to the <u>context node</u> 29.	
context item /	The context item is the item (node or string value) relative to which an expression is evaluated. A context node is a context item that is a node. The context item can change within an expression, for example, with each location step, or within a filter expression (predicate).	

30 Introduction Terminology

context node

current node The current node is the node being currently processed. The current node is the same as the context node in expressions that do not have sub-expressions. But where there are sub-expressions, the context node may change. Note that the current () function is an XSLT function, not an XPath function.

document element

In a well-formed XML document, the outermost element is known as the document element. It is a child of the <u>document node</u> 30, and, in a well-formed XML document, there is only one document element. In the GUI the document element is referred to as the root element.

document node

local

main

main

schema

template

template

The document node represents and contains the entire document. It is the root node of the tree representation of the document, and it is represented in an XPath expression as: '/'. In the Schema Tree window of StyleVision, it is represented by the legend: '/ Root elements'.

StyleVision-specific terms

Terms that refer to StyleVision mechanisms, concepts, and components.

Blueprint A blueprint image is one that is used as the background image of a <u>layout container</u> and would typically be the scan of a form. The SPS design can be modelled on the blueprint image, thus recreating the form design.

dynamic Items that originate in XML data sources. Dynamic items may be text, tables, and lists; also images and hyperlinks (when the URIs are dynamic).

An element in the Global Elements list in the Schema Tree window. In an XML Schema, all elements defined as global elements will be listed in the Global Elements list. In a DTD, all elements are global elements and are listed in the Global Elements list. Global templates can be defined only for global elements.

A global template may be defined for a global element . Once defined, a global template can be used for that element wherever that element occurs in the document. Alternatively to the global template, processing for a global element may be defined in a local template.

LayoutA Layout Container is a design block in which design elements can be laid out and absolutely positioned. If a design is to be based on a form, it can be created as a Layout Container, so that design elements of the form can be absolutely positioned. Alternatively, a design can be free-flowing and have layout containers placed within the flow of the document.

A local template is the template that defines how an element (global or non-global) is processed within the <u>main template</u> 30. The local template applies to that particular occurrence of the element in the <u>main template</u> 30. Instead of the local template, a <u>global template</u> 30 can be applied to a given occurrence of an element in the <u>main template</u> 30.

One of the assigned schema sources is designated the main schema; the document node of the Working XML File 31 associated with the main schema is used as the starting point for the main template 30.

The main entry-point template. In StyleVision, this template matches the <u>document</u> <u>element</u> and is the first to be evaluated by the XSLT processor. In the Schema Tree window, it is listed as the child of the <u>document node</u>. The <u>main template</u> defines the basic output document structure and defines how the input document/s are to be processed. It can contain <u>local templates</u> and can reference <u>global templates</u>.

Introduction Terminology 31

output

The output produced by processing an XML document with an XSLT stylesheet. Output files that can be generated by StyleVision would be HTML, RTF, PDF, and Word 2007-and-higher format. Authentic View is not considered an output, and is referred to separately as Authentic View. XSLT stylesheets generated by StyleVision are also not considered output and are referred to separately as XSLT stylesheets.

static items Items that originate in the SPS and not in XML data sources. Static items may be text, tables, and lists; also images, hyperlinks, and bookmarks (when the URIs are static).

SPS

An SPS component can be: (i) a schema node (for example, an element node); (ii) a static component SPS component such as an Auto-Calculation 371 or a text string; or (iii) a predefined format 451 (represented in the SPS by its start and end tags).

template

Defined loosely as a set of instructions for processing a node or group of nodes.

Template XML File A Template XML File is assigned to an SPS in StyleVision (Enterprise and Professional editions). It is an XML file that provides the starting data of a new XML document created with a given SPS when that SPS is opened in Authentic View. The Template XML File must be conformant with the schema on which the SPS is based.

Userdefined element An element that is neither a node in the schema tree nor a predefined element or a design element, but one that is specified by the user. An element can be specified with attributes.

Userdefined template A template that is created for a sequence specified in an XPath expression.

Userdefined XMLtext blocks XML Text blocks can be freely inserted at any location in the design

Working File

A Working XML/XBRL File is an XML data file that is assigned to an SPS in StyleVision in XML/XBRL order to preview the Authentic View and output of the XML document in StyleVision. Without a Working XML/XBRL File, the SPS in StyleVision will not have any dynamic XML data to process. If the SPS is based on a schema that has more than one global element, there can be ambiguity about which global element is the document element. Assigning a Working XML/XBRL File resolves such ambiguity (because a valid XML document will, by definition, have only one document element (30). Note that XBRL functionality is available only in the Enterprise edition.

XMLdocument

XML document is used in two senses: (i) to refer to a specific XML document; (ii) to refer to any XML data source, including DB sources (from which XML data documents are generated for use with an SPS). Which sense is intended should be clear from the context.

32 Introduction About This Documentation

1.6 About This Documentation

This documentation is the user manual delivered with StyleVision. It is available as the built-in Help system of StyleVision, can be viewed online at the <u>Altova website</u>, and can also be downloaded from there as a PDF, which you can print.

The user manual is organized into the following sections:

- An introduction, which explains what an SPS is and introduces the main features and concepts of StyleVision.
- A description of the user interface 34, which provides an overview of the StyleVision GUI.
- A tutorial 66 section, which is a hands-on exercise to familiarize you with StyleVision features.
- <u>Usage Overview</u> 103, which describes usage at a high level: for example, schema sources used to create an SPS, the broad design process, Authentic View deployment, and projects.
- <u>SPS File Content</u> ¹³⁰, which explains how static (stylesheet-originated) and dynamic (XML document-originated) components are created and edited in the SPS.
- SPS File Structure (291), which shows how an SPS file can be structured and modularized, and describes the handling of StyleVision's templates.
- <u>SPS File Advanced Features</u> ³⁷⁰, which describes advanced design features, such as the automatic generation of calculations, the setting up of conditions, grouping and sorting on user-defined criteria, and how to build tables of contents and cross-references in the output document.
- SPS File Presentation 450, which explains how SPS components are formatted and laid out.
- <u>SPS File Additional Editing Functionality</u> ^[541], which describes a range of additional features that can make your SPS more powerful. These features include: global resources for leveraging functionality in other Altova products, additional validation, scripts, and variables and parameters.
- SPS File and Databases 628, which explains how databases can be used with SPSs.
- SPS File and XBRL (135), which describes how output can be designed for XBRL documents in StyleVision's XBRL View.
- Authentic View 444, which describes how XML documents are edited in Authentic View. The StyleVision GUI contains an Authentic View preview tab, in which you can immediately test the Authentic View output.
- Automated Processing 892, which explains how the generation of output files can be automated.
- <u>StyleVision's integration features</u>, which contains the documentation for integrating StyleVision in other applications. There is also information on how to use StyleVision in <u>Visual Studio</u> and <u>Eclipse</u>
- A <u>reference</u> 912 section containing descriptions of all symbols and commands used in StyleVision.
- <u>Appendices</u> containing information about the Altova XSLT Engine information and the conversion of DB datatypes to XML Schema datatypes; technical data about StyleVision; and license information.

How to use

We suggest you read the Introduction, <u>User Interface</u> and <u>Usage Overview</u> sections first in order to get an overview of StyleVision features and general usage. Doing the <u>tutorial</u> hext would provide hands-on experience of creating an SPS. The SPS File sections (<u>SPS File Content</u> sections), <u>SPS File Structure</u> SPS File Advanced Features SPS File Presentation SPS File Additional Functionality SPS File and Databases Databases Databases Databases Section provides a concise description of all toolbar icon, design symbols, and menu commands, organized according to toolbar and menu. The <u>Authentic View</u> section provides information about editing in Authentic View.

Introduction About This Documentation 33

File paths in Windows

File paths given in this documentation will not be the same for all operating systems. You should note the following correspondences:

 (My) Documents folder: Located by default at the following locations. Example files are located in a sub-folder of this folder.

Windows 7/8/10/11	C:\Users\ <username>\Documents</username>

Application folder: The Application folder is the folder where your Altova application is located. The path
to the Application folder is, by default, the following.

Windows 7/8/10/11	C:\Program Files\Altova\
32-bit version on 64-bit OS	C:\Program Files (x86)\Altova\

Note: StyleVision is also supported on Windows Server 2016 or newer.

Support options

Should you have any question or problem related to StyleVision, the following support options are available:

- 1. Check the Help 19 file (this documentation). The Help file contains a full text-search feature, besides being fully indexed.
- 2. Check the FAQs and Discussion Forum at the Altova Website.
- 3. Contact Altova's Support Center.

Commonly used abbreviations

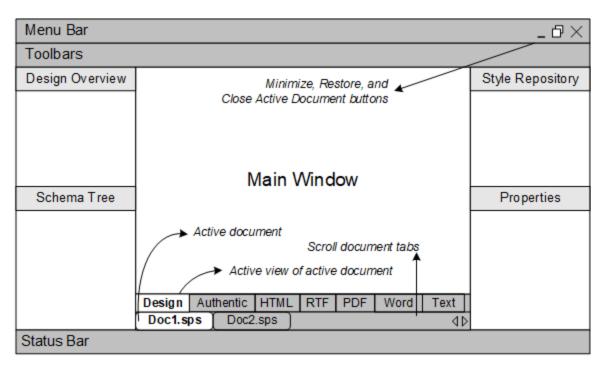

The following abbreviations are used frequently in this documentation:

- SPS: StyleVision Power Stylesheet
- **DB**: Database
- CSS: Cascading Style Sheets
- FAQ: Frequently Asked Questions

2 User Interface

The StyleVision GUI (illustration below, in which not all sidebars are shown) consists of the following parts:

- A **menu bar**. Click on a menu to display the items in that menu. All menus and their items are described in the <u>User Reference</u> section. The menu bar also contains the Minimize, Restore, and Close Active Document buttons.
- A **toolbar area**. The various <u>toolbars</u> ⁹³⁴ and the command shortcuts in each toolbar are described in the <u>User Reference</u> ⁹¹² section.
- A tabbed Main Window 35, which displays one or more open SPS documents at a time. In this window, you can edit the design of the SPS 36, edit the content of Authentic View 38 (in the Authentic eForm tab), and preview the XSLT stylesheets and output 39.
- The <u>Design Sidebars</u> 42—the <u>Design Overview</u> 45, <u>Schema Tree</u> 48, <u>Design Tree</u> 51, <u>Style</u> Repository 54, <u>Styles</u> 57, <u>Properties</u> 58, and <u>Project</u> 62 windows—which can be docked within the application GUI or made to float on the screen.
- A **status bar**, which displays application status information. If you are using the 64-bit version of StyleVision, this is indicated in the status bar with the suffix (x64) after the application name. There is no suffix for the 32-bit version.

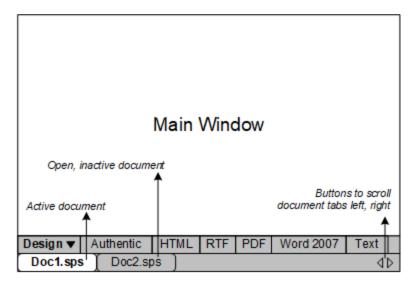

The Main Window and Design sidebars are described in more detail in the sub-sections of this section.

Note: The menu bar and toolbars can be moved by dragging their handles to the required location.

User Interface Main Window 35

2.1 Main Window

The **Main Window** (*illustration below*) is where the SPS design, Authentic View, XSLT stylesheets, and output previews are displayed.

SPS documents in the Main Window

- Multiple SPS documents can be open in StyleVision, though only one can be active at any time. The
 names of all open documents are shown in tabs at the bottom of the Main Window, with the tab of the
 active document being highlighted.
- To make an open document active, click its tab. Alternatively, use the options in the Windows menu.
- If so many documents are open that all document tabs are not visible in the document-tab bar, then click the appropriate scroll button (at the right of the document-tab bar; see illustration above) to scroll the tabs into view.
- To close the active document, click the **Close Document** button in the menu bar at the top right of the application window (or select File | Close (952)).

Document views

A document is displayed in the following views, one of which can be active at a time:

- <u>Design View</u> 30, in which you design the SPS and edit JavaScript functions for use in that SPS. The view can be toggled between the design document and the JavaScript Editor by clicking the dropdown menu arrow and selecting Design or JavaScript, as required.
- Authentic View (Authentic eForm tab), which enables you to immediately see the Authentic View of an XML document (the Working XML File (31)). The SPS is dynamically applied to the Working XML File (31), thus enabling you to try out Authentic View.
- Output Views (HTML, Text, RTF, PDF, and Word 2007+ output). These views are a preview of the actual output format and of the XSLT stylesheet used to generate that output. The view can be toggled between the output preview and the XSLT stylesheet by clicking the dropdown menu arrow and making the appropriate selection.

Each of the views listed above is available as a tab at the bottom of the Main Window in the Views Bar. To select a view, click on its tab. The tab of the selected view is highlighted.

36 User Interface Main Window

Output Preview

The Output Preview feature enables you to view the design or Authentic View in the left pane and preview the output in the right pane. This enables you to preview output even as you design and to then modify your design accordingly—not only in terms of presentation but also in terms of content.

You can click the **Output Preview** icon (*circled red in the screenshot below*) to split the Main Window into two vertical panes: (i) <u>Design View</u> or Authentic View in the left pane and (ii) Output Previews in the right pane. The **Output Preview** icon (*see screenshot below*) is located at the bottom left of the Main Window. In either pane, select the view you want by clicking its tab at the bottom of the pane (<u>Design View</u> or Authentic View in the left pane; the output preview in the right pane). To switch off Output Preview, click the **Output Preview** icon again.

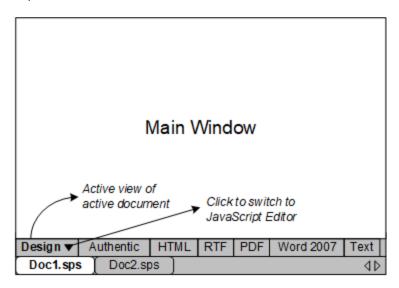

In the output-previews pane:

- Click the icon at extreme left to regenerate the currently selected output preview.
- Click the icon at extreme right to toggle between vertical and horizontal output previews.

2.1.1 Design View

The **Design View** (*illustration below*) is the view in which the SPS is designed. In Design View, you create the design of the output document by (i) inserting content (using the sidebars, the keyboard, and the various content creation and editing features provided in the menus and toolbars); and (ii) formatting the content using the various formatting features provided in the sidebars and menus. These aspects of the Design View are explained in more detail below.

Design View can also be switched to a <u>JavaScript Editor</u> or (Authentic) Scripting Editor. In the JavaScript Editor you can create and edit <u>JavaScript functions</u> which then become available in the GUI for use in the SPS. In the Scripting Editor you can create and edit scripts for Authentic View. To switch to the <u>JavaScript Editor</u> or (Authentic) Scripting Editor, click the dropdown button in the Design tab (*see illustration*) and select JavaScript or (Authentic) Scripting Editor from the dropdown menu. To switch back to Design View, click the dropdown button in the JavaScript or (Authentic) Scripting Editor tab and select Design from the dropdown menu.

In Design View, the SPS can have several templates: the main template, global templates, page layout templates, and Design Fragments. You can control which of these template types is displayed in Design View by using <u>Template Display Filters</u> 43, which are available as <u>toolbar icons</u> 543. These display filters will help you optimize and switch between different displays of your SPS.

Displaying markup tags

The display of markup tags in Design View can be controlled via the markup icons (below).

The icons shown above are toggles. They are, from left: (i) Show small design markups (tags without names); and (ii) Show large design markups (tags with names). When small markup is switched on, the path to a node is displayed when you mouseover that node.

Output Preview

The Output Preview feature enables you to view the design or Authentic View in the left pane and preview the output in the right pane. This enables you to preview output even as you design and to then modify your design accordingly—not only in terms of presentation but also in terms of content.

You can click the **Output Preview** icon (*circled red in the screenshot below*) to split the Main Window into two vertical panes: (i) <u>Design View</u> or Authentic View in the left pane and (ii) Output Previews in the right pane. The **Output Preview** icon (see screenshot below) is located at the bottom left of the Main Window. In either pane, select the view you want by clicking its tab at the bottom of the pane (<u>Design View</u> or Authentic View in the left pane; the output preview in the right pane). To switch off Output Preview, click the **Output Preview** icon again.

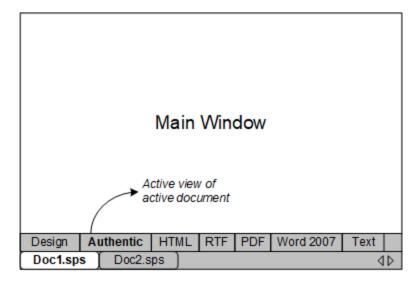

In the output-previews pane:

- Click the icon at extreme left to regenerate the currently selected output preview.
- Click the icon at extreme right to toggle between vertical and horizontal output previews.

2.1.2 Authentic View

In the **Authentic View** tab of the Main Window (the Authentic eForm tab), you can view and edit the Working ML File in its Authentic View. This view enables you (i) to see how your Authentic XML document will look, and (ii) to test the Authentic View created by the SPS. This is particularly useful if you wish to test the dynamic features of Authentic View. For example, you could test how Authentic View behaves when you:

- Add new elements and attributes
- Add new paragraphs or table rows
- Change values that affect conditional templates

Authentic View and the Working XML File

In order for Authentic View to be displayed, a <u>Working XML File</u> must be assigned to the active SPS document This Working XML File must be valid according to the schema on which the SPS is based.

StyleVision creates a temporary XML file that is based on the Working XML File, and it is this temporary file that is displayed in the Authentic View tab of the Main Window. Modifications that you make in Authentic View will modify the temporary XML file. The Working XML File itself will not be modified till you explicitly save the modifications (with the menu command File | Save Authentic XML Data [955]).

If no Working XML File is assigned, you will be prompted to assign a Working XML File when you click the Authentic View tab.

Output Preview

The Output Preview feature enables you to view the design or Authentic View in the left pane and preview the output in the right pane. This enables you to preview output even as you design and to then modify your design accordingly—not only in terms of presentation but also in terms of content.

You can click the **Output Preview** icon (*circled red in the screenshot below*) to split the Main Window into two vertical panes: (i) <u>Design View</u> or Authentic View in the left pane and (ii) Output Previews in the right pane. The **Output Preview** icon (*see screenshot below*) is located at the bottom left of the Main Window. In either pane, select the view you want by clicking its tab at the bottom of the pane (<u>Design View</u> or Authentic View

in the left pane; the output preview in the right pane). To switch off Output Preview, click the **Output Preview** icon again.

In the output-previews pane:

- Click the icon at extreme left to regenerate the currently selected output preview.
- Click the icon at extreme right to toggle between vertical and horizontal output previews.

Authentic View limitations

The Authentic View in the Main Window is similar to the full-fledged Authentic View available in XMLSpy and Authentic Desktop except in the following major respects:

- Authentic View entry helpers are not available in the GUI. To insert or append nodes, you must rightclick and use the context menus.
- CALS/HTML tables are not available for insertion.
- Text state icons are not available.

To test these features, you should use the full-fledged Authentic View in XMLSpy or Authentic Desktop. A full description of how to use Authentic View is given in the section <u>Editing in Authentic View</u>. For additional information, please see the Authentic View tutorial in the XMLSpy or Authentic Desktop user manual.

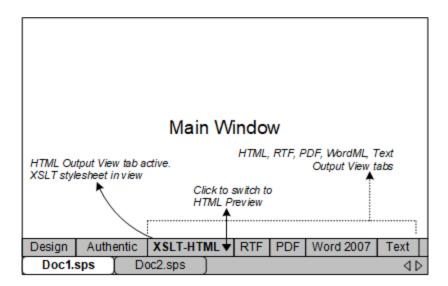

2.1.3 Output Views

There are five **Output View** tabs, one each for HTML, RTF, PDF, Word 2007+, and Text outputs. Each output view tab (*illustration below*) displays: (i) the XSLT stylesheet for that output; and (ii) a preview of the output produced by transforming the Working XML File with the XSLT stylesheet. In the PDF Preview tab there are two additional tab options: (i) XSL-FO, which displays the FO document produced by processing the XML document with the XSLT-FO (XSLT stylesheet); and (ii) FO Result, which displays the message output of the FO Processor when processing the FO document for PDF output.

Note: In order for the different views to work correctly, you will need to install programs relevant to each view as described in the section <u>Setting up StyleVision</u> 27.

Note: You can also split the Main Window to show the design in one half and the outputs in the other half. See Splitt

In an Output View tab, the view can be switched between the XSLT stylesheet and the output preview by clicking the dropdown button in the Output View tab and selecting the XSLT option or the output preview option as required.

XSLT view

The XSLT view displays the XSLT stylesheet generated for that output format from the currently active SPS. The stylesheet is generated afresh each time the XSLT view is selected.

A stylesheet in an Output View tab is displayed with line-numbering and expandable/collapsible elements; click the + and – icons in the left margin to expand/collapse elements. The stylesheet in XSLT view cannot be edited, but can be searched (select <u>Edit | Find</u> ⁽⁷³⁾) and text from it can be copied to the clipboard (with <u>Edit | Copy</u> ⁽⁷³⁾).

Note: The XSLT stylesheets generated from the SPS can be separately generated and saved using the <u>File</u> | <u>Save Generated Files</u> command.

Output preview

The Output preview displays the output produced by transforming the Working XML File with the XSLT stylesheet for that output format. The output is generated afresh each time the Output preview tab is clicked. Note that it is the saved version of the Working XML File that is transformed—not the temporary version that is edited with Authentic View. This means that any modifications made in Authentic View will be reflected in the Output preview only after these modifications have been saved to the Working XML File (File | Save Authentic XML Data).

If no Working XML File 31 is assigned when the Output preview is selected in the Output View tab, you will be prompted to assign a Working XML File. For DB-based SPSs, there is no need to assign a Working XML File 31 since a temporary non-editable XML file is automatically generated when the DB is loaded and this XML file is used as the Working XML File 31.

Note: The output files generated from the SPS can be separately generated and saved using the <u>File | Save Generated Files</u> command.

Output Preview

The Output Preview feature enables you to view the design or Authentic View in the left pane and preview the output in the right pane. This enables you to preview output even as you design and to then modify your design accordingly—not only in terms of presentation but also in terms of content.

You can click the **Output Preview** icon (*circled red in the screenshot below*) to split the Main Window into two vertical panes: (i) <u>Design View</u> or Authentic View in the left pane and (ii) Output Previews in the right pane. The **Output Preview** icon (see screenshot below) is located at the bottom left of the Main Window. In either pane, select the view you want by clicking its tab at the bottom of the pane (<u>Design View</u> or Authentic View in the left pane; the output preview in the right pane). To switch off Output Preview, click the **Output Preview** icon again.

In the output-previews pane:

- Click the icon at extreme left to regenerate the currently selected output preview.
- Click the icon at extreme right to toggle between vertical and horizontal output previews.

2.2 Sidebars

The **Sidebars** (also called sidebar windows or windows) are GUI components that help you design the SPS and provide you with information related to the active view. Each sidebar (*listed below*) is described in a subsection of this section.

- Design Overview 45
- Schema Tree 48
- Design Tree 51
- Style Repository 54
- Styles 57
- Properties 58
- Project 62
- Messages 63
- Find and Replace 64

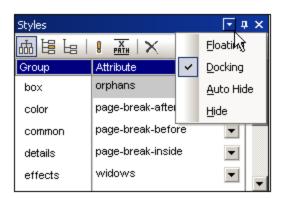

Layout of the views

The layout of a view refers to what sidebars are available in that view and how these sidebars are positioned within the GUI. Layouts can be customized for separate view categories, and the customization consists of two parts: (i) switching on or off the display of individual sidebars in a view (via the **View** menu or by right-clicking the sidebar's title bar and selecting **Hide**); (ii) positioning the sidebar within the GUI as required. The layout defined in this way for a view category is retained for that particular view category till changed. So, for example, if in Design View, all the sidebars except the Styles sidebar are switched on, then this layout is retained for Design View over multiple view changes, till the Design View layout is changed. Note that the layout defined for any output preview (HTML, Text, , RTF, PDF, and Word 2007+ Previews) applies to all output previews. The view categories are: (i) no document open; (ii) Design View; (iii) Output Views; and (iv) Authentic View.

Docking and floating the Sidebar windows

Sidebar windows can be docked in the StyleVision GUI or can be made to float on your screen. To dock a window, drag the window by its title bar and drop it on any one of the four inner or four outer arrowheads that appear when you start to drag. The inner arrowheads dock the dragged window relative to the window in which the inner arrowheads appear. The four outer arrowheads dock the dragged window at each of the four edges of the interface window. To make a window float, (i) double-click the title bar; or (ii) drag the title bar and drop it anywhere on the screen except on the arrowheads that appear when you start to drag.

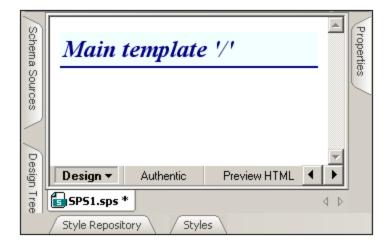

Alternatively, you can also use the following mechanisms. To float a docked window, click the **Menu** button at the top-right of a docked window (*see screenshot below*) and select Floating. This menu can also be accessed by right-clicking the title bar of the docked window.

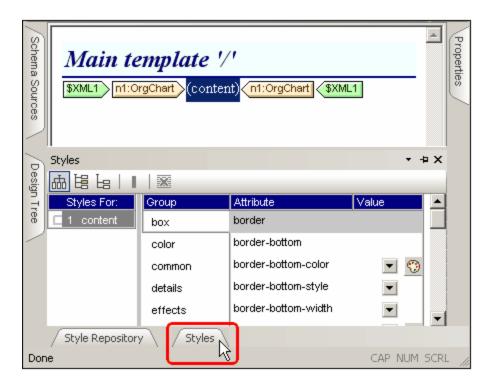

To dock a floating window, right-click the title bar of the floating window and select Docking from the menu that appears; the window will be docked in the position in which it was last docked.

Auto-Hiding Design sidebar windows

A docked window can be auto-hidden. When a sidebar window is auto-hidden, it is minimized to a tab at the edge of the GUI. In the screenshot below, five sidebars have been auto-hidden: two at the left edge of the GUI, two at the bottom edge, and one at the right edge.

Placing the cursor over the tab causes that window to roll out into the GUI and over the Main Window. In the screenshot below, placing the cursor over the Styles tab causes the Styles sidebar to roll out into the Main Window.

Moving the cursor out of the rolled-out window and from over its tab causes the window to roll back into the tab at the edge of the GUI.

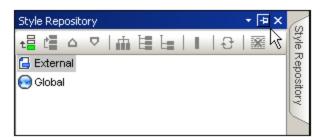

The Auto-Hide feature is useful if you wish to move seldom-used sidebars out of the GUI while at the same time allowing you easy access to them should you need them. This enables you to create more screen space for the Main Window while still allowing easy access to Design sidebar windows.

To auto-hide a window, in a docked window, click the Auto Hide button (the drawing pin icon) at the top right of the window (*screenshot below*). Alternatively, in the Menu select Auto Hide; (to display the Menu sight click the title bar of the window or click the Menu button in the title bar of the docked window).

The window will be auto-hidden.

To switch the Auto-Hide feature for a particular window off, place the cursor over the tab so that the window rolls out, and then click the Auto Hide button (*screenshot below*). Alternatively, in the Menu (screenshot below), deselect Auto Hide; (to display the Menu (screenshot below)), right-click the title bar of the window or click the Menu button (screenshot below).

Note: When the Auto-Hide feature of a sidebar window is off, the drawing pin icon of that window points downwards; when the feature is on, the drawing pin icon points left.

Hiding (closing) sidebar windows

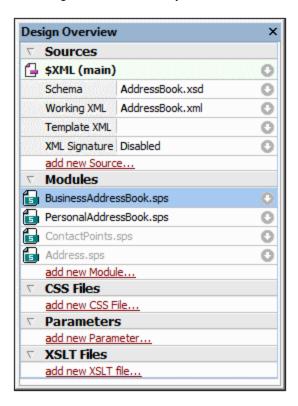

When a sidebar window is hidden it is no longer visible in the GUI, in either its maximized form (docked or floating) or in its minimized form (as a tab at an edge of the GUI, which is done using the <u>Auto-Hide feature</u> (43)).

To hide a window, click the **Close** button at the top right of a docked or floating window. Alternatively, in the Menu select **Hide**; (to display the Menu in the title bar of the window or click the Menu in the title bar of the window).

To make a hidden (or closed) window visible again, select the name of the Design sidebar in the <u>View</u> menu. The Design sidebar window is made visible in the position at which it was (docked or floating) when it was was hidden.

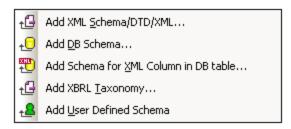

2.2.1 Design Overview

The **Design Overview** sidebar (*screenshot below*) enables you to add schema sources, global parameters, SPS modules, and CSS files to the active SPS. It gives you an overview of these components and enables you to manage them conveniently in one location.

Adding schema sources

Schema sources may be added to an empty SPS or to an SPS with an already existing schema source. A schema source is added by clicking the command **Add New Source** under the Sources heading. This pops up a menu (*screenshot below*) that enables you to add: (i) an XML Schema or DTD or an XML Schema that is automatically generated by StyleVision from an XML file; (ii) a schema generated by StyleVision from a DB; (iii) a user-defined schema; or (iv) an XBRL taxonomy.

The Working XML File and Template XML File

When a schema is added, it is listed under the Sources item. Each schema has two sub-items :

- The Working XML File 31
- The <u>Template XML File</u> ³¹.

Enabling XML Signature in Authentic

The XML file of the **main source** can have an XML signature enabled. This enables the Authentic View user to sign and verify XML documents. Note that a signature can only be enabled for the main source and not for additional sources. For information about enabling and configuring XML signatures, see the section, XML Signatures 605.

Adding modules, CSS files, parameters, and XSLT files

Click the respective **Add New** commands at the bottom of the Modules, CSS Files, Parameters and XSLT Files sections to add a new item to the respective section.

Design Overview features

The following features are common to each section (Sources, Parameters, etc) in the Design Overview sidebar:

- Each section can be expanded or collapsed by clicking the triangular arrowhead to the left of the section name.
- Files in the Sources, Modules, and CSS Files sections are listed with only their file names. When you mouseover a file name, the full file path is displayed in a popup.
- Items that are listed in gray are present in an imported module, not in the SPS file currently active in the GUI.
- Each section also has a **Add New <Item>** command at the bottom of the section, which enables you to add a new item to that section. For example, clicking the **Add New Parameter** command adds a new parameter to the SPS and to the Parameters list in the Design Overview.

• Each item in a section has a context menu which can be accessed either by right-clicking that item or clicking its **Context Menu** icon (the downward-pointing arrow to the right of the item).

- The **Remove** icon in the context menu removes the selected item. This command is also available in context menus if the command is applicable.
- The context menu command Edit File in XMLSpy opens the selected file in the Altova application XMLSpy.
- The context menu commands, **Move Up** and **Move Down**, are applicable only when one of <u>multiple</u> modules are in the Modules section is selected. Each button moves the selected module, respectively, up or down relative to the immediately adjacent module.

Sources

The Sources section lists the schema that the SPS is based on and the Working XML File and Template XML File assigned to the SPS. You can change each of these file selections by accessing its context menu (by right-clicking or clicking the Context Menu icon), and then selecting the appropriate **Assign...** option.

In the Enterprise Edition of StyleVision, multiple schema sources can be used in an SPS. In the Enterprise Edition, therefore, the **Add New Schema Source** command enables you to add additional schema sources. When more than one schema source is present, one of these must be set as the main schema source, and it is indicated by the word (main) next to its header. By default the main schema source is the first schema source to have been added. If you wish to set another schema source as the main schema, select it, and in its context menu select the **Set as Main Schema** command.

Modules

The Modules section lists the <u>SPS modules</u> used by the active SPS. New modules are appended to the list by clicking the **Add New Module** command and browsing for the required SPS file. Since the order in which the modules are listed is significant, if more than one module is listed, the **Move Up / Move Down** command/s (in the context menu of a module) can be used to change the order. The context menu also provides a command for opening the selected module in StyleVision.

Note: The Design Overview sidebar provides an overview of the modules, enabling you to manage modules at the file level. The various module objects (objects inside the modules), however, are listed in the Design Tree sidebar 51.

CSS Files

The CSS Files section lists the CSS files used by the active SPS. New CSS files are appended to the list by clicking the **Add New CSS File** command and browsing for the required CSS file. Since the order in which the CSS files are listed is significant, if more than one CSS file is listed, the **Move Up / Move Down** command/s (in the context menu) become active when a CSS file is selected. The selected CSS file can be moved up or down by clicking the required command. The context menu also provides a command for opening the selected module in XMLSpy.

Note: The Design Overview sidebar provides an overview of the CSS files, enabling you to manage CSS files at the file level. The various <u>CSS rules</u> to inside the CSS files, however, are listed in the <u>Style Repository</u> sidebar.

Parameters

The Parameters section lists the global parameters in the SPS. You can add new parameters using the **Add New Parameter** command at the bottom of the section. Double-clicking the parameter name or value enables

you to edit the name or value, respectively. To remove a parameter, select the parameter and then click the **Remove** command in the context menu.

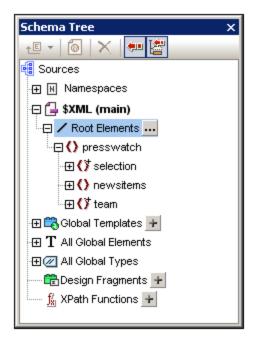

XSLT Files

The XSLT Files section lists the XSLT files that have been imported into the SPS. XSLT templates in these XSLT files will be available to the stylesheet as global templates. For a complete description of how this works, see XSLT Templates 300.

2.2.2 Schema Tree

The **Schema Tree** sidebar (*screenshot below*) enables you to do the following:

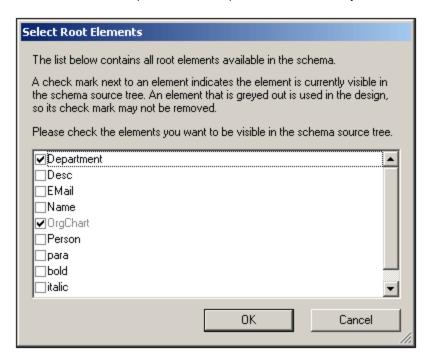

- Select multiple root elements (document elements) for a schema.
- Drag nodes (elements, attributes, global types) from a schema tree and drop them into the design. These nodes represent the XML content that is to be included in the output.
- View listings of all global elements and types in all schema sources. Enables a global element or global type to be created as a global template.
- View a listing of all namespaces used in the SPS.
- Insert and edit <u>Design Fragments</u> 356.
- Insert and and edit user-defined XPath functions 572 for the SPS.

Root elements

For each schema, under the \$XML heading, the selected Root elements (or document elements) are listed. This list consists of all the root elements you select for the schema (see below for how to do this). Each root element can be expanded to show its content model tree. It is from the nodes in these root element trees that the content of the main template is created. Note that the entry point of the main template is the document node of the main schema, which you can select or change at any time (see below for how to do this).

To select the root elements for a schema, do the following: Click the **Select** button at the right of the Root Elements item. This pops up the Select Root Elements dialog (*screenshot below*), in which you can select which of the global elements in the schema is/are to be the root elements. See <u>SPS Structure | Schema Sources</u> for an explanation of the possibilities offered by a selection of multiple root elements.

Additionally, all the global elements in all added schemas are listed under the All Global Elements item. For each global element, a global template (345) can be created.

Global elements and global types

Global elements and global types can be used to create <u>global templates</u> which can be re-used in other templates. Additionally, global types can also be used directly in templates.

However, global types only work with valid XML instances. If the XML instance is invalid, then the type will not match and no content will be displayed.

Design Fragments

All the <u>Design Fragments</u> in the document are listed under this item and can be viewed when the Design Fragments item is expanded. The following Design Fragment functionality is available:

- Creating a Design Fragment by clicking the **Add** icon of the Design Fragments item.
- Double-clicking the name of a Design Fragment in the Schema Tree enables the name of that Design Fragment to be edited.
- A Design Fragment can be enabled or disabled by, respectively, checking or unchecking the check box next to the Design Fragment.
- A Design Fragment can be dragged from the schema tree into the design.

See the section <u>Design Fragments</u> ³⁵⁰ for information about working with Design Fragments.

User-defined XPath Functions

A user-defined XPath function can be added by clicking the **Add** icon to of the Xpath Functions item. After an XPath function has been created, it is listed in the Schema Tree. Double-clicking an XPath function opens the function in its dialog for editing. The following XPath functionality is available:

- An XPath function can be enabled or disabled by, respectively, checking or unchecking the check box next to the XPath Functions item.
- Right-clicking an XPath function also opens a context menu which contains commands to rename and remove an XPath function.

See the section, <u>User-Defined XPath Functions</u> ⁵⁷², for detailed information about working with XPath functions.

Namespaces

The namespaces used in the SPS are listed under the Namespaces heading together with their prefixes. The namespaces in this list come from two sources: (i) namespaces defined in the referenced schema or schemas (see note below); and (ii) namespaces that are added to every newly created SPS by default. Referring to such a list can be very useful when writing XPath expressions. Additionally, you can set an XPath default namespace for the entire SPS by double-clicking the value field of the xpath-default-ns entry and then entering the namespace.

Note: If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Toolbar and schema tree icons

The following toolbar icons are shortcuts for common Schema Tree sidebar commands.

In a <u>user-defined schema</u> 306, adds a child element to the document element or appends a sibling element to the selected element. More commands for building a user-defined schema sibling element to the selected element. are available by clicking the dropdown arrow of the icon.

(9)

Make/Remove Global Template, enabled when a global element or global type is selected.

Remove the selected item.

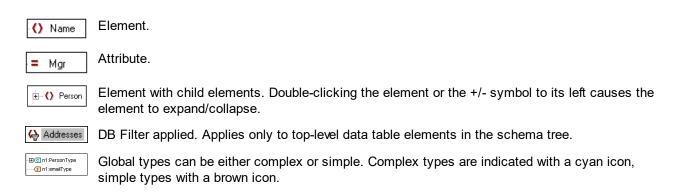

Synchronize tree toggle. When toggled on (icon has border), selecting a node in the tree selects (i) the corresponding node in the design, and (ii) the corresponding node in the Design Tree if the Synchronize Tree icon in the Design Tree window is toggled on. When toggled off, the corresponding node in the design is not selected. Switch the toggle off if dragging a node from the tree and dropping it to the desired location in the design proves difficult.

Auto-collapses other items in the schema tree when the Synchronize Tree toggle is turned on and an item is selected in the design. Note that this toggle is enabled only when the Synchronize Tree toggle is turned on.

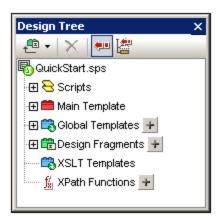

Symbols used in schema trees

Given below is a list of the symbols in schema trees.

2.2.3 Design Tree

The **Design Tree** sidebar (*screenshot below*) provides an overview of the SPS design.

At the root of the Design Tree is the name of the SPS file; the location of the file is displayed in a pop-up when you mouseover. The next level of the Design Tree is organized into the following categories:

- Scripts 593, which shows all the JavaScript functions that have been defined for the SPS using the JavaScript Editor of StyleVision.
- Main Template 344, which displays a detailed structure of the main template.
- <u>Global Templates</u> ³⁴⁵, which lists the global templates in the current SPS, as well as the global templates in all included SPS modules.
- <u>Design Fragments</u> 53, which shows all the Design Fragments in the design, and enables you to create, edit, rename, and delete them.
- XSLT Templates 4, which provides the capability to view XSLT templates in imported XSLT files.
- <u>User-Defined XPath Functions</u> which enables you to create, edit, rename, and remove your own XPath functions.

Toolbar icons

The following toolbar icons are shortcuts for common Design Tree sidebar commands.

Adds a Design Fragment, main template, or layout item to the design. Clicking the left-hand part of the icon adds a Design Fragment. Clicking the dropdown arrow drops down a list with commands to

add a Design Fragment or any of various layout items.

Remove the selected item; icon is active when item in the Global Templates or Layout sub-trees is selected.

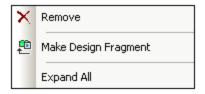

Synchronize tree toggle. When toggled on (icon has border), selecting a node in the tree selects (i) the corresponding node in the design, and (ii) the corresponding node in the schema tree if the Synchronize Tree icon in the schema tree is toggled on. When toggled off, the corresponding nodes in the design and schema tree are not selected.

Auto-collapses other items in the design tree when the Synchronize Tree toggle is turned on and an item is selected in the design. Note that this toggle is enabled only when the Synchronize Tree toggle is turned on.

Modifying the Design Tree display

The display of the Design Tree can be modified via the context menu (*screenshot below*), which pops up on right-clicking an item in the Design Tree.

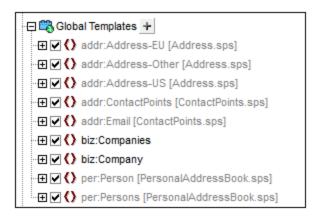

The **Remove** command removes the selected Design Tree item from the Design Tree. **Make Design**Fragment creates a <u>Design Fragment</u> in the design and adds an item for it in the Design Tree. **Expand All** expands all the items of the Design Tree.

Scripts and Main Template

The Scripts listing displays all the scripts in the Design, including those in imported modules. The Main Template listing displays a tree of the main template. Items in the tree and the design can be removed by right-clicking the item and selecting **Remove**.

Global Templates

The <u>Global Templates</u> tem lists all global templates in the current SPS and in all added SPS modules. Global templates defined in the current SPS are displayed in black, while global templates that have been defined in added modules are displayed in gray (see screenshot below). Each global template has a check box to its left, which enables you to activate or deactivate it. When a global template is deactivated, it is removed from the design.

A global template in the current SPS (not one in an added module) can be removed by selecting it and clicking the **Remove** button in the toolbar or the **Remove** command in the context menu. The component is removed from the design and the tree.

Design Fragments

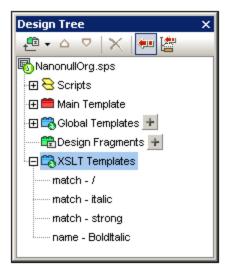

The <u>Design Fragments</u> item lists all the Design Fragments in the current SPS and in all added SPS modules. Design Fragments defined in the current SPS are displayed in black, while Design Fragments that have been defined in added modules are displayed in gray (see screenshot below). Each Design Fragment has a check box to its left, which enables you to activate or deactivate it. A Design Fragment in the current SPS (not one in an added module) can be removed by selecting it and clicking the **Remove** command in the context menu. The component is removed from the design and the tree.

A Design Fragment can be added by clicking the Add icon to the right of the Design Fragments item. Each Design Fragment is designed as a tree with expandable/collapsible nodes. Any component in a Design Fragment tree (that is defined in the current SPS) can be removed by selecting it and clicking the **Remove** button in the toolbar or the **Remove** command in the context menu. The component is removed from the design and the tree.

XSLT Templates

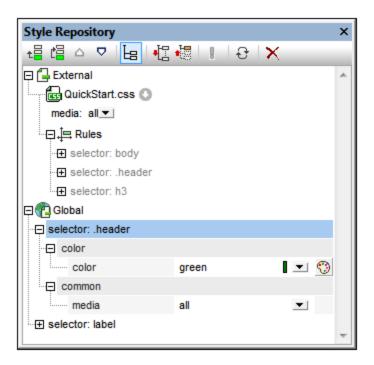

In the Design Tree sidebar (*screenshot below*), the XSLT Templates contained in the imported XSLT file are displayed under the XSLT Templates heading.

There are two types of imported XSLT templates: (i) match templates (indicated by *Match*), and (ii) named templates (indicated by *Name*). In the Design Tree, these two types are listed with (i) the value of the select attribute of match templates, and (ii) by the value of the name attribute of named templates, respectively. For a complete description of how XSLT Templates work, see XSLT Templates (indicated by *Match*), and (ii) named templates respectively. For a

2.2.4 Style Repository

In the **Style Repository** sidebar (*screenshot below*), you can assign external CSS stylesheets and define global CSS styles for the SPS. Style rules in external CSS stylesheets and globally defined CSS styles are applied to Authentic View and the HTML output document.

The Style Repository sidebar contains two listings, **External** and **Global**, each in the form of a tree. The External listing contains a list of external CSS stylesheets associated with the SPS. The Global listing contains a list of all the global styles associated with the SPS.

The structure of the listings in the Style Repository is as follows:

External

```
- CSS-1.css (Location given in popup that appears on mouseover)
- Media (can be defined in Style Repository window)
- Rules (non-editable; must be edited in CSS file)
- Selector-1
- Property-1
- ...
- Property-N
- ...
- Selector-N
+ ...
+ CSS-N.css
    Global
- Selector-1
+ Selector-1
Properties
- ...
+ Selector-N
```

Precedence of style rules

If a global style rule and a style rule in an external CSS stylesheet have selectors that identify the same document component, then the global style rule has precedence over that in the external stylesheet, and will be applied. If two or more global style rules select the same document component, then the rule that is listed last from among these rules will be applied. Likewise, if two or more style rules in the external stylesheets select the same document component, then the last of these rules in the last of the containing stylesheets will be applied

Managing styles in the Style Repository

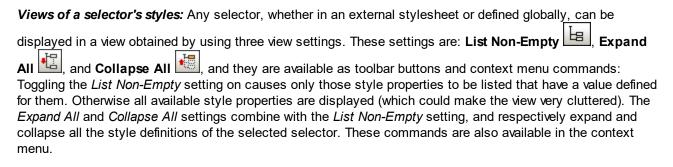

In the Style Repository sidebar you can do the following, using either the icons in the toolbar and/or items in the context menu:

Add: The Add icon adds a new external stylesheet entry to the External tree or a new global style entry to the Global tree, respectively, according to whether the External or Global tree was selected. The new entry is appended to the list of already existing entries in the tree. The Add command is also available in the context menu. For more details about using external stylesheets and global styles, see Working with CSS Styles 165.

Note that an external CSS stylesheet can also be added or a stylesheet removed via the Design Overview sidebar 165.

Insert: The **Insert** icon inserts a new external stylesheet entry above the selected external stylesheet (in the External tree) or a new global style entry above the selected global style (in the Global tree). The **Insert** command is also available in the context menu. For more details about using external stylesheets and global styles, see Working with CSS Styles 465.

Move Up/Down: The Move Up icon and Move Down icon move the selected external stylesheet or global style respectively up and down relative to the other entries in its tree. These commands are useful for changing the priority of external stylesheets relative to each other and of global style rules relative to each other. The Move Up and Move Down commands are also available in the context menu. For more details about how to change the precedence of styles, see Working with CSS Styles. ■

Toggle Important: Clicking the Toggle Important icon sets the CSS value !important on or off for the selected CSS rule.

Reload All: The Reload All icon Treloads all the external CSS stylesheets.

Reset: The **Reset** icon deletes the selected external stylesheet or global style.

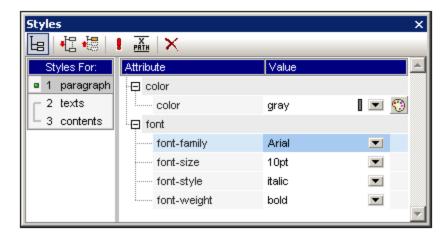

Editing CSS styles in the Style Repository

The following editing mechanisms are provided in the Style Repository:

- You can add and remove a CSS Stylesheet, and you can specify the media to which each external CSS stylesheet applies. How to do this is explained in the section <u>External CSS Stylesheets</u> 465.
- Global styles can have their selectors and properties directly edited in the Style Repository window. How this is done is described in the section Defining CSS Styles Globally 470.

2.2.5 Styles

The **Styles** sidebar (*screenshot below*) enables CSS styles to be defined **locally** for SPS components selected in the Design View. This is as opposed to styles which are set globally in the <u>Styles Repository</u> ⁵⁴ sidebar.

The Styles sidebar is divided into two broad parts:

- The left-hand-side, **Styles-For column**, in which the selected component types are listed. You should note that when a selection is made in Design View, it could contain several components. The selected components are listed in the Styles-For column, organized by component type. One of these component types may be selected at a time for styling. If there is only one instance of the component type, then that one instance is selected for styling. If there are several instances of the component type, then all the selected instances can be styled together. The defined styles are applied locally to each instance. If you wish to style only one specific instance, then select that specific component instance in Design View and style it locally in the Styles sidebar. You can also select a component range by selecting the start-of-range and then the end-of-range component with the **Shift**-key pressed. For detailed information about the selection of component types, see <u>Defining CSS Styles Locally</u>
- The right-hand-side, **Style Definitions pane**, in which CSS styles are defined for the component type/s selected in the Styles-For column. The Style Definitions pane can be displayed in three views (see below for description). For the details of how to set style definitions, see <u>Setting CSS Style</u>
 - Values Values. The XPath icon toggles on and off the application of XPath expressions as the source of style values. If a style property is selected and if the XPath icon is toggled on, then an XPath expression can be entered for this property and the return value of the XPath expression is used as the value of that style property. In this way, the value of a node in an XML document can be returned at runtime as the value of a property. When the XPath icon is toggled off, a static value can be entered as the value of the property.

Settings for Definitions-View

The view of definitions can be changed to suit your editing needs. Three view-settings (*listed below*) are available as buttons in the toolbar and as commands in context menus.

• List Non-Empty : When this setting is toggled on, for the component type selected in the left-hand column, only those properties with values defined for them are displayed, in alphabetical order. Otherwise all properties are displayed. This setting is very useful if you wish to see what properties are defined for a particular component type. If you wish to define new properties for the selected component type, this setting must be toggled off so that you can access the required property.

- **Expand All**: For the component type selected in the left-hand column, all the properties displayed in the right-hand pane are expanded. This setting can be combined with the **List Non-Empty** setting.
- Collapse All For the component type selected in the left-hand column of the window, all the properties displayed in the right-hand pane are collapsed. This setting can be combined with the List Non-Empty setting.

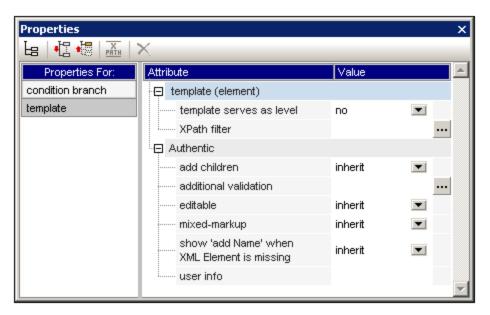

Toggle Important and Reset toolbar icons

Clicking the Toggle Important icon sets the CSS value !important on or off for the selected CSS rule.

Clicking the Reset icon resets the value of the selected property.

2.2.6 Properties

The **Properties** sidebar (*screenshot below*) enables properties to be defined for SPS components selected in Design View.

The Properties sidebar is divided into two broad parts:

• The **Properties-For column**, in which the selected component-types are listed. One of these component types may be selected at a time and properties assigned for it. (In the screenshot above, the *template* component is selected.) For detailed information about how components with properties are grouped, see the section Components and their Property Groups below.

• The **Property Definitions pane**, in which component properties are defined for the component type selected in the Properties For column. The Property Definitions pane can be displayed in three views (see below). For the details of what properties are in each property group, see the section Property Groups below.

Settings for Definitions-View

The view of definitions can be changed to suit your editing needs. Three view-settings (*listed below*) are available as buttons in the toolbar and as commands in context menus.

- List Non-Empty: When this setting is toggled on, for the component type selected in the left-hand column, only those properties with values defined for them are displayed, in alphabetical order. Otherwise all properties are displayed. This setting is very useful if you wish to see what properties are defined for a particular component type. If you wish to define new properties for the selected component type, this setting must be toggled off so that you can access the required property.
- **Expand All**: For the component type selected in the left-hand column, all the properties displayed in the right-hand pane are expanded. This setting can be combined with the **List Non-Empty** setting.
- Collapse All For the component type selected in the left-hand column of the window, all the properties displayed in the right-hand pane are collapsed. This setting can be combined with the List Non-Empty setting.

Reset toolbar icon

Clicking the Reset icon resets the value of the selected property to its default.

Components and their property groups

The availability of property groups is context-sensitive. What property groups are available depends on what design component is selected. The table below lists SPS components and the property groups they have.

Component	Property Group
Template	Template; Authentic
Content	Content; Authentic; Common; Event
Text	Text; Common; Event
Auto-Calculation	AutoCalc; Authentic; Common; Event
Condition Branch	When
Data-Entry Device	Authentic; Common; [Data-Entry Device]; Event; HTML

Image	Image; Authentic; Common; Event; HTML
Link	Link; Authentic; Common; Event; HTML
Table	Table; Authentic; Common; Event; HTML; Interactive
Paragraph	Paragraph; Authentic; Common; Event; HTML

The following points about component types should be noted:

- Template components are the main template, global templates, and all schema nodes in the design.
- Content components are the content and rest-of-contents placeholders. These represent the text content of a node or nodes from the XML document.
- A text component is a single string of static text. A single string extends between any two components other than text components, and includes whitespace, if any is present.
- Data-entry devices are input field, multiline input fields, combo boxes, check boxes, radio buttons and buttons; their properties cover the data-entry device as well as the contents of the data-entry device, if any.
- A table component refers to the table structure in the design. Note that it contains sub-components, which are considered components in their own right. The sub-components are: row, column, cell, header, and footer.
- A paragraph component is any predefined format.

The table below contains descriptions of each property group.

Property Group	Description
AutoCalc	These properties are enabled when an Auto-Calculation is selected. The Value Formatting property specifies the formatting of an Auto-Calculation that is a numeric or date datatype. The XPath property specifies the XPath expression that is used for the Auto-Calculation 371.
Authentic	These are SPS-specific properties that are available for templates, contents, AutoCalculations, data-entry devices, images, links, tables, and paragraphs. What properties within the group are available are component-specific. For more details, see Authentic Node Properties 559.
Common	The <i>Common</i> property group is available for all component types except the Template and AutoCalc component types. It contains the following properties that can be defined for the component: class (a class name), dir (the writing direction), id (a unique ID), lang (the language), and title (a name).
Data-Entry Device	Specifies the value range of combo boxes, check boxes, and radio buttons. Note that this property group does not apply to input fields and buttons.
Event	Contains properties that enable <u>JavaScript functions</u> to be defined for the following client-side HTML events: onclick, ondblclick, onkeydown, onkeypressed, onkeyup, onmousedown, onmousemove, onmouseout, onmouseover, onmouseup.
HTML	Available for the following component types: data-entry devices; image 176; link 440; table 149; paragraphs 451. Note that there are different types of data-entry devices 263 and paragraphs 451, and that tables 149 have sub-components. These properties are HTML properties that can be set on the corresponding HTML elements (img, table, p, div, etc). The available properties therefore vary according to the component selected. Values for these properties can be selected using XPath expressions.

In addition, there are component-specific properties for <u>images</u> (176), <u>links</u> (442), <u>paragraphs and other predefined</u> (133), and <u>condition branches</u> (134). These properties are described in the respective sections.

Setting property values

Property values can be entered in one, two, or three ways, depending on the property:

- Entered directly in the Value column. To do this, select a property, double-click in its Value column, enter the value using the keyboard, and press **Enter** or click anywhere in the GUI.
- By selecting a value from the dropdown list of the combo box for that property. Click the down arrow of the combo box to drop down the list of property-value options.
- By using the Edit button at the right-hand side of the Value column for that property. Clicking the Edit button pops up a dialog relevant to that property.

For some properties, in the Common and HTML groups of properties, XPath expressions can be used to provide the values of the property. The XPath icon toggles on and off the application of XPath expressions

as the source of property values. With a property selected, if the XPath icon is toggled on, then an XPath expression can be entered for this property and the return value of the XPath expression is used as the value of that property. In this way, the value of a node in an XML document can be returned, at runtime, as the value of a property. When the XPath icon is toggled off, a static value can be entered as the value of the property. Also see <u>Style Properties Via XPath</u> 476.

Modifying or deleting a property value

To modify a property value, use any of the applicable methods described in the previous paragraph, <u>Setting</u>

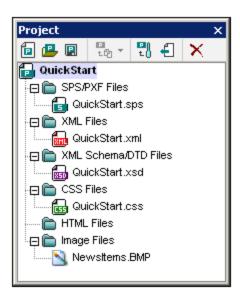

Property Values
To delete a property value, select the property and click the Reset icon in the toolbar of the Properties sidebar.

2.2.7 Project

StyleVision projects are an efficient way of grouping, managing, and working with related files. Once collected in a project, files can be accessed easily from the Project sidebar when designing an SPS. For example, an SPS file can be dragged from the Project sidebar to the Design Tree sidebar and created there as a module; or an image file can be dropped into the design as a static image; or a CSS stylesheet can be dragged to the Style Repository sidebar as an external stylesheet.

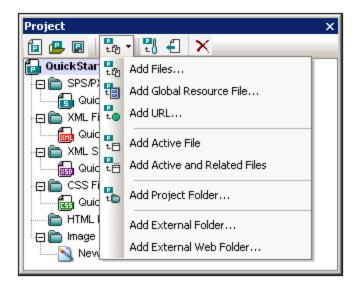

A complete description of how to work with projects is given in the section Projects in StyleVision 119.

The **Project** sidebar (*screenshot below*) shows the currently active project. Commands in the <u>Project menu</u> apply to the currently active project. The currently active project can be changed by either creating a new project (<u>Project | New Project</u>) or by opening an existing project (<u>Project | Open Project</u>). These two commands are also available as the first and second buttons in the toolbar of the Project sidebar (*see screenshot below*). You can name a newly created project when you save it (<u>Project | Save Project</u>); third button in the toolbar of the Project sidebar).

The **Add Files** button in the toolbar (*fourth button in the screenshot below*) contains the commands shown in the screenshot below. These commands enable files and folders to be added to the active project and are described in the <u>User Reference</u> A useful command is the Add Active and Related Files command, which

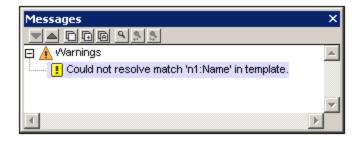

adds to the project all the files related to the currently active SPS. For example, with the tutorial file, <code>QuickStart.sps</code>, active, clicking this command will add all related files as shown in the screenshot above.

The **Project Properties** button (fifth button in the toolbar) pops up the Properties dialog of (i) the project; (ii) a folder; or (iii) a file, depending on which type of these three items is currently selected in the Project sidebar. If the project or a file is selected, the Properties dialog displays the location of the file. The Properties dialog of a folder allows you to edit the name of the folder and to specify the file extensions to associate with that folder; only files with the associated file extensions are displayed in that project folder. See <u>Projects in StyleVision</u> for details.

2.2.8 Messages

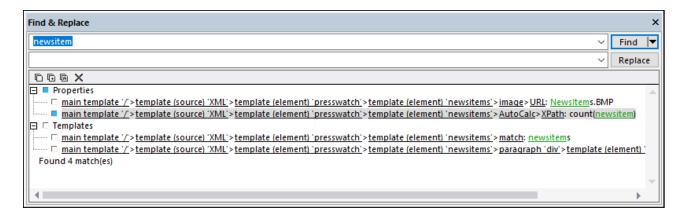

When StyleVision is opened for the first time, the Messages sidebar (*screenshot below*) is displayed below the Main Window of the GUI. To toggle the Messages sidebar on and off, click **View | Messages**.

The Messages sidebar displays warnings in Design View and Authentic View. In Design View, the warnings relate to various aspects related to the SPS document, from a missing Working XML File to errors in the design structure. In Authentic View, the warnings are about the validity of the XML data entered, whether valid according to the underlying schema or according to additional validation criteria.

2.2.9 Find and Replace

The Find & Replace sidebar (*screenshot below*) enables you to search and replace text in Design View. Click the dropdown arrow of the **Find** button (*highlighted blue in the screenshot below*) to select the search options. You can search in text, styles, properties, variables, template matches, and XPath expressions for strings that you enter directly in the *Find* field or construct with regular expressions. All searches carried out in this sidebar apply to Design View. The menu commands **Edit | Find** and **Edit | Replace** sets the focus to this sidebar and places the cursor in the *Find* field, enabling you to proceed with a search in Design View. The results of the search are displayed in the sidebar. You can click on a result to go to the corresponding location in the design. To toggle the Find & Replace sidebar on and off, click **View | Find & Replace**.

For information about searching in other views (JavaScript Editor, Authentic View, and XSLT stylesheets), see the menu-reference topic <u>Find</u>, <u>Find</u> <u>Next</u>, <u>Replace</u> 199 .

Finding

Enter the term you want to search for in the *Find* field. Then click the dropdown arrow of the **Find** button (*highlighted blue in the screenshot above*) to select the search options. The following options are available:

- Where to search: The respective Include <component> item should be toggled on for that component to be included in the search.
- Case and/or whole-word matches: These are toggle options.
- Regular expressions: Your entry will be treated as a regular expression. For a description of how to use regular expressions, see the menu-reference topic Find, Find Next, Replace [88].

Results

The results are organized into groups according to the component in which the matched string appears (see screenshot above). Each result item is show as a hierarchical path. You can click any of the links in the hierarchy to go to that item in Design View.

The results pane has a toolbar with icons for the following commands, from left: copy an item or a group of items to the clipboard; clear the results pane.

Replacing

After the results are displayed, you can select one or more of the result items for replacement. The selected item/s will be indicated with a blue bullet (see screenshot above) and the **Replace** button will become enabled.

Enter the replacement string in the *Replace* text box and click **Replace**. The replacement is carried out and the blue bullet becomes a green bullet.

3 Quick Start Tutorial

The objective of this tutorial is to take you quickly through the the key steps in creating an effective SPS. It starts with a section on creating and setting up the SPS, shows you how to insert content in the SPS, how to format the components of the SPS, and how to use two powerful SPS features: Auto-Calculations and conditions. Along the way you will get to know how to structure your output efficiently and how to use a variety of structural and presentation features.

Files required

Files related to this Quick Start tutorial are in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\QuickStart:

- QuickStart.xsd, the XML Schema file on which the SPS is based.
- QuickStart.xml, the Working XML File, which is the source of the data displayed in the output previews.
- QuickStart.sps, which is the finished SPS file; you can compare the SPS file you create with this
 file.
- QuickStart.css, which is the external CSS stylesheet used in the tutorial.
- NewsItems.BMP, an image file that is used in the SPS.

Doing the tutorial

It is best to start at the beginning of the tutorial and work your way through the sections. Also, you should open the XSD and XML files before starting the tutorial and take a look at their structure and contents. Keep the XSD and XML files open while doing the tutorial, so that you can refer to them. Save your SPS document with a name other than <code>QuickStart.sps</code> (say <code>MyQuickStart.sps</code>) so that you do not overwrite the supplied SPS file. And, of course, remember to save after successfully completing every part.

3.1 Creating and Setting Up a New SPS

In this section, you will learn:

- How to create a new SPS document 67
- How to add a schema source for the SPS 69
- How to select the XSLT version of the SPS 70
- How to assign the Working XML File 70
- How to specify the output encoding 70
- How to save the SPS document 70

Files in this section

Files referred to in this section are located in the (My) Documents folder (My), C:\Documents and Settings\<username>\My

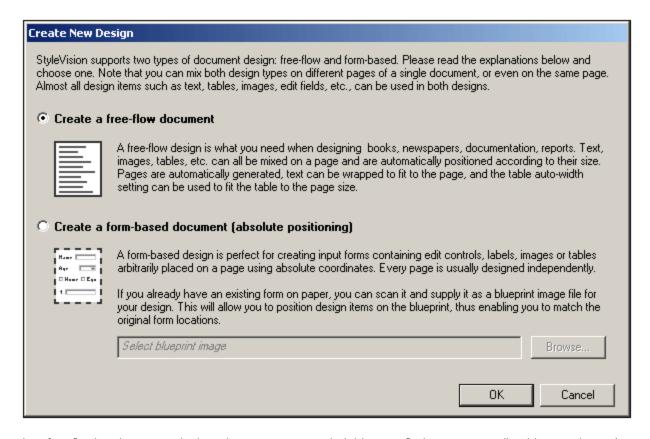

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\QuickStart:

- QuickStart.xsd, the XML Schema file on which the SPS is based.
- QuickStart.xml, the Working XML File, which is the source of the data displayed in the output previews.
- QuickStart.sps, which is the finished SPS file; you can compare the SPS file you create with this
 file.

Creating a new SPS document

Create a new SPS document by clicking <u>File | New | New (Empty)</u> or select **New (Empty)** in the dropdown list of the <u>New icon</u> in the application toolbar. The Create New Design dialog pops up.

The Create New Design dialog (*screenshot below*) prompts you to select either: (i) a free-flowing document design, or (ii) a form-based document design (in which components are positioned absolutely, as in a layout program).

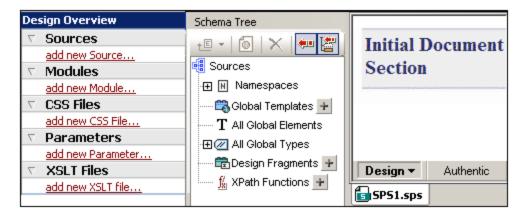

In a free-flowing document design, document content is laid out to fit the output media object or viewer (paper or screen). Items in the document content can only be placed relative to each other, and not absolutely. This kind of design is suited for documents such as reports, articles, and books.

In a form-based document, a single <u>Layout Container</u> is created, in which design components can be positioned absolutely. The dimensions of the Layout Container are user-defined, and Layout Boxes can be positioned absolutely within the Layout Container and document content can be placed within individual Layout Boxes. If you wish the design of your SPS to replicate a specific form-based design, you can use an image of the original form as a <u>blueprint image</u>. The blueprint image can then be included as the background image of the Layout Container. The blueprint image is used to help you design your form; it will not be included in the output.

You will be creating a free-flowing document, so select this option by clicking the *Create a free-flow document* radio button, then click **OK**.

A new document titled SPS1.sps is created and displayed in Design View (screenshot below).

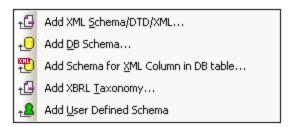

In <u>Design View</u>³⁶, an empty main template is displayed. In the <u>Design Overview</u>⁴⁵ and <u>Schema Tree</u>⁴⁸ sidebars, there are no schema entries.

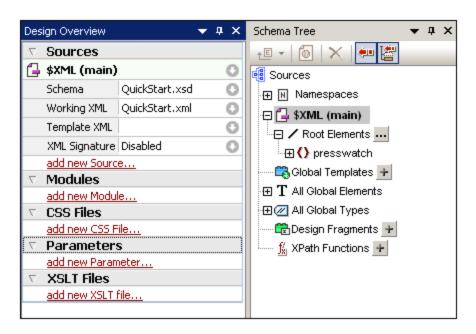

Adding a schema source

For this SPS, you will use the schema, <code>QuickStart.xsd</code>. To add this schema as the schema source, do the following:

 In the Design Overview sidebar, under the Sources heading, click the Add New Source command (screenshot above). In the menu that pops up (screenshot below), select Add XML Schema/DTD/XML.

- 2. In the Open dialog that pops up browse for the file QuickStart.xsd in the (My) Documents folder (see above), and click Open.
- 3. You will be prompted to select a Working XML File. Select the option to select the file from the filesystem, then browse for the file <code>QuickStart.xml</code> in the (My) Documents folder (see above), and click Open. The schema will be added as a schema source in the Design Overview sidebar and in the Schema Tree sidebar (screenshot below). Also, in the Design Overview, the Working XML File you chose will be assigned to the schema.

You should note the following points: (i) In Design Overview, the \$XML entry for the schema source lists the schema and the Working XML File 31 and Template XML File 31; (ii) In the Schema Tree sidebar, the Root Elements tree would list the one or more root elements (document elements) 30 you select from among the global elements 30 defined in the schema. In the case of this schema, the element presswatch is selected by default because it is the one global element 30 in the schema that lies clearly at the top of the hierarchy defined in the schema; (iii) All global elements 30 in the schema are listed in the All Global Elements tree 48.

Selecting the XSLT version

For this SPS you will use XSLT 2.0. To specify the XSLT version, in the application toolbar, click the [20] icon.

Assigning or changing the Working XML File

While adding the XML Schema to the SPS in the previous step, you also assigned a Working XML File to the schema. A Working XML File provides the SPS with a source of XML data to process. To assign, change, or unassign a Working XML File for a given schema, in the Design Overview sidebar, right-click anywhere in the Working XML File line you wish to modify (or click the Context Menu icon at the right), and select the required command from the context menu that pops up. The Working XML File to now assigned, and the filename is entered in the Design Overview. Before proceeding, ensure that you have correctly assigned the file QuickStart.xml, which is in the (My) Documents folder as the Working XML File.

Specifying the encoding of output

In the Default Encoding tab of the Options dialog (<u>Tools | Options</u>⁽⁰⁰³⁾), set the HTML encoding to Unicode UTF-8, and RTF and PDF encoding to UTF-8.

Saving the SPS document

After you have set up the SPS as described above, save it as MyQuickStart.sps in the (My) Documents folder. Do this via the menu command File | Save Design or Ctrl+S. In the Save Design dialog that pops up, select the Save as SPS option, and enter the name of the SPS file to save..

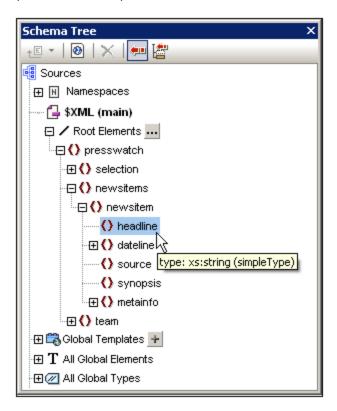

3.2 Inserting Dynamic Content (from XML Source)

This section introduces mechanisms to insert data from nodes in the XML document. In it you will learn how to drag element and attribute nodes from the schema tree into the design and create these nodes as contents. When a node is created as contents, the data in it is output as a string which is the concatenation of the content of that element's child text nodes and the text nodes of all descendant elements.

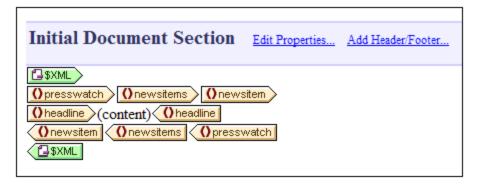

Inserting element contents

In your SPS, do the following:

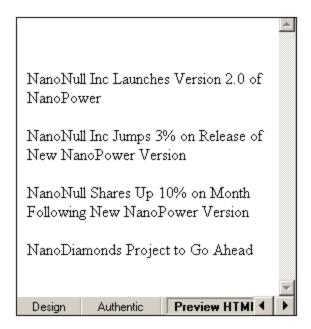

1. In the <u>Schema Tree sidebar</u> (screenshot below).

- 2. Select the headline element (notice that the element's datatype is displayed in a pop-up when you mouseover; *screenshot above*). Drag the element into <u>Design View</u> 2, and, when the arrow cursor turns to an insertion point, drop it into the main template.
- 3. In the context menu that pops up, select **Create Contents**. The start and end tags of the headline element are inserted at the point where you dropped the headline element, and they contain the content placeholder. The headline tags are surrounded by the start and end tags of the ancestor elements of headline (screenshot below).
- 4. In the design put elements on different lines (by pressing Enter) as shown in the screenshot below.

Click the HTML tab to see a <u>preview of the HTML output</u> (screenshot below). The HTML preview shows the contents of the headline child elements of newsitem, each as a text string.

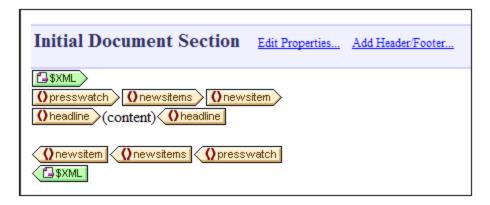

You should also check the preview of Authentic View and the RTF, PDF, and Word 2007+ output.

Note: You can also create the contents of a node by using the following steps: (i) Click the the Insert Contents icon in the <u>Insert Design Elements toolbar</u> (ii) Click the location in the design where you wish to insert the content, (iii) Select, from the Schema Selector tree that pops up, the node for which you wish to create contents.

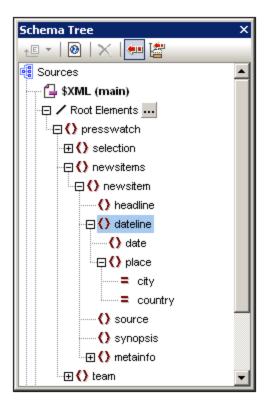

Inserting attribute contents

When an element is inserted into the design as contents, the contents of its attributes are not automatically inserted. You must explicitly drag the attribute node into the design for the attribute's value to be output. In your SPS, now do the following:

1. Place the cursor after the end tag of the headline element and press **Enter**. This produces an empty line (*screenshot below*).

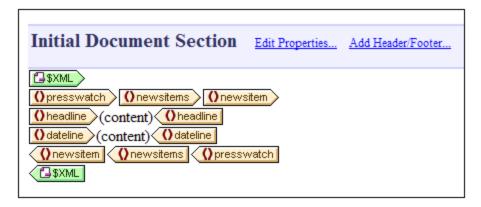

2. In the Schema Tree sidebar, expand the dateline element (screenshot below).

Notice that the dateline element has two child elements, date and place, and that the place element has two attributes, city and country.

3. Drag the dateline element into the design and drop it at the beginning of the newly created empty line (screenshot below).

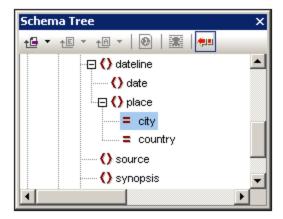

4. Switch to HTML Preview and look carefully at the output of dateline (screenshot below).

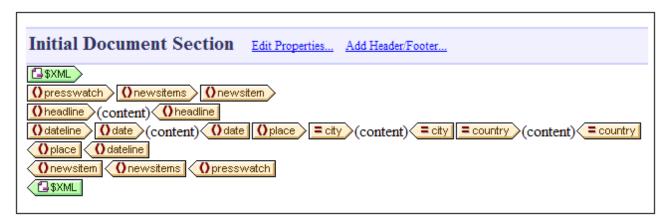

Notice that while the contents of the date children of dateline elements have been output, no contents have been output for the place children of dateline. This is because the place data is contained in the attributes of the place element (in the attributes city and country) and attribute contents are not output when the attribute's parent element is processed.

- 5. In Design View, go to the menu command Authentic | Auto-Add Date Picker (D41), and toggle it off to deactivate the auto-addition of the date picker (588). (The icon will have no border when toggled off.) This step is required if the date picker is not to be inserted automatically when a node of type xs:date or xs:dateTime is inserted into the design (which you will do in the next step). Drag the date element from the Schema Tree sidebar (48) and drop it (create it as contents) in between the start and end tags of the dateline element.
- 6. Select the city attribute of the dateline/place element (screenshot below) in the Schema Tree sidebar 48.

- 7. Drag the @city attribute node into Design View 36, and drop it (create as contents) just after the end tag of the date element.
- 8. Drag the @country attribute node into Design View 36, and drop it (create as contents) just after the end tag of the @city attribute.

When you are done, the SPS design should look something like this:

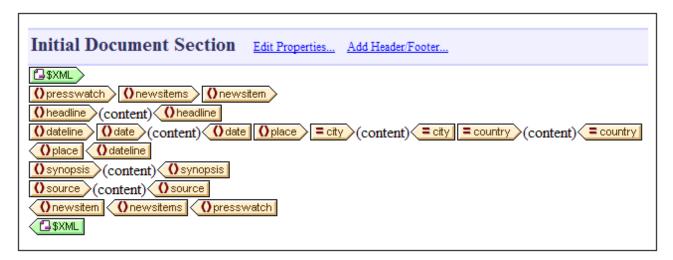

The HTML Preview 39 will look like this:

Notice that the values of the @city and @country attributes are now included in the output.

Adding more dynamic content

The contents of elements and attributes from the XML data source can be inserted anywhere in the design using the method described above. To complete this section, add the synopsis and source elements to the design so that the design now looks like this:

 are placed in the <u>main template</u> is the order in which they will appear in the output (see the section, <u>Templates and Design Fragments</u> 44), for more information about structuring the output document).

Another important point to note at this stage is the form in which a node is created in the design. In the https://docs.preciew you will see that all the nodes included in the design have been sent to the output as text strings. Alternatively to being output as a text string, a node can be output in some other form, for example, as a table or a combo box. In this section, you have, by creating all the nodes as (contents), specified that the output form of all nodes are text strings. In the section, Using Conditions you will learn how to create a node as a combo box, and in the section, Using Global Templates and Rest-of-Contents node as a (dynamic) table.

Make sure to save the file before moving to the next section.

3.3 Inserting Static Content

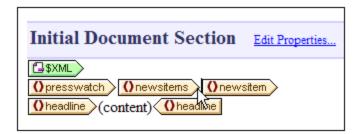

Static content is content you enter or insert directly in the design—as opposed to content that comes from the XML source. A variety of static components can be placed in an SPS design. In this part of the tutorial, you will learn how to insert the following static components:

- An image 79
 A horizontal line 80
- Text⁸⁰

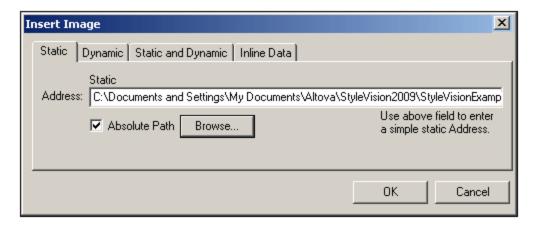

Inserting a static image

The static image to insert is in the (My) Documents folder 33: C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\QuickStart\NewsItems.BMP. It will be used as the header of the document. To insert this image at the head of the document, do the following:

1. Place the cursor between the start-tags of newsitems and newsitem (screenshot below).

Notice that the cursor is within the newsitems element but outside the newsitem element. It will therefore be inserted in the output once, at the start of processing of the newsitems element (because there is only one newsitems element defined in the schema).

- 3. In the Static tab, click the Absolute Path check box, then browse for the file NewsItems.BMP and select it.
- 4. Click **OK** to finish.

The HTML preview will look something like this:

Summary of News Items

NanoNull Inc Launches Version 2.0 of NanoPower 2006-04-01BostonUSA

Nanonull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips; and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed. NewTech Online

Inserting horizontal lines

The first horizontal line you will insert is between the document header and document body. Do this as follows:

- 1. Place the cursor immediately after the recently inserted static image.
- 2. Right-click, and select Insert | Horizontal Line 1008. A horizontal line is inserted.

Set properties for the line as follows:

- 1. With the line selected in <u>Design View</u> 36, in the <u>Properties sidebar</u> 58, select the *line* component (in the Properties For column) and then the *HTML* group of properties.
- 2. Assign color and size properties for the line.
- 3. With the line selected in <u>Design View</u> 36, in the <u>Styles sidebar</u> 57, select the *line* component and then the *box* group of properties. Define a margin-bottom property of 12pt.
- 4. Check the output in HTML Preview 39.

Now insert a horizontal line at the end of each news item. To do this the cursor would have to be placed immediately before the end-tag of the <code>newsitem</code> element. This will cause the line to be output at the end of each <code>newsitem</code> element. You can change the thickness of the line by setting the line's <code>size</code> property to a number with no unit (in the Properties sidebar, select *line*, and set a value of, say 3).

Inserting static text

You have already added static text to your design. When you pressed the **Enter** key to obtain new lines (in the section <u>Inserting Dynamic Content (from XML Source)</u>), whitespace (static text) was added. In this section, you will add a few static text characters to your design.

The SPS you have designed up to this point will produce output which looks something like this:

Summary of News Items

NanoNull Inc Launches Version 2.0 of NanoPower 2006-04-01BostonUSA

Nanonull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips; and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.

NewTech Online

Notice that in the output of the <code>dateline</code> element, the contents of the <code>date</code> element and <code>place/@city</code> and <code>place/@country</code> attributes are run together without spacing. You can add the spacing as static text. In the design, place the cursor after the <code>date</code> element and enter a colon and a space. Next, enter a comma and space after the <code>@city</code> attribute (<code>screenshot below</code>)

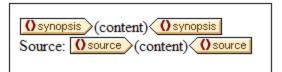

This part of the output will now look like this:

NanoNull Inc Launches Version 2.0 of NanoPower 2006-04-01: Boston, USA

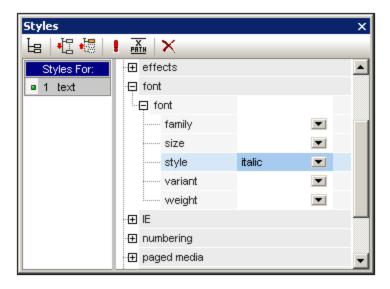

Notice the colon, spacing and comma in the dateline output. All of these text items are static text items that were inserted directly in the design.

You will now add one more item of static text. In the design, type in the string "Source: " just before the starttag of the source element (screenshot below).

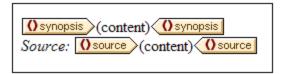

Formatting static text

To format static text, highlight the text to be formatted and specify local style properties. In the design, highlight the text "Source:" that you just typed. In the <u>Styles sidebar</u> (screenshot below), notice that the 1 text component is selected. Now expand the font group of properties as shown in the screenshot below, and, for the font-style property, select the italic option from the dropdown menu.

The static text (that is, the string "source:") will be give an italic style in the design, and will look like this:

The output will look like this in HTML Preview:

NanoNull Inc Launches Version 2.0 of NanoPower 2006-04-01: Boston, USA

Nanonull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips; and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.

Source: NewTech Online

If you think there is too little vertical space between the source item and the horizontal line separating two newsitem elements, then, in the design, insert a blank line between the source and the horizontal line (by pressing **Enter**).

After you are done, save the file.

In this section you have learned how to insert static content and format it. In the next section you will learn more about how design components can be formatted using CSS principles and properties.

3.4 Formatting the Content

StyleVision offers a powerful and flexible <u>styling mechanism</u> 465, based on CSS, for formatting components in the design. The following are the key aspects of StyleVision's styling mechanism:

- CSS style rules can be defined for both block components and inline components.
- Predefined formats ⁴⁵¹ are block components that have inherent styles and can be used as wrappers
 for a group of components that need to be treated as a block. The inherent styles of these predefined
 formats can be overridden by styles you specify locally on each component. This is in keeping with the
 cascading principle of CSS.
- Class attributes can be declared on components in the design, and the class can be used as a selector of external 460 or global 470 style rules.
- You can specify styles at three levels. These are, in increasing order of priority: (i) style rules in external stylesheets (ii) global style rules and (iii) local style rules Note, however, that certain types of selectors in external and global style rules, such as name-based selectors (h1, a, img, etc), will apply only to Authentic View and HTML output, not to RTF, PDF, and Word 2007+ output. Rules that have class selectors will apply to HTML, RTF, PDF, and Word 2007+ formats.

In this section, you will learn how to:

- Assign predefined formats 84
- Assign a component a class attribute
- Define styles in an external CSS stylesheet and add this stylesheet to the style repository of the SPS
- Define local styles for a selection of multiple design components
- Define <u>local styles for a single component</u> 88

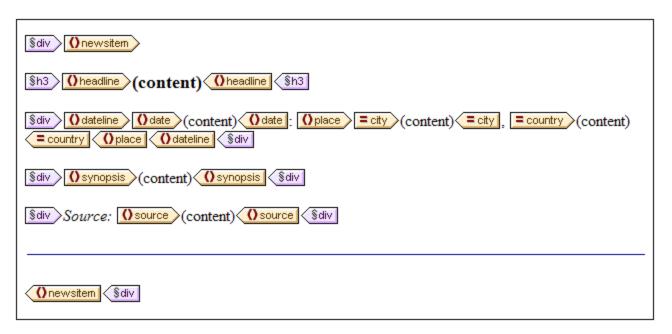

Assigning predefined formats

One reason to assign a <u>predefined format</u> (451) is to give a component the inherent styling of that <u>predefined format</u> (451). In the design, select the <u>headline</u> element and then select **Enclose with | Special Paragraph | Heading 3 (h3)** (alternatively use the Predefined Formats combo box in the toolbar). The predefined format tags are created around the <u>headline</u> element (*screenshot below*).

Notice that the font properties of the contents change and that vertical spacing is added above and below the predefined format. These property values are inherent in the h3 predefined format.

Another use of predefined formats is to group design components in a block so that they can be formatted as a block or assigned inline properties as a group. The most convenient predefined property for this purpose is the div predefined format, which creates a block without spacing above or below. In your design, assign the newsitem, dateline, synopsis, and source nodes separate div components. Your design should look something like the screenshot below. Note that the static text "source: " is also included in the div component that contains the source element, and that the entire newsitem element is inside a div component.

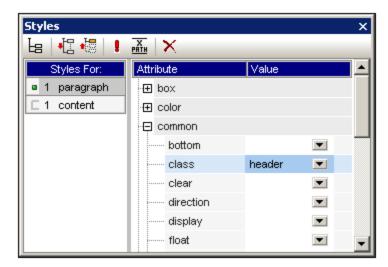

You have now grouped components together in different div blocks. <u>Later in this section</u> you will learn how to assign styles to such blocks of grouped components.

Assigning components to class attributes

A style rule can be defined for a class of components. For example, all headers can be defined to have a set of common properties (for example, a particular font-family, font-weight, and color). To do this you must do two things: (i) assign the components that are to have the common properties to a single class; (ii) define the styling properties for that class.

In your design, select the h3 tag, and, in the Styles sidebar, select 1 paragraph (to select the predefined format), and the common group of properties. Expand the common group of properties, then double-click in the Value field of the class property and enter header.

This particular instance of the h3 format is now assigned to a class named header. When you define styling properties for the header class (styles from an external stylesheet or global SPS styles), these properties will be applied to all components in the SPS that have the header class.

Adding an external CSS stylesheet to the style repository

Style rules in an external CSS stylesheet can be applied to components in the SPS design. External stylesheets must, however, first be added to the style repository in order for rules in them to be applied to components. In the <u>Style Repository sidebar</u> ⁵⁴ (in Design View), do the following:

- 1. Select the External item.
- 2. Click the **Add** button in the toolbar of the Style Repository sidebar 4. This pops up the Open dialog.
- 3. Browse for the file C:\Documents and Settings\<username>\My
 Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\QuickStart\QuickStart.
 css, which is in the (My) Documents folder 33, and click Open.

The stylesheet is added to the style repository. It contains the following rules that are relevant at this stage:

The style rules for the header class and h3 element are combined and produce the following HTML output for the headline element.

NanoNull Inc Launches Version 2.0 of NanoPower

2006-04-01: Boston, USA

Nanonull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips; and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.

Source: NewTech Online

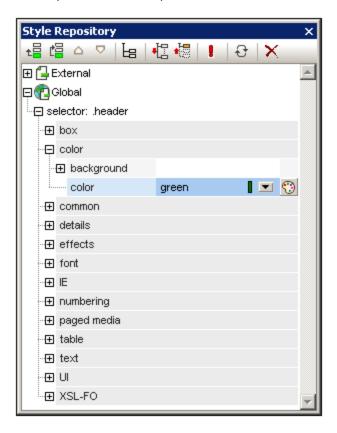

Defining global style rules

Global style rules 470 can be defined for the entire SPS using CSS selectors. The rules are defined directly in the Style Repository sidebar 54. Create a global style rule for the header class as follows:

1. With <u>Design View</u> 36 active, in the <u>Style Repository sidebar</u> 36, select the Global item.

2. Click the **Add** button in the toolbar. This creates an empty rule for the wildcard selector (*), which is highlighted.

- 3. Type in .header to replace the wildcard as the selector.
- 4. Expand the *color* group of properties, and select green from the dropdown list of the color property values (*screenshot below*).

Where the global style rule defines a property that is also defined in the external stylesheet (the color property), the property value in the global rule takes precedence. In the HTML preview, the contents of the headline will therefore be green. Other property definitions from the external stylesheet (not over-ridden by a property in a global style rule) are retained (in this case, font-family and font-weight).

NanoNull Inc Launches Version 2.0 of NanoPower

2006-04-01: Boston, USA

Nanonull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips; and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.

Source: NewTech Online

Note: Since the global style rule uses the class selector, this rule also applies to RTF, PDF, and Word 2007+ output—in addition to Authentic View and HTML output.

Defining local styles for multiple components at once

Local styles can be defined for multiple components at once. In your design, to specify that the entire text contents of a news item should have Arial as its font, click the div component surrounding the newsitem element and, in the Styles sidebar for in the Styles For column, select 1 paragraph. Then, in the font group of properties, assign Arial as the font-family. This property setting will be inherited by all five descendant predefined formats.

Now, in the design, select the three div components surrounding the dateline, synopsis, and source nodes (by keeping the **Shift** key pressed as you click each div component). In the <u>Styles sidebar</u> 57, select 3 paragraphs, then the *font* group of properties, and set a font-size of 10pt. (The h3 component was not selected because it already has the required font-size of 12pt.)

Finally, in the design, select the div component surrounding the dateline element. In the Styles For column of the Styles sidebar of the Styles sidebar of paragraph. In the font group of properties, set font-weight to bold and font-style to italic. In the color group of properties, set color to gray. The output of the dateline will look like this

2006-04-01: Boston, USA

Notice that the styling defined for the div component has been applied to the static text within the div component as well (that is, to the colon and the comma).

Defining local styles for a single component

A local style defined on a single component overrides all other styles defined at higher levels of the SPS for that component. In the design, select the headline element and assign it a color of navy (color property in the color group of style properties). The locally defined property (color:navy) overrides the global style for the header class (color:green).

Select the div component surrounding the source element. In the Styles sidebar ⁵⁷, with the 1 paragraph item in the Styles For column selected, set the color property (in the *color* group of style properties) to gray. In the *font* group of style properties, set font-weight to bold. These values are applied to the static text. Remember that in the last section the static text "Source: " was assigned a font-style value of italic. The new properties (font-weight:bold and color:gray) are additional to the font-style:italic property.

Now, in Design View, select the (content) placeholder of the source element. In the Styles For column, with 1 content selected, set the color property (in the color group of style properties) to black. In the font group of properties, set font-weight to normal. The new properties are set on the contents placeholder node of the source element and override the properties defined on the div component (see screenshot below).

Completing the formatting

To complete the formatting in this section, select the div component on the synopsis element and, in the Predefined Formats combo box in the toolbar, select p. This gives the block the inherent styles of HTML's p element. The HTML preview should now look something like this:

NanoNull Inc Launches Version 2.0 of NanoPower

2006-04-01: Boston, USA

Nanonull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips; and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.

Source: NewTech Online

After you are done, save the file.

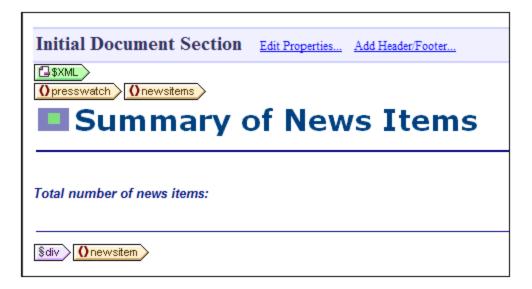

3.5 Using Auto-Calculations

Auto-Calculations are a powerful mechanism for providing additional information from the available XML data. In this section you will add two pieces of information to the design: the total number of news items and the time period covered by the news items in the XML document. Neither piece of information is directly available in the XML document but has to be calculated or manipulated from the available data.

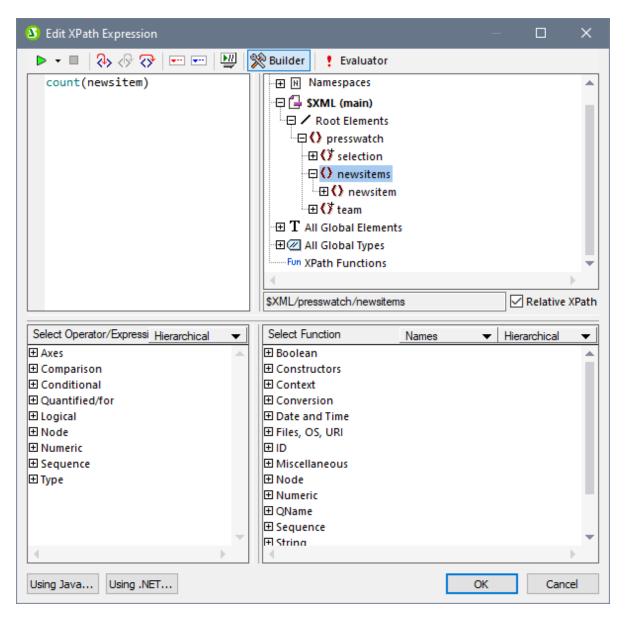

Counting the news item nodes

In the design, do the following:

 Create space, as shown in the screenshot below, for a line of static text (on which the Auto-Calculation will also be placed). Use the **Return** key to add new lines and insert a horizontal line below the space you create (see screenshot).

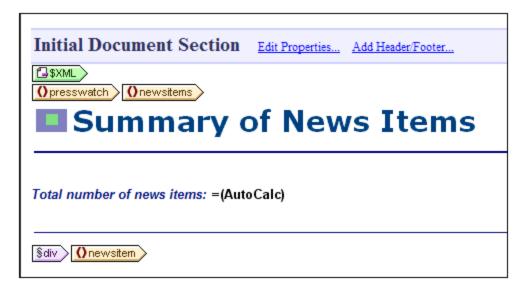

- 2. Type in the static text "Total number of news items: " as shown in the screenshot above.
- 3. Apply local styling of your choice to the static text. Do this as described in the section Formatting the Content 80.
- 4. Place the cursor after the colon and select Insert | Auto-Calculation | Value. This pops up the Edit XPath Expression dialog (screenshot below). (Alternatively, you can right-click and select the command in the context menu.)

5. In the schema tree, note that the context node is <code>newsitems</code>, which is highlighted. Now, in the <code>Expression</code> text box either type in the expression <code>count(newsitem)</code> or build the expression using the entry-helper panes below the Expression text box. (Double-click the <code>count</code> function (found in the <code>Sequence</code> group of functions) to enter it, then (in the expression in the text box) place the cursor within the parentheses of the function and double-click the <code>newsitem</code> node in the schema tree. You can see what the XPath expression returns by clicking the <code>Evaluator</code> button. The result of the evaluation will be in the <code>Results</code> pane (<code>see screenshot below</code>). For a detailed description of the Edit XPath Expression dialog, see the section <code>Edit XPath Expression</code> [917].

6. Click **OK** to finish. The Auto-Calculation is inserted in the design at the cursor location (*screenshot below*). Format the Auto-Calculation using <u>local styles</u> 88.

Your HTML output will look like this:

Summary of News Items

Total number of news items: 4

Displaying the period covered by news items

The period covered by all the news items together can be obtained by getting the date of the earliest news item and the date of the latest news item. This can be achieved with XPath expressions like those given below. The first expression below outputs the contents of the date node. The second expression is a refinement, outputting just the month and year values in the date node. You can use either of these.

```
    concat(min(//date), ' to ', max(//date)).
```

concat(month-from-date(min(//date)), '/', year-from-date(min(//date)), ' to ', month-from-date(max(//date)), '/', year-from-date(max(//date)))

In the design, insert the static text and Auto-Calculation as shown in the screenshot below. Apply whatever local styling you like.

Total number of news items: =(AutoCalc)
Period covered by news items: =(AutoCalc)

The HTML preview will look something like this:

Total number of news items: 4
Period covered by news items: 4/2006 to 5/2006

After you are done, save the file.

3.6 Using Conditions

If you look at <code>QuickStart.xml</code>, you will see that each <code>newsitem</code> element has a <code>metainfo</code> child element, which in turn can contain one or more <code>relevance</code> child elements. In the SPS design, you can create a combo box that has a dropdown list which you can populate with unique <code>relevance</code> element values. When the Authentic View user selects an item from the dropdown list in the combo box, that item can be passed as a value to a node in the XML document. A condition can test what the user selection is (by looking up that node) and provide appropriate processing (displays) for each user selection. In this section, you will create a conditional template that displays those news items that have a <code>relevance</code> element that matches the user selection.

We will proceed as follows:

- 1. Create a combo box in which the Authentic View user can select the byrelevance value. The values in the dropdown list of the combo box are obtained by using an XPath expression, which dynamically compiles a list of all unique relevance node values.
- 2. Insert a condition around the newsitem element. This condition selects all newsitem elements that have a relevance element with content matching the content of the byrelevance node. The content that is surrounded by a branch of a condition is known as a conditional template.
- 3. Within the conditional template, list each relevance node of that news item.
- 4. Highlight the relevance element (in the list of relevance elements) that matches the byrelevance element. This is done by creating a condition to select such relevance elements and then applying special formatting to this conditional template.
- 5. In the condition for the newsitem element, insert a branch that selects all news items.

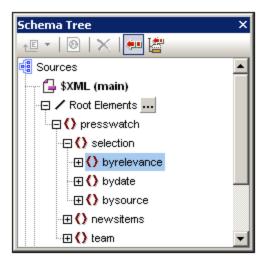

Creating the combo box to select unique node values

In the XML document, the node that will contain the user selection is /presswatch/selection/byrelevance. This is the node you will create as the combo box. Do this as follows:

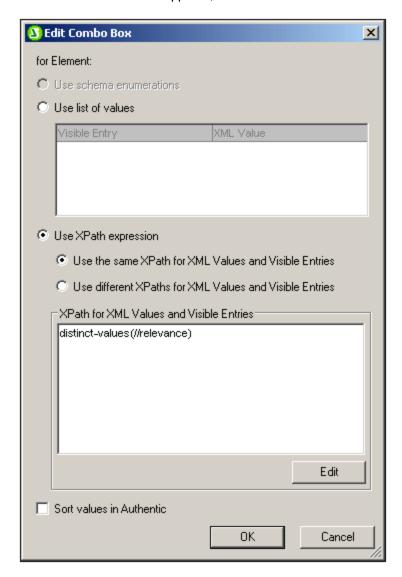

1. Insert the static text "Select by relevance: " at the head of the document and just below the second Auto-Calculation (screenshot below).

Total number of news items: =(AutoCalc)
Period covered by news items: =(AutoCalc)
Select by relevance:

2. Drag the byrelevance node from the <u>Schema Tree sidebar</u> (screenshot below), and drop it after the newly entered static text.

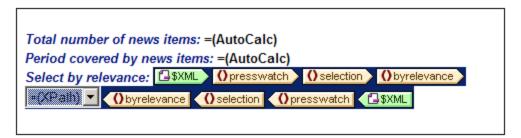

3. In the context menu that appears, select Create Combo Box. This pops up the dialog shown below.

4. In the Edit Combo Box dialog (*screenshot above*), select Use XPath Expression and then Use the Same XPath for XML Values and Visible Entries. In the XPath for XML Values and Visible Entries, enter the XPath expression: distinct-values(//relevance). This expression selects unique values of all relevance elements in the XML document.

5. Click **OK** to finish. The combo box is inserted and the design will look something like this:

6. Switch to <u>Authentic View</u> 38. When you click the dropdown arrow of the combo box, notice that the list contains the unique values of all relevance nodes (*screenshot below*). Check this against the XML document. This is a dynamic listing that will be augmented each time a new relevance value is added to the XML document.

Inserting a condition to display news items having the selected relevance

The condition selects newsitem elements that have a metainfo/relevance element with a value that is the same as that selected by the user (and passed to the /presswatch/selection/byrelevance element). Insert the condition as follows:

1. Select the contents of the newsitem part of the design which is to be contained inside the condition (highlighted in the screenshot below).

```
$\frac{1}{2} & \text{() newsitem} \\
\text{$\text{$h3}} & \text{() headline} & \text{() content} & \text{() date} & \text{() content} & \text{() date} & \text{() content} & \text{() cont
```

- 2. Select the menu command (or context menu command) <u>Enclose with | Condition [027]</u>. This pops up the <u>Edit XPath Expression dialog [917]</u>.
- 3. Enter the expression metainfo/relevance=/presswatch/selection/byrelevance. This expression evaluates to true when the value of the metainfo/relevance descendant of the current newsitem is the same as the value of the /presswatch/selection/byrelevance element (the user selection).
- 4. Click **OK**. The condition is created around the contents of the newsitem element (screenshot below).

```
$\frac{1}{2} & \text{ (content) () headline } \frac{1}{2} & \text{ (content) () headline } \frac{1}{2} & \text{ (content) () date } \text{ (content) () date } \text{ (content) () content) () content
```

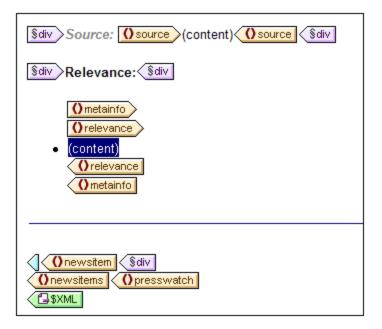

Note that there is a single branch in this condition. News items for which the condition test evaluates to true are displayed, those for which the condition test does not evaluate to true are not displayed. The condition in this case, therefore, works as a filter. Later in this section, you will add a second branch to this condition.

Inserting the relevance node as a list

In order to display the relevance nodes of each newsitem element, insert them in the design as follows (see screenshot below):

1. Create some vertical space below the div component for the source element and within the end-tag of the conditional template.

- 2. Type in the static text "Relevance:" and create a predefined format of div around it (highlight the static text and insert the predefined format).
- 3. Drag the relevance element from the Root elements tree in the Schema Tree sidebar and drop it into the design below the static text Relevance:
- 4. Create it as a list. (In the context menu that pops up when you drop the node in the design, select Bullets and Numbering, and then select the desired list format.)
- 5. Apply text formatting to the contents of the list. When you are done, the design should look something like this:

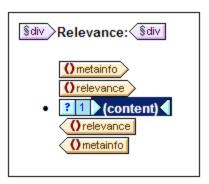

Now, in Authentic View, check the results for different selections of relevance; use the combo box to change the selection.

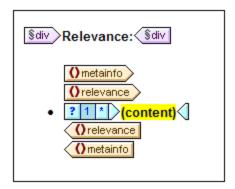

Making the selected relevance element bold

Some news items have more than one relevance element. In such cases, the design would be improved if the relevance that matches the user-selection were visually highlighted while the others were not. You can do this in the following way:

- 1. Select the relevance element in the design.
- 2. Insert a condition, giving it an XPath expression of: .=/presswatch/selection/byrelevance. This creates a condition with a single branch (*screenshot below*) that selects relevance elements that match the byrelevance element.

- 3. Select the contents placeholder and give it a local formatting (in the Styles sidebar) of bold (*font* group) and yellow background-color (*color* group).
- 4. Right-click the condition and, from the context menu, select Copy Branch.
- 5. In the Edit XPath Expression dialog 1917 that pops up, check the Otherwise check box (top right-hand side).
- 6. Click **OK** to finish. A new branch (Otherwise) is created (*screenshot below*). This condition branch selects all relevance elements that do not match the byrelevance element.

7. Notice that the contents of the <code>otherwise</code> branch are a copy of the first branch; the <code>contents</code> placeholder is bold and has a yellow background. Remove this formatting (bold and background-color) from the <code>contents</code> placeholder.

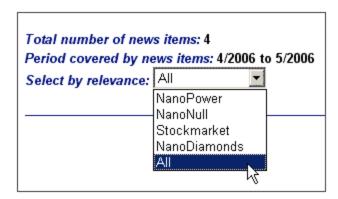

You have put a condition with two branches (each with its conditional template) that carries out the following test on each relevance element: If the contents of relevance match those

of /presswatch/selection/byrelevance, then the contents of relevance are displayed bold and with a yellow background. Otherwise (the second branch) they are displayed normal. Check this in Authentic View.

Modifying the combo box and inserting a second condition branch

In the combo box where the Authentic View user selects a byrelevance value, there is no dropdown list option for selecting all news items. To include this option do the following:

- 1. In Design View, select the combo box.
- 2. In the Properties sidebar, with *combobox* selected in the Properties For column, click the **Edit** button of the *Combo box entry value* property (in the *combo box* group of properties).
- 3. In the Edit Combo Box that pops up, modify the XPath expression from distinct-values (//relevance) to distinct-values (//relevance), 'All'. This adds the string All to the sequence of items returned by the XPath expression.
- 4. Check the dropdown list of the combo box in Authentic View (screenshot below).

Now if the user selection is All, then this value (All) is passed to the node /presswatch/selection/byrelevance. The idea is that when the byrelevance node contains the value All, all news items should be displayed.

The condition that displays the news item template has a single branch with the expression <code>metainfo/relevance=/presswatch/selection/byrelevance</code>. Since no <code>metainfo/relevance</code> node has the value <code>All</code>, no news item will be displayed when <code>All</code> is the value of the <code>byrelevance</code> node. What you have to do is create a second branch for the condition, which will test for a value of <code>All</code>. By creating the news item template within this branch, you will be outputting the news item if the test is true. Do this as follows:

- 1. In Design View, select the news item condition.
- 2. Right-click the condition and, from the context menu, select **Copy Branch**.
- 3. In the <u>Edit XPath Expression dialog</u> that pops up, enter the expression: /presswatch/selection/byrelevance='All'.
- 4. Click **OK** to finish. A second branch is created.

The second branch has as its contents the same template as the first branch. What the second branch does is output the news item template if the user selection is All.

After you have completed this section, save the design.

3.7 Using Global Templates and Rest-of-Contents

Global templates are useful for specifying the processing of an element globally. This enables the rules of the global template (defined in one location) to be used at multiple locations in the stylesheet. A global template can be used in two ways:

- The rules of the global template can be copied to the local template.
- A local template (in the main template) can pass processing of that node to the global template. After
 the global template is executed, processing resumes in the main template. In this case, the global
 template is said to be invoked or used from the main template.

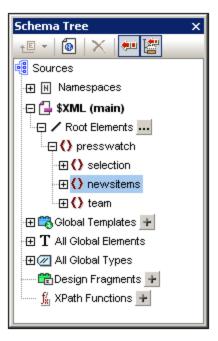

There are two mechanisms that are used to invoke a global template from the main template:

- A local template references a global template.
- A (rest-of-contents) instruction in the main template applies templates to the descendant elements of the current element (that is, to the rest-of-contents of the current element). If a global template exists for one of the descendant elements, the global template is applied for that element. Otherwise the built-in template for elements is applied. (The built-in template for elements processes child elements and outputs the text content of elements. As a result, the text content of all descendants elements will be output. Note that the values of attributes are **not** output.)

In this section, you will create a design for the team-members' template using the rest-of-contents instruction and a global template for the global element member.

Inserting the rest-of-contents instruction

The broad structure of the schema is shown in the screenshot below.

The document element presswatch contains three children: (i) selection; (ii) newsitems; and (iii) team. The main template you have created this far processes the /presswatch element. Within the presswatch element,

only the newsitems element is processed. The selection and team elements are not processed within the presswatch element (although selection has been processed within the newsitems element). Inserting the rest-of-contents instruction within presswatch will therefore cause the selection and team elements to be processed.

Insert the rest-of-contents instruction in the design by placing the cursor between the end-tags of newsitems and presswatch, and selecting the menu command or context menu command Insert | Rest of Contents 938. The rest-of-contents placeholder is inserted (screenshot below).

If you look at the HTML preview, you will see a string of text (screenshot below):

AllAndrewBentincka.bentinck@nanonull.comNadiaEdwardsn.edwar

This string is the result of the application of the built-in templates to the selection and team elements. The built-in template for elements processes child elements. The built-in template for text nodes outputs the text in the text node. The combined effect of these two built-in templates is to output the text content of all the descendant nodes of the selection and team elements. The text All comes from selection/byrelevance, and is followed by the text output of team/member descendant nodes, first, last, email, in document order. Note that the id attribute of member is not output (because, as an attribute, it is not considered a child of member).

Creating a global template for selection

Since the content of selection is not required in the output, you should create an empty global template for selection so that its contents are not processed. Do this as follows:

- 1. In Design View, right-click selection in the All Global Elements tree in the Schema Tree sidebar (48).
- 2. In the context menu that pops up, select **Make / Remove Global Template**. A global template for selection is created (screenshot below).

- 3. In the global template, click the contents placeholder and press the **Delete** key of your keyboard. The contents placeholder is deleted.
- 4. Check the HTML preview. The text All is no longer present in the line of text output by the built-in templates (*screenshot below*).

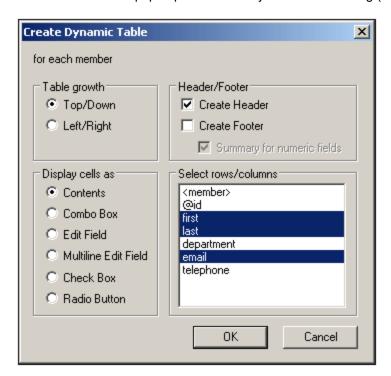

AndrewBentincka.bentinck@nanonull.comNadiaEdwardsn.e

Since the global template for selection is empty, the child elements of selection are not processed.

Creating a global template for team/member

The objective is to create a table to display details of the members of the press monitoring team. This table will be created in a global template for the team element. Do this as follows:

- 1. Create a global template for the element team (right-click team in the All Global Elements list of the Schema Tree sidebar and select **Make / Remove Global Template**).
- 2. In the All Global Elements list, expand the team element and drag its member child element into the global template of team (in the design).
- 3. In the context menu that pops up when you drop the element into the global template of team, select **Create Table**. This pops up the Create Dynamic Table dialog (*screenshot below*).

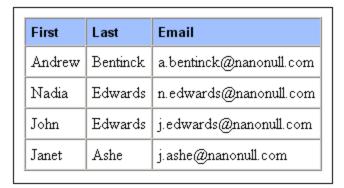

- 4. In the attributes/elements list deselect @id, department and telephone (see screenshot), and click OK. The dynamic table is created.
- 5. Place the cursor in a cell of the table body, and in the <u>Properties sidebar</u> (58), with table selected in the Properties For column, specify table properties as shown in the screenshot below.

6. Set additional properties as required in the Properties and Styles sidebars. For example, a background color can be set for the header row by placing the cursor in the header row, and with trow selected in the Styles For column of the Styles sidebar, specifying a value for the background-color property (color group). You can also edit the headers, which are strings of static text. Also, if the content placeholder of the team element is still present in the global template, delete it.

The HTML preview of the table will look something like this:

Quick Start Tutorial That's It! 105

3.8 That's It!

Congratulations for having successfully completed the tutorial. You have learned the most important aspects of creating an SPS:

- How to <u>create the structure</u> of the document (<u>main template</u> and <u>global templates</u> 101).
- How to insert dynamic and static occurrent in the design, using a variety of dynamic and static SPS components..
- How to use <u>CSS styles</u> 72, in <u>external stylesheets</u> 86, in <u>global style rules</u> 86, and in <u>local style rules</u> 88.
- How to use <u>Auto-Calculations</u> to derive additional information from the available XML data.
- How to use <u>conditions</u> to filter the XML data and how to obtain different outputs depending on values in the XML data.
- How to use global templates 102 and rest-of-contents 101.

For a more detailed description of these features, see the corresponding sections in the following four sections:

- SPS File: Content 130
- SPS File: Structure ²⁹¹
- SPS File: Advanced Features
 370
- SPS File: Presentation 450

These sections also contain descriptions of several other StyleVision features not encountered in the Quick Start tutorial.

Using the SPS

After completing the SPS, you should also try out the two main uses of SPS:

- Editing XML documents in the Authentic View of XMLSpy or Authentic Desktop. (The Enterprise and Professional editions contain an Authentic View preview tab, which does not have a few features such as sidebars and Text State Icons.) These two products provide a full-feature Authentic View, in which you can try out the sidebars and context menu. To edit QuickStart.xml in Authentic View in XMLSpy or Authentic Desktop, associate the XML file with MyQuickStart.sps and switch to Authentic View.
- Generating XSLT stylesheets for transforming the XML file to HTML, Text, RTF, and PDF output. The XSLT stylesheets can be generated using the File | Save Generated Files command or via the command line Try generating XSLT stylesheets from MyQuickStart.sps and then using these stylesheets to transform QuickStart.xml.

4 Usage Overview

Objectives

SPS documents that you create in StyleVision can be used for two broad purposes:

- To control the display of XML source documents in Authentic View and to enable data to be entered in XML documents or DBs via the Authentic View interface.
- To generate XSLT stylesheets for HTML, Text, RTF, PDF, and Word 2007+ output.

In this way, the SPS can be used to enable XML document editing and to generate HTML, Text, RTF, PDF, and Word 2007+ output from the edited XML document. Additionally, the generated XSLT stylesheets can be used to transform other XML documents based on the same schema as the SPS.

Steps for creating an SPS

Given below is an outline of the steps involved in creating a new SPS.

- 1. Assign a schema 48 to the newly created empty SPS. The schema may be: (i) a schema file (DTD or XML Schema); (ii) an XML Schema generated from a DB (*Enterprise and Professional editions only*); (iii) a schema based on an XBRL taxonomy (*Enterprise edition only*); (iv) a user-defined schema (created directly in StyleVision). This is done in the <u>Design Overview sidebar</u> 45. If required, additional schemas can be added (via the <u>Design Overview sidebar</u> 45) so that nodes in multiple XML documents can be addressed. Alternatively, a new SPS can be created directly with a schema via the **File | New** command.
- 2. Assign a Working XML File 48 to the SPS. The Working XML File 31 provides the XML data processed by the SPS when generating Authentic View and output previews. The Working XML File is assigned in the Design Overview sidebar 45. The Working XML File enables you to preview output in StyleVision. If required, the Working XML Files 31 for additional schemas can be assigned (via the Design Overview sidebar 45) to enable previews involving multiple XML documents.
- 3. <u>Select the required XSLT version</u> 110. In order to generate Text output, the XSLT version must be XSLT 2.0 or XSLT 3.0
- 4. Select the Internet Explorer Compatibility to match the installed Internet Explorer version.
- 5. The SPS document is designed in <u>Design View</u> 35 using the various design components available to the designer. The <u>design process</u> 109 consists of creating a document structure and defining <u>presentation properties</u> 450. If <u>print output</u> 494 is required, then additional <u>print formatting properties</u> 494 can be specified.
- 6. The Authentic View and outputs are tested. If modifications to the design are required, these are made and the SPS document is re-tested.
- 7. If XSLT files or output files are required, these are generated 116.
- 8. If required, assign a Template XML File. The <u>Template XML File</u> provides the starting data for a new XML document that can be edited in Authentic View using the SPS.
- 9. The SPS is deployed for use among multiple Authentic View users.

Usage Overview SPS and Sources 107

4.1 SPS and Sources

Creating a new SPS file

To create a new SPS document, select an option from under the File | New (Ctrl+N) (C

After a new SPS document is created, the source files for the SPS must be assigned.

Assigning source files for the SPS

There are three types of source files that can be assigned to an SPS:

- Schema sources 107
- Working XML File 107
- Template XML File 107

These source file assignments are made in the <u>Design Overview sidebar</u> 45. How to make the assignments is described in the section, <u>Design Overview</u> 45. The significant points about each type of source file are given below.

Schema sources

At least one schema source file must be assigned to an SPS so that a structure for the design document can be created. Optionally, additional schema sources can be assigned. This enables nodes from other documents to be addressed, and thus included, in the SPS. Schema sources are assigned in the Design Overview sidebar 45. A schema may be an XML Schema file (.xsd file), an XML Schema generated from an XML file, an XML Schema generated from a DB file, a DTD, a schema based on an XBRL taxonomy, or a user-defined schema. One of the assigned schema sources is designated the main schema 30. The main schema is significant because the document node 30 of the Working XML File 31 associated with the main schema 30 is used as the starting point for the main template 30. For each schema, one optional Working XML File 107 and one optional Template XML File 107 can be assigned.

Note: If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Working XML File

Each schema source can, optionally, have a <u>Working XML File</u> associated with it. The function of the <u>Working XML File</u> is to provide the XML data source for output previews in StyleVision, and it must therefore be valid according to the schema with which it is associated. The <u>Working XML File</u> is assigned in the <u>Design Overview sidebar</u>.

Template XML File

Each schema source can have a <u>Template XML File</u> optionally associated with it. The function of the <u>Template XML File</u> is to provide the starting data of the new XML document that is created each time that

108 Usage Overview SPS and Sources

SPS is opened in the <u>Authentic View</u> of a product other than StyleVision. The <u>Template XML File</u> must be valid according to the schema with which it is associated. It is assigned in the <u>Design Overview sidebar</u> 15.

Usage Overview Creating the Design 109

4.2 Creating the Design

In the SPS design, you specify:

1. What content (from the XML document or DB) should go to the output; additionally content can be inserted directly in the SPS for inclusion in the output;

- 2. How the output should be structured 109; and
- 3. What presentation (formatting) properties are applied to the various parts of the output.

Content for output

The content for the output can come from:

- 1. The XML document or DB, or from multiple XML documents and the DB, to which the SPS is applied. Content from the XML document is included in the SPS by dragging the required XML data node from the relevant schema tree in the Schema Tree sidebar and dropping this node at the desired place in the SPS.
- 2. An external XML document that is accessible to the application (that is, to StyleVision or an Authentic View product). By using the doc() function of XPath 2.0 in an Auto-Calculation, content from external XML document sources can be accessed. An XML document accessed via the doc() function in an XPath expression does not need to be referenced via the Schema Sources associations.
- 3. The SPS itself. Text and other content (such as images and tables) can be inserted directly in the SPS using the keyboard and other GUI features. Such input is independent of the XML document.
- 4. Manipulated dynamic (XML source) data, with the manipulations being achieved using XPath expressions. Manipulations are typically achieved with <u>Auto-Calculations</u> [37].
- 5. For the HTML output, <u>JavaScript functions</u> ⁵⁹³ can be used to generate content.

Structure of output

In the SPS design, the <u>structure of the output</u> and can be controlled by using either: (i) a procedural approach, in which the output structure is specified in an <u>entry-level template</u> (StyleVision's <u>main template</u> and can be independent of the structure of the XML document; (ii) a declarative approach, in which <u>template rules</u> are <u>declared for various nodes</u> (StyleVision's <u>global templates</u>), thus generating an output that follows the structure of the XML document; or (iii) a combination of the procedural and declarative approaches. In Design View, you can use a mix of <u>main template</u> and <u>global templates</u> to obtain the desired structure for the output document. The use of <u>Modular SPSs</u> and <u>Design Fragments</u> provides additional flexibility in the way an SPS is structured.

Presentation (or formatting) of the output

In Design View, presentation properties are applied to design components using CSS styles. Styles can be defined locally on the component, for HTML selectors declared at the document level, and for HTML selectors declared in an external CSS stylesheet. Additionally, certain HTML elements can be applied to components using predefined formats (451). Specifying presentation properties is described in detail in the section, Presentation Procedures (450).

110 Usage Overview XSLT and XPath Versions

4.3 XSLT and XPath Versions

- Which of the three XSLT engines in StyleVision is used for transformations; StyleVision has separate XSLT 1.0, XSLT 2.0, and XSLT 3.0 engines.
- What XSLT functionality (1.0, 2.0, or 3.0) is displayed in the interface and allowed in the SPS. For example, XSLT 3.0 uses XPath 3.0, which is a much more powerful language than XPath 1.0 (which is used in XSLT 1.0) or XPath 2.0 (which is used in XSLT 2.0). Additionally, some SPS features, such as the table-of-contents feature, is available only with XSLT 2.0 and XSLT 3.0.

Note: In order to generate Text output, the XSLT version must be XSLT 2.0 or XSLT 3.0

XSLT transformations

XSLT transformations in StyleVision are used: (i) to generate output views in the interface; and (ii) to generate and save output files (HTML, Text, RTF, PDF, and Word 2007+) from within the interface and via StyleVision Server. The XSLT engine used for transformations (Altova XSLT 1.0, 2.0, or 3.0 Engines) corresponds to the XSLT version selected in the SPS.

XSLT functionality in GUI

The functionality appropriate for each XSLT version relates mostly to the use of the correct XPath version (XPath 1.0 for XSLT 1.0, XPath 2.0 for XSLT 2.0, XPath 3.0 for XSLT 3.0). XPath expressions are widely used in StyleVision—most commonly in features such as Auto-Calculations and Conditional Templates —and there are interface mechanisms that require, and help you build, XPath expressions. The functionality of the correct XPath version is automatically made available in the interface according to the XSLT version you select.

4.4 Internet Explorer Compatibility

Internet Explorer (IE) must be installed on the StyleVision machine to correctly display the SPS design (in Design View) and output previews (in Authentic View and HTML Preview). Given below are notes about the IE versions that are supported:

- Internet Explorer 5.5 or higher
- Internet Explorer 6.0 and higher has better XML support and is recommended.
- Internet Explorer 9 (IE9) or higher provides additional features, such as support for more image formats and for new CSS styles. If you plan to use these additional features in your design, you might want to consider using IE9.

IE9 feature-support in StyleVision

The following features of IE9 or higher are supported in StyleVision:

- Additional image formats supported: TIFF, JPEG XR, and SVG. (SVG documents must be in XML format and must be in the SVG namespace.) These image formats will be displayed in IE9, but not in older versions of IE. For a complete listing of images supported in the various outputs, see Image Types and Output
- Support for new CSS styles (including CSS3 styles), which are listed below. Application of these styles is limited to Authentic View and HTML output.
 - background-clip
 - background-origin
 - background-size
 - box-sizing
 - box-shadow
 - border-radius (border-*-radius)
 - font-stretch
 - ruby-align
 - ruby-overhang
 - ruby-position
 - overflow-x, overflow-y
 - outline (outline-color, outline-style, outline-width)
 - text-align-last (partial)
 - text-overflow (partial)
- Support for the new CSS length function calc()
- Support for the new CSS color functions rgba(), hsl() and hsla()
- Support for the new CSS length units rem, vw, vm, vh and ch
- HTML5 elements that are supported by IE9 can be inserted in the design as <u>user-defined elements</u> ¹⁴⁶.

Design View and IE versions

You can set up Design View for a specific IE version by specifying, in the <u>Properties</u> dialog, the IE version with which you wish Design View to be compatible. This has the following effects:

 All CSS styles that can be rendered by the selected IE version will be automatically displayed in the Styles sidebars of StyleVision. (Note, however, that if IE9 is selected, then IE9 must be installed for the IE9-supported CSS styles to be available in the design interface.) For example, if IE9 is installed

- and IE9 is selected as the compatibility version, then the CSS3 styles supported in IE9 will be available in the design interface.
- HTML elements corresponding to the selected IE version can be entered as <u>predefined formats</u> or as <u>user-defined elements</u>. The HTML element will be rendered in Authentic View and HTML Preview according to how the installed IE version renders this element. For example, if IE9 is installed and IE9 selected as the compatibility version, then the supported HTML5 elements will be rendered in Authentic View and HTML Preview.

Setting up Design View for a specific IE version

To set up Design View for a specific IE version, select the menu command File | Properties and, in the Output tab, select the required IE (compatibility) version. See <u>File | Properties</u> for details.

Compatibility of older SPS designs with IE9

If you open an SPS design that has been created for an older IE version, and if the newer IE9 version or higher is installed on the StyleVision machine, then StyleVision will detect the newer version and ask in a dialog whether you wish to change the compatibility to IE9-compatibility. Changing to the new compatibility will provide additional Design View options as indicated above. The appearance of the document in Design View, Authentic View and HTML output will remain unchanged except for **table columns**, which are handled differently by IE9. If you change the IE compatibility to IE9-compatibility, then check whether the table columns are generated as required. If not, you can modify the properties of the table columns or switch, in the Properties of the table columns version.

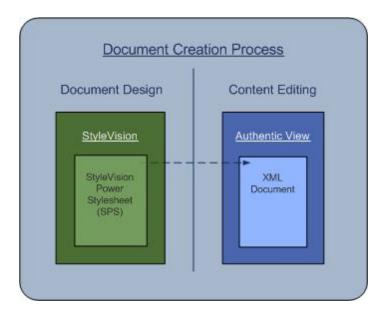

Usage Overview SPS and Authentic View 113

4.5 SPS and Authentic View

One of the core uses of the SPS you create with StyleVision is to control the input of data and the display of an XML document in <u>Authentic View</u>, which is a document view available in Altova products. With Authentic View, users who are unfamiliar with XML can easily enter and edit XML document content correctly.

A document creation and editing process that involves Authentic View consists of two separate stages:

• **Document design.** The Authentic View of the XML document, which is graphical view, is designed in StyleVision. The design document is an SPS. The SPS not only processes the XML document for display in Authentic View and for final output; it also provides mechanisms, in Authentic View, for **inputting data into the XML file or DB.**

• Content editing. This SPS created in the document design stage is linked to the XML document to be edited. (The XML document must be valid according to the schema on which the SPS is based.) An XML document which is linked to an SPS is presented graphically in the Authentic View of an Altova product as the Authentic View of that XML document. When a new Authentic XML document is created, it can be assigned an SPS and then be edited in Authentic View using the document template (Template XML File (31)) and controls specified in the SPS. If an existing XML document is opened and assigned an SPS, the existing data is displayed in Authentic View according to the design in the SPS, and the document can be edited in Authentic View.

The user of Authentic View is not expected to be knowledgeable about either XML or the schema being used for the document. The document display in Authentic View should make content editing as easy and non-technical as possible. It is, therefore, the task of the person who designs the SPS to produce a user-friendly Authentic View display. For detailed information about using Authentic View, see the <u>Authentic View documentation</u> in the user manual of XMLSpy or Authentic Desktop.

114 Usage Overview SPS and Authentic View

SPSs for standard industry schemas

Altova's Authentic View package includes SPSs for a number of standard industry schemas. Users can therefore immediately create an XML document based on a standard schema in Authentic View. The screenshot below shows a partial Authentic View of the NCA Invoice standard.

NCA XML Invoice add documentID Invoice Type: (Proforma, Final, Debit Note, Credit Note) Status: (Draft, Final, Ammended)	This is a template for the NCA Invoice used to define a detailed list of goods shipped or services rendered, with an account of costs. Information created could consist of parties assoicated with the transaction, type of goods shipped or method of shipment.
Required General Information	Optional
References and other general information pertain	ing to the contract and this document.
Date of Issue: (yyyy-mm-dd) Document Creator Identifer: Document Number: Invoice Number:	Contract Id <u>add contractExtension add documentVersion add contractTy</u> er <u>add buyerContractIdentifier</u> <u>add sellerContractIdentifier</u> <u>add brokerContrac</u>

You can easily customize any of the supplied standard industry SPSs, which are available in the <code>Examples/IndustryStandards</code> folder of your application folder.

4.6 Synchronizing StyleVision and Authentic

Each new release of StyleVision contains features that add to the power and capability of <u>Authentic View</u> 160.

However, the following must be taken into account:

- An SPS file created with a later version of StyleVision might be incompatible with an older version of Authentic View.
- New SPS file functionality (created using a later version of StyleVision) will be interpretable only by a corresponding version (or later) of Authentic View.

So, if a later version of StyleVision is used to create an SPS file, all deployed <u>Authentic View products</u> must be synchronized with this version of StyleVision. This means, for example, that if **StyleVision 2008 release 2** was used to create an SPS file, then **Authentic Desktop 2008 release 2** (or another Authentic View product from this release) must be used to properly edit this SPS file.

Note that a later version of an <u>Authentic View product</u> will be able to interpret SPSs created with previous versions of StyleVision.

Synchronization steps when a deployed SPS file is modified using a later version of StyleVision

If an SPS is already deployed among multiple Authentic View users, and if, subsequently, new Authentic View functionality is added to the SPS using a later version of StyleVision, then the developer should go about the task of synchronization in the following sequence:

- 1. The developer obtains a license key for the new version of Authentic View for himself.
- 2. The developer successfully tests SPS modifications using the new StyleVision and Authentic View pair.
- 3. The new version of the Authentic View product 28 is distributed to all Authentic View users.
- 4. Only after all three steps above have been successfully carried out, should the modified SPS be deployed to Authentic View users.

116 Usage Overview Generated Files

4.7 Generated Files

In StyleVision, XSLT stylesheets and output files can be generated using the <u>File | Save Generated Files some</u> command or <u>StyleVision Server</u>. Alternatively, if you wish only to validate or transform XML using XSLT, you can do this directly with <u>RaptorXML(+XBRL) Server</u> some

The following files can be generated from StyleVision:

- XSLT stylesheets based on the SPS design. Separate XSLT stylesheets are generated for HTML, Text, RTF, PDF, and Word 2007+ output.
- Output files, generated by processing the Working XML File 31 assigned in the SPS with the XSLT stylesheets generated from the SPS.

The markup for the output is contained in the SPS. The data for the output is contained in the XML document or DB. It is the XSLT stylesheet that brings markup and data together in the output. Both the XSLT stylesheets as well as the actual output can be previewed in StyleVision in the Output Views 39.

Note: If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Altova website: & XML reporting

Output documents

Given below are important points to note about the generated documents:

• HTML output and stylesheets: (1) The formatting and layout of the generated HTML document will be identical to the HTML Preview of StyleVision and near-identical to the Authentic View of the XML document. (2) Data-input devices (text input fields, check boxes, etc) in the HTML file do not allow input. These data-input devices are intended for XML data input in Authentic View and, though they are translated unchanged into the graphical HTML equivalents, they cannot be used for data-entry in the HTML document.

Altova website: AML to HTML

- *RTF output and stylesheets:* (1) The RTF design requires specifications for paged media. You can provide these specifications (cover page design, left/right pagination, etc) in the <u>Properties sidebar</u> and the <u>Design Tree sidebar</u>. Note that the design specifications for paged media are used for RTF, PDF (XSL-FO), and Word 2007+ output. (2) If data-input devices have been used in the SPS, then, where possible, these are rendered as graphics on the RTF page. When a data-entry device cannot easily be simulated as a graphic (e.g. check boxes), a substitute presentation is used.
- **Text output and stylesheets:** Since the plain text format does not use formatting, style properties in the design are not passed to the text output.
- **PDF output and stylesheets for FO:** (1) To render a document to paged media requires some special specifications, such as for left/right pagination, the location and composition of headers and footers, the design of a cover page, etc. You can design these additional features for your document (using the Properties sidebar and Design Tree sidebar), and these are included in the XSLT stylesheet for XSL-FO. Note that these design specifications for paged media are used not only for PDF (XSL-FO) output, but also for RTF and Word 2007+. (2) If data-input devices have been used in the SPS, then,

Usage Overview Generated Files 117

where possible, these are rendered as graphics on the PDF page. When a data-entry device cannot easily be simulated as a graphic (e.g. check boxes), a substitute presentation is used.

Altova website:

XML to PDF

• Word 2007+ output and stylesheets: You can design paged media features, such as pagination, headers and footers, and a cover page using the <u>Properties sidebar</u> and <u>Design Tree sidebar</u> and these are included in the XSLT stylesheet for Word 2007+. Note that the design specifications for paged media are used not only for Word 2007+ output, but also for PDF (XSL-FO) and RTF output.

RTF output

RTF output is generated from your XML file in a single step by processing the XML document with the XSLT-for-RTF file generated from the SPS. The properties of the RTF output are defined in the SPS, and you can preview the output in the RTF Preview window. To obtain the RTF file, you must generate it (using <u>File | Save Generated Files</u> or <u>StyleVision Server</u>).

Note: If there is a problem with an embedded preview, StyleVision will attempt to open the preview document in an external application (usually MS Word or Adobe Reader). An error message about the embedded preview will appear in StyleVision. If the preview document is opened in an external application, you will need to close the external application before regenerating the temporary output document, otherwise you will get an error message saying the file is being used by another process. You should also close the external application before closing the SPS design, otherwise StyleVision will not be able to close the temporary output document due to the file lock placed on the document by the external application.

Text output

Since Text output generates plain text, note the following points:

- Style and page layout properties that are defined in the design will not be applied to the Text output.
- In order to generate Text output, the XSLT version selected for the SPS must be XSLT 2.0 or XSLT 3.0.

PDF output

Generating PDF output from your XML file is a two-step process:

- 1. An XSLT transformation is used to transform the XML file into an XSL-FO file (FO file). In the transformation process, page sequencing and page layout properties are added, so that the FO file contains this information in addition to the content.
- 2. The FO file is processed by an FO processor to generate the PDF.

The XSLT-for-FO and the PDF output can be previewed in the PDF Preview tab. The XSLT-for-FO, the FO document, and the PDF document can be generated using <u>File | Save Generated Files</u> or <u>StyleVision Server</u>. The FO document can also be generated using <u>RaptorXML</u> ⁸⁹⁷.

Note: If there is a problem with an embedded preview, StyleVision will attempt to open the preview document in an external application (usually MS Word or Adobe Reader). An error message about the embedded preview will appear in StyleVision. If the preview document is opened in an external application, you will need to close the external application before regenerating the temporary output document, otherwise you will get an error message saying the file is being used by another process. You should also close the external application before closing the SPS design, otherwise StyleVision will not be able to close the temporary output document due to the file lock placed on the document by the external application.

118 Usage Overview Generated Files

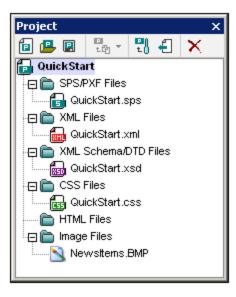

Word 2007+ output

Word 2007+ output is generated from your XML file in a single step by processing the XML document with the XSLT-for-Word 2007+ file generated from the SPS. The properties of the Word 2007+ output are defined in the SPS, and you can preview the output in the Word 2007+ Preview window. To obtain the Word 2007+ file, you must generate it (using <u>File | Save Generated Files</u> or <u>StyleVision Server</u>).

Note: If there is a problem with an embedded preview, StyleVision will attempt to open the preview document in an external application (usually MS Word or Adobe Reader). An error message about the embedded preview will appear in StyleVision. If the preview document is opened in an external application, you will need to close the external application before regenerating the temporary output document, otherwise you will get an error message saying the file is being used by another process. You should also close the external application before closing the SPS design, otherwise StyleVision will not be able to close the temporary output document due to the file lock placed on the document by the external application.

4.8 Projects in StyleVision

Files that are related to each other can be collected in a project in the Project sidebar (*screenshot below*). This enables the files in a project to be accessed easily when designing an SPS. For example, an SPS file can be dragged from the Project sidebar to the Design Tree sidebar and created there as a module; or an image file can be dropped into the design as a static image; or a CSS stylesheet can be dragged to the Style Repository sidebar as an external stylesheet.

Creating and saving a project

A new project is created using the **Project | Create Project** command. When it is created, a project contains separate folders for separate types (*see screenshot above*). File types are assigned to a folder via the folder's Properties dialog. A project is named when it is saved (with the extension .svp) for the first time. To subsequently change the name of a project, you change the project file's name at its location, using an application such as Windows File Explorer.

Project folders

Folders can be added both to the main project folder as well as to folders within the main project folder and to sub-folders down to an unlimited number of levels. Three types of folders can be added: (i) a project folder; (ii) an external folder (which is added by browsing and selecting); (iii) an external web folder (which is added via a URL). Each of these three folder types is added to the main project folder using the following Project commands, respectively: (i) Add Project Folder to Project; (ii) Add External Project Folder to Project; (iii) Add External Web Folder to Project. To add each of these folder types to a folder or sub-folder within the main project, select the relevant command from the context menu for that folder or sub-folder.

Each folder can be assigned one or more file types in its Properties dialog (*screenshot below*). To pop up the Properties dialog, right-click the folder for its context menu, and select **Properties**.

120 Usage Overview Projects in StyleVision

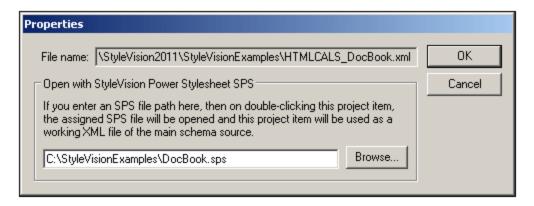

In the Properties dialog, you can edit the folder name and the file type extensions for that folder (each file type extension must be separated by a semi-colon). Project folder names can also be edited by selecting the folder in the Project sidebar, pressing **F2**, and editing the name. When a folder has file type extensions defined for it, files with that extension, when added using the **Add File to Project** command, are added to the folder. If more than one folder has the same file type extension defined, the file is added to the first folder in the Project sidebar having that extension. In the Project sidebar, folders can be reordered using drag-and-drop. However, on the first level (that is at the level immediately below the main project folder), folders are ordered as follows: (i) project folders; (ii) external folders; (iii) external web folders.

Project files

Files can be added both to the main project folder as well as to folders and sub-folders within the main project folder. Files can be added using the following commands in the Project menu:

- Add Files to Project: One or more files are selected in a Browse window for addition. Each of the
 added files goes into the first folder for which its file type extension has been defined.
- Add Global Resource to Project. A file is added via a global resource.
- Add URL to Project: A file is added via its URL (which is defined in the Add URL to Project dialog).
- Add Active File to Project. The active (SPS) file is added to the first folder in the Project sidebar that has .sps defined as its file type extension.
- Add Active and Related Files to Project: The active (SPS) file plus related files, such as the
 schema/s, Working XML Files, CSS files, static image files, etc, are added to the project, in their
 respective folders as determined by the file type extensions of the folders. This is a very useful
 command for quickly gathering into a project all the files relevant to a given design.
- **Properties**. When any project file is selected, clicking the **Properties** icon in the Project Window toolbar or selecting the Properties command from the context menu pops up a window that displays the location of the file. XML files additionally enable you to select an SPS with which the file can be associated (see screenshot below).

When an SPS file is associated with an XML file that is in a project, double-clicking that XML file in the Project window will open the associated SPS file with the XML file assigned as the Working XML File

of the SPS. This is useful if multiple XML files use a single SPS. This feature helps to speed up your work by cutting out the bother of browsing for the SPS file and/or Working XML File.

The commands listed above add files to the main project according to the file type extensions of the folders in the main project folder. To add files to specific folders or sub-folders, right-click the required folder, and in the context menu that pops up, select the corresponding command. Within a folder, files are listed in alphabetical order. Note files can also be dragged to another folder. To see the location of a file, click the **Properties** command in its context menu.

Global resources

A global resource of file- or folder-type can be added to a folder. A file-type global resource is an alias for a file resource. An alias can have multiple configurations with each configuration pointing to a file resource. So if a global resource is used in a project, it can link to any of the target resources, depending on which configuration is currently active in StyleVision. A folder-type global resource, similarly, is an alias that can target any one of multiple folders according to the configuration that is currently active. If a folder-type global resource is used in the design to identify a file (say, a Working XML File or CSS file), the folder-type global resource will identify a folder only; the path from that folder to the required file will need to be specified additionally. For more information on how to use global resources, see <u>Using Global Resources</u>

Drag-and-drop

In the Project sidebar, a folder can be dragged to another folder or to another location within the same folder. A file can be dragged to another folder, but cannot be moved within the same folder (within which files are arranged alphabetically). Additionally, files and folders can be dragged from Windows File Explorer to the Project sidebar.

Using projects

Files in a project can be used in various ways depending on what kind of file it is. For each file in the Project sidebar, the actions available are listed in its context menu (right-click to display). Additionally, dragging the file to a location where an action can be executed pops up a menu that contains the relevant command/s; in the case of some commands, the command is executed directly the file is dropped at the relevant location. Given below is a list of available actions for various file types.

SPS Files

- *Open Design* opens the SPS in a new design window. (This command also becomes available when you drag an SPS file from the Project sidebar into Design View.)
- Import as Module imports the SPS as a module in the currently active SPS; the imported file will be listed under the Modules heading in the Design Tree. (You can also import the file as a module by dragging it to the Modules heading in the Design Overview sidebar.)

XML Files

- Edit File in XMLSpy opens the XML file in XMLSpy.
- Create New Design creates a new SPS. The schema for the SPS is an XML Schema generated from the XML document. The Working XML File of the SPS is the XML file. (You can also drag the file into the Main Template bar of Design View to use this command.)
- Add as New Schema Source adds an XML Schema generated from the XML file as an additional schema source; the XML file is assigned as the Working XML File for this new schema source. (You can also drag the file to the Schema entry of the Design Overview sidebar to generate a schema and add the schema as a new schema source.)

122 Usage Overview Projects in StyleVision

Assign as Working XML File assigns the XML File as the Working XML File of the SPS. (You can also
drag the file to the Working XML entry of the Design Overview sidebar to add it as the Working XML
File.)

- Assign as Template XML File assigns the XML File as the Template XML File of the SPS. (You can
 also drag the file to the Template XML entry of the Design Overview sidebar to add it as the Template
 XML File.)
- **Note:** When an XML file is double-clicked, one of three actions will be executed according to what is specified in the Project tab of the Options dialog: (i) Edit file in XMLSpy; (ii) Create a new design based on the XML file; (iii) Ask the user which action to execute.

XML Schema / DTD Files

- Edit File in XMLSpy opens the schema file in XMLSpy.
- Create New Design creates a new SPS based on the selected schema. (You can also drag the file into the Main Template bar of Design View to create a new SPS with the selected schema as the schema source.)
- Add as New Schema Source adds an XML Schema generated from the XML file as an additional schema source; the XML file is assigned as the Working XML File for this new schema source. (You can also drag the file to the Schema entry of the Design Overview sidebar to create an additional schema source.)
- Assign as Schema File assigns the selected schema as the schema source of the currently active SPS, replacing the current schema source. This command is most useful for quickly changing schemas, for example, if the schema location has changed or to correct a wrong assignment. (To use this command, you can also drag the file to the Schema entry of the Design Overview sidebar.)
- **Note:** When a schema file is double-clicked, one of three actions will be executed according to what is specified in the Project tab of the Options dialog: (i) Edit file in XMLSpy; (ii) Create a new design based on the schema file; (iii) Ask the user which action to execute.

CSS Files

- Edit File in XMLSpy opens the CSS file in XMLSpy.
- Import into Style Repository adds the CSS file to the External CSS files of the Style Repository (External heading in the Styles Repository sidebar). (You can also drag the file to the External heading in the Styles Repository sidebar to import the file into the style repository.)

HTML Files

- Edit File in XMLSpy opens the HTML file in XMLSpy.
- Open opens the HTML file in the default browser.
- Create New Design creates a new SPS, in which you can create the schema based on the HTML document. (You can also drag the file into Design View to use this command.)

Image Files

- When you hover over an image file that has been placed in a project folder, a preview of the image is displayed (.png, .jpeg, .gif, .bmp, .tiff, and .ico formats). Double-click the image to open it in the system's default image viewer/editor application.
- The context menu command *Open* opens the image file in the default image viewer/editing application.
- The context menu command *Insert Image in Design* inserts the image as a static image in the SPS. (You can also insert the image at a particular location by dragging it there.)

All file types

• Explore Containing Folder opens a Windows File Explorer window displaying the contents of the folder in which the selected file is located.

- Cut, Copy, Paste, Delete commands work in the standard Windows way, cutting and copying the selected file to the clipboard; pasting files from the clipboard; and deleting. These commands also work for a selection of multiple files.
- Select All selects all the files in the project.
- Properties pops up the Properties dialog, in which the location of the file is given.

Find in project

You can search for project files and folders using their names or a part of their name. If the search is successful, files or folders that are located are highlighted one by one.

To start a search, select the project folder in the Project sidebar that you wish to search, then select the command **Edit | Find** (or the shortcut **Ctrl+F**). In the Find dialog that pops up (*screenshot below*) enter the text string you wish to search for and select or deselect the search options (*explained below*) according to your requirements.

The following search options are available:

- Whole-word matching is more restricted since the entire string must match an entire word in the file or folder name. In file names, the parts before and after the dot (without the dot) are also each treated as a word.
- It can be specified that casing in the search string must exactly match the text string in the file or folder name.
- Folder names can be included in the search. Otherwise, only file names are searched.
- External folders (991) can be included or excluded from the search. External folders are actual folders on the system or network, as opposed to project folders, which are created within the project and not on the system.

If the search is successful, the first matching item is highlighted in the Project sidebar. You can then browse through all the returned matching items by clicking the **Find Next** and **Find Prev** buttons in the Find dialog.

4.9 Catalogs in StyleVision

The XML catalog mechanism enables files to be retrieved from local folders, thus increasing the overall processing speed, as well as improving the portability of documents—since only the catalog file URIs then need to be changed. See the section How Catalogs Work for details.

Altova's XML products use a catalog mechanism to quickly access and load commonly used files, such as DTDs and XML Schemas. This catalog mechanism can be customized and extended by the user, and it is described in the sections Catalog Structure in StyleVision and Customizing your Catalogs Tables for Windows System Locations (128) list Windows variables for common system locations. These variables can be used in catalog files to locate commonly used folders.

This section is organized into the following sub-sections:

- How Catalogs Work 124
- Catalog Structure in StyleVision 125
- Customizing your Catalogs 126
- Variables for Windows System Locations 128

For more information on catalogs, see the XML Catalogs specification.

4.9.1 How Catalogs Work

Catalogs can be used to redirect both DTDs and XML Schemas. While the concept behind the mechanisms of both cases is the same, the details are different and are explained below.

DTDs

Catalogs are commonly used to redirect a call to a DTD to a local URI. This is achieved by mapping, in the catalog file, public or system identifiers to the required local URI. So when the **DOCTYPE** declaration in an XML file is read, its public or system identifier locates the required local resource via the catalog file mapping.

For popular schemas, the PUBLIC identifier is usually pre-defined, thus requiring only that the URI in the catalog file map the PUBLIC identifier to the correct local copy. When the XML document is parsed, the PUBLIC identifier in it is read. If this identifier is found in a catalog file, then the corresponding URL in the catalog file will be looked up and the schema will be read from this location. So, for example, if the following SVG file is opened in StyleVision:

The catalog is searched for the PUBLIC identifier of this SVG file. Let's say the catalog file contains the following entry:

In this case, there is a match for the PUBLIC identifier. As a result, the lookup for the SVG DTD is redirected to the URL schemas/svg/svg11.dtd (which is relative to the catalog file). This is a local file that will be used as the DTD for the SVG file. If there is no mapping for the Public ID in the catalog, then the URL in the XML document will be used (in the SVG file example above, this is the Internet URL: http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd).

XMI Schemas

In StyleVision, you can also use catalogs with **XML Schemas**. In the XML instance file, the reference to the schema will occur in the xsi:schemaLocation attribute of the XML document's top-level element. For example,

```
xsi:schemaLocation="http://www.xmlspy.com/schemas/orgchart OrgChart.xsd"
```

The value of the xsi:schemaLocation attribute has two parts: a namespace part (green above) and a URI part (highlighted). The namespace part is used in the catalog to map to the alternative resource. For example, the following catalog entry redirects the schema reference above to a schema at an alternative location.

```
<uri name="http://www.xmlspy.com/schemas/orgchart" uri="C:\MySchemas\OrgChart.xsd"/>
```

Normally, the URI part of the xsi:schemaLocation attribute's value is a path to the actual schema location. However, if the schema is referenced via a catalog, the URI part need not point to an actual XML Schema but must exist so that the lexical validity of the xsi:schemaLocation attribute is maintained. A value of foo, for example, would be sufficient for the URI part of the attribute's value to be valid.

4.9.2 Catalog Structure in StyleVision

When StyleVision starts, it loads a file called <code>RootCatalog.xml</code> (structure shown in listing below), which contains a list of catalog files that will be looked up. You can modify this file and enter as many catalog files to look up as you like, each of which is referenced in a <code>nextCatalog</code> element. These catalog files are looked up and the URIs in them are resolved according to their mappings.

Listing of RootCatalog.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog"
    xmlns:spy="http://www.altova.com/catalog_ext"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="urn:oasis:names:tc:entity:xmlns:xml:catalog Catalog.xsd">
    <nextCatalog catalog="%PersonalFolder%/Altova/%AppAndVersionName%/CustomCatalog.xml"/>
    <!-- Include all catalogs under common schemas folder on the first directory level -->
    <nextCatalog spy:recurseFrom="%CommonSchemasFolder%" catalog="catalog.xml"
spy:depth="1"/>
```

```
<nextCatalog spy:recurseFrom="%ApplicationWritableDataFolder%/pkgs/.cache"
catalog="remapping.xml" spy:depth="0"/>
    <nextCatalog catalog="CoreCatalog.xml"/>
    </catalog>
```

The listing above references a custom catalog (named CustomCatalog.xml) and a set of catalogs that locate commonly used schemas (such as W3C XML Schemas and the SVG schema).

- CustomCatalog.xml is located in your Personal Folder (located via the variable %PersonalFolder%). It is a skeleton file in which you can create your own mappings. You can add mappings to CustomCatalog.xml for any schema you require that is not addressed by the catalog files in the Common Schemas Folder. Do this by using the supported elements of the OASIS catalog mechanism (see next section).
- The Common Schemas Folder (located via the variable %commonSchemasFolder%) contains a set of commonly used schemas. Inside each of these schema folders is a catalog.xml file that maps public and/or system identifiers to URIs that point to locally saved copies of the respective schemas.
- Schemas related to XBRL and various XBRL taxonomies are large and are installed locally on demand with the help of Altova's Taxonomy Manager. Individual schemas and taxonomies are mapped in the catalog remapping.xml, which is located in the pkgs/.cache subfolder of the Program Data Folder (located via the variable %ApplicationWritableDatFolder%). Please do not edit this file; the smallest error could seriously compromise large sets of references.
- CoreCatalog.xml is located in the StyleVision application folder, and is used to locate schemas and stylesheets used by StyleVision-specific processes, such as StyleVision Power Stylesheets which are stylesheets used to generate Altova's Authentic View of XML documents.

Location variables

The variables that are used in RootCatalog.xml (listing above) have the following values:

%PersonalFolder%	Personal folder of the current user, for example C: \Users\ <name>\Documents</name>
%CommonSchemasFolder%	C:\ProgramData\Altova\Common2025\Schemas
% ApplicationWritableDataFolde r%	C:\ProgramData\Altova

Location of catalog files and schemas

Note the locations of the various catalog files.

- RootCatalog.xml and CoreCatalog.xml are in the StyleVision application folder.
- CustomCatalog.xml is located in Your MyDocuments\Altova\StyleVision folder.
- The catalog.xml files are each in a specific schema folder, these schema folders being inside the Common Schemas Folder.

4.9.3 Customizing Your Catalogs

When creating entries in CustomCatalog.xml (or any other catalog file that is to be read by StyleVision), use only the following elements of the OASIS catalog specification. Each of the elements below is listed with an explanation of their attribute values. For a more detailed explanation, see the XML Catalogs specification. Note

that each element can take the xml:base attribute, which is used to specify the base URI of that element.

```
    <public publicId="PublicID of Resource" uri="URL of local file"/>
    <system systemId="SystemID of Resource" uri="URL of local file"/>
    <uri name="filename" uri="URL of file identified by filename"/>
    <rewriteURI uriStartString="StartString of URI to rewrite" rewritePrefix="String to replace StartString"/>
    <rewriteSystem systemIdStartString="StartString of SystemID" rewritePrefix="Replacement string to locate resource locally"/>
```

Note the following points:

- In cases where there is no public identifier, as with most stylesheets, the system identifier can be directly mapped to a URL via the system element.
- A URI can be mapped to another URI using the uri element.
- The rewriteURI and rewriteSystem elements enable the rewriting of the starting part of a URI or system identifier, respectively. This allows the start of a filepath to be replaced and consequently enables the targeting of another directory. For more information on these elements, see the XML Catalogs specification.

From release 2014 onwards, StyleVision adheres closely to the XML Catalogs specification (OASIS Standard V1.1, 7 October 2005) specification. This specification strictly separates external-identifier look-ups (those with a Public ID or System ID) from URI look-ups (URIs that are not Public IDs or System IDs). Namespace URIs must therefore be considered simply URIs—not Public IDs or System IDs—and must be used as URI look-ups rather than external-identifier look-ups. In StyleVision versions prior to version 2014, schema namespace URIs were translated through public> mappings. From version 2014 onwards, <ur>

```
Prior to V2014: <public publicID="http://www.MyMapping.com/ref"
    uri="file:///C:/MyDocs/Catalog/test.xsd"/>
V-2014 onwards: <uri name="http://www.MyMapping.com/ref"
    uri="file:///C:/MyDocs/Catalog/test.xsd"/>
```

How StyleVision finds a referenced schema

A schema is referenced in an XML document via the xsi:scemaLocation attribute (shown below). The value of the xsi:schemaLocation attribute has two parts: a namespace part (green) and a URI part (highlighted).

```
xsi:schemaLocation="http://www.xmlspy.com/schemas/orgchart OrgChart.xsd"
```

Given below are the steps, followed sequentially by StyleVision, to find a referenced schema. The schema is loaded at the first successful step.

- 1. Look up the catalog for the URI part of the xsi:schemaLocation value. If a mapping is found, including in rewriteURI mappings, use the resulting URI for schema loading.
- 2. Look up the catalog for the namespace part of the xsi:schemaLocation value. If a mapping is found, including in rewriteURI mappings, use the resulting URI for schema loading.
- 3. Use the URI part of the xsi:schemaLocation value for schema loading.

XML Schema specifications

XML Schema specification information is built into StyleVision and the validity of XML Schema (.xsd) documents is checked against this internal information. In an XML Schema document, therefore, no references

should be made to any schema that defines the XML Schema specification.

The catalog.xml file in the %AltovaCommonSchemasFolder%\Schemas\schema folder contains references to DTDs that implement older XML Schema specifications. You should not validate your XML Schema documents against these schemas. The referenced files are included solely to provide StyleVision with entry helper info for editing purposes should you wish to create documents according to these older recommendations.

4.9.4 Variables for Windows System Locations

Shell environment variables can be used in the <code>nextCatalog</code> element to specify the path to various system locations (see RootCatalog.xml listing above). The following shell environment variables are supported:

%PersonalFolder%	Full path to the Personal folder of the current user, for example C: \Users\ <name>\Documents</name>	
%CommonSchemasFolder %	C:\ProgramData\Altova\Common2025\Schemas	
<pre>% ApplicationWritableD ataFolder%</pre>	C:\ProgramData\Altova	
%AltovaCommonFolder%	C:\Program Files\Altova\Common2025	
%DesktopFolder%	Full path to the Desktop folder of the current user.	
%ProgramMenuFolder%	Full path to the Program Menu folder of the current user.	
%StartMenuFolder%	Full path to Start Menu folder of the current user.	
%StartUpFolder%	Full path to Start Up folder of the current user.	
%TemplateFolder%	Full path to the Template folder of the current user.	
%AdminToolsFolder%	Full path to the file system directory that stores administrative tools of the current user.	
%AppDataFolder%	Full path to the Application Data folder of the current user.	
<pre>%CommonAppDataFolder %</pre>	Full path to the file directory containing application data of all users.	
%FavoritesFolder%	Full path of the Favorites folder of the current user.	
%PersonalFolder%	Full path to the Personal folder of the current user.	
%SendToFolder%	Full path to the SendTo folder of the current user.	
%FontsFolder%	Full path to the System Fonts folder.	
%ProgramFilesFolder%	Full path to the Program Files folder of the current user.	
%CommonFilesFolder%	Full path to the Common Files folder of the current user.	

Full path to the Windows folder of the current user.

%WindowsFolder%

%SystemFolder% Full path to the System folder of the current user.

Full path to the file system directory that serves as the data repository for local

%LocalAppDataFolder% (nonroaming) applications.

%MyPicturesFolder% Full path to the MyPictures folder.

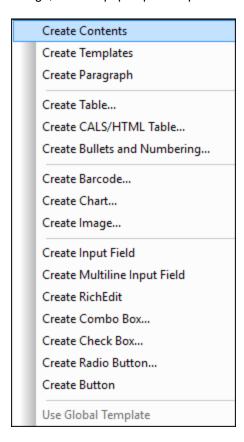

5 SPS Content

This section describes in detail the core procedures used to create and edit SPS document components that are used to create locations in the document design for XML data content. The procedures are listed below and described in detail in the sub-sections of this section. These mechanisms are used to design any kind of template: main 344, global 345, or named 356.

- <u>Inserting XML Content as Text</u> (33). XML data can be inserted in the design by dragging the relevant nodes (element, attribute, type, or CDATA) into the design and creating them as (contents) or (rest-of-contents).
- Inserting MS Word Content 138
- <u>User-Defined Templates</u> 143
- User-Defined Elements, XML Text Blocks 146
- Working with Tables (149). Tables can be inserted by (i) the SPS designer, directly in the SPS design (static tables) or using XML document sub-structures, and (ii) the Authentic View user.
- <u>Creating Lists</u> 1711. Static lists, where the list structure is entered in the SPS design, and dynamic lists, where an XML document sub-structure is created as a list, provide powerful data-ordering capabilities.
- <u>Using Graphics</u> ¹⁷⁶: Graphics can be inserted in the SPS design using a variety of methods to determine the target URI (static, dynamic, a combination of both, and unparsed entity URIs).
- Charts 182
- <u>Using Data-Entry Devices (or Form Controls)</u> 285. XML data can be input by the Authentic View user via data-entry devices such as input fields and combo boxes. This provides a layer of user help as well as of input constraints. Individual nodes in the XML document can be created as data-entry devices.
- Links 273
- Barcodes 274
- Layout Modules 278
- <u>The Change-To Feature</u> . This feature enables a different node to be selected as the match for a template and allows a node to be changed to another content type.

5.1 Inserting XML Content as Text

Data from a node in the XML document is included in the design by dragging the corresponding schema node from the Schema Tree window and dropping it into the design. When the schema node is dropped into the design, a menu pops up with options for how the node is to be created in the design (*screenshot below*).

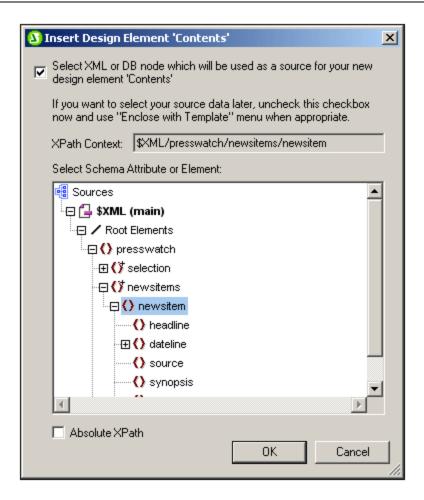

Types of schema nodes

Schema nodes that can be dropped from the Schema Tree sidebar into the design are of three types: (i) element nodes; (ii) attribute nodes; and (iii) datatype nodes.

Using the Insert Contents toolbar icon

The **Insert Contents** icon in the <u>Insert Design Elements toolbar</u> also enables you to insert the contents of a node in the design. Insert contents as follows:

- 1. Select the Insert Contents icon.
- 2. Click the location in the design where you wish to insert contents. The Insert Contents Selector pops up (screenshot below).

- 3. The context of the insertion location in the design is displayed in the *XPath Context* field. Select the node for which you wish to create contents.
- 4. Click **OK**. The contents placeholder is created. If the node you selected is anything other than the context node, additional template tags with the path to the selected node will be created around the contents placeholder.

Outputting text content of nodes

To output the text contents of the node, the node should be created as contents. When a node is created as contents, the node will look something like this in the design document:

In the screenshot above, the <code>Desc</code> element has been created as contents. The output will display the text content of <code>Desc</code>. If <code>Desc</code> has descendant elements, such as <code>Bold</code> and <code>Italic</code>, then the text content of the descendant elements will also be output as part of the contents of <code>Desc</code>. Note that attribute nodes of <code>Desc</code> are not considered its child nodes, and the contents of the attribute nodes will therefore not be output as part of the contents of <code>Desc</code>. Attribute nodes have to be explicitly inserted in order to be processed.

CDATA sections

If CDATA sections are present in the XML document they will be output, and in Authentic View, are indicated with tags when markup is switched on (using the menu command <u>Authentic | Markup (1045</u>). CDATA sections can also be inserted in the XML document when editing the document in Authentic View (via the context menu).

Note: In Authentic View, CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). They can only be entered within elements that are displayed in Authentic View as text content components.

In this section

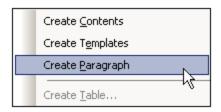

In the sub-sections of this section, we describe other aspects of inserting XML content as text:

- How the text content of a node can be <u>marked up with a predefined format directly</u> when the node is inserted.
- How the structure of the source schema determines the effect of Authentic View usage (134).
- How descendant nodes not explicitly included within a node can be included for processing. See Restof-Contents 139.

Note: You can create an **empty template rule** by deleting the (content) placeholder of a node. An empty template rule is useful if you wish to define that some node not be processed, i.e. produce no output.

5.1.1 Inserting Content with a Predefined Format

The text content of a node can be directly inserted with the markup of one of StyleVision's predefined formats. To do this, drag the node from the Schema Tree window and drop it at the desired location. In the menu that pops up, select **Create Paragraph** (*screenshot below*).

The predefined format can be changed by selecting the predefined format tag and then choosing some other predefined format from the <u>Format combo box in the toolbar</u> (screenshot below) or using the menu command **Insert | Format**.

The predefined format can also be changed by changing the value of the paragraph type property of the paragraph group of properties in the Properties window, or by changing the paragraph type via the node-template's context menu command. SEZ Enclose With | Special Paragraph SEZ.

Each paragraph type has particular formatting features that can be used to advantage. Note that the pre format type enables carriage returns and linefeeds to be output as such instead of them being normalized to whitespace.

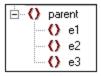

5.1.2 Adding Elements in Authentic View

When creating elements in the design, the way you create the elements determines how Authentic View will respond to user actions like pressing the Tab key and clicking the Add... prompt. The basic issue is what elements are created in Authentic View when an element is added by the user. For example, when the user adds an element (say, by clicking the **Insert Element** icon in the Elements sidebar), what child elements are created automatically?

The most important point to bear in mind is that Authentic View follows the structure specified in the underlying schema. In order to ensure that Authentic View implements the schema structure correctly there are a few design rules you should keep in mind. These are explained below.

Unambiguous content model

A content model is considered unambiguous when it consists of a single sequence (with maxoccurs=1) of child elements (with no choices, groups, substitutions, etc). In such cases, when the element is added, the sequence of child elements is unambiguously known, and they are automatically added. In the screenshot example below, the three child elements are all mandatory and can occur only once.

When the element parent is added in Authentic View, its child elements are automatically inserted (screenshot below). Pressing the tab key takes you to the next element in the sequence.

If the e2 element were optional, then, when the element parent is added in Authentic View, the elements e1 and e3 are automatically inserted, and the element e2 appears in the Elements sidebar so that it can be inserted if desired (*screenshot below*). Pressing the tab key in e1 takes the user to e3.

The above content model scenario is the only scenario Authentic View considers unambiguous. All other cases are considered ambiguous, and in order for Authentic View to disambiguate and efficiently display the desired elements the design must adhere to a few simple rules. These are explained below.

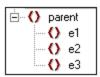

Ambiguous content model

For Authentic View to correctly and efficiently display elements while an XML document is being edited, the SPS must adhere to the following rules.

- Child elements will be displayed in the order in which they are laid out in the design.
- In order for Authentic View to disambiguate among sibling child elements, all child elements should be laid out in the design document in the required order **and within a single parent node**. If the sibling relationship is to be maintained in Authentic View, it is incorrect usage to lay out each child element of a single parent inside multiple instances of the parent node.

These two rules are illustrated with the following example.

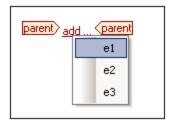

We consider a content model of an element parent, which consists of a single sequence of mandatory child elements. This content model is similar to the unambiguous content model discussed above, with one difference: the single sequence is optional, which makes the content model ambiguous—because the presence of the sequence is not a certainty. If you create a design document as shown in the screenshot below, there will be ambiguity in Authentic View.

The Authentic View of the parent element will look like this (since the sequence is optional):

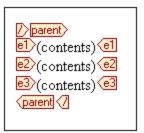

Clicking add... pops up a menu of the three child elements:

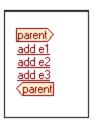

If you select one of these elements, it will be inserted (*screenshot below*), but since Authentic View cannot disambiguate the sequence it does not insert any of the remaining two elements, nor does it offer you the opportunity of inserting them:

The **correct** way to design this content model (following the rules given above) would be to explicitly create the required nodes in the desired order within the single parent node. The design document would look like this:

Note that all three child elements are placed **inside a single parent node**. The design shown above would produce the following Authentic View:

The Authentic View user clicks the respective add element prompt to insert the element and its content.

Note:

- If an element can occur multiple times, and if the rules above are followed, then the element appears in the sidebar till the number of occurrences in Authentic View equals the maximum number of occurrences allowed by the schema (maxOccurs).
- Creating each child element inside a separate parent node (see screenshot below) not only creates isolated child–parent relationships for each child element so instantiated; it also increases processing time because the parent node has to be re-traversed in order to locate each child element.

```
parent e1 (contents) e1 (parent parent) e2 (contents) e2 (parent parent) e3 (contents) e3 (parent parent) e3
```

5.1.3 Rest-of-Contents

The rest-of-contents placeholder applies templates to all the remaining child elements of the element for which the template has been created. As an example consider the following:

• An element parent has 4 child elements, child1 to child4.

• In the template for element parent, some processing has been explicitly defined for the child1 and child4 child elements.

This results in only the <code>child1</code> and <code>child4</code> child elements being processed. The elements <code>child2</code> and <code>child3</code> will not be processed. Now, if the <code>rest-of-contents</code> placeholder is inserted within the template for <code>parent</code>, then, not only will <code>child1</code> and <code>child4</code> be processed using the explicitly defined processing rules in the template. Additionally, templates will be applied for the <code>child2</code> and <code>child3</code> child elements. If <code>global templates</code> for these are defined then the global templates will be used. Otherwise the built-in default templates (for element, attribute, and text nodes) will be applied.

Important: It is important to note what nodes are selected for rest-of-contents.

- As described with the example above, all child element nodes and child text nodes are selected by the rest-of-contents placeholder. (Even invalid child nodes in the XML document will be processed.)
- Attribute nodes are not selected; they are not child nodes, that is, they are not on the child axis of XPath.
- If a global template of a child element is used in the parent template, then the child element does not count as having been used locally. As a result, the rest-of-contents placeholder will also select such child elements. However, if a global template of a child element is "copied locally", then this usage counts as local usage, and the child element will not be selected by the rest-of-contents placeholder.

Note: You can create an **empty template rule** by deleting the (content) placeholder of a node. An empty template rule is useful if you wish to define that some node not be processed, i.e. produce no output.

5.2 Inserting MS Word Content

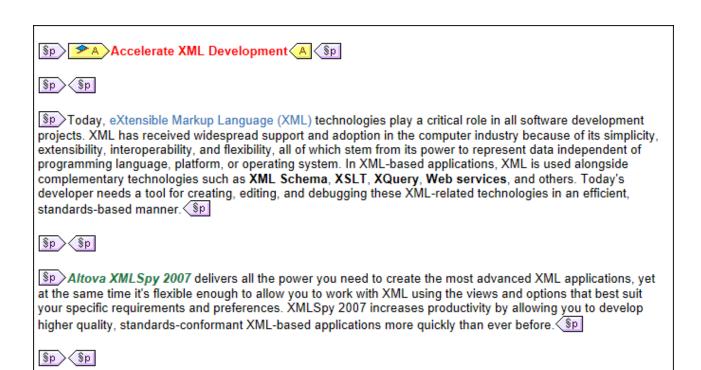

If Microsoft Word 2007+ is installed on your machine, then content can be pasted from Word documents into the design as **static content**. The Word content will be inserted within suitably corresponding design components, and text formatting properties will be carried over from the Word content. For example, text content that is in a Word paragraph block will be inserted within a <u>Paragraph component</u> (133), and the formatting of the text will be preserved (*see screenshots below*).

Accelerate XML Development

Today, eXtensible Markup Language (XML) technologies play a critical role in all software development projects. XML has received widespread support and adoption in the computer industry because of its simplicity, extensibility, interoperability, and flexibility, all of which stem from its power to represent data independent of programming language, platform, or operating system. In XML-based applications, XML is used alongside complementary technologies such as XML Schema, XSLT, XQuery, Web services, and others. Today's developer needs a tool for creating, editing, and debugging these XML-related technologies in an efficient, standards-based manner.

Altova XMLSpy 2007 delivers all the power you need to create the most advanced XML applications, yet at the same time it's flexible enough to allow you to work with XML using the views and options that best suit your specific requirements and preferences. XMLSpy 2007 increases productivity by allowing you to develop higher quality, standards-conformant XML-based applications more quickly than ever before.

Word content.

Word content pasted into a design. A suitable paragraph format has been applied and text formatting has been preserved.

Note: In addition to Word content, *any content that can be pasted into a Word document* can also be pasted into a StyleVision design. This includes **MS Excel tables** and **HTML page content**.

Note: To create an SPS that contains static content from an entire Word document, create a new SPS with the File | New | New from Word 2007+ 949 command.

Supported Word features

The following Word structures and formats are supported when Word content is copy-pasted into a design:

- Formatted text
 - o Different fonts, size, weights, style, text-decoration, etc.
 - o Color
 - o Background color
 - Border around text
- Paragraphs
- Page breaks
- Horizontal line
- Hyperlinks
- Bookmarks
- Tables
 - o Rowspans, colspans
 - Formatted/rich content
 - Nested tables
 - o Headers, footers

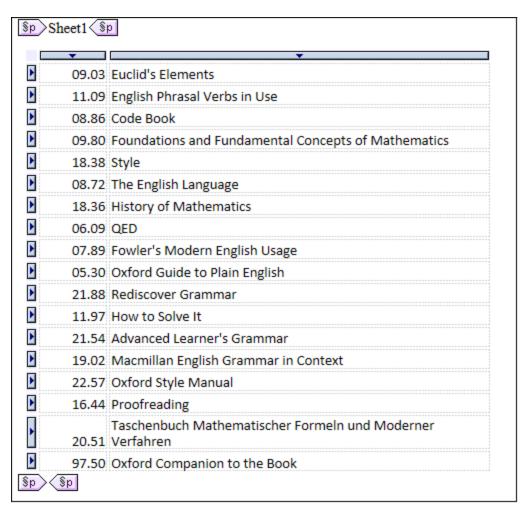

- Lists, sublists
 - o Bulletted: different styles
 - o Enumerated: different styles
- Images

5.3 Inserting MS Excel Content

If Microsoft Excel 2007+ is installed on your machine, then content can be pasted from Excel documents into the design as **static content**. The Excel content will be inserted as static tables and other suitably corresponding design components. Formatting properties will be preserved (*see screenshots below*). Each Excel sheet is inserted as a separate static table.

\square	Α	В	
1	09.03	Euclid's Elements	
2	11.09	English Phrasal Verbs in Use	
3	08.86	Code Book	
4	09.80	Foundations and Fundamental Concepts of Mathematics	
5	18.38	Style	
6	08.72	The English Language	
7	18.36	History of Mathematics	
8	06.09	QED	
9	07.89	Fowler's Modern English Usage	
10	05.30	Oxford Guide to Plain English	
11	21.88	Rediscover Grammar	
12	11.97	How to Solve It	
13	21.54	Advanced Learner's Grammar	
14	19.02	Macmillan English Grammar in Context	
15	22.57	Oxford Style Manual	
16	16.44	Proofreading	
17	20.51	Taschenbuch Mathematischer Formeln und Moderner Verfahren	
18	97.50	Oxford Companion to the Book	

Excel sheet.

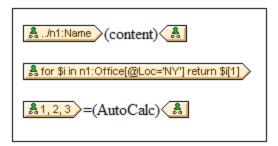

Excel content imported into a design as a static table with text formatting preserved.

Note: In addition to Excel content, *any content that can be pasted into an Excel document* can also be pasted into a StyleVision design. This includes **MS Word content** and **HTML page content**.

Note: To create an SPS that contains static content from an entire Excel document, create a new SPS with the File | New | New from Excel 2007+ 946 command.

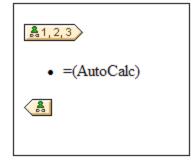

5.4 **User-Defined Templates**

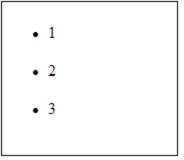

User-Defined Templates are templates for items generated by an XPath expression you specify. These items may be atomic values or nodes. In the screenshot below, which shows three User-Defined Templates, note the User-Defined Template icon on the left-hand side of the tags (a green person symbol). User-Defined Templates are very useful because they provide extraordinary flexibility for creating templates. Note, however, that content generated by User-Defined Templates cannot be edited in Authentic View.

The XPath expression of each of the three User-Defined templates shown in the screenshot above do the following:

- Selects a node in a source schema. By using an XPath expression, any node in any of the schema sources can be reached from within any context node. If StyleVision can unambiguously target the specified node, the template will be changed automatically from a User-Defined Template to a normal template, enabling Authentic View editing. If it is a User-Defined Template, this will be indicated by the green User-Defined Template icon on the left-hand side of the template tags.
- Selects a node that fulfills a condition specified by the for construct of XPath 2.0 and XPath 3.0. Such templates can never resolve to normal templates (but will remain User-Defined Templates) because the for construct does not allow StyleVision to unambiguously resolve the target from only the schema information it currently has at its disposal.
- Selects a sequence of atomic values {1, 2, 3}. While it is allowed to create a template for an atomic value, you cannot use the contents placeholder within such a template. This is because the xsl:apply-templates instruction (which is what the contents placeholder generates) can only be applied to node items (not atomic values). You could, however, use an Auto-Calculation in combination with some design element such as a list. For example, the User-Defined Template at left would generate the output at right.

Note: If the SPS uses XSLT 1.0, then the XPath expression you enter must return a node-set. Otherwise an error is reported.

Advantage of using XPath to select template node

The advantage of selecting a schema node via an XPath expression (User-Defined Templates) is that the power of XPath's path selector mechanism can be used to select any node or sequence of items, as well as to filter or set conditions for the node selection. As a result, specific XML document nodes can be targeted for any given template. For instance, the XPath expression //Office/Department [@Location="NY"] will select only those Department nodes that have a Location attribute with a value of NY. Also see the other examples in this section.

Note: If an XPath expression contains multiple location path steps, then it is significant—especially for grouping and sorting—whether brackets are placed around the multiple location path steps or not. For example, the XPath expression /org/office/Dept will be processed differently than (/org/office/Dept). For the former expression (without brackets), the processor loops through each location step. For the latter expression (with brackets), all the Dept elements of all Office elements are returned in one undifferentiated nodeset.

Brackets	Underlying XSLT Mechanism	Effect
No	<pre><xsl:for-each select="Org"> <xsl:for-each select="Office"> <xsl:for-each select="Dept"></xsl:for-each></xsl:for-each></xsl:for-each></pre>	Each Office element has its own Dept population. So grouping and sorting can be done within each Office.
Yes	<pre><xsl:for-each select="/Org/Office/Dept"> </xsl:for-each></pre>	The Dept population extends over all Office elements and across Org.

This difference in evaluating XPath expressions can be significant for grouping and sorting.

Inserting a User-Defined Template

To insert a User-Defined Template, do the following:

- 1. Click the Insert User-Defined Template icon in the Insert Design Elements toolbar and then click the design location where you wish to insert the template. Alternatively, right-click the design location where you wish to insert the template and, from the context menu that appears, select the **Insert** User-Defined Template command.
- 2. In the Edit XPath Expression 917 dialog that pops up, enter the XPath expression you want, and click **OK**. Note that the context node of the XPath expression will be the node within which you have clicked. An empty node template will be created. Sometimes a joined node is created. When a node is joined, the targeted instance nodes are selected as if at a single level, whereas if a node is not joined (that is if it is split into multiple hierarchic levels), then the node selection is done by looping through each instance node at every split level. The nodeset returned in both cases of selection (joined and split) is the same unless a grouping or sorting criterion is specified. For a discussion of the effect joined nodes have on the grouping and sorting mechanisms, see Node-Template Operations 352.

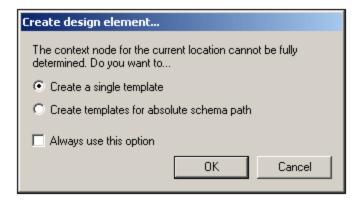

Editing a Template Match

The node selection of any node template (user-defined or normal) can be changed by using an XPath

expression to select the new match expression. To edit the template match of a node template, right-click the node template, then select the **Edit Template Match** command. This pops up the Edit XPath Expression dialog, in which you enter the XPath expression to select the new node. Then click **OK**.

Adding nodes to User-Defined Templates

If a node from the schema tree is added to a User-Defined Template, the context for the new node will not be known if the User-Defined Template has been created for a node or sequence that cannot be placed in the context of the schema source of the SPS. You will therefore be prompted (*screenshot below*) about how the new node should be referenced: (i) by its name (essentially, a relative path), or (ii) by a full path from the root of the schema source.

Prompting for advice on how to proceed is the default behavior. This default behavior can be changed in the Design tab of the Tool | Options dialog (103).

5.5 User-Defined Elements, XML Text Blocks

<u>User-Defined Elements</u> and <u>User-Defined XML Text Blocks</u> enable, respectively, (i) any element, and (ii) any XML text block to be inserted into the design. The advantage of these features is that designers are not restricted to adding XML elements and design elements from source schemas and the palette of StyleVision design elements. They can create (i) templates for elements they define (User-Defined Elements), and (ii) independent and self-contained XML code (User-Defined Blocks) that creates objects independently (for example ActiveX objects).

There is one important difference between User-Defined Elements and User-Defined XML Text Blocks. A User-Defined Element is created in the design as a template node for a single XML element (with attributes). All content of this template must be explicitly created. This content consists of the various design elements available to the SPS. A User-Defined XML Text Block may not contain any design element; it is an independent, self-contained block. Since a User-Defined Element is created empty, it does not lend itself for the creation of an object requiring a number of lines of code. For the latter purpose, User-Defined XML Text Blocks should be used.

Note: User-Defined Elements and User-Defined Text Blocks are supported in Authentic View only in the Enterprise Editions of Altova products.

5.5.1 User-Defined Elements

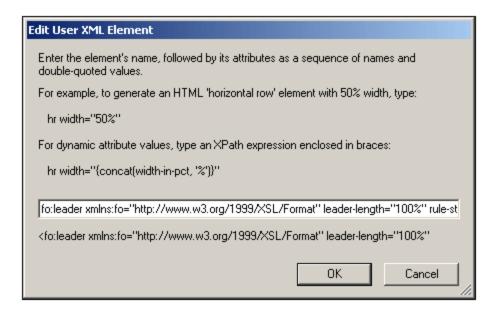

User-Defined Elements are elements that you can generate in the output without these elements needing to be in any of the schema sources of the SPS. This means that an element from any namespace (HTML or XSL-FO for example) can be inserted at any location in the design. SPS design elements can then be inserted within the inserted element.

Note: User-Defined Elements are supported in Authentic View only in the Enterprise Editions of Altova products.

Inserting User-Defined Elements

The mechanism for using User-Defined Elements is as follows:

- 1. Right-click at the location in the design where you wish to insert the User-Defined Element.
- 2. From the context menu that appears, select Insert User-Defined Item | User-Defined Element.
- 3. In the dialog that appears (*screenshot below*), enter the element name, the desired attribute-value pairs, and, a namespace declaration for the element if the document does not contain one.

In the screenshot above an XSL-FO element called <code>leader</code> is created. It has been given a prefix of <code>fo:</code>, which is bound to the namespace declaration <code>xmlns:fo="http://www.w3.org/1999/XSL/Format"</code>. The element has a number of attributes, including <code>leader-length</code> and <code>rule-style</code>, each with its respective value. The element, its attributes, and its namespace declaration must be entered without the angular tag brackets.

4. Click **OK** to insert the element in the design. The element is displayed in the design as an empty template with start and end tags (*screenshot below*).

5. You can now add content to the template as for any other template. The User-Defined Element may contain static content, dynamic content from the XML document, as well as more additional User-Defined Elements.

Note: A User-Defined Element that is intended for a particular output should be enclosed in a suitable output-based condition so as to avoid unexpected results in alternative outputs.

5.5.2 User-Defined XML Text Blocks

A User-Defined XML Text Block is an XML fragment that will be inserted into the XSLT code generated by the SPS. It is placed in the SPS design as a self-contained block to which no design element may be added. Such an XML Text Block should therefore be applicable as XSLT code at the location in the stylesheet at which it occurs.

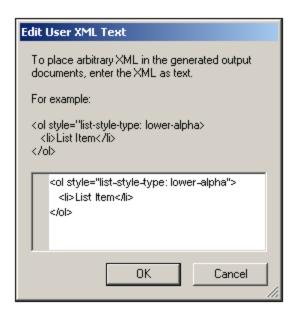

The usefulness of this feature is that it provides the stylesheet designer a mechanism with which to insert XSLT fragments and customized code in the design. For example, an ActiveX obect can be inserted within an HTML SCRIPT element.

Note: This feature will be enabled **only in Enterprise editions of Authentic View** (that is, in the Enterprise editions of StyleVision, Authentic Desktop, Authentic Browser, and XMLSpy).

Inserting User-Defined XML Text Blocks

To insert an XML Text Block, do the following:

- 1. Right-click at the location in the design where you wish to insert the User-Defined Block.
- 2. From the context menu that appears, select Insert User-Defined Item | User-Defined Block.
- 3. In the dialog that now appears (*screenshot below*), enter the XML Text Block you wish to insert. Note that the XML text block should be well-formed XML to be accepted by the dialog.

In the screenshot above an XML Text Block is added that generates an HTML ordered list.

4. Click **OK** to insert the element in the design. The XML Text Block is displayed in the design as a text box.

Note: An XML Text Block that is intended for a particular output should be enclosed in a suitable output-based condition so as to avoid unexpected results in alternative outputs.

5.6 Tables

In an SPS design, two types of tables may be used: **SPS tables** and **CALS/HTML tables**. There are differences between the two types, and it is important to understand these. This section contains a detailed description of how to use both types of tables.

SPS tables

An **SPS table** is a component of an SPS design. It is structured and formatted in the design. It can be created anywhere in the design and any number of SPS tables can be created.

SPS tables are entirely presentational devices and are represented using the presentational vocabulary of Authentic View and the output format. The structure of an SPS table is **not represented by nodes in the XML document**—although the content of table cells may come from nodes in the XML document.

There are two types of SPS tables:

- Static tables are built up, step-by-step, by the person designing the SPS. After the table structure is created, the content of each cell is defined separately. The content of cells can come from random locations in the schema tree and even can be of different types. Note that the rows of a static table do not represent a repeating data structure. This is why the table is said to be static: it has a fixed structure that does not change with the XML content.
- **Dynamic tables** are intended for data structures in the XML document that repeat. They can be created for schema elements that have a substructure—that is, at least one child attribute or element. Any element with a substructure repeats if there is more than one instance of it. Each instance of the element would be a row in the dynamic table, and all or some of its child elements or attributes would be the columns of the table. A dynamic table's structure, therefore, reflects the content of the XML file and changes dynamically with the content.

CALS/HTML tables

The content model of a CALS table or HTML table is defined in the XML document—by extension in the DTD or schema—and follows the respective specification (CALS or HTML). In the SPS design you can then specify that CALS/HTML table/s are to be processed as tables. The XML data structure that represents the CALS/HTML table will in these cases generate table markup for the respective output formats. The formatting of CALS/HTML tables can be specified in the XML instance document or the SPS, or in both.

Shown below is the HTML Preview of an HTML table.

Name	Phone
John Merrimack	6517890
Joe Concord	6402387

The HTML code fragment for the XML table shown in the illustration above looks like this:

```
Phone
```

The original XML document might look like this:

```
<phonelist border="1" width="40%">
  <items>
    <person>
      <data>Name</data>
      <data>Phone</data>
    </person>
    <person>
      <data>John Merrimack</data>
      <data>6517890</data>
    </person>
    <person>
      <data>Joe Concord</data>
      <data>6402387</data>
    </person>
  </items>
</phonelist>
```

Note that element names in the XML document do not need to have table semantics; the **table structure**, however, must correspond to the HTML or CALS table model. Also note the following:

- Note that only one XML element can correspond to the HTML column element
- A CALS/HTML table can be inserted at any location in the XML document where, according to the schema, the element corresponding to the table element is allowed.
- In Authentic View, data is entered directly into table cells. This data is stored as the content of the corresponding CALS/HTML table element.
- The formatting properties of a CALS/HTML table could come from the XML document, or they could be specified in the SPS design.

Summary for the designer

From the document designer's perspective, the following points should be noted:

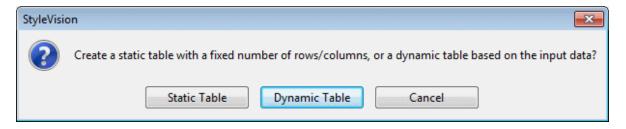

- The structure of an SPS table is defined in the SPS. The structure of a CALS/HTML table on the other hand is specified in the schema and must follow that of the CALS/HTML table model; the element names in the schema may, however, be different than those in the CALS or HTML table models.
- **Colspans and rowspans** in SPS tables are specified in the SPS. But in CALS/HTML tables, colspans and rowspans are specified in the XML instance document.

• **Table formatting** of SPS tables is specified in the SPS. The formatting of CALS/HTML tables is specified in the XML instance document and/or the SPS.

5.6.1 Static Tables

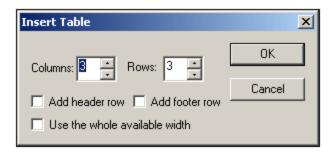

To create a static table, do the following:

- 1. Use one of the following commands: **Table | Insert Table** or **Insert | Table**, or click the **Insert Table** icon in the Insert Design Elements toolbar.
- 2. All of these commands pop up the Create Table dialog (screenshot below).

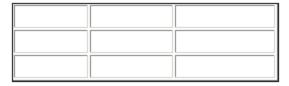

Click Static Table.

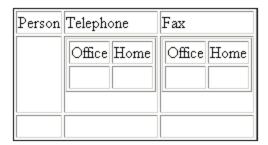

3. The Insert Table dialog (*screenshot below*) pops up, in which you specify the dimensions of the table and specify whether the table should occupy the whole available width.

4. Click OK. An empty table with the specified dimensions, as shown below, is created.

5. You can now enter content into table cells using regular StyleVision features. Cell content could be text, or elements dragged from the schema tree, or objects such as images and nested tables. The figure below shows a table containing nested tables.

Static SPS tables are especially well-suited for organizing XML data that is randomly situated in the schema hierarchy, or for static content (content not derived from an XML source).

Deleting columns, rows, and tables

To delete a column, row, or table, place the cursor in the column, row, or table to be deleted, and click the menu item **Table | Delete Column**, **Table | Delete Row**, or **Table | Delete Table**, respectively. If you have nested tables, these commands will apply, respectively, to the column, row, and table containing the cursor.

Toolbar table editing icons

The table editing icons, which are by default in the second row of the toolbar, are shortcuts to the **Table** menu commands. These commands allow you to insert, delete, edit the structure of, and assign formatting properties to the static table. These icons can also be used for dynamic SPS tables. They **cannot be used for CALS/HTML tables** are not formatted in this way.

Structure of static tables for PDF output

To ensure that tables are correctly rendered in the PDF output, the number of columns specified for a table (in the FO document) must be correct. (The number of columns can vary from row to row when cells span columns.) The following points should be noted to ensure correct table definition for PDF output:

- The number of columns in a table is the maximum number of columns in any row when all rows are considered. For example, if a table has three rows, with Row1 having 6 columns, Row2 having 5 columns, and Row3 having 7 columns, the number of columns in the table is 7. It is best, therefore, to specify, when inserting the static table, that the table should have 7 columns. Cells in the table can subsequently be joined (using **Table** menu commands) so that they span columns. It is important to note that splitting a cell creates a new column in the graphic view but that is not added to the table's column count. In such an event, the table structure and dimensions will be incorrectly rendered in the PDF.
- If the width of columns is to be specified, the total of all columns should add up to 100% or to an absolute measurement that is smaller than the width of the body-area of the page.
- Make sure that widths are defined for each column, and not only for cells of a table. To check whether
 column widths have been correctly assigned, click the XSL-FO tab and check the widths of the
 fo:table-column child elements of the fo:table tag. For example, consider the table definition
 below:

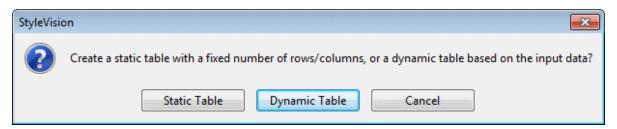

<fo:table-body>

In the listing above, the table is defined as having 5 columns, with the widths of each column being given in percentages.

5.6.2 Dynamic Tables

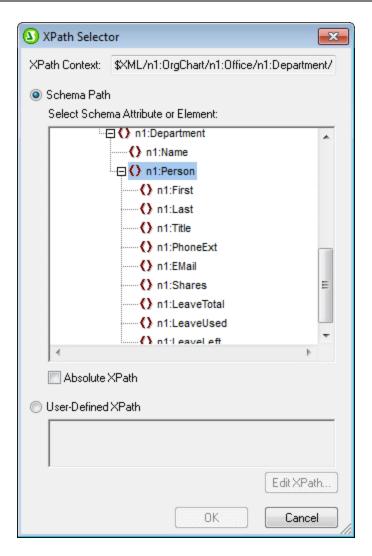

To insert a dynamic table, do the following:

- 1. Use one of the following commands: **Table | Insert Table** or **Insert | Table**, or click the **Insert Table** icon in the Insert Design Elements toolbar.
- 2. All of these commands pop up the Create Table dialog (*screenshot below*). If you clicked the Insert Table icon in the toolbar, the Create Table dialog will pop up when you click at the location in the design where you want to insert the table.

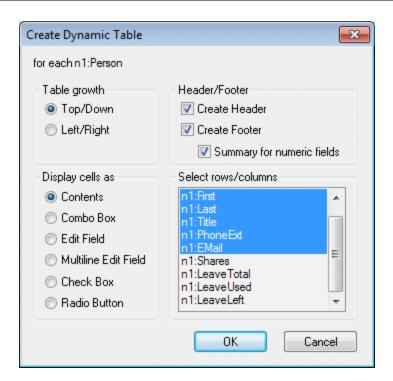

Click **Dynamic Table**.

3. In the XPath Selector dialog (screenshot below) that pops up, notice that the XPath Context is the context of the insertion location, and it cannot be changed in the dialog. Select the node that is to be created as the dynamic table. In the screenshot below, the context node is n1:Department, and the n1:Person node has been selected as the node to be created as a table.

If you select the User-defined XPath option, then you can enter an XPath expression to select the node to be created as the dynamic table.

4. Click **OK**. The Create Dynamic Table dialog (screenshot below) pops up.

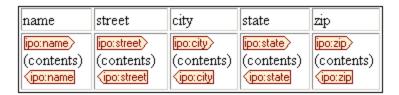

5. The child elements and attributes of the element that has been dragged into the Design window are displayed In the "Select rows/columns" list and can be created as columns of the table. Deselect the child nodes that you do not want and select any attribute/element you want to include as columns. (In the figure above, the elements Shares, LeaveTotal, LeaveUsed and LeaveLeft have been deselected.) An explanation of the other options is given below. Click **OK** when done. Note that columns are created only for child elements and attributes, and for no descendant on a lower level.

Note: If you specified a User-defined XPath to select the node to be created as the dynamic table, then StyleVision will probably not know unambiguously which node is being targeted. Consequently, the Create Dynamic Table will, in such cases, not display a list of child attributes/elements to select as the fields (columns) of the table. The table that is created will therefore have to be manually populated with node content. This node content should be child attributes/elements of the node selected to be created as the table.

Note: Another way of creating a schema node as a table is to drag the node from the schema tree into the design and to specify, when it is dropped, that it be created as a table.

Table grows down or right

When a table grows top-down, this is what it would look like:

When a table grows left-right it looks like this:

Headers and footers

Columns and rows can be given headers, which will be the names of the column and row elements. Column headers are created at the top of each column. Row headers are created on the left hand side of a row. To include headers, check the Create Header check-box. If the table grows top-down, creating a header, creates a header row above the table body. If the table grows left-right, creating a header, creates a column header to the left of the table body.

To include footers, check the Create Footer check-box. Footers, like headers, can be created both for columns (at the bottom of columns) and rows (on the right hand side of a row). The footer of numeric columns or rows will sum each column or row if the *Summary for Numeric Fields* check box is checked.

Via the **Table** menu, header and footer cells can be joined and split, and rows and columns can be inserted, appended, and deleted; this gives you considerable flexibility in structuring headers and footers. Additionally, headers and footers can contain any type of static or dynamic content, including conditional templates and auto-calculations.

Note: Headers and footers must be created when the dynamic table is defined. You do this by checking the Create Header and Create Footer options in the Create Dynamic Table dialog. Appending or inserting a row within a dynamic table does not create headers or footers but an extra row. The difference is significant. With the Create Header/Footer commands, real headers and footers are added to the top and bottom of a table, respectively, and to the top and bottom of the table on new pages if the table runs on to a new PDF page. If a row is inserted or appended, then the row occurs for each occurrence of the element that has been created as a dynamic table.

Nested dynamic tables

You can nest one dynamic table within another dynamic table if the element for which the nested dynamic table is to be created is a child of the element that has been created as the containing dynamic table. Do the following:

- 1. Create the outer dynamic table so that the child element to be created as a dynamic table is created as a column.
- 2. In the dynamic table in Design View, right-click the child element.
- 3. Select Change to | Table. This pops up the Create Dynamic Table dialog.
- 4. Define the properties of the nested dynamic table.

To nest a dynamic table in a static table, drag the element to be created as a dynamic table into the required cell of the static table. When you drop it, select **Create Table** from the context menu that appears.

Tables for elements with text content

To create columns (or rows) for child elements, the element being created as a table must have a **child element or attribute node**. Having a **child text node** does not work. If you have this kind of situation, then create a child element called, say, <code>Text</code>, and put your text node in the <code>TableElement/Text</code> elements. Now you will be able to create <code>TableElement</code> as a dynamic table. This table will have one column for <code>Text</code> elements. Each row will therefore contain one cell containing the text node in <code>Text</code>, and the rows of the table will correspond to the occurrences of the <code>TableElement</code> element.

Contents of table body cells

When you create a dynamic table, you can create the node content as any one of a number of StyleVision components. In the examples above, the table body cells were created as contents; in the Create Dynamic Table dialog, the option for Display Cells As is *contents*. They could also have been created as data-entry devices. There are two points to note here:

- The setting you select is a global setting for all the table body cells. If you wish to have an individual cell appear differently, edit the cell after you have created the table: right-click in the cell and, in the context menu that appears, select "Change to" and then select the required cell content type.
- If you create cells as element contents, and if the element has descendant elements, then the content of the cell will be a concatenation of the text strings of the element and all its descendant elements.

Deleting columns, rows, and tables

To delete a column, row, or table, place the cursor in the column, row, or table to be deleted, and click the menu item **Table | Delete Column**, **Table | Delete Row**, or **Table | Delete Table**, respectively. If you have nested tables, the table immediately containing the cursor will be deleted when the **Table | Delete Table** command is used.

Toolbar table editing icons

The table editing icons in the toolbar are shortcuts to the **Table** menu commands. These commands allow you to insert, delete, edit the structure of, and assign formatting properties to the dynamic table. These icons can also be used for static tables. They **cannot be used for CALS/HTML** tables, since CALS/HTML tables are not formatted in this way. CALS/HTML tables can only be enabled in StyleVision.

Creating dynamic tables in global templates

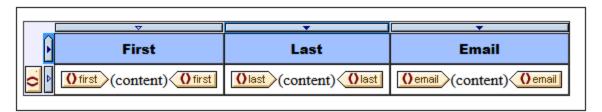

You can also create dynamic tables on elements inside global templates. The process works in the same way as for Main Template elements (described above). The important point to note is that, in a global template, a dynamic table can only be created for **descendant elements** of the global template node; it cannot be created for the global template node itself. For example, if you wish to create a dynamic table for the element authors within a global template, then this dynamic table must be created within the global template of the parent element of authors, say contributors. It cannot be created within the global template of the authors element.

5.6.3 Conditional Processing in Tables

Conditional processing can be set on individual columns and rows of static and dynamic tables, as well as on column and row headers, to display or hide the column, row, or header depending on the truth of the condition. If the condition evaluates to true, the column, row, or header is displayed. Otherwise it is not.

Adding and editing conditional processing

To add conditional processing to a column, row, or header, right click the respective design component and select **Edit Conditional Processing**. (In the screenshot below, the column-header design-component at top left is shown highlighted in blue; the second-column design-component is shown outlined in blue; the only row component is below the column-header design-component.)

Clicking the **Edit Conditional Processing** command pops up the <u>Edit XPath Expression dialog</u> ⁹¹⁷, in which you enter the XPath expression of the condition. Here are some ways in which conditional processing could be used.

- On a column, row, or table, enter the XPath expression false() to hide the column, true() to display
 it
- A column is output only if the sum of all the values in that column exceeds a certain integer value.
- A column or row is output only if no cell in that column or row, respectively, is empty.
- A column or row is output only if a certain cell-value exists in that column or row, respectively.

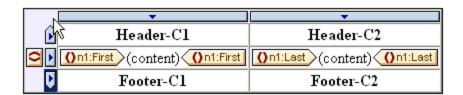

To edit an already created condition, right click the respective design component and select **Edit Conditional Processing**. In the <u>Edit XPath Expression dialog</u> that pops up, edit the XPath expression that tests the truth of the condition.

Removing conditional processing

To remove the conditional processing of a column, row, or header, right click the respective design component and select **Clear Conditional Processing**.

5.6.4 Tables in Design View

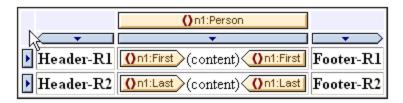

The main components of static and dynamic SPS tables are as shown in the screenshots below with the table markup (**Table | View Table Markup**) switched on.

The screenshot above shows a simple table that grows top-down and that has a header and footer.

A column is indicated with a rectangle containing a downward-pointing arrowhead. Column indicators
are located at the top of columns. To select an entire column—say, to assign a formatting property to
that entire column—click the column indicator of that column.

- A row is indicated with a rectangle containing a rightward-pointing arrow. Click a row indicator to select that entire row.
- In tables that grow top-down (*screenshot above*), headers and footers are indicated with icons pointing up and down, respectively. In tables that grow left-right, headers and footers are indicated with icons pointing left and right, respectively (*screenshot below*).
- To select the entire table, click in the top left corner of the table (in the screenshots above and below, the location where the arrow cursor points).
- When any table row or column is selected, it is highlighted with a dark blue background. In the screenshot above, the footer is selected.
- In tables that grow top-down, the element for which the table has been created is shown at the extreme left, outside the column-row grid (*screenshot above*). In tables that grow left-right, the element for which the table has been created is shown at the top, outside the column-row grid (*screenshot below*).

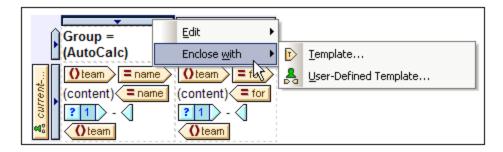

After a column or row or table has been selected, styles and/or properties can be set for the selection in the Styles and Properties Windows.

Drag-and-drop functionality

The columns and rows of an SPS table (static or dynamic) can be dragged to alternative locations within the same table and dropped there.

Enclosing and removing templates on rows and columns

A row or column can be enclosed with a template by right-clicking the row or column indicator and, from the context menu that pops up (*screenshot below*), selecting **Enclose With | Template** or **Enclose With | User-Defined Template**. In the next step, you can select a node from the schema tree or enter an XPath expression for a <u>User-Defined Template</u> (349). A template will be created around the row or column.

A template that is around a row or column can also be removed while leaving the row or column itself intact. To do this, select the template tag and press the **Delete** key.

The enclosing with, and removing, templates feature is useful if you wish to remove a template without removing the contents of a row or column, and then, if required, enclosing the row or column with another template. Enclosing with a <u>User-Defined Template</u> also allows the use of interesting template-match results within the row or column (via Auto-Calculations, for example).

5.6.5 Table Formatting

Static and dynamic tables can be formatted using:

- HTML table formatting properties (in the Properties sidebar)
- CSS (styling) properties (in the Styles sidebar).

Note: For Text output, tables will be generated using a <u>user-selected character as the cell separator</u> ⁹⁷¹. The default character is the semicolon. It can be changed in the XSD/XSLT/XBRLtab of the <u>Properties dialog</u> ⁹⁷¹.

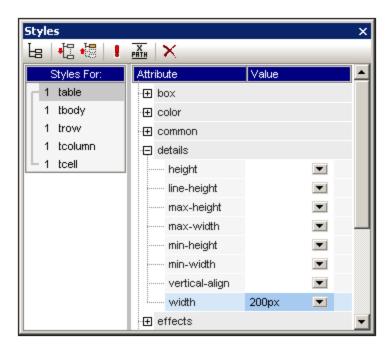

Properties sidebar

The HTML table formatting properties are available in the Properties sidebar (*screenshot below*). These properties are available in the *HTML* group of properties for the table component and its sub-components (body, row, column, and cell).

Styles sidebar

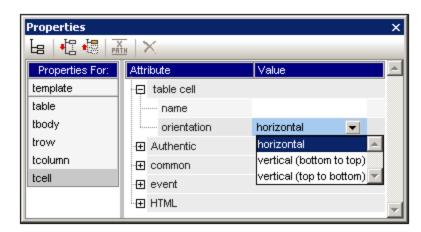

The CSS table formatting properties are available in the Styles sidebar (*screenshot below*). CSS properties are available for the table component and its sub-components (body, row, column, and cell).

Note: If all table cells in a row are empty, Internet Explorer collapses the row and the row might therefore not be visible. In this case, you should use the HTML workaround of putting a non-breaking space in the appropriate cell/s.

Vertical text

Text in table cells can be rotated 90 degrees clockwise or anti-clockwise, so that the text is vertical, reading from top-to-bottom or bottom-to-top, respectively. To do this, in the design, select the content in the table cell that is to be rotated and, in the Properties sidebar (*screenshot below*), select tcell. In the *Table Cell* group of properties, select the required value for the *Orientation* property.

Note the following points:

- The rotation will be applied to the output, but will not be be displayed in the design.
- This property is intended to be applied to text and should not be used for other content.
- Besides being applicable to text in table cells, the property can also be applied to text in <u>Text</u> boxes 283.

Table formatting via Properties and Styles

Some formatting properties are available in both the Properties sidebar as well as in the Styles sidebar. The table below lists some of the more important table properties available in both sidebars.

Table component	Properties sidebar	Styles sidebar		
Table	border, frame, rules; cellpadding, cellspacing; bgcolor; height, width (overriden by height, width in Styles sidebar if the latter exist); align	borders and padding in Box styles; height, width in Details group (they override height and width in Properties sidebar); color, font, and text styles		
Body	align, valign	height, vertical-align; color, font, and text styles		
Column	align, valign	width, vertical-align; color, font, and text styles; box styles		
Row	align, valign	height, vertical-align; color, font, and text styles; box styles		
Cell	align, valign	height, width, vertical-align; color, font, and text styles; box styles		

Height and width

The height and width of tables, rows, columns, and cells must be set in the Styles sidebar (in the Details group of styles). When a table, column, or row is resized in the display by using the mouse, the altered values are entered automatically in the appropriate style in the Styles sidebar. Note, however, that the height and width styles are not supported for cells that are spanned (row-spanned or column-spanned).

Centering a table

To center a table, set the <code>align</code> property in the HTML group of table properties to <code>center</code>. The <code>align</code> property can be accessed by selecting the table, then selecting the menu command **Table | Table Properties**. Alternatively, the property is available in the HTML group of properties in the Properties sidebar.

Centering the table in the PDF output will require additional settings according to the FOP processor you are using. According to the FO specification the correct way to center a table is to surround the fo:table element with an fo:table-and-caption element and to set the text-align attribute of the fo:table-and-caption element to center. Stylevision does not automatically create an fo:table-and-caption element when a table is inserted in the design, but you can add this element as a User-Defined Element If you are using the Apache FOP processor, however, you should note that the fo:table-and-caption element might not be supported, depending on which FOP version you are using. In this case there is a simple workaround: Make the table a fixed-width table. Do this by specifying a length value, such as 4in or 120mm, as the value of the width property of the HTML group of table properties (accessed via the menu command Table | Table Properties).

Giving alternating rows different background colors

If you want alternating background colors for the rows of your dynamic table, do the following:

1. Select the row indicator of the row for which alternating background colors are required. Bear in mind that, this being a dynamic table, one element is being created as a row, and the design contains a single row, which corresponds to the element being created as a table.

- 2. With the row indicator selected, in the Properties sidebar, click the *Properties for:* trow.
- 3. Select the bgcolor property.
- 4. Click the XPath icon in the toolbar of the Properties window, and, in the <u>Edit XPath Expression</u> dialog ⁹¹⁷ that appears, enter an XPath expression similar to this:

```
if (position() mod 2 = 0 ) then "white" else "gray"
```

This XPath expression specifies a bgcolor of white for even-numbered rows and a bgcolor of gray for odd-numbered rows

You can extend the above principle to provide even more complex formatting.

Numbering the rows of a dynamic table

You can number the rows of a dynamic table by using the <code>position()</code> function of XPath. To do this, first insert a column in the table to hold the numbers, then insert an Auto-Calculation in the cell of this column with an XPath of: <code>position()</code>. Since the context node is the element that corresponds to the row of the dynamic table, the <code>position()</code> function returns the position of each row element in the set of all row elements.

Table headers and footers in PDF output

If a table flows over on to more than one page, then the table header and footer appear on each page that contains the table. The following points should be noted:

- If the footer contains Auto-Calculations, the footer that appears at the end of the table segment on each page contains the Auto-Calculations for the whole table—not those for only the table segment on that page.
- The header and footer will not be turned off for individual pages (for example, if you want a footer only at the end of the table and not at the end of each page).

In order to omit the header or footer being displayed each time the page breaks, use the table-omit-header-at-break and/or table-omit-footer-at-break properties (attributes) on the table element. These properties are available in the Styles sidebar, in the XSL-FO group of properties for the table. To omit the header or footer when the page breaks, specify a value of true for the respective attribute. (Note that the default value is false. So not specifying these properties has the effect of inserting headers and footers whenever there is a break.)

Hyphenating content of table cells

If you wish to hyphenate text in table cells of your PDF output, note that the XSL:FO specification uses the hyphenate attribute of the fo:block element to do this. So, to apply hyphenation, you must explicitly, in the FO document, set the hyphenate property of the respective fo:block elements to true.

5.6.6 Row and Column Display

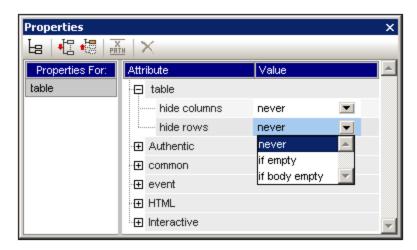

For tables, the following row and column display options are available in the **HTML output only**. These features are **not supported in Authentic View** and they require XSLT 2.0 or XSLT 3.0 to be selected as the XSLT version of the SPS.

- Empty rows and columns can be automatically hidden.
- Each column can have a Close button, which enables the user to hide individual columns.
- Row elements with descendant relationships can be displayed with expand/collapse buttons.

Hiding empty rows and columns by default

To hide empty rows and/or columns in the HTML output, do the following:

- 1. In Design View, select the table or any part of it (column, row, cell).
- 2. In the Properties sidebar, select properties for *Table*, and the *Table* group of properties (*screenshot below*).

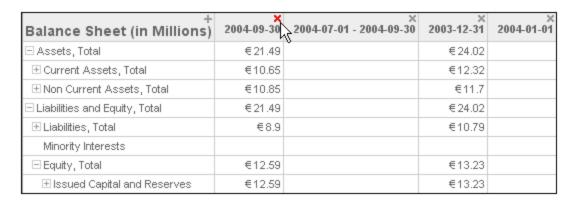

3. Select the required value for the *Hide Columns* and *Hide Rows* properties. The options for each of these two properties are the same: *Never*, *If empty*, and *If body empty*. The *If empty* option hides the column or row if the entire column/row (including header and footer) is empty. *If body empty* requires only that the body be empty.

Note: If a non-XBRL table has row or column spans (where cells of a row or a column have been joined), the hiding of empty rows and columns might not work.

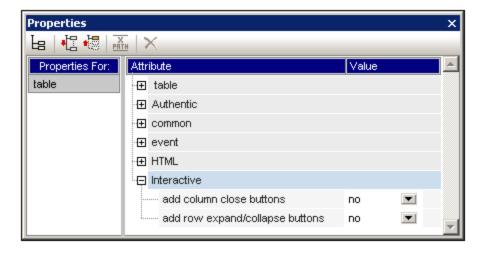

User interaction to hide columns expand/collapse rows

It can be specified in the design that each table column contain a **Close** button in the HTML output (see screenshot below). The user can then hide individual columns by clicking the **Close** button. After the user hides a column, a plus symbol appears in the first column (see screenshot below). Clicking this symbol re-displays all hidden columns.

Also, row elements that have descendant elements can be displayed in the HTML output with an expand/collapse (plus/minus) symbol next to it (see screenshot above). Clicking these symbols in the HTML output expands or collapses that row element. In the design, you can specify indentation for individual rows using CSS properties.

The settings for these two features are made in the *Interactive* group of properties of the *Table* properties (*screenshot below*).

The options for both properties are Yes (to add the feature) and No (to not add the feature).

5.6.7 CALS/HTML Tables

A CALS/HTML table is a hierarchical XML structure, the elements of which: (i) define the structure of a CALS or HTML table, (ii) specify the formatting of that table, and (iii) contain the cell contents of that table. This XML structure must correspond exactly to the CALS or HTML table model.

To create a CALS/HTML table in the design, do the following:

- 1. Define the XML structure as a CALS/HTML table structure 167
- 2. Specify formatting styles for the table 169
- 3. Insert the CALS/HTML table in the SPS design (169)

Enabling CALS/HTML table structures for output

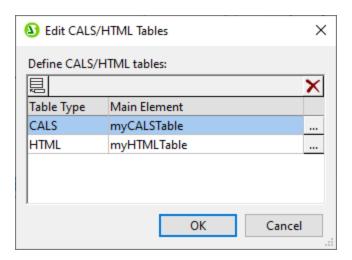

An XML document may have a data structure that defines the structure and content of a table. For example, the following XML data structure corresponds to the HTML table model and in fact has the same element names as those in the HTML table model:

Alternatively, the XML data structure could have a structure corresponding to the HTML table model but different element names than in the HTML table model. For example:

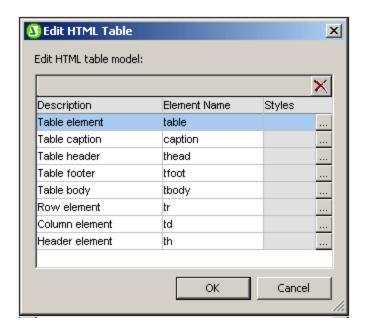

This table structure, which is defined in the XML document, can be used to directly generate a table in the various output formats. To do this you need to define this XML data structure as a CALS or HTML table. If the XML data structure is not defined as a CALS or HTML (the default), the elements in the data structure will be treated as ordinary non-table elements and no table markup will be added to the output document.

To enable CALS/HTML table markup in the output do the following:

- 1. Select the command Table | Edit CALS/HTML Tables.
- 2. In the dialog that pops up (*screenshot below*), add an entry for the XML data structure you wish to use as a CALS/HTML table, according to whether the data structure follows the CALS or HTML table model. (For information about the CALS table model, see the <u>CALS table model at OASIS</u>. For an example of a table element having an HTML table structure, open HTMLTable1.sps, which is in the Basics folder of the Examples project folder (in the Project window of the GUI).) So, if you wish to enable an element in your schema as a CALS or an HTML table element, click the Add CALS/HTML table button in the top left part of the dialog and then select either the Add CALS Table command or the Add HTML Table command. (In the screenshot below, the elements table and informaltable have been enabled as CALS tables (as well as HTML tables).) Click OK to confirm.

3. A dialog (Edit CALS Table or Edit HTML table) appears showing the elements of the table type you selected (screenshot below). The element names that are listed in this dialog are, by default, the element names in the selected table model (CALS or HTML). If the SPS schema contains elements with the same names as the names of the CALS/HTML table model, then the names are shown in black (as in the screenshot below). If a listed element name is not present in the SPS schema, that element name is listed in red. You can change a listed element name to match a schema name by double-clicking in the relevant Element Name field and editing the name.

- 4. Click **OK** to define this XML data structure as a CALS or HTML table.
- 5. You can add entries for as many XML data structures as you like (see screenshot in Step 2 above). The same main element can be used once each for CALS and HTML table types.
- 6. After you have finished defining the XML data structures you wish to enable as CALS/HTML tables, click **OK** to finish.

If a CALS/HTML table has been defined and the XML data structure is correctly inserted as a CALS/HTML table, then the data structure will be sent to the output as a table. To **remove a CALS/HTML table**

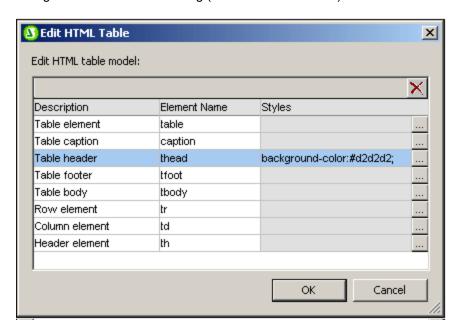

definition, in the Edit CALS/HTML table dialog select the definition you wish to delete and click the **Delete** button at the top right of the Define CALS/HTML Tables pane.

Table formatting

CALS/HTML tables receive their formatting in two ways:

1. From formatting attributes in the source XML document. The CALS and HTML table models allow for formatting attributes. If such attributes exist in the source XML document they are passed to the presentation attributes of the output's table markup.

2. Each individual element in the table can be formatted in the Styles column of the Edit CALS Table dialog or Edit HTML Table dialog (see screenshot below).

To assign a style to a particular element, click the **Add Styles** button for that element and assign the required styles in the <u>Styles sidebar of</u> that pops up. Each style is added as an individual CSS attribute to the particular element. Note that a style added via the <code>style</code> attribute will have higher priority than a style added as an individual CSS attribute (such as <code>bgcolor</code>). For example, in <thead <code>style="background-color: red" bgcolor="blue"/> the style="background-color: red" attribute will have priority over the <code>bgcolor="blue"</code> attribute.</code>

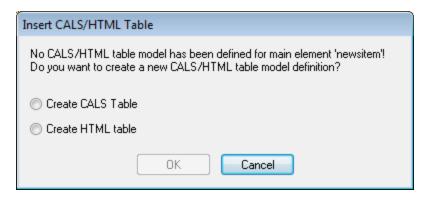

To remove a style that has been assigned to an element in the CALS/HTML table definition, select that element (for example in the screenshot above the thead element has been selected) and click the **Delete** button. The styles for that element will be removed.

Inserting a CALS/HTML table in the design

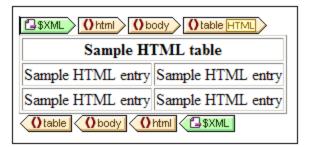

A CALS/HTML table structure can be inserted in the design in two ways:

- 1. The parent of the table element is inserted in the design as (contents). When the contents of the parent are processed, the table element will be processed. If CALS/HTML table output is enabled, then the element is output as a table. Otherwise it is output as text.
- 2. The table element can be dragged from the Schema Tree. When it is dropped at the desired location in the design, it can be created as a CALS/HTML table (with the **Create CALS/HTML Table** command).

If the element has not been <u>defined as a CALS/HTML table</u> the Insert CALS/HTML Tables dialog (screenshot below) pops up and you can define the element as a CALS or HTML table.

If the element has been created in the design as a CALS/HTML table, a placeholder for the CALS/HTML table design element is inserted at the location (*screenshot below*).

Global templates of table elements

If global templates ³⁴⁵ of the following table elements are created they will be used in the CALS/HTML table output. For CALS tables: title and entry. For HTML tables: caption, th, and td.

Example files

Example files are in the the Examples project folder (in the Project window of the GUI).

5.7 Lists

There are two types of lists that can be created in the SPS:

• <u>Static lists</u> which are lists, the contents of which are entered directly in the SPS. The list structure is not dynamically derived from the structure of the XML document.

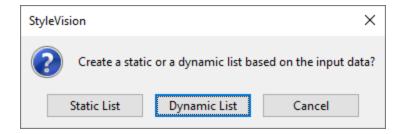

<u>Dynamic lists</u> ⁽⁷³⁾, which are lists that derive their structure and contents dynamically from the XML document.

How to create these two list types are described in detail in the sub-sections of this section.

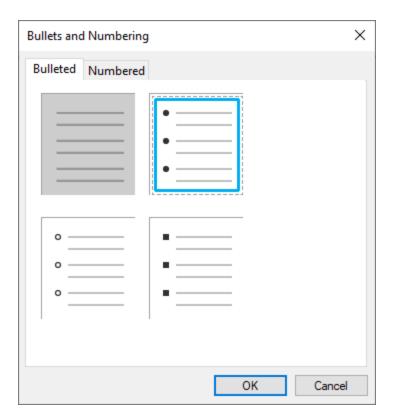

5.7.1 Static Lists

A static list is one in which list item contents are entered directly in the SPS. To create a static list, do the following:

1. Place the cursor at the location in the design where you wish to create the static list and select the Insert | Bullets and Numbering menu command (or click the Bullets and Numbering icon in the Insert Design Elements toolbar (screenshot below).

2. Click Static List. This pops up the Bullets and Numbering dialog (screenshot below).

- 3. Select the desired list item marker and click **OK**. An empty list item is created.
- 4. Type in the text of the first list item.
- 5. Press **Enter** to create a new list item.

To create a nested list, place the cursor inside the list item that is to contain the nested list and click the Insert | Bullets and Numbering menu command. Then use the procedure described above once again.

Note: You can also create a static list by placing the cursor at the location where the list is to be created and clicking either the Bullets icon or Numbering icon in the Bullets or Numbering icons in the Formatting toolbar ⁹³⁶. The first list item will be created at the cursor insertion point.

Changing static text to a list

To change static text to a list, do the following:

Highlight the text you wish to change to a list, select the command Enclose With | Bullets and
Numbering
Mumbering
<a hre

Lists in Text output

When a list is generated in Text output, each list item is indicated by a minus symbol at the start of the list item.

5.7.2 Dynamic Lists

Dynamic lists display the content of a set of sibling nodes of the same name, with each node represented as a single list item in the list. The element, the instances of which are to appear as the list items of the list, is created as the list. The mechanism and usage are explained below.

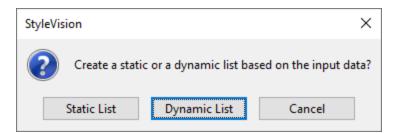

General usage mechanism

- Any element can be created as a list.
- When an element is created as a list, the instances of that element are created as the items of the list. For example, if in a department element, there are several person elements (i.e. instances), and you wanted to create a list of all the persons in the department, then you must create the person element as the list.
- Once the list has been created for the element, you can modify the appearance or content of the list or list item by inserting additional static or dynamic content such as text, Auto-Calculations, dynamic content, etc.

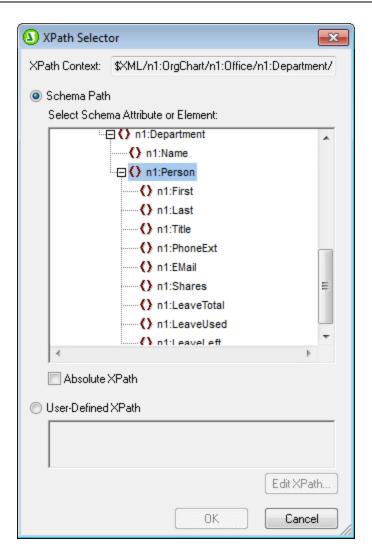

Creating a dynamic list

Create a dynamic list as follows:

1. Place the cursor at the location in the design where you wish to create the dynamic list and select the Insert | Bullets and Numbering menu command. This pops up a dialog asking whether you wish to create a static list or dynamic list (screenshot below).

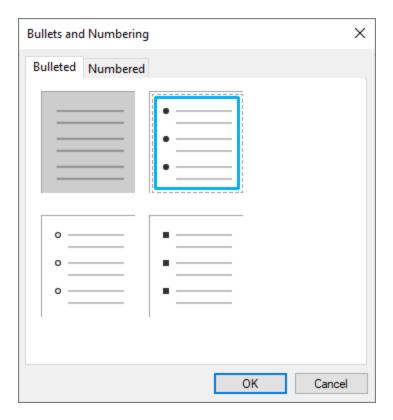

- 2. Click **Dynamic List**. This pops up the XPath Selector dialog (screenshot below).
- 3. In the XPath Selector dialog, notice that the XPath Context is the context of the insertion location, and that it cannot be changed in the dialog. Select the node that is to be created as the dynamic list. In the screenshot below, the context node is n1:Department, and the n1:Person node has been selected as the node to be created as a list. This means that the content of each n1:Person node will be created as an item in the list.

If you select the User-defined XPath option, then you can enter an XPath expression to select the node to be created as the dynamic table. Clicking **OK** pops up the Bullets and Numbering dialog described in the next step.

4. In the Bullets and Numbering dialog, select the kind of list you wish to create. You can choose from a bulleted list (with a bullet, circle, or square as the list item marker), or a numbered list. Clicking **OK** creates the list with the type of list item marker you selected.

Lists in Text output

When a list is generated in Text output, each list item is indicated by a minus symbol at the start of the list item.

5.8 Graphics

There are two ways in which graphics are used in an SPS:

• As images in the design document 176, and

Note: Graphics are not rendered in Text output.

When inserting images in the design document, the location of the image can be specified directly in the SPS (by the SPS designer) or can be taken or derived from a node in the XML document. How to specify the location of the image is described in the section Image URIs 176. What type of images are supported in the various outputs are listed in the section Image Types and Output 1773. The section <a href="Image Interest Image Image

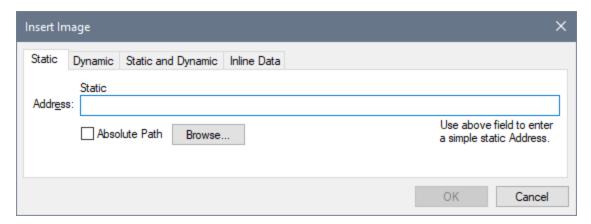

Image properties

Images can be set in the Properties window. Do this as follows. Select the image in the design. Then, in the Properties window, (i) select *image* in the Properties for column, (ii) select the required property group, and (iii) within the selected property group, select the the required property. For example, to set the height and width of the image, set the height and width properties in the *HTML* group of properties.

5.8.1 Images: URIs and Inline Data

Images can be inserted at any location in the design document. These images will be displayed in Authentic View and the output documents; in Design View, inserted images are indicated with thumbnails or placeholders.

To insert an image, click the <u>Insert | Image</u> menu command, which pops up the Insert Image dialog (screenshot below).

Images can be accessed in two ways:

• The image is a file, which is accessed by entering its URI in the Insert Image dialog.

The image is encoded as Base-16 or Base-64 text in an XML file.

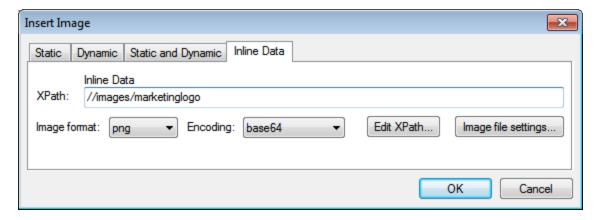

Inserting an image file

An image file is inserted in the design by specifying its URI. This file is accessed at runtime and placed in the document. There are three ways in which the URI of the image can be entered in the Insert Image dialog (screenshot above):

- In the Static tab, the URI is entered directly as an absolute or relative URI. For example, nanonull.gif (relative URI; see section below 178), and C:/images/nanonull.gif (absolute URI).
- In the Dynamic tab, as an XPath expression that selects a node containing either (i) a URI (absolute or relative), or (ii) an <u>unparsed entity name selects</u>. For example, the entry <u>image/@location</u> would select the <u>location</u> attribute of the <u>image</u> element that is the child of the context node (that is, the node within which the image is inserted). The location node in the XML document would contain the image URI. How to use unparsed entities is described in the section <u>Unparsed Entity URIs</u> selects.
- In the Static and Dynamic tab, an XPath expression in the Dynamic part can be prefixed and/or suffixed with static entries (text). For example, the static prefix could be C:/XYZCompany/Personnel/Photos/; the dynamic part could be concat(First, Last); and the static suffix could be .png. This would result in an absolute URI something like: C:/XYZCompany/Personnel/Photos/JohnDoe.png.

Inserting an image that is encoded text

An image can be stored in an XML file as Base-16 or Base-64 encoded text. The advantage of this is that the image does not have to be accessed from a separate file (linked to it), but is present as text in the source XML file. To insert an image that is available as encoded text in the XML source, use the Inline Data tab of the Insert Image dialog (see screenshot below).

Use an XPath expression to locate the node in the XML document that contains the encoded text of the image. Select an option from the Image Format combo box to indicate in what format the image file must be generated. (An image file is generated from the encoded text data, and this file is then used in the output document.) In the Encoding combo box, select the encoding that has been used in the source XML. This enables StyleVision to correctly read the encoded text (by using the encoding format you specify).

The Image File Settings dialog (accessed by clicking the **Image File Settings** button) enables you to give a name for the image file that will be created. You can choose not to provide a name, in which case StyleVision will, by default, generate a name.

If you wish to embed an inline image in HTML output, select the *Image Embedding with Data URI Scheme* option in the <u>Properties dialog</u> of the SPS.

Accessing the image for output

The image is accessed in different ways and at different times in the processes that produce the different output documents. The following points should be noted:

- Note the output formats available for your edition: (i) HTML in Basic Edition; (ii) HTML and RTF in Professional; (iii) HTML, RTF, PDF, and Word 2007+ in Enterprise Edition.
- For Design View and Authentic View in StyleVision, as well as for Authentic View in Altova products, you can set, in the Properties dialog (971), whether relative paths to images should be relative to the SPS or to the XML file.
- For HTML output, the URI of the image is passed to the HTML file and the image is accessed by the browser. So, if the path to the image is relative, it must be relative to the location of the HTML file. For the HTML Preview in StyleVision, a temporary HTML file is created in the same folder as the SPS file, so, for rendition in HTML Preview, relative paths must be relative to this location.
- For RTF output, the URI of the image is passed as an object link to the RTF file and is accessed by the RTF application (typically MS Word) when the file is opened. If the URI is relative, it must be relative to the location of the RTF file. For the RTF Preview in StyleVision, a temporary RTF file is created in the same folder as the SPS file, so, for rendition in RTF Preview, relative paths must be relative to this location.
- For PDF output, the URI is passed to the FO document and the image is accessed when the FO document is processed with the FO processor. This means that, if the URI is relative, it must be relative to the FO document at the time the FO document is processed. For the PDF Preview in StyleVision, a temporary FO file is created in the same folder as the SPS file, so, for rendition in PDF Preview, relative paths must be relative to this location.
- Whether the URI is relative or absolute, the image must be physically accessible to the process that renders it.

Editing image properties

To edit an image, right-click the image placeholder in Design View, and select **Edit URL** from the context menu. This pops up the Edit Image dialog, which is the same as the Insert Image dialog (*screenshot above*) and in which you can make the required modifications. The Edit Image dialog can also be accessed via the URL property of the *image* group of properties in the Properties window. The *image* group of properties also includes the alt property, which specifies alternative text for the image.

Deleting images

To delete an image, select the image and press the **Delete** key.

5.8.2 Image Types and Output

The table below shows the image types supported by StyleVision in the various output formats supported by StyleVision. Note that different editions of StyleVision support different sets of output formats: *Enterprise Edition*, HTML, Authentic, RTF, PDF, and Word 2007+; *Professional Edition*, HTML, Authentic, RTF; *Basic Edition*, HTML.

JPEG	Yes	Yes	Yes	Yes	Yes
GIF	Yes	Yes	Yes	Yes	Yes
PNG	Yes	Yes	Yes	Yes	Yes
ВМР	Yes	Yes	Yes	Yes	Yes
TIFF	Yes*	Yes*	Yes	Yes	Yes
SVG	Yes*	Yes*	No	Yes	No
JPEG XR	Yes	Yes	No	No	No

^{*} See notes immediately below

Note the following points:

- In Design View, images will be displayed only if their location is a static URL (i.e. directly entered in the SPS).
- For the display of TIFF and SVG images in Authentic View and HTML View, Internet Explorer 9 or higher is required.
- In RTF output, TIFF images can only be linked, not embeded. So re-sizing is not possible.
- SVG documents must be in XML format and must be in the SVG namespace.
- FOP reports an error if an image file cannot be located and does not generate a PDF.
- If FOP is being used to produce PDF, rendering PNG images requires that the JIMI image library be installed and accessible to FOP.
- For more details about FOP's graphics handling, visit the FOP website.

Example file

An example file, Images.sps, is located in the folder:

C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Images

Image resizing in RTF output

Resizing an image in the RTF output is only supported for JPG and PNG images. The following points should be noted:

- Resizing is supported only in designs that use XSLT 2.0 or XSLT 3.0, not XSLT 1.0
- The height and width attributes of the image must be set in the *Details* group of the <u>Styles</u> sidebar of the height and width attributes in the *HTML* group of the Properties sidebar are **not** used.
- Only absolute units (px, cm, in, etc) are supported. Percentage values and auto are not supported.
- JPG and PNG images are embedded in the RTF file. This embedding is implemented using a proprietary Altova XSLT 2.0 extension functionality.

Image embedding in RTF and Word 2007+

In the RTF and Word 2007+ output, images can either be embedded (when XSLT 2.0 or XSLT 3.0 is used) or linked. This setting is made for each SPS individually. To embed images, do the following:

- 1. With the required SPS active, open the Properties dialog (File | Properties).
- 2. Check the Embed Images check box (default setting is checked). Note that images will only be embedded if XSLT 2.0 or XSLT 3.0 is set as the XSLT version of the active SPS.
- 3. Click **OK** and save the SPS. The setting is saved for the active SPS.

To make this setting for another SPS, make this SPS active and repeat the steps listed above.

If the Embed Images check box is not checked, images will be linked according to the image file path specified in the images properties (select the image and select URL in the <u>Properties sidebar</u> ⁵⁹). For information about how paths are resolved, see the section <u>Image URIs</u> ¹⁷⁶.

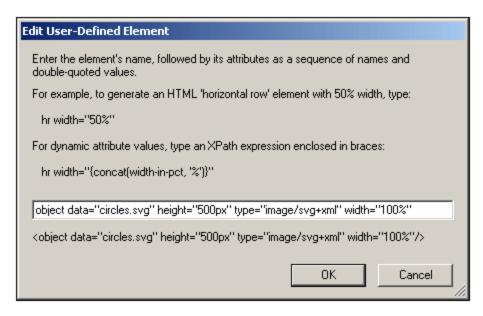

Note: The RTF format supports embedded images only for EMF, JPG, and PNG files.

SVG images in HTML

When an external SVG file with code for mouse events is used as an image, the SVG file is rendered within the image and will no longer be interactive. This limitation can be overcome by using the external SVG image file as an object or by including the SVG code fragment as a User-Defined XML Block.

Given below are the three ways in which SVG images can be included in a web page.

- 1. External SVG <u>inserted as image</u> 176: This generates an in the generated HTML file, and interactivity will be lost.
- 2. External SVG inserted as an object via the <u>User-Defined Element feature</u> (see screenshot below). Be sure to insert the type attribute correctly: ke type="image/svg+xml". When inserted in this way, the SVG object is still interactive and the mouse hover-functionality will work.

3. Inline SVG inserted via a <u>User-Defined XML Block</u> 147. See screenshot below for an example of an SVG code fragment. In this case, interactivity will work. Note that the svg element does not need to be in the SVG namespace if the output method is HTML 4.0 or 5.0, but the namespace is required if the output method is XHTML.

SPS Content Graphics 181

```
Edit User-Defined Block
  To place arbitrary XML in the generated output documents, enter the XML as text.
  For example:

    style="list-style-type: lower-alpha">

   List Item
  1 = <svg xmlns="http://www.w3.org/2000/svg">
          <style type="css">circle:hover {fill-opacity:0.9; stroke-width:2mm;}</style>
   3
          <g style="fill-opacity:0.7; stroke:black; stroke-width:1mm;">
   4
             <circle cx="6cm" cy="2cm" r="100" fill="red" transform="translate(0,50)"/>
   5
             <circle cx="6cm" cy="2cm" r="100" fill="blue" transform="translate(70,150)"/>
   6
             <circle cx="6cm" cy="2cm" r="100" fill="green" transform="translate(-70,150)"/>
          </a>
   8
        </sva>
                                                                                               ٠
                                                                       OK
                                                                                       Cancel
```

5.8.3 Example: A Template for Images

The StyleVision package contains an SPS file that demonstrates the use of images in StyleVision. This file is in the (My) Documents folder 33: C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Images.sps. The Images document (Images.xml and Images.sps) consists of three parts:

- The first part shows how text state icons can be used in Authentic View (can be created in Enterprise and Professional editions only). When you open the file Images.xml in the Authentic View of XMLSpy, Authentic Desktop, or Authentic Browser, you can try out the use of text state icons. Note that text state icons are not available in the Authentic Preview of StyleVision, so you cannot try out this feature in StyleVision. How to create text state icons is described in the Reference | Autnetic Menu | Custom toolbar buttons section of this user manual.
- The second part contains a table showing which image formats are supported in the various StyleVision output formats. In Design View, only images with static URIs will be displayed. All the image formats listed in the table are displayed in Part 3 of the Images document.
- In Part 3, all the popular image formats supported by StyleVision are displayed one below the other. After opening the file Images.sps in StyleVision, you can switch among the various previews of StyleVision to see how each image is displayed in that preview. Since the location of the image is in an XML node, you can also enter the location of your own images in Authentic View and test their appearances in the preview windows.

5.9 Charts

Charts in the SPS provide a graphical representation of data in the source XML document. In an SPS design that <u>uses XSLT 2.0 or 3.0 110</u>, a chart is set up by specifying a sequence of items for each axis of the chart. StyleVision then automatically generates the chart in the various output formats.

The table below shows the types of charts that can be created in an SPS design and the kind of data items that are required for each of the chart's axes. The dataset to be used for each axis is specified separately with an XPath expression.

Chart type	X-Axis (Category)	Y-Axis (Value)	Number of Series (on Z-Axis)
Pie Charts (2D, 3D)	Text	Numeric	1
Bar Charts Ungrouped (2D, 3D)	Text	Numeric	1
Bar Charts Grouped (2D, 3D)	Text	Numeric	> 1
Category Line Graphs	Text	Numeric	1 line = 1 series
Value Line Graphs	Numeric	Numeric	1 line = 1 series
Area and Stacked Area Charts	Text	Numeric	1 area = 1 series
Candlestick Charts	Text	Numeric	3 or 4
Gauge	_	Numeric	1
Overlay Charts	Text	Numeric	= 1 or > 1 per chart

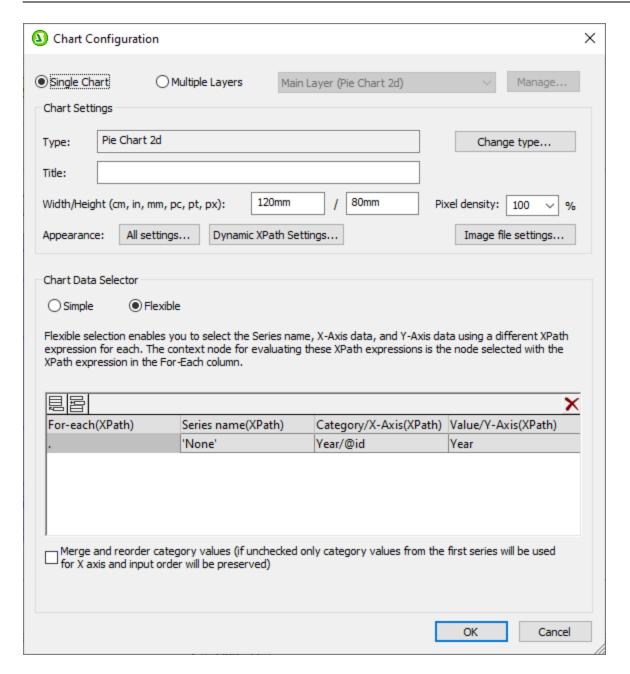

Note: Pie charts and gauge charts have a single nominal series, which requires no name. So if a series name is entered in the data selection, it is ignored. For ungrouped bar charts, however, the name of the single series, if present, is used for the legend. For gauge charts, in addition to any Series Name entry being ignored, the X-Axis data selection is also ignored; only the Y-Axis selection is used for gauge charts.

Note: Charts are not rendered in Text output.

Inserting a Chart

The XML Schema node within which a chart is created in the design will be the context node of the XPath expressions to select the chart's axes and other chart data. A chart must therefore be inserted within a suitable context node: one from which correct XPath expressions to select the required data can easily be constructed.

To insert a chart, right-click at the required location and select **Insert Chart** from the menu that pops up (or use the menu command **Insert | Insert Chart**). Alternatively, select the **Insert Chart** icon in the toolbar of StyleVision and then click in the design at the location where you wish to insert the chart. These insertion methods pop up the Chart Configuration dialog (*screenshot below*).

The Chart Configuration dialog has three parts:

- <u>Single or Multiple layers</u> Multiple layers can be selected to create overlay charts, in which multiple charts can be presented, one overlaid upon the other in a sequence of layers.
- <u>Chart Settings</u> ¹⁸⁷: To select the chart type and define the appearance of the chart
- Chart Data Selection: To select the data for the various axes of the chart using either the simple option or flexible option of flexible option

On clicking **OK** in the Chart Configuration dialog, the chart is inserted in the design.

Editing chart settings and data selection

If you wish to change chart settings or a chart's data selection after a chart has been created, right-click the chart in the design and select **Edit Chart Settings**. This pops up the Chart Configuration dialog (*screenshot above*) of that chart. You can edit the chart's settings or data selection in the dialog, then click **OK** to finish.

5.9.1 Chart Basics

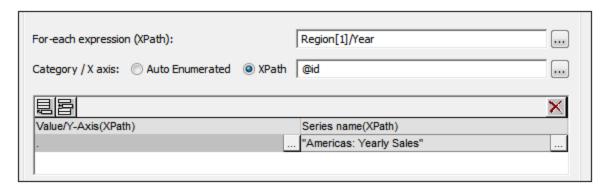

In this section we present simple examples to illustrate how charts work. These charts are in the SPS file SimpleCharts.sps. The SPS design is based on the XML Schema YearlySales.xsd and it uses YearlySales.xml (screenshot below) as its Working XML File. All three files are located in the (My) Documents folder 33, C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

```
■ XML file used in charts example: YearlySales.xml
```

```
<?xml version="1.0" encodina="UTF-8"?>
<Data xm]ns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
     xsi:noNamespaceSchemaLocation="YearlySales.xsd">
      <ChartType>Pie Chart 2D</ChartType>
      <Region id="Americas">
             <Year id="2005">30000</year>
             <Year id="2006">90000</year>
             <Year id="2007">120000
             <Year id="2008">180000</year>
             <Year id="2009">140000</year>
             <Year id="2010">100000</year>
      </Region>
      <Region id="Europe">
             <Year id="2005">50000</year>
             <Year id="2006">60000</year>
             <Year id="2007">80000</year>
             <Year id="2008">100000
             <Year id="2009">95000</year>
             <Year id="2010">80000</year>
      </Region>
      <Region id="Asia">
             <Year id="2005">10000</year>
             <Year id="2006">25000</year>
             <Year id="2007">70000</year>
             <Year id="2008">110000
             <Year id="2009">125000
             <Year id="2010">150000
      </Region>
</Data>
```

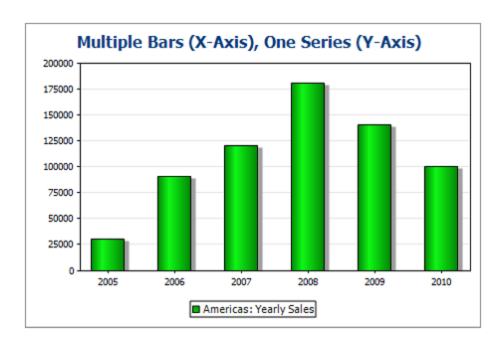

After opening the SPS file in StyleVision, check the chart settings to see how data has been selected for the two axes. Do this by right-clicking the charts and selecting the **Edit Chart Settings** command. This pops up

the Chart Configuration dialog, at the bottom of which is the Chart Data Selector pane with fields for entering the XPath expressions for data selection (*screenshot below*). To view the charts, switch to Authentic Preview.

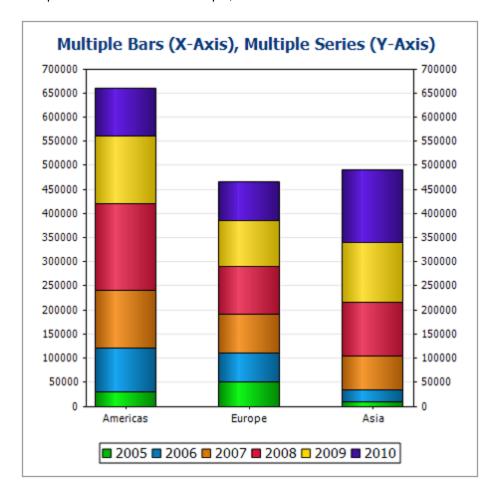

The four XPath expressions in the Chart Data Selector pane work together and do the following:

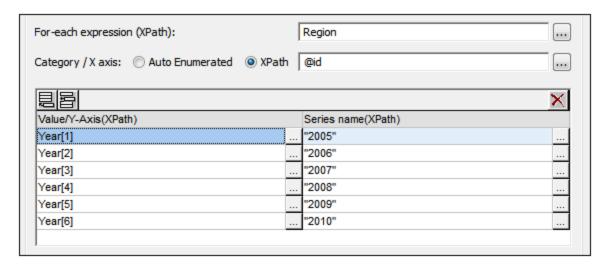

- For-Each XPath expression: (i) Sets the context for the other three XPath expressions; (ii) Sets the number of items in the returned sequence as the number of ticks on the X-Axis. In the case of the screenshot above, the Region[1]/Year expression returns six node items; so there will be six ticks on the X-Axis (see screenshot below).
- X-Axis XPath expression: The items in the returned sequence provide the label text for the corresponding ticks on the X-Axis. In the example shown above, the @id expression returns the id attribute value of each Year element. These values become the labels of the corresponding ticks (see screenshot below). Since we have specified that this will be a bar chart, bars are drawn at the ticks.
- Y-Axis XPath expression: The Y-Axis can display multiple series, each of which is defined in one row of the Y-Axis table. Each series is defined by two XPath expressions: one for the series value, the other for the series name. In our example, the self::node() XPath expression (indicated by its abbreviated form of a period) selects the current node, which is the Year element that is the context node. So, for each Year element (represented by a bar on the X-Axis), the Year element's content will be read as the Y-Axis value of that year, and therefore plotted as the height of the bar (see screenshot below). The screenshot further below shows a chart with multiple series on the Y-Axis.
- Series Name XPath expression: This expression provides the legend text for the series. In our example, the legend text (which appears at the bottom of the chart, screenshot below) is obtained from an XPath expression that is a text string (see screenshot above).

The screenshot above shows a bar chart with a single series, while that below is of a stacked bar chart with multiple series. In the latter example, the value of each series is stacked on to the bar.

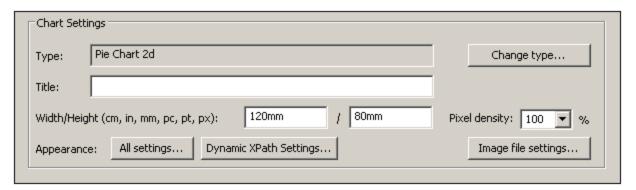

See the chart configuration dialog of the example file SimpleCharts.sps to see how the chart settings were defined. The XPath expressions for this chart are shown in the screenshot below.

5.9.2 Chart Settings: Quick Reference

Chart settings select the chart type and define the appearance of the chart. They are made via the Chart Settings pane (*screenshot below*) of the Chart Configuration dialog. There are two groups of settings: <u>basic</u> (which are made directly in the Chart Settings pane) and <u>advanced</u> (which are accessed via the **All Settings** and **Dynamic XPath Settings** buttons).

The **Image File Settings** button pops up a dialog in which the location and name of the image file can be specified. This location is used when a preview is generated or when the <u>Save Generated Files</u> command is used. Image files created for previews are deleted when StyleVision is closed.

This section contains the following parts:

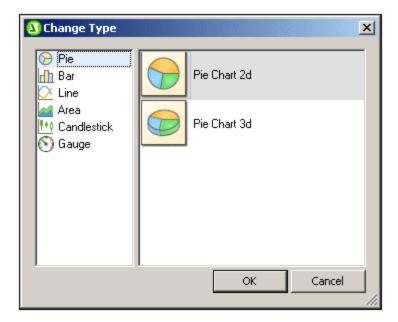

- <u>Basic chart settings</u> ¹⁸³, which are the chart settings available in the Chart Settings pane (see screenshot above) of the <u>Chart Configuration dialog</u> ¹⁸².
- Advanced chart settings (188), which can be accessed via the All Settings button in the Chart Settings pane (see screenshot above).

• <u>Dynamic XPath settings</u> (191), which can be accessed via the **Dynamic XPath Settings** button in the Chart Settings pane (see screenshot above).

Basic chart settings

The basic chart settings are: the chart type, chart title, chart width, and chart height.

To select the chart type, click the **Change Type** button and, in the Change Type dialog that pops up (*screenshot below*), select the chart type you want, and click **OK**.

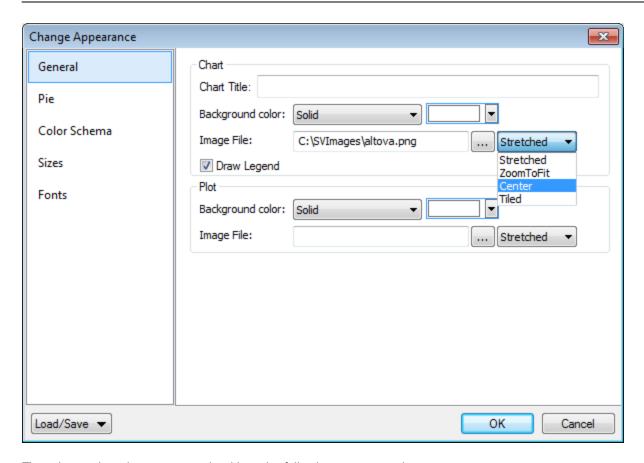

The chart's **title**, **width**, and **height** can be entered as static values directly in the Chart Settings pane. If you wish to obtain the chart's title by evaluating an XPath expressions, then the XPath expression for the title must be set in the <u>Dynamic XPath Settings</u> dialog (accessed with the **Dynamic XPath Settings** button).

The **Pixel Density** setting specifies the resolution of the chart image in the output. It is set as a percentage of the height and width setting. For example: If a chart is specified to have a height of 250px and a width of 250px, and the pixel density has been set to 200%, then a chart image file is created measuring 500px x 500px. In the output, this image file will be constrained to a width of 250px x 250px, thus producing an image of higher resolution.

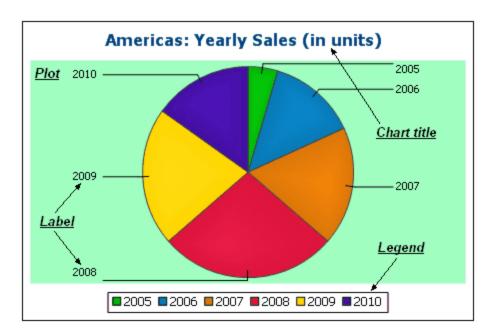

Advanced chart settings

A chart's advanced settings are accessed by clicking the **All Settings** button in the Chart Configuration dialog (see screenshot above). This pops up the Change Appearance dialog for that particular chart type (the screenshot below shows the Change Appearance dialog of a pie chart).

The advanced settings are organized into the following common tabs:

• General: The chart title (see screenshot below) is the same as the basic setting (see above) and can be edited as an advanced setting also. Other settings in this dialog are the background color of the chart and the plot. In the screenshot below, the plot has been given a pale green background color. An image file can also be set as the background image of the chart and/or the plot. This image can be stretched to cover the entire area of the chart or plot; zoomed to fit so that the zoom matches one of the two dimensions (of chart/plot); centered; or tiled. The legend is the key to the color codes in the chart, and it can be turned on or off.

- **Color scheme:** Four predefined color schemes are available plus a user-defined color scheme. You can modify any of the color schemes by adding and/or deleting colors to a scheme. The color scheme selected in this tab will be used in the chart.
- Sizes: Sizes of various aspects of the chart can be set, either as pixels or as a percentage ratio.
- **Font:** The font properties of the chart title and of legends and labels can be specified in this tab. Sizes can be set as a percentage of the chart size or absolutely as points.
- Load/Save button: Settings can be saved to an XML file and can be loaded from an XML file having the correct structure. To see the structure, save the settings of a chart and then open the XML file. Clicking this button also gives you the option of resetting chart settings to the default.

Additionally, each type of chart has settings specific to its type. These are listed below:

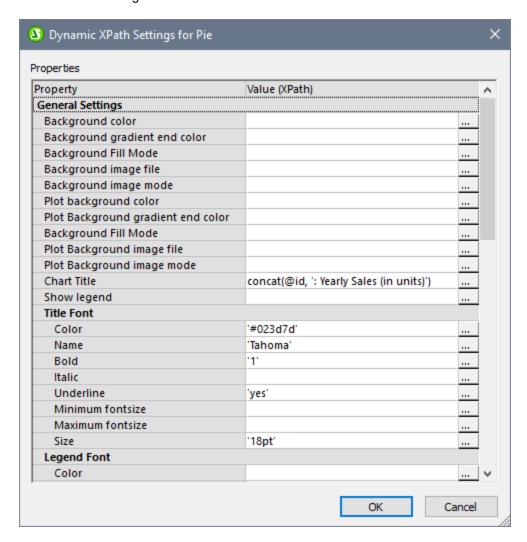

- **Pie charts:** Settings for: (i) the angle from which the first slice should be drawn; (ii) the direction in which slices should be drawn; (iii) the outline color; (iv) whether the colors receive highlights (in 3D pie charts: whether dropshadows and transparency are used); (v) whether labels should be drawn; and (vi) whether values and percentages should be added to labels and how many decimal places should be added to the percentages.
- **Bar charts:** Settings for: (General) Drawing the X and Y axes exchanged generates a horizontal bar chart; (Bar) Bar outlines and dropshadows (dropshadows in 2D bar charts only); (X-Axis) Label and color of the x-axis, and vertical gridlines; (Y-Axis) Label and color of the y-axis, horizontal gridlines, the range of values to be displayed, and the tick marks on the y-axis; (Z-Axis, 3D only) Label and color of the z-axis; (3D) the vertical tilt, horizontal rotation, and the width of the view.
- **Line graphs:** Settings for: (*General*) Drawing the X and Y axes exchanged; (*Line*) including the plot points or not; (*X-Axis*) Label and color of the x-axis, and vertical gridlines; (*Y-Axis*) Label and color of the y-axis, horizontal gridlines, the range of values to be displayed, and the tick marks on the y-axis.
- **Gauge:** Settings for: (i) the angle at which the gauge starts and the angular sweep of the scale; (ii) the range of the values displayed; (iii) the interval and color of major and minor ticks; (iv) colors of the dial, the needle, and the border.
- **Area:** The transparency of areas can be set as a value from 0 (no transparency) to 255 (maximum transparency). In the case of non-stacked area charts transparency makes parts of areas that lie under other areas visible top the viewer. Outlines for the areas can also be specified.
- **Candlestick:** The fill color can be specified for the two situations: (i) when the closing value is greater than the opening value, and (ii) when the opening value is greater than the closing value. In the latter

case, the Series color is also available as an option. The Series color is specified in the Color Schema tab of the Change Appearance dialog.

Dynamic XPath Settings

Dynamic XPath Settings are very useful if you wish to use dynamic data from the XML document in the settings of the chart. For example, the title of a chart about a Region element might need to have data about that Region element (such as its name) in the title of the chart. If there are several Region elements, any one of which will be used at a time for the chart, then the data for the chart title can only be obtained dynamically via an XPath expression. The Dynamic XPath Settings dialog enables such data to be accessed via XPath expressions.

The Dynamic XPath Settings dialog (*screenshot below*) is accessed by clicking the **Dynamic XPath Settings** button in the Chart Settings pane of the <u>Chart Configuration dialog</u> 182. A number of chart settings can be entered in this dialog.

Note the following points:

• All entries in this dialog are evaluated as XPath expressions, so string literals must be enclosed in quotes. For example: 'Tahoma', '1', '18pt', and '#3366FF'.

 On hovering over a setting or its value, a tooltip appears giving information about enumerations and formats.

- The Dynamic XPath Settings have precedence over settings made in the Chart Configuration dialog or Change Appearance dialog. For example, a chart title made as a dynamic XPath setting has precedence over one set in the Chart Configuration dialog.
- The colors of the color schema will be used when the User-Defined color schema is selected in the Change Appearance dialog as the color schema to use. Colors are set in the RGB hexadecimal format: #RRGGBB. So an XPath expression to specify the color red would be: '#FF0000'.

5.9.3 Chart Settings and Appearance

Chart settings are organized as follows:

- <u>Basic Chart Settings</u> (192), which enable you to select the type of chart and its title. Basic chart settings are defined in the Chart Settings pane of the Chart Configuration dialog (see screenshot below).
- Advanced Chart Settings (199), which enable you to change the appearance of a chart (its title, legend, colors, fonts, etc.). Advanced settings are defined in the Change Appearance dialog (199). To access this dialog, click All Settings in the Chart Configuration dialog (see screenshot below).
- <u>Dynamic XPath Settings</u> 219, which can be accessed by clicking **Dynamic XPath Settings** in the Chart Settings pane (see *screenshot below*).

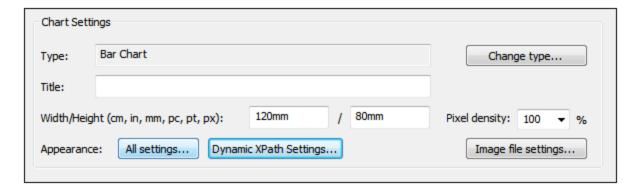

5.9.3.1 Basic Chart Settings

This section:

- Setting the chart type 192
- <u>List of chart types</u> ¹⁹³
- Other basic settings 198

Setting the chart type

The most basic chart setting is the chart type. To select the chart type, click **Change Type** in the <u>Chart Settings pane</u> of the Chart Configuration dialog.

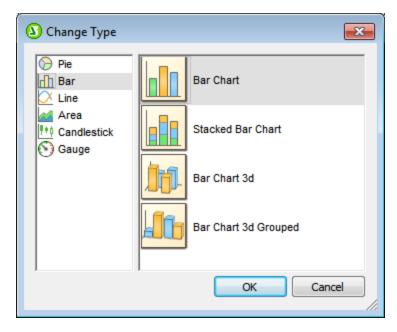

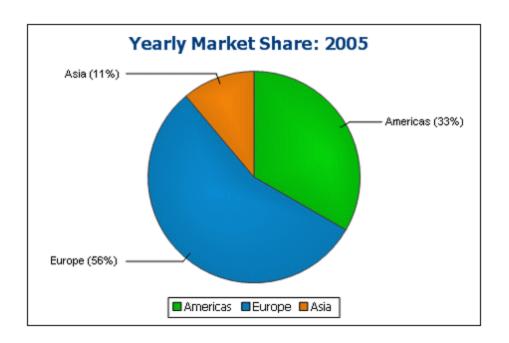

Chart types

The various types of charts that are available are listed below. In the <u>Change Type dialog</u> (screenshot above), select the chart type you want and click **OK**.

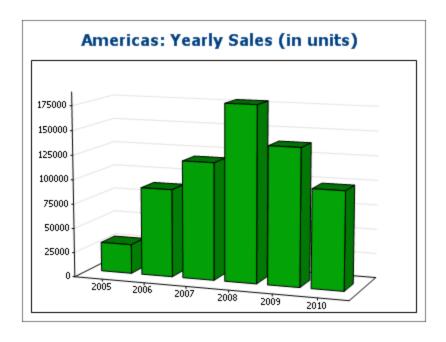

▼ Pie charts

In pie charts, one column/axis provides the values, another column/axis provides labels for these values. The labeling column/axis can take non-numeric values.

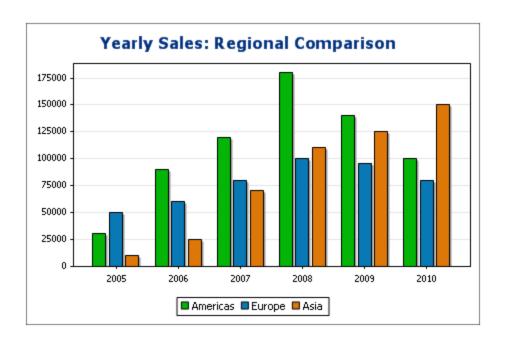

▼ Bar charts

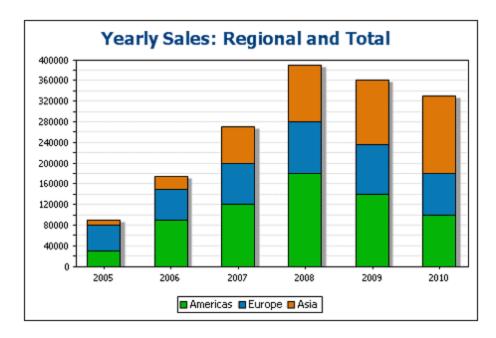

Bar charts can have two sets of values used along two axes (below).

They can also use three sets of values, as in the example below: (i) continent, (ii) year, (iii) sales volume. Bar charts can be displayed in 2D (*below*) or 3D (*above*).

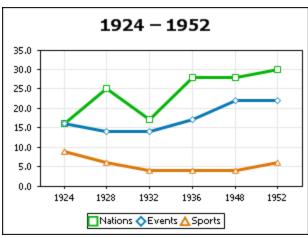

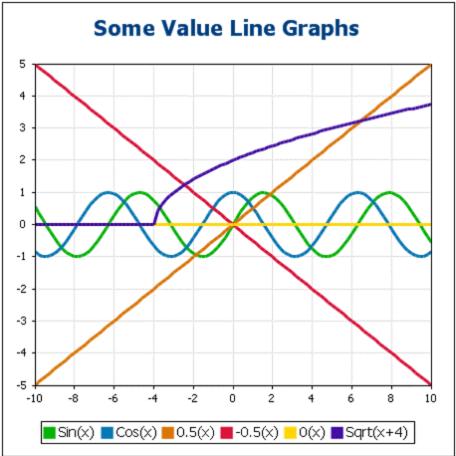

A three-axis bar chart can also be stacked if you need to show totals. Compare the stacked chart below with the chart above. The stacked chart shows the total of sales on all continents.

▼ Line charts

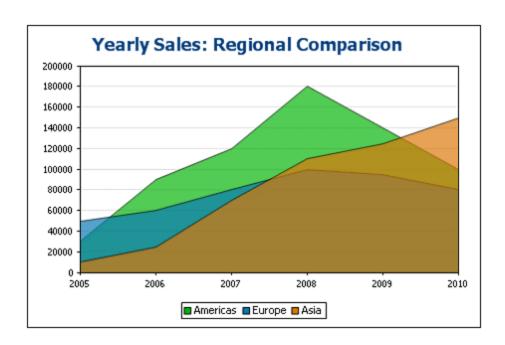

The difference between a line chart (*below left*) and a value line chart (*below right*) is that value line charts only take numerical values for the X-axis. If you need to display line charts with text values on the X-axis, use line charts.

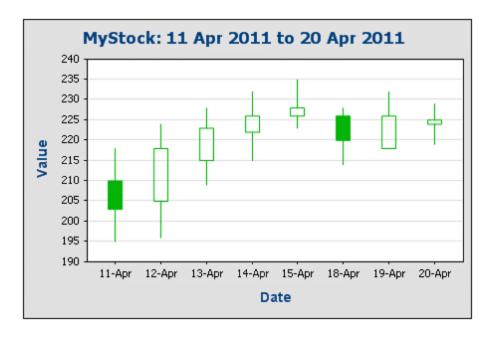

Area charts

Area charts are a variation of line charts, in which the areas below the lines are also colored. Note that area charts can also be stacked (see bar graphs above).

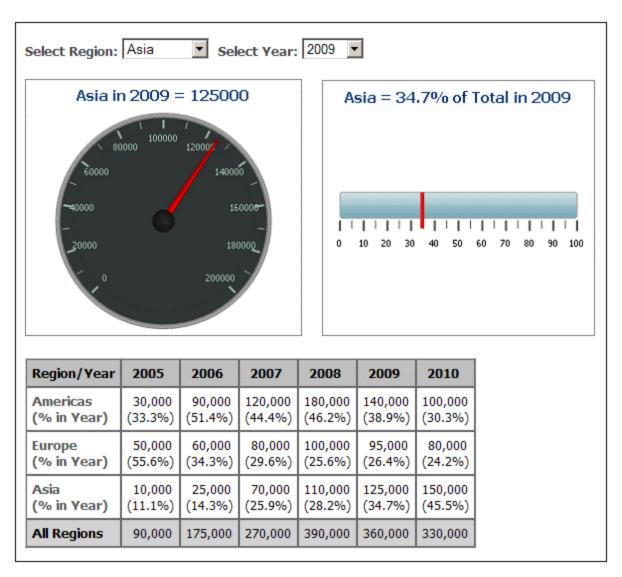

▼ Candlestick charts

A candlestick chart can be used to depict price movements of securities, commodities, currencies, etc over a period of time. The chart indicates not only how prices developed over time, but also the daily close, high, low, and (optionally) open. The Y-axis takes three or four series (close, high, low, and (optionally) open). The screenshot below shows a four-series candlestick chart.

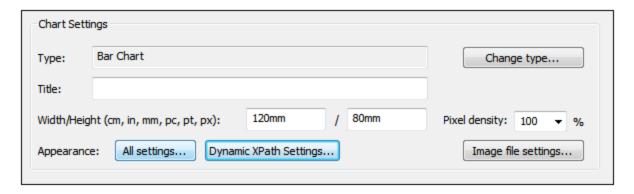

Gauge charts

Gauge charts are used to illustrate a single value and show its relation to a minimum and a maximum value.

Other basic settings

In the Chart Settings pane, you can also set the title of the chart (see screenshot below).

Additionally:

- The chart's width and height can be entered as static values directly in the Chart Settings pane.
- The *Pixel Density* setting specifies the resolution of the chart image in the output. It is set as a percentage of the height and width setting. For example: If a chart is specified to have a height of 250px and a width of 250px, and the pixel density has been set to 200%, then a chart image file is created measuring 500px x 500px. In the output, this image file will be constrained to dimensions of 250px x 250px, thus producing an image of higher resolution.
- Click the **Image File Settings** button to specify the location and name of an image file for the chart. This image file is used when a preview is generated or when the <u>Save Generated Files</u> command is used. Image files created for previews are deleted when StyleVision is closed.

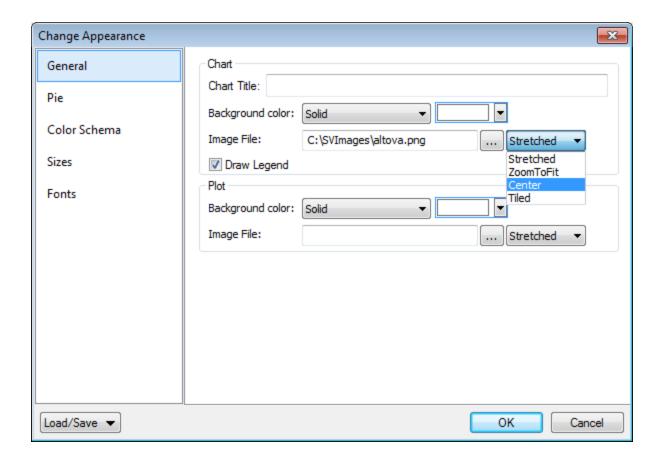

5.9.3.2 Advanced Chart Settings

This section:

- Accessing the advanced settings 199
- Overview of advanced settings 200
- Loading, saving, resetting chart settings 202

Accessing the advanced settings

To access a chart's advanced settings do the following: Click <u>All Settings</u> in the Chart Configuration dialog. This displays the Change Appearance dialog for that particular chart type (the screenshot below shows the Change Appearance dialog of a pie chart).

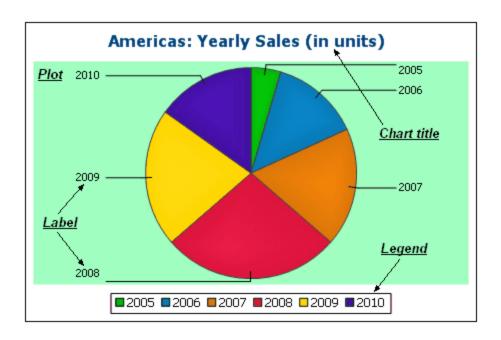

Overview of advanced settings

The advanced settings are organized into tabs that are common to all chart types and those that are specific to a single chart type.

Common chart settings

▼ General

The chart title (see screenshot below) is the same as the basic setting (see above) and can be edited as an advanced setting also. Other settings in this dialog are the background color of the chart and the plot. In the screenshot below, the plot has been given a pale green background color. An image file can also be set as the background image of the chart and/or the plot. This image can be stretched to cover the entire area of the chart or plot; zoomed to fit so that the zoom matches one of the two dimensions (of chart/plot); centered; or tiled. The legend is the key to the color codes in the chart, and it can be turned on or off.

▼ Color scheme

Four predefined color schemes are available plus a user-defined color scheme. You can modify any of the color schemes by adding colors to and/or deleting colors from a scheme. The color scheme selected in this tab will be used in the chart.

▼ Sizes

Sizes of various aspects of the chart can be set, either as pixels or as a percentage ratio.

▼ Font

The font properties of the chart title and of legends and labels can be specified in this tab. Sizes can be set as a percentage of the chart size or absolutely as points.

▼ Load/Save button

Settings can be saved to an XML file and can be loaded from an XML file having the correct structure. To see the structure, save the settings of a chart and then open the XML file. Clicking this button also gives you the option of resetting chart settings to the default.

Type-specific chart settings

▼ Pie charts

Settings for: (i) the angle from which the first slice should be drawn; (ii) the direction in which slices should be drawn; (iii) the outline color; (iv) whether the colors receive highlights (in 3D pie charts: whether

dropshadows and transparency are used); (v) whether labels should be drawn; and (vi) whether values and percentages should be added to labels and how many decimal places should be added to the percentages.

Bar charts

Settings for: (General) Drawing the X and Y axes exchanged generates a horizontal bar chart; (Bar) Bar outlines and dropshadows (dropshadows in 2D bar charts only); (X-Axis) Label and color of the x-axis, and vertical gridlines; (Y-Axis) Label and color of the y-axis, horizontal gridlines, the range of values to be displayed, and the tick marks on the y-axis; (Z-Axis, 3D only) Label and color of the z-axis; (3D) the vertical tilt, horizontal rotation, and the width of the view.

Line graphs

Settings for: (General) Drawing the X and Y axes exchanged; (Line) including the plot points or not; (X-Axis) Label and color of the x-axis, and vertical gridlines; (Y-Axis) Label and color of the y-axis, horizontal gridlines, the range of values to be displayed, and the tick marks on the y-axis.

Gauge charts

Settings for: (i) the angle at which the gauge starts and the angular sweep of the scale; (ii) the range of the values displayed; (iii) the interval and color of major and minor ticks; (iv) colors of the dial, the needle, and the border.

Area charts

The transparency of areas can be set as a value from 0 (no transparency) to 255 (maximum transparency). In the case of non-stacked area charts transparency makes parts of areas that lie under other areas visible to the viewer. Outlines for the areas can also be specified.

▼ Candlestick charts

The fill color can be specified for the two situations: (i) when the closing value is greater than the opening value, and (ii) when the opening value is greater than the closing value. In the latter case, the Series color is also available as an option. The Series color is specified in the Color Schema tab of the Change Appearance dialog.

Loading, saving, resetting chart settings

Chart settings that are different from the default settings can be saved in an XML file. These settings can subsequently loaded as the settings of a chart, which can help you save time and effort. The **Load/Save** button (see first screenshot in this section (1999)) provides the following options when clicked:

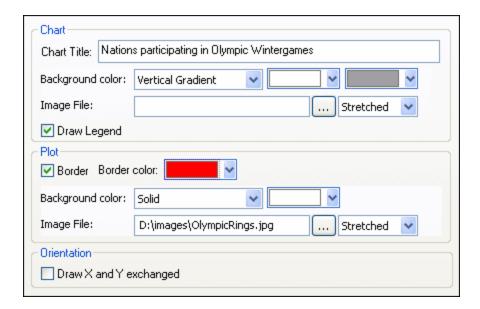

• Set to default: Rejects changes made to the settings, and restores the default settings to all settings sections.

• **Load from file**: Enables settings to be imported that have been previously saved in an XML file (see next command). The command displays the Open dialog, in which you enter the location of the required file.

• Save to file: Opens the Save As dialog box. You can specify an XML file in which to save the settings. This file lists those settings that are different from the default settings.

5.9.3.2.1 General

The General section of the Change Appearance dialog box lets you define the title of the chart, add or remove a legend, and define background pictures and colors and—for bar, line, area, and candlestick charts—orientation of the chart.

Chart

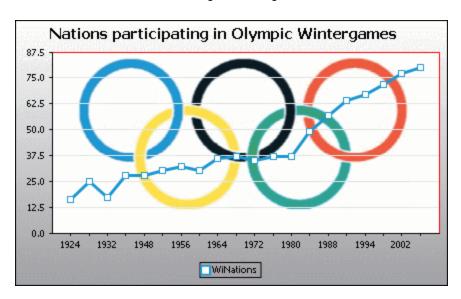

Enter a descriptive title for your chart into the Chart Title field and select a background color for the entire chart from the drop-down list. You can choose a solid background, vertical gradient, or horizontal gradient and define start and end colors for the gradient, if applicable. In addition, or instead of a colored background, you can also define a background image and choose one of the available display options from the drop-down list:

- Stretched: the image will be stretched to the height and width of the chart
- Zoom to Fit: the image will be fit into the frame of the chart and the aspect ratio of the image will be maintained
- Center: the image will be displayed in its original size in the center of the chart
- Tiled: if the image is smaller than the chart, duplicates of the image will be displayed to fill the background area

The Draw Legend check box is activated by default, clear the check box if you do not want to display a legend in your chart.

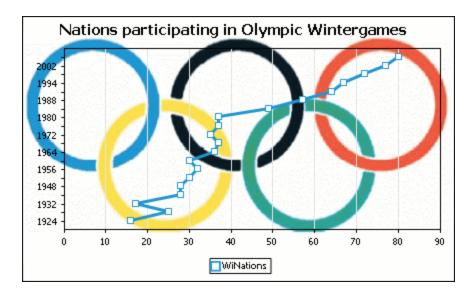

Plot

The Plot is the area where the actual data of the chart is displayed. You can draw a border around the plot and specify a different background color and/or image for the plot area. In the screenshot below, the background color of the chart has been changed to gray (vertical gradient) whereas the plot is still white, a red border has been drawn around it, and a background image has been added.

Orientation

If you have a small series of large values it may be convenient to swap the X and Y axis for a better illustration. Note that in the screenshot below also the background color of the plot has been set to "Transparent" and the background image has been applied to the chart.

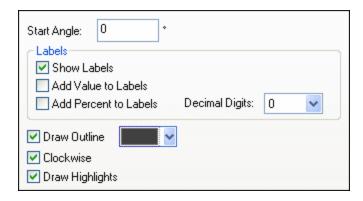

Note that this option is not available for pie and gauge charts.

5.9.3.2.2 Type-Related Features

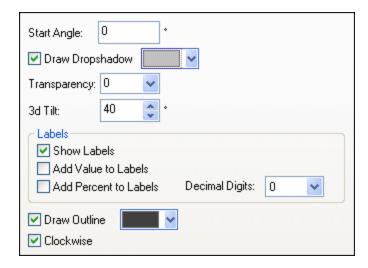

For each of the chart types, and even for the various sub-types, the Change Appearance dialog box provides a section where you can define the type-related features of the chart.

Pie chart

Most settings are the same for the 2d and 3d versions. In 2d pie charts, you can additionally draw highlights.

In 3d pie charts, you can display drop shadows, add transparency and define the 3d tilt.

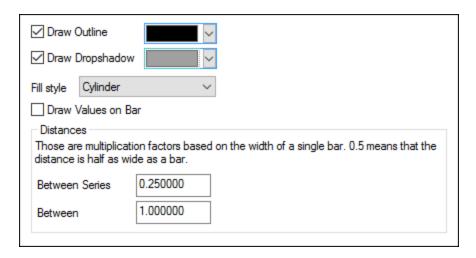

The $Start\ Angle\ value\ defines\ where\ the\ first\ row\ of\ the\ selected\ column\ will\ be\ displayed\ in\ the\ chart.$ An angle of 0 degrees corresponds to 12 o'clock on a watch.

You can show labels in addition to, or instead of, the legend, add values and/or percentage to the labels, and define for the percentage values the number of decimal digits to be displayed.

The color that you can select next to the <code>Draw Outline</code> check box is used for the optional border drawn around the chart and the individual pie segments. The <code>Clockwise</code> check box allows you to specify whether the rows should be listed clockwise or counter-clockwise.

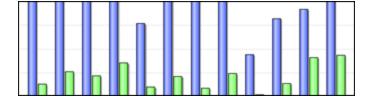

In 3d pie charts, you can draw a drop shadow and define its color, add transparency to the chart, and define the 3d tilt. In 2d charts, the <code>Draw Highlights</code> option adds additional structure to the chart.

Bar chart

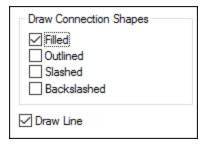

For bar charts, you can make the following setting:

- Add an outline to the bars and define its color.
- In 2d bar charts, you can also draw a drop shadow and define its color (this option is not available for 3d bar charts).
- By default, the shape of the bars resembles a cylinder, however you can also choose "Vertical Gradient" or "Solid" from the Fill style drop-down list (this option is available for 2d bar charts only).
- The values of a bar (corresponding to the height of the bar on the Y-axis) can be drawn on the bar. The font of the values can be specified in the *Fonts* settings (this option is available only for 2d bar charts, not stacked).
- The distance between the series of a bar-group and between bar-groups can be specified as a decimal fraction of the width of a single bar. For example, in the screenshot below, which shows bar-groups that each consist of a blue series and a green series, the distance between the series has been set to a 25% (=0.25) of the width of a bar; the distance between bar-groups has been set to 100% (=1.0) of the width of a bar. This option is available only for 2d bar charts.

Line chart

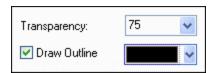

To draw connection shapes that mark the values in line charts, you need to activate at least one check box in the Draw Connection Shapes group box. You can use five different shapes to mark a series: square, rhomb, triangle, inverted triangle, and circle. If there are more than five series in your chart you can combine the connection shapes by selecting more than one option in the Draw Connection Shapes group box. In the screenshot below, both Filled and Slashed have been selected and the Slashed type is used for the sixth series and beyond.

The *Draw Line* option enables the graph to be drawn with (i) only connection shapes, or (ii) with connection shapes joined by a line.

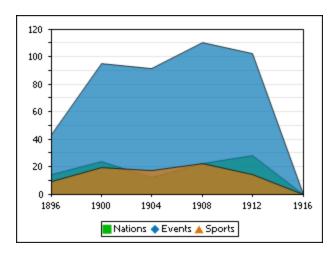

Connection shapes are available for both line charts and value line charts.

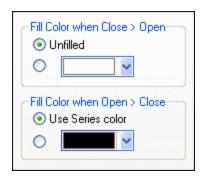

Area chart

Among the properties that you can change for area charts is transparency; this way you can prevent that one series is hidden by another series in the chart. In addition, you can add an outline to the individual data areas and define its color (see screenshot below).

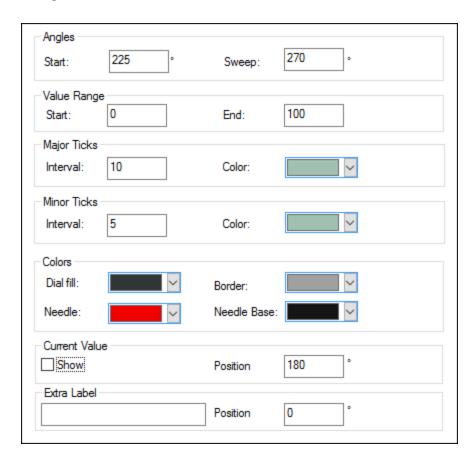

Candlestick chart

If both opening and closing value are defined as series, you can choose the colors and whether or not the candle should be filled if the closing value is greater than the opening value.

Gauge chart

The Start value in the Angles group box defines the position of the 0 mark and the Sweep value is the angle that is used for display. In the Value Range group box you can define the minimum and maximum values to be displayed. Tick marks are displayed with (major ticks) or without (minor ticks) the corresponding value; you can define separate colors for them. In the Colors group box you can define colors for the dial fill, needle, needle base (hides the first part of the needle in the center of the chart), and the border that surrounds the chart. The current value and an extra label can be shown at any angle you like.

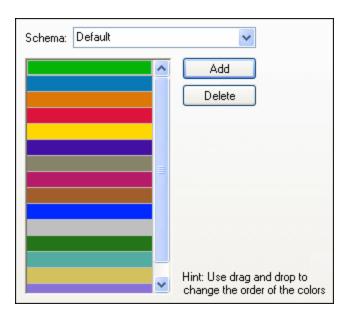

5.9.3.2.3 Colors

Depending on the chart type you have selected, StyleVision provides two different sections for the definition of colors to be used in charts:

- Color Schema for pie, bar, line, area, and candlestick charts
- Color Range for gauge charts

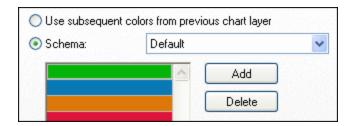

Color Schema

The Color Schema section of the Change Appearance dialog box provides four predefined color schemas (i.e., default, grayscale, colorful, and pastel) that can be customized; in addition you can also define your own color schema from scratch.

The top color will be used for the first series, then the second color and so on. You can change the order of the colors by selecting a color and dragging it to its new position with the mouse. To add a new or delete an unwanted color, click the corresponding button. In candlestick charts, only the first color will be used.

If you have appended one or several layers of overlay charts to a Charts window, the Color Schema section of the Change Appearance dialog box contains the additional radio button Use subsequent colors from previous chart layer which is activated by default.

When the radio button is activated, the color schema from the previous layer will be used and you cannot choose a separate color schema for the overlay. The series of the active layer will be displayed using subsequent colors from the color schema of the previous layer. This way, all series of the Charts window have different colors and can therefore be distinguished more easily.

You can break this link on any additional layer that you add and choose a different color schema that then can also be re-used in subsequent layers.

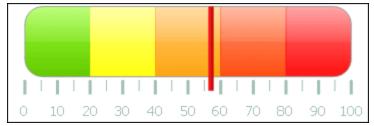

Color Range

In gauge charts, you can customize the appearance of the gauge by applying colors to certain value ranges.

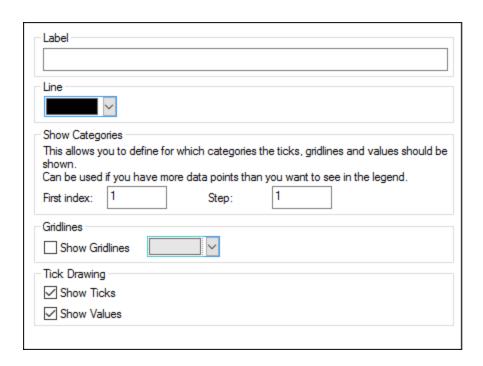

The definition shown in the screenshot above will appear in the gauge charts as follows:

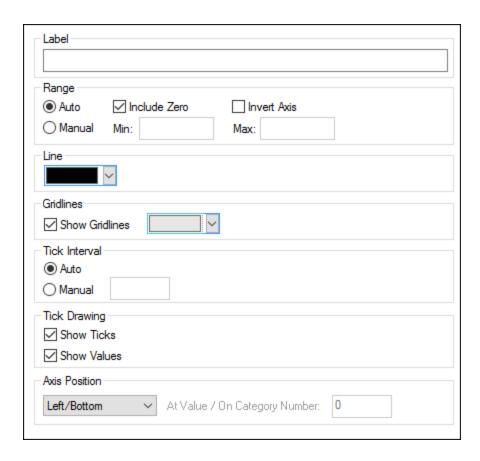

5.9.3.2.4 X-Axis

In the X-axis section of the Change Appearance dialog box, you can enter a label for the axis, and define colors for the axis and the grid lines (if displayed). You can also define whether or not you want to display tick marks and axis values. This section is the same for all bar, line, area, and candlestick charts. The *Show Categories* options enables you to specify that only a subset of all categories (X-Axis values) are displayed, that is, only the ticks, grid lines, and values of the selected categories will be displayed. Create the subset of displayed categories by entering (i) the index of the first value to display, and (ii) the number of indices to step. For example, if there are 101 categories, from 1900, 1901, 1902 ... 1999, 2000, then you can show every tenth year from 1900 to 2000 by setting *First index* to 1 and *Step* to 10.

In Value Line Charts however, you can also define the value range, and define at what interval tick marks should be displayed.

<u>Label</u>

The text entered into the Label field will be printed below the axis as a description of the X-axis.

Range

By default, the Auto radio button is selected in the Range group box. If you want to display a fragment of the chart in greater detail, activate the Manual radio button and enter minimum and maximum values into the respective fields. If the column that is used for the X-axis does not include zero, you can deactivate the Include Zero check box and the X-axis will start with the minimum value that is available in the series. The Invert Axis option enables you to invert the values of the X-Axis. For example, if the values run from the 0 to 360, selecting this option will generate the X-Axis so that 360 is at the origin and the values progress down to 0 as the X-Axis goes upwards.

Line

The axis is displayed in the color that you choose from the Line drop-down-list. You can use one of the preselected colors, or click the **Other color...** button to choose a standard color or define a custom color. Click the **Select...** button on the Custom tab and use the pipette to pick a color that is displayed somewhere on your screen.

Grid lines

If the Show Grid lines check box is activated, you can choose a color from the corresponding drop-down list box.

Tick Interval

If you are not satisfied with the default tick marks, you can activate the Manual radio button in the Tick Interval group box and enter the difference between the individual tick marks into the corresponding field.

Tick Drawing

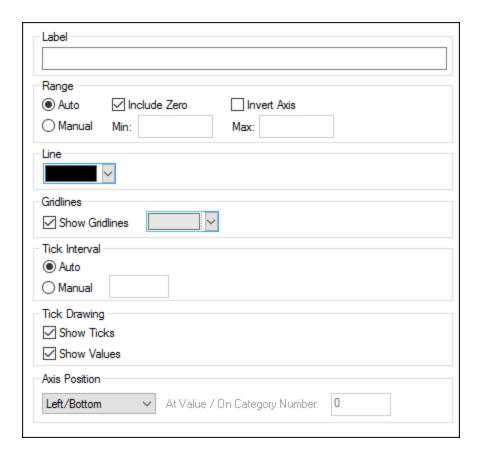

You can switch the display of tick marks on the axis and/or axis values on or off.

Axis Position

From the drop-down list, you can choose the position where the axis is to be displayed. When selecting "At Value / On Category Number", you can also position the axis anywhere within the plot.

5.9.3.2.5 Y-Axis

In the Y-axis section of the Change Appearance dialog box, you can enter a label for the axis, define colors for the axis and the grid lines (if displayed), define the value range, and decide if and where tick marks should be displayed and whether or not you want to show the axis values. This section is the same for all bar and line charts.

Label

The text entered into the Label field will be printed to the left of the axis as a description of the Y-axis.

Range

By default, the Auto radio button is selected in the Range group box. If you want to display a fragment of the chart in greater detail, activate the Manual radio button and enter minimum and maximum values into the respective fields. If the column that is used for the Y-axis does not include zero, you can deactivate the Include Zero check box and the Y-axis will start with the minimum value that is available in the series. The Invert Axis option enables you to invert the values of the Y-Axis. For example, if the values run from the 0 to 360, selecting this option will generate the Y-Axis so that 360 is at the origin and the values progress down to 0 as the Y-Axis goes upwards.

Line

The axis is displayed in the color that you choose from the Line drop-down-list. You can use one of the preselected colors, or click the **Other color...** button to choose a standard color or define a custom color. Click the **Select...** button on the Custom tab and use the pipette to pick a color that is displayed somewhere on your screen.

Grid lines

If the Show Grid lines check box is activated, you can choose a color from the corresponding drop-down list box.

Tick Interval

If you are not satisfied with the default tick marks, you can activate the Manual radio button in the Tick Interval group box and enter the difference between the individual tick marks into the corresponding field.

Tick Drawing

You can switch the display of tick marks on the axis and/or axis values on or off.

Axis Position

From the drop-down list, you can choose the position where the axis is to be displayed. When selecting "At Value / On Category Number", you can also position the axis anywhere within the plot.

5.9.3.2.6 Z-Axis

In the Z-axis section of the Change Appearance dialog box, you can enter a label for the axis, define colors for the axis, and decide whether or not you want to show tick marks on the axis. This section is the same for all 3d bar charts (Bar Chart 3d and Bar Chart 3d Grouped).

Label

The text entered into the Label field will be printed to the right of the axis as a description of the Z-axis.

<u>Line</u>

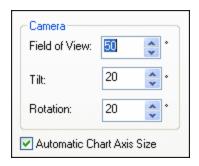

The axis is displayed in the color that you choose from the Line drop-down-list. You can use one of the preselected colors, or click the **Other color...** button to choose a standard color or define a custom color. Click the **Select...** button on the Custom tab and use the pipette to pick a color that is displayed somewhere on your screen.

Tick Drawing

You can switch the display of tick marks on the axis on or off.

5.9.3.2.7 3D Angles

In 3d bar charts you can customize the 3d appearance of the chart in the 3d Angles section of the Change Appearance dialog box.

The **Field of view** option causes the diagram to appear as if observed from a small or great distance. Values ranging from 1 through 120 are valid. Higher values cause the diagram to appear as if observed from a greater distance.

The **Tilt** value determines the rotation around the X-axis, whereas the **Rotation** value defines the rotation around the Y-axis. You can automatically adapt the size of the chart axis to the Chart window width by selecting the corresponding check box.

If the **Automatic Chart Axis Size** check box is selected, StyleVision will automatically calculate the optimum size of the X-axis as well as the Y-axis for the current Chart window size. The width and height of the chart will change dynamically when you resize the Chart window.

5.9.3.2.8 Sizes

In the Sizes section of the Change Appearance dialog box, you can define different margins as well as the size of axis and gauge ticks. Note that not all the properties listed below are available for all chart types.

General

Outside margin Space between the plot and the edge of the Chart window.

Title to Plot Space between the chart title and the upper edge of the plot. Legend to Plot Space between the lower edge of the plot and the legend.

<u>Pie</u>

Plot to Label In pie charts, the space between the most left and right edge of the pie and its labels.

Pie Height In 3d pie charts, the height of the pie.

Pie Drop Shadow In 3d pie charts, the length of the shadow (if it is activated in the Pie section).

X-Axis

X-Axis to Axis In bar and line charts, the space between the X-axis and its label.

Label

X-Axis to Plot In 2d bar charts and line charts, the space between the X-axis and the plot.

X-Axis Tick Size In bar and line charts, the length of the ticks on the X-axis.

Y-Axis

Y-Axis to Axis In bar and line charts, the space between the Y-axis and its label.

Label

Y-Axis to Plot In 2d bar and line charts, the space between the Y-axis and the plot.

Y-Axis Tick Size In bar and line charts, the length of the ticks on the Y-axis.

<u>Z-Axis</u>

Z-Axis to Axis In 3d bar charts, the space between the Z-axis and its label.

Label

Z-Axis Tick Size In 3d bar charts, the length of the ticks on the Z-axis.

<u>Line Drawing</u>

Connection Shape In line charts, the size of the squares that mark the values in the chart.

Size

Line width In line charts, the width of the line.

3d Axis Sizes

Manual X-Axis In 3d bar charts, defines the relation between the length of the X-axis and the Chart Size of Base window size. Please note that the Automatic Chart Axis Size check box in the 3d

window size. I load the title Automatic chart Axis Size Glock box in the

Angles section must be deactivated, otherwise the size will still be calculated

automatically.

Manual Y-Axis In 3d bar charts, defines the relation between the length of the Y-axis and the Chart Size of Base window size. Please note that the Automatic Chart Axis Size check box in the 3d

section must be deactivated, otherwise the size will still be calculated automatically.

Z-Axis Series In 3d bar charts, the distance on the Z-axis between the individual series.

Margin

Gauge

Border Width In round gauge charts, the width of the border around the gauge.

Gauge Ticks

Border to Tick In round gauge charts, the space between the inner edge of the border and the ticks that

Distance mark the values.

Major Tick Length In round gauge charts, the length of the major ticks (i.e., ticks that show a label).

Major Tick Width In round gauge charts, the width of the major ticks (i.e., ticks that show a label).

Minor Tick Length In round gauge charts, the length of ticks that do not have a value displayed.

Minor Tick Width In round gauge charts, the width of ticks that do not have a value displayed.

Gauge Needle

Needle Length In round gauge charts, the length of the needle. (Note that the percentage is calculated

from the diameter of the gauge, so if you choose a value greater than 50%, the needle will

point to somewhere outside the gauge!)

Needle Width at

Base

In round gauge charts, the width of the needle at the center of the gauge.

Needle Base

Radius

In round gauge charts, the radius of the base that covers the center of the gauge.

Gauge Color Range

Border to Color In round gauge charts, the space between the inner edge of the border and the outer edge of the color range 211. Range Distance

Color Range Width In round gauge charts, the width of the customizable color range. (Note that the percentage is calculated from the diameter of the gauge!)

Gauge Value

Offset to Center Distance from the center at which the gauge value is displayed.

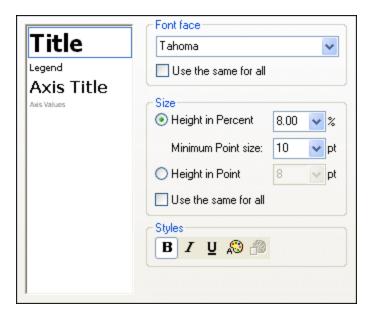

Extra Value

Distance from the center at which the extra label (defined in the Gauge Chart settings [25]) Offset to Center

is displayed.

5.9.3.2.9 **Fonts**

The Fonts section of the Change Appearance dialog box lets you configure fonts for objects in the Chart window.

Font settings

You can choose the font face, size, and style for the individual elements displayed in the Chart window. You can define the size as a percentage of the chart size and define a minimum size in points, or specify an

absolute value (in points). To apply the same font and/or size to all text elements, activate the respective Use the same for all check box.

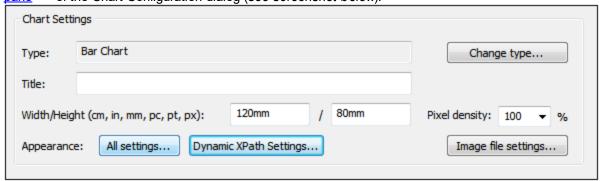

The element names in the list box are defined as follows:

- **Title**: The name of a chart
- Legend: The key to the colors used in the chart
- Labels: The designation of the pieces of a pie chart
- Axis Title: The name of the X, Y, and Z axis in a bar or line chart
- Axis Values: The units displayed on an axis in a bar or line chart
- Tick Values: The units displayed on a gauge chart
- Values: The values displayed on the bars of a bar chart

5.9.3.3 Dynamic XPath Settings

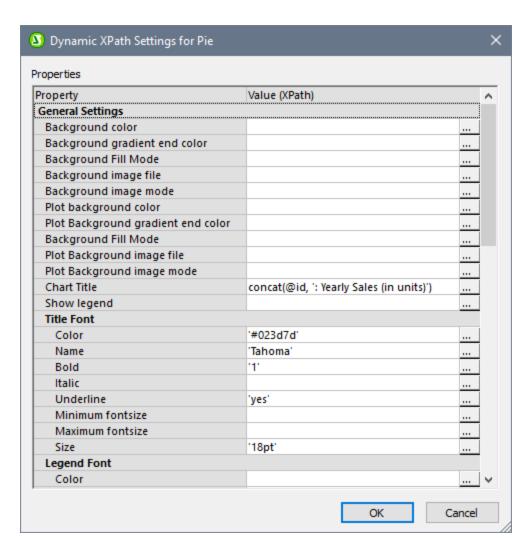

Dynamic XPath Settings are very useful if you wish to use dynamic data from the XML document in the settings of the chart. For example, the title of a chart about a Region element might need to have data about that Region element (such as its name) in the title of the chart. If there are several Region elements, any one of which will be used at a time for the chart, then the data for the chart title can only be obtained dynamically via an XPath expression. The Dynamic XPath Settings dialog enables such data to be accessed via XPath expressions.

To access the chart's Dynamic XPath Settings dialog, click **Dynamic XPath Settings** in the <u>Chart Settings</u> pane 1922 of the Chart Configuration dialog (see screenshot below).

Dynamic XPath Settings

The Dynamic XPath Settings dialog (*screenshot below*) is accessed by clicking the **Dynamic XPath Settings** button in the Chart Settings pane of the Chart Configuration dialog. A number of chart settings can be entered in this dialog.

Note the following points:

- All entries in this dialog are evaluated as XPath expressions, so string literals must be enclosed in quotes. For example: 'Tahoma', '1', '18pt', and '#FF3366'.
- On hovering over a setting or its value, a tooltip appears giving information about enumerations and formats.
- The colors of the color schema will be used when the user-defined color schema is selected in the Change Appearance dialog as the color schema to use. Colors are set in the RGB hexadecimal format: #RRGGBB. So an XPath expression to specify the color red would be: '#FF0000'.

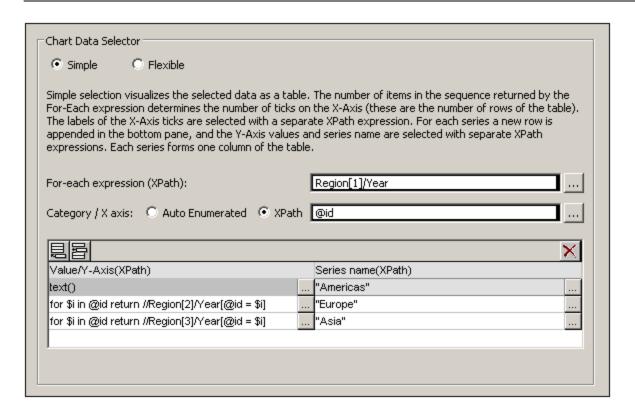

5.9.4 Chart Data Selection: Simple

In the Chart Data Selector pane of the <u>Chart Configuration dialog</u> (182), the Simple option enables the data selection to be visualized as a table. We will use the XML document below to explain the visualization.

```
■ XML file used in charts example: YearlySales.xml

   <ChartType>Pie Chart 2D</ChartType>
         <Region id="Americas">
               <Year id="2005">30000</year>
               <Year id="2006">90000</year>
               <Year id="2007">120000
               <Year id="2008">180000</year>
               <Year id="2009">140000
               <Year id="2010">100000</year>
         </Region>
         <Region id="Europe">
               <Year id="2005">50000</year>
               <Year id="2006">60000</year>
               <Year id="2007">80000</year>
               <Year id="2008">100000</year>
               <Year id="2009">95000</year>
               <Year id="2010">80000</year>
         </Region>
         <Region id="Asia">
               <Year id="2005">10000
               <Year id="2006">25000</year>
               <Year id="2007">70000</year>
               <Year id="2008">110000
               <Year id="2009">125000</year>
               <Year id="2010">150000
         </Region>
   </Data>
```

In the SPS design we insert a chart inside the <code>Data</code> node. In the Chart Data Selector pane (*screenshot below*) we make the data selection as shown in the screenshot. Since the chart has been inserted within the <code>Data</code> node, the context node for the For-Each expression is the <code>Data</code> node.

The chart data table can be visualized as the table below. What happens is that for each <code>Region[1]/Year</code> element a row is created and the X-Axis and Y-Axis XPath expressions are evaluated within the respective <code>Region[1]/Year</code> element's context.

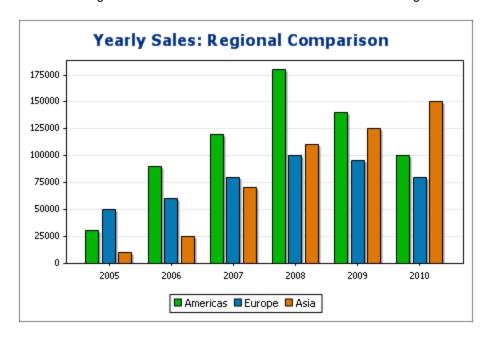

For-Each XPath	X-Axis	Y-Axis for Series		
		Americas	Europe	Asia
Region[1]/Year[1]	@id	text()	XPath-1	XPath-2
Region[1]/Year[2]	@id	text()	XPath-1	XPath-2
Region[1]/Year[3]	@id	text()	XPath-1	XPath-2
Region[1]/Year[4]	@id	text()	XPath-1	XPath-2
Region[1]/Year[5]	@id	text()	XPath-1	XPath-2
Region[1]/Year[6]	@id	text()	XPath-1	XPath-2

- The For-Each expression Region[1]/Year returns six nodes (which become the rows of the table). The number of items in the sequence returned by the For-Each expression determines the **number of ticks** on the X-Axis.
- The XPath expression for the X-Axis returns the @id attribute value of each Region[1]/Year element. These values will be the labels of the X-Axis ticks. If there are more labels than ticks then extra ticks will be generated so that all labels are plotted. If there are fewer labels than ticks, then the latter ticks (for which no corresponding labels exist) will be unlabelled. The Auto-Enumerated option generates a sequence of integers starting with 1, and assigns each integer sequentially to an X-Axis tick.
- The XPath expression for the Americas series (text()) returns the content of each of the Region[1]/Year elements. This expression could also have been one similar to that for the Europe and Asia series (explained below)—as long as it efficiently returns the values we want.

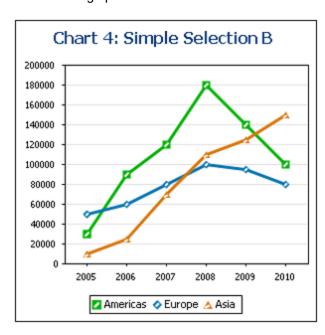

• The XPath expression for the Europe series is: for \$i in @id return //Region[2]/Year[@id=\$i]. This expression does the following: (i) looks for the current Region[1]/Year/@id attribute value, (ii) returns the content of the Region[2]/Year element that has the same @id value as the @id value of the current Region[1]/Year element.

• The XPath expression for the Asia series works in a similar way to the XPath expression for the Europe series.

The bar chart generated with this data selection would look something like this:

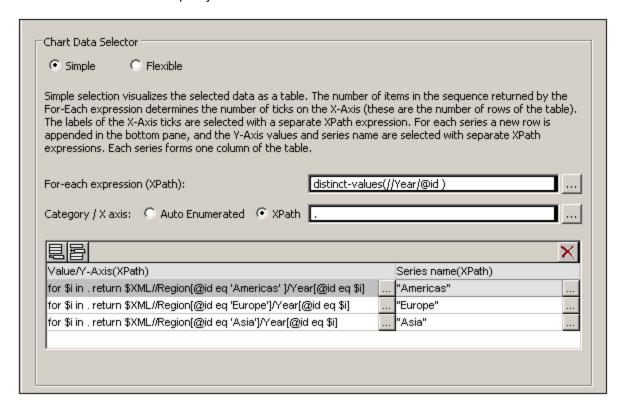

And the line graph chart for this data selection would look like this:

The data selection described above is that for one of the line graphs contained in the example SPS file YearlySales.sps. The SPS design is based on the XML Schema YearlySales.xsd and it uses YearlySales.xml (XML file screenshot above) as its Working XML File. All three files are located in the (My) Documents folder 33, C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

If the For-Each expression returns items that are not nodes

Since the number of X-Axis ticks is primarily dependent on the number of items returned by the For-Each XPath expression, the XPath expression in the screenshot below (distinct-values(//Year/@id)), which returns the six unique year values, will also generate six ticks on the X-Axis. The items returned by the sequence, however, are atomic values, not nodes. Consequently, although they can be used as context items, they cannot be used as context nodes for locating nodes in the XML tree. They can, however, be used to locate nodes on the basis of the equality of values—which is how we will use them.

In the data selection shown in the screenshot above, note the following:

- The X-Axis and Y-Axis data selections use the atomic values returned by the For-Each expression, respectively, as direct output and as filter test values.
- Location steps in XPath expressions start at the document node (the \$XML in \$XML//Region...). This is necessary because the atomic values provide no locational context.

The chart data table would evaluate to the following:

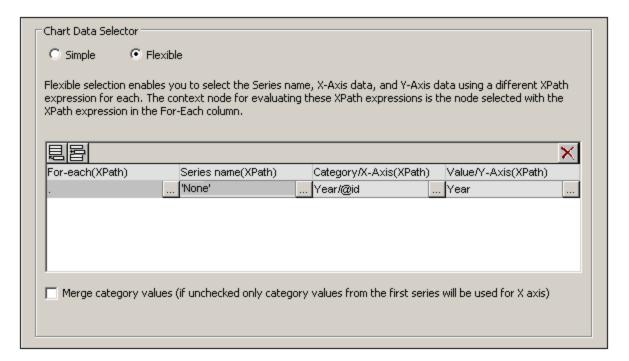

For-Each	X-Axis	Y-Axis for Series		
XPath		Americas	Europe	Asia
2005	2005	XPath-1	XPath-2	XPath-3

2006	2006	XPath-1	XPath-2	XPath-3
2007	2007	XPath-1	XPath-2	XPath-3
2008	2008	XPath-1	XPath-2	XPath-3
2009	2009	XPath-1	XPath-2	XPath-3
2010	2010	XPath-1	XPath-2	XPath-3

5.9.5 Chart Data Selection: Flexible

In the Chart Data Selector pane (*screenshot below*) of the <u>Chart Configuration dialog</u> (182), the Flexible option enables the Series Axis (Z-Axis), X-Axis, and Y-Axis data to be selected freely using XPath expressions. The XPath expression for an axis returns the sequence of items that are to be plotted on that axis. These sequences (of items) for the axes are then collated to generate the chart.

Note the following points:

A series refers to a series of values plotted for a set of X-Axis (Category Axis) ticks. A second series would plot a second set of values on the same X-Axis ticks. For example, if the X-Axis represented the years 2008, 2009, and 2010, and the Y-Axis represented sales turnover, then Series 1 could represent America (sales in America for those three years) while Series 2 could represent Europe (sales in

Europe for those three years). If this data were selected for a bar chart, then for each year (2008, 2009, 2010) on the X-Axis, there would be two bars (America and Europe), one for each series. In the case of pie charts and single-bar charts, only one series is possible. See the <u>chart type table</u> for more information about each chart type.

- Each row in the Chart Data Selector pane represents a series.
- The XPath expression in the For-Each column provides the context for the evaluation of each of the other three XPath expressions. The For-Each XPath expression is itself evaluated in the context of the node in the design within which it was inserted.

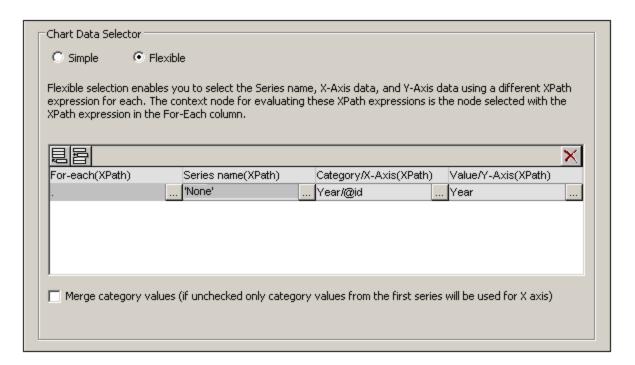

The following example illustrates important points to consider when selecting data for the axes. We will use the XML document below.

```
■ XML file used in charts example: YearlySales.xml

   <?xml version="1.0" encoding="UTF-8"?>
   <Data xm]ns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
         xsi:noNamespaceSchemaLocation="YearlySales.xsd">
          <ChartType>Pie Chart 2D</ChartType>
          <Region id="Americas">
                 <Year id="2005">30000
                 <Year id="2006">90000</year>
                 <Year id="2007">120000
                 <Year id="2008">180000</year>
                 <Year id="2009">140000</year>
                 <Year id="2010">100000</year>
          </Region>
          <Region id="Europe">
                 <Year id="2005">50000</year>
                 <Year id="2006">60000</year>
                 <Year id="2007">80000</year>
                 <Year id="2008">100000
                 <Year id="2009">95000</year>
                 <Year id="2010">80000</year>
          </Region>
          <Region id="Asia">
                 <Year id="2005">10000</year>
                 <Year id="2006">25000</year>
                 <Year id="2007">70000</year>
                 <Year id="2008">110000
                 <Year id="2009">125000</year>
                 <Year id="2010">150000
          </Region>
   </Data>
```

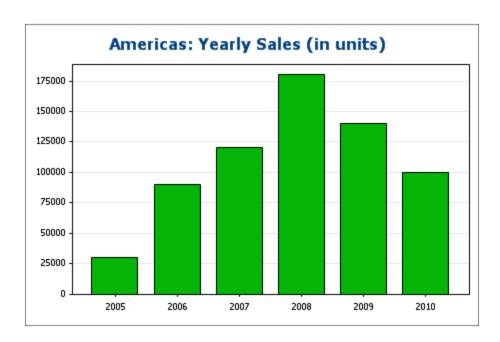

One row, one series

Say we wish to generate a 2D bar chart for each Region element (there are three such elements: for the Americas, Europe, and Asia). Let us create the chart in the design within the Region element node. The context node for the For-Each XPath expressions in the Chart Data Selector will therefore be the Region element.

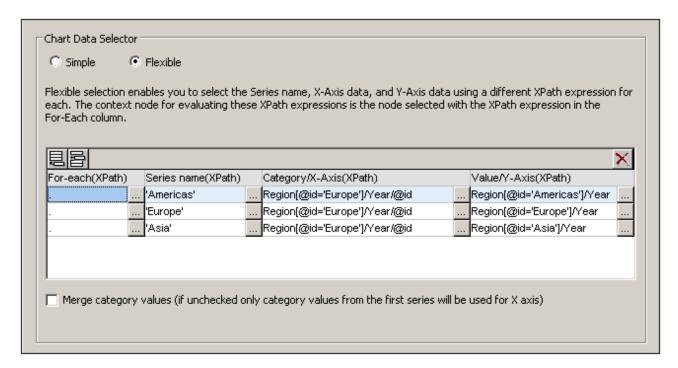

In the chart data selection shown in the screenshot above, the For-Each expression returns the current node (which is the Region element), so the Region element will be the context node for all the other three XPath expressions (series, X-Axis, and Y-Axis). Since there is only one series in this chart, we do not need a series name and so we leave this column blank. The X-Axis selection returns six values. Six will therefore be the number of ticks on the X-Axis and the six items of the sequence will be the respective labels of the X-Axis ticks. The Y-Axis selection also returns six items, each of which is plotted on the Y-Axis for its corresponding X-Axis tick. Since the chart was created within the Region element, the XSLT engine will iterate over the three Region elements to produce three charts, one for each Region element. For each chart, that particular Region element's descendant nodes will be used.

The chart for the Americas region would look something like this in the output:

Three rows, three series, category values not merged

To create multiple series, additional rows can be added to the chart data selection, as shown in the screenshot below.

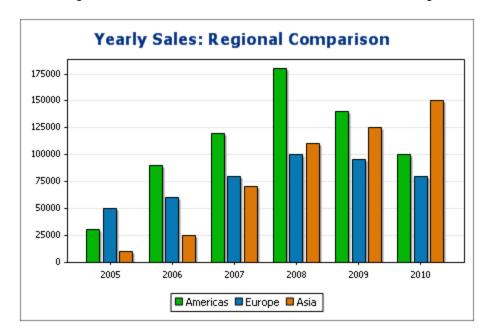

The important points to note about the data selection above are:

• Each row defines a series and all rows have the Data element as its context node (since the chart is created inside a Data node).

• The first row is set to define the Americas series and is given a string expression as its series name. The X-Axis values are selected using the Year/@id values of the Europe region (it doesn't matter which region is selected since all have the same Year/@id values). The Y-Axis values of the first (Americas) series are selected for the Americas region using a predicate filter.

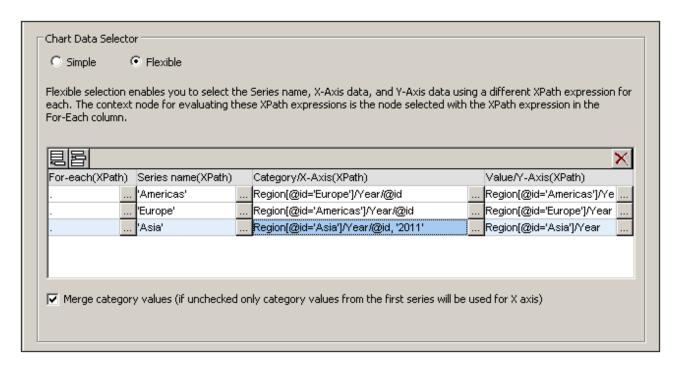

• The second and third series follow the same pattern as the first series. Note, however, that the X-Axis selection for each series is identical. But since the *Merge Category Values* check box is not checked, the second and third expressions are ignored. (Even if the values were merged, it would not make a difference because the values of each series are identical; only new distinct values would be added to the category values.)

The chart generated with the data selection above would look something like this:

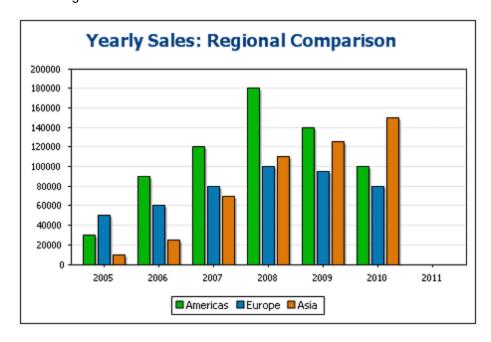

Three rows, three series, category values merged

The data selection in this example (*see screenshot below*) is different from the previous example in three respects: (i) the X-Axis selection for the third series has an extra item (2011) added to the series, and (ii) the *Merge Category Values* check box has been checked, and (iii) the <u>Y-Axis tick interval has been manually set</u> to 20000.

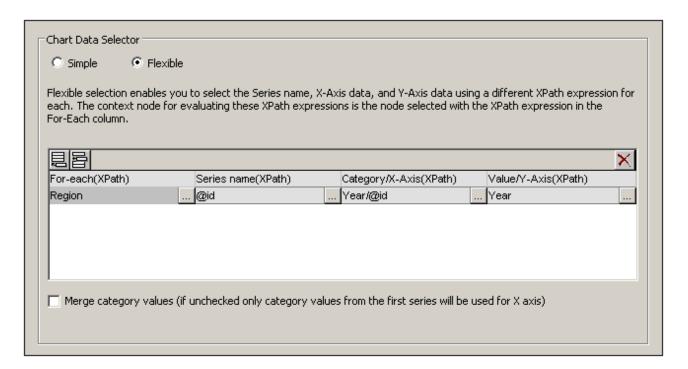

The effect of this change is to add one new item (2011) to the X-Axis result sequence. The chart would look something like this:

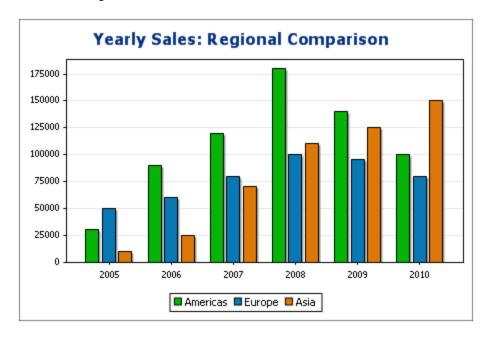

One row, three series

The chart in this example is created within the Data node (see XML document above). Only one row is used for data selection, but it generates three series. This is because the XPath expression in the For-Each column returns a sequence of three items, thus implicitly creating three series.

For each series, the series name, X-Axis, and Y-Axis selections will be correspond to the different regions because each series has a different Region element as its context node. The chart for this data selection will look something like this:

Rules for chart data selection

The following points should be noted when using the Chart Data Selector to select data for the various chart axes:

1. The number of bars (or pie chart slices, etc) is equal to the number of items in the larger of the X-Axis or Y-Axis sequences of a single data row selection. So if the X-Axis (which gives labels) has five items and the Y-Axis (which gives values) has six items, then six bars will be plotted with the last one being unlabelled. If the X-Axis has six items and the Y-Axis five items, then six bars will be plotted with the last one being labeled but having a value of zero.

- 2. The number of series is equal to the cumulative number of items in all the sequences returned by expressions in the For-Each column.
- 3. The name of a series is selected with the XPath expression of the Z-Axis (or Series Name Axis). If, in a data selection row, this XPath expression is left empty, then a no-name series is created. Also if the XPath expression returns a sequence with a lesser number of items than the number of series, then some series will have no name.

For more examples of how data is selected with the Flexible option, see the examples in the following sections. These examples include:

- The use of editable Authentic variables for data selection 235, also in Gauges 259
- XPath expressions for complex data selection 237
- Using the Series Axis to generate grouped bars
 240
- Using the Series Axis to generate line graphs
- Using literal sequences from an XPath expression as values 246
- Using Java and .NET functions 246

5.9.6 Example: Pie Charts

In this section, we discuss the 2D and 3D pie charts contained in the SPS file YearlySales.sps. The SPS design is based on the XML Schema YearlySales.xsd and it uses YearlySales.xml (screenshot below) as its Working XML File. All three files are located in the (My) Documents folder (C:\Documents and Settings\\u00cdusername>\My Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

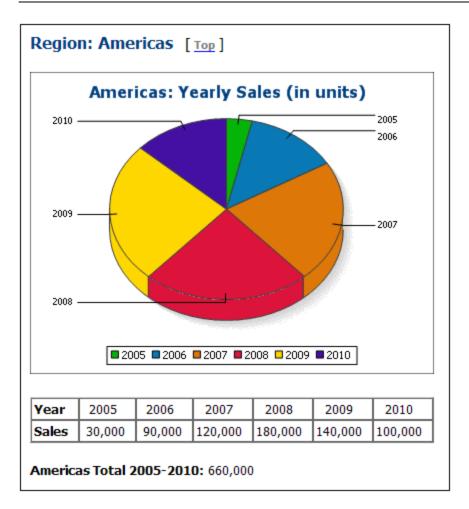

```
■ XML file used in charts example: YearlySales.xml
```

```
<Region id="Europe">
             <Year id="2005">50000</year>
             <Year id="2006">60000</year>
             <Year id="2007">80000</year>
             <Year id="2008">100000
             <Year id="2009">95000</year>
             <Year id="2010">80000
      </Region>
      <Region id="Asia">
             <Year id="2005">10000</year>
             <Year id="2006">25000</year>
             <Year id="2007">70000</year>
             <Year id="2008">110000</year>
             <Year id="2009">125000
             <Year id="2010">150000
      </Region>
</Data>
```

After opening the SPS file in StyleVision, switch to Authentic Preview, and, in the *Chart Type* combo box (*screenshot below*), select Pie Chart 2D and Pie Chart 3D to see the two kinds of chart.

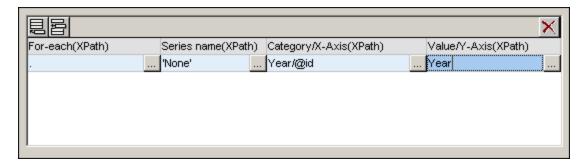

For each chart type (2D pie charts and 3D pie charts), there are four charts. The first three charts of each chart type show the yearly sales of the three sales regions. Each of these pie charts (*see screenshot of a 3D pie chart below*) represents a single region, and the slices of the pie chart represent the region's sales per year for the six years from 2005 to 2010.

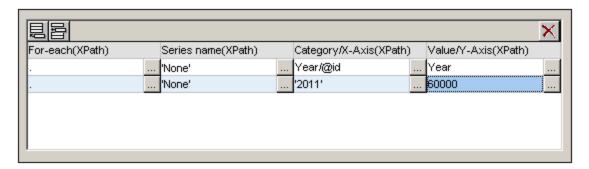

To view the chart settings of these charts, switch to Design View, select the appropriate branch (Pie Chart 2D or Pie Chart 3D) in the first condition of the design, right-click the chart, and select **Edit Chart Settings**. This pops up the Chart Configuration dialog 182.

Note the following points about the Regional Yearly Sales charts:

- 1. The charts have been inserted within the Region element, so the context node is the Region element. A chart is therefore created for each iteration of the XSLT Engine over the Region element.
- 2. The <u>title of each chart</u> (BT) contains the value of the Region/@id attribute. Click the **Dynamic XPath**Settings button to see how this is done.
- 3. Since no more than one series is required, we can leave the Z-Axis or Series Name Axis empty. This results in a default no-name series being created.
- 4. The X-Axis selects the labels to be used for the slices of the pie chart, in this case the years 2005 to 2010, which are obtained with the XPath expression Year/@id (see screenshot below).

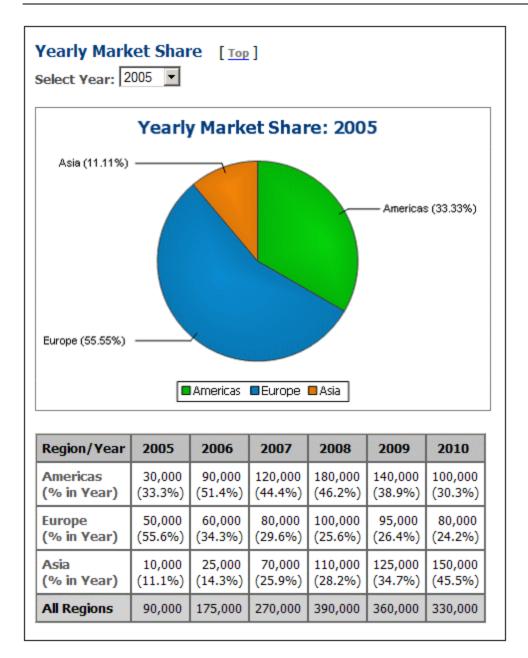

- 5. The Y-Axis selects the values that appear for each of the slices of the pie chart. In our example, these are the contents of the Year element children of the Region element.
- 6. The number of slices in the pie chart is determined according to the <u>Chart Data Selector Rules</u> 31. So, if the selection were made as in the screenshot below, then another slice for the year 2011 would be added with a value of 60000.

- 7. The items of the sequence selected for the X-Axis will be assigned, in corresponding order, as the label for each slice of the pie chart. Each X-Axis item also generates a <u>legend item</u> 188.
- 8. The number of X-Axis and Y-Axis items in each series should be the same (see screenshot above), though it is not an error if they are not the same. If there are fewer X-Axis items than Y-Axis items, then the latter slices of the pie chart (which do not have a corresponding X-Axis item) will be unlabelled. If there are more X-Axis items than Y-Axis items, then the extra X-Axis items will be ignored for label-generation, but they will be generated as legend items.

Using variables in XPath expressions that select axes data

The 2D Pie Chart example has a fourth pie chart at the bottom of the page: the Yearly Market Share pie chart (screenshot below).

In Authentic Preview, when the year selection is changed in the *Select Year* combo box, the pie chart changes to show the correct values for the selected year. This is achieved by (i) storing the user selection in an <u>editable variable for Authentic (\$SelectYear</u>), and (ii) using this editable variable in an XPath predicate to determine which years are selected for the Y-Axis: for \$i in //Year[@id=\$SelectYear] return \$i. In Design View, open the Chart Configuration dialog to see the data selection settings. Also, the labels of the X-Axis contain the percentage share of the pie of that X-Axis tick; the percentage can be toggled on and off in the Pie settings of the <u>advanced settings</u> of the chart. In these settings you can also specify whether the Y-Axis value should be shown in the labels or not.

Using XPath capabilities for complex data selection

The important thing to bear in mind is that the data selection for each axis (X and Y) must return the sequence of required atomic items. The last 3D pie chart shows the yearly worldwide sales. The XPath expressions for the data selection are as follows:

```
X-Axis: for $i in distinct-values(//Year/@id) return $i
The selection could as easily have been: 2005, 2006, 2007, 2008, 2009, 2010
```

```
Y-Axis: for $i in distinct-values(//Year/@id) return sum(//Year[@id=$i])
```

The selection returns, for each year, the sum of worldwide sales for that year, that is, for a given year, the sum of sales in all three regions.

```

    Chart Data Selection: Flexible 225
```

5.9.7 Example: Bar Charts

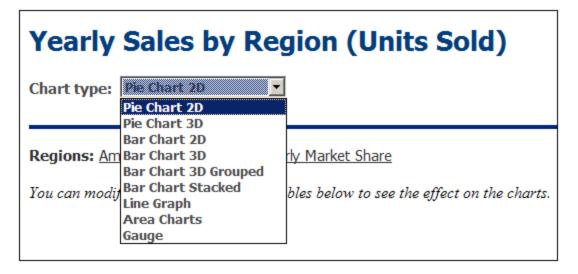

In this section, we discuss the 2D and 3D bar charts (including grouped bar charts and stacked bar charts) contained in the SPS file <code>YearlySales.sps</code>. The SPS design is based on the XML Schema <code>YearlySales.xsd</code> and it uses <code>YearlySales.xml</code> (screenshot below) as its Working XML File. All three files are located in the (My) Documents folder . C:\Documents and Settings\cusername>\My

Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

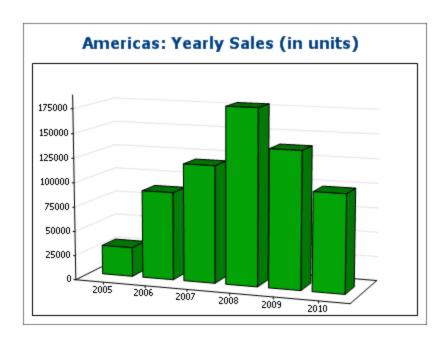

```
■ XML file used in charts example: YearlySales.xml
```

```
<?xml version="1.0" encoding="UTF-8"?>
<Data xm]ns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
     xsi:noNamespaceSchemaLocation="YearlySales.xsd">
      <ChartType>Pie Chart 2D</ChartType>
      <Region id="Americas">
             <Year id="2005">30000</year>
             <Year id="2006">90000</year>
             <Year id="2007">120000
             <Year id="2008">180000</year>
             <Year id="2009">140000
             <Year id="2010">100000
      </Region>
      <Region id="Europe">
             <Year id="2005">50000</year>
             <Year id="2006">60000</year>
             <Year id="2007">80000</year>
             <Year id="2008">100000</year>
             <Year id="2009">95000
```

After opening the SPS file in StyleVision, switch to Authentic Preview, and, in the *Chart Type* combo box (*screenshot below*), select, one after the other, Bar Chart 2D, Bar Chart 3D, Bar Chart 3D Grouped, and Bar Chart Stacked to see the four kinds of chart.

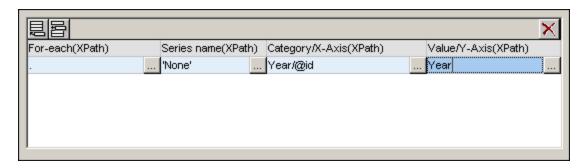

The first three charts of the 2D bar charts page and 3D bar charts page show the yearly sales of the three sales regions. Each of these bar charts (see screenshot of a 3D bar chart below) represents a single region, and the bars represent the region's sales per year for the six years from 2005 to 2010.

To view the chart settings of these charts, switch to Design View, select the appropriate branch (Bar Chart 2D or Bar Chart 3D) in the first condition of the design, right-click the chart, and select **Edit Chart Settings**. This pops up the Chart Configuration dialog (187).

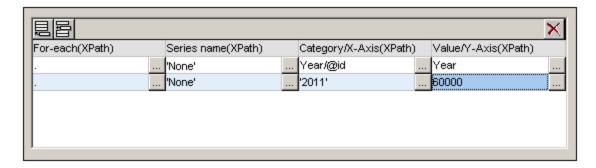

Note the following points about the Regional Yearly Sales charts:

- 1. The charts have been inserted within the Region element, so the context node is the Region element. A chart is therefore created for each iteration of the XSLT Engine over the Region element.
- 2. The <u>title of each chart</u> (187) contains the value of the Region/@id attribute. Click the **Dynamic XPath Settings** button to see how this is done.
- 3. Since no more than one series is required, we can leave the Z-Axis or Series Name Axis empty. This results in a default no-name series being created.
- 4. The X-Axis selects the labels to be used for the bars of the bar chart, in this case the years 2005 to 2010, which are obtained with the XPath expression Year/@id (see screenshot below).

5. The Y-Axis selects the values of each bar of the bar chart. The number of bars in the chart is equal to the number of items in the sequence returned by the XPath expression for the Y-Axis. In our example, the XPath expression returns a sequence of items that are the contents of the Year element children of the Region element. The vertical number scale of the Y-Axis is automatically generated on the basis of the items selected for the Y-Axis.

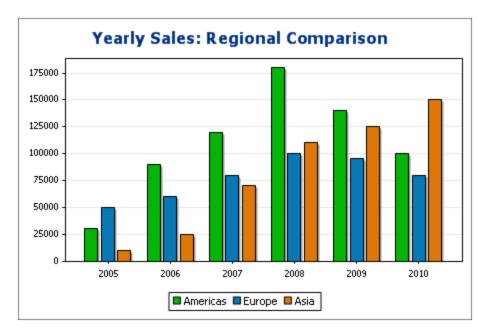

6. The number of bars in the bar chart is determined according to the <u>Chart Data Selector Rules</u> So, if the selection were made as in the screenshot below, then another bar for the year 2011 having a value of 60000 would be added to the chart.

- 7. The items of the sequence selected for the X-Axis will be assigned, in corresponding order, as the label for each bar of the bar chart.
- 8. The number of X-Axis and Y-Axis items in each data selection row of the Chart Data Selector pane (see screenshot above) must be the same, though it is not an error if they are not the same. If there are fewer X-Axis items than Y-Axis items, then the latter bars (which do not have a corresponding X-Axis item) will be unlabelled. If there are more X-Axis items than Y-Axis items, then the extra X-Axis items will be ignored for label-generation.

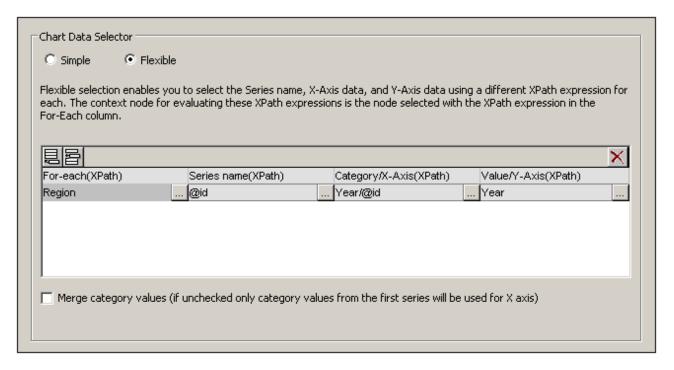

Using the Series Axis to generate grouped bars and stacked bars

If we have the years on the X-Axis, it would be convenient to group region bars for a single year together, as in the screenshot below. Such grouped charts are present in the example file: the last chart, respectively, in the Bar Chart 2D (screenshot below) and Bar Chart 3D pages. The one chart in the Bar Chart 3D Grouped page is also a grouped chart. Stacked bar charts use the same data selection principles as grouped bar charts, but are different from them in appearance. They are discussed farther below.

The grouping of bars in these charts is achieved with the Z-Axis or Series Name Axis. For the Series Name Axis, we select the names of the three regions. To do this, we create the chart, not within a Region element,

but one level higher (within the Data element; *refer to XML document above*), so that we can now target all three Region elements easily. Our XPath expressions for the three axes would be as in the screenshot below.

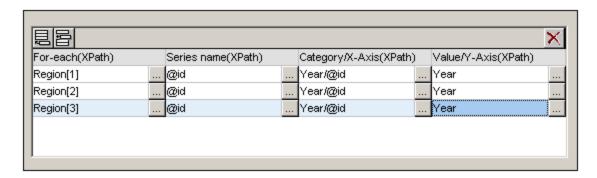

Note the following points about these charts that group all the regions by year:

- The context node of the chart is one level higher than the Region element: It is the Data element.
- The Z-Axis (Series Name Axis) selects the name of the region (Region/@id).
- As with the bar charts showing regional yearly sales, the X-Axis selects the names of the years
 (Region/Year/@id) and the Y-Axis selects the sales for each year (content of the Region/Year element).

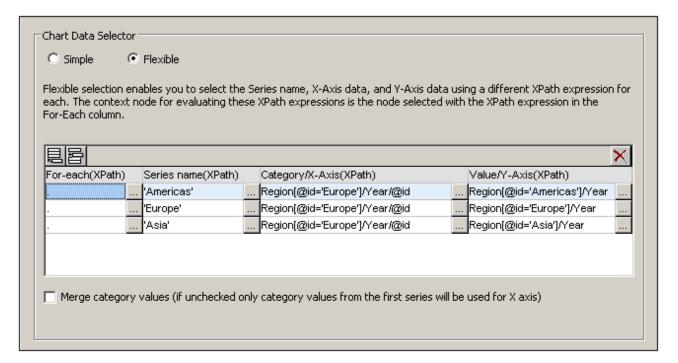

What the data selection above does is this: For each Region element, it selects a series name (the value of the Region element's id attribute), then generates the X-Axis for the Region (using the sequence obtained with the values of the Year/@id attributes). It then generates the Y-Axis values (using the sequence obtained with the content of the Year elements). This is done for all three Region elements, in sequence, generating the chart shown above.

For more information about data selection for the various axes, see the section Rules for Chart Data Selection 231.

The same effect is obtained with the data selection shown in the screenshot below. In this data selection, each region and its axes are selected individually, with one region following on another. Note that, since the X-Axis items of the second and third series will be ignored, it is safe to leave these fields in the dialog box empty.

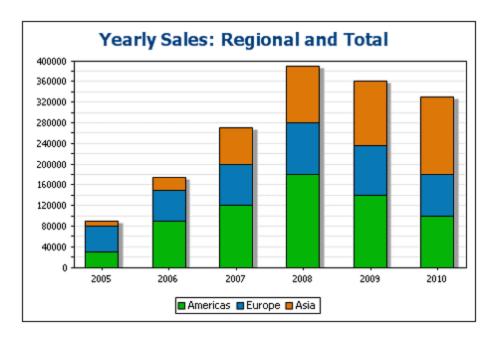

Yet another way to select the same data would be with the XPath expressions in the screenshot below.

Notice that the X-Axis expression in all three data selection rows is identical. What is required is that the XPath data selection returns the correct sequence of items. The sequence can also be entered directly in the XPath expression. For example: "2005, 2006, 2007, 2008, 2009, 2010". Something similar has actually been done for the Series Axis.

Stacked bar charts

Stacked bar charts, such as the stacked bar chart in the Bar Chart Stacked page of the example file, YearlySales.xml (screenshot below), use the same data selection principles as those for grouped charts. All three axes are selected exactly as they are selected for the grouped charts described above. However, instead of the bars of a group being located side-by-side, they are stacked on top of each other, so that for each X-Axis tick, each member of the series at that X-Axis tick is represented within a single stacked bar (screenshot below).

Stacked bar charts provide a good view of the break-up of a composite. For example, in the screenshot above, each bar is a composite that represents total sales in a specific year and it is composed of the yearly sales of each of the regions.

    Chart Data Selection: Flexible 225
```

5.9.8 Example: Line Charts

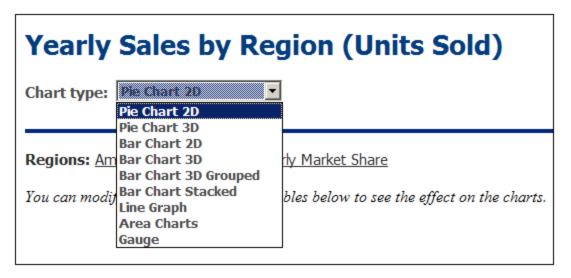

In this section, we discuss the line graphs (or category line graphs) contained in the SPS file YearlySales.sps. The SPS design is based on the XML Schema YearlySales.xsd and it uses YearlySales.xml (screenshot below) as its Working XML File. All three files are located in the (My) Documents folder 33, C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

```
■ XML file used in charts example: YearlySales.xml
```

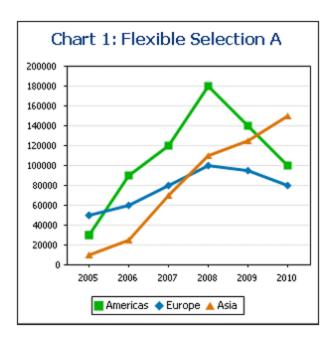

```
<?xml version="1.0" encoding="UTF-8"?>
<Data xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="YearlySales.xsd">
        <ChartType>Pie Chart 2D</ChartType>
        <Region id="Americas">
              <Year id="2005">30000</Year>
        <Year id="2006">90000</Year>
        <Year id="2007">120000</Year>
```

```
<Year id="2008">180000
             <Year id="2009">140000</year>
             <Year id="2010">100000
      </Region>
      <Region id="Europe">
             <Year id="2005">50000</year>
             <Year id="2006">60000</year>
             <Year id="2007">80000</year>
             <Year id="2008">100000</year>
             <Year id="2009">95000</year>
             <Year id="2010">80000</year>
      </Region>
      <Region id="Asia">
             <Year id="2005">10000</year>
             <Year id="2006">25000</year>
             <Year id="2007">70000</year>
             <Year id="2008">110000</year>
             <Year id="2009">125000</year>
             <Year id="2010">150000
      </Region>
</Data>
```

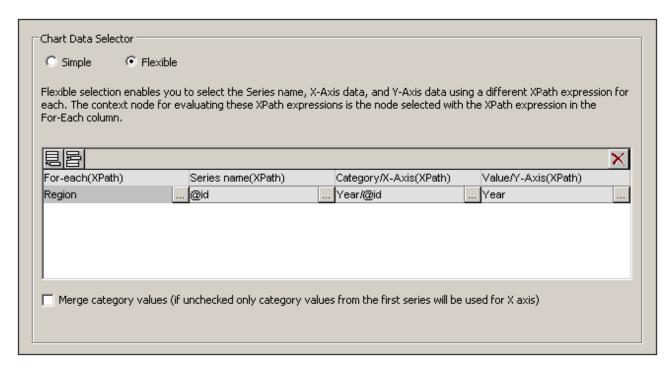

After opening the SPS file in StyleVision, switch to Authentic Preview, and, in the *Chart Type* combo box (screenshot below), select Line Charts to see the line charts.

The line graph charts show the yearly sales of each region (see screenshot below). The X-Axis of the chart shows the years, the Y-Axis shows the units sold. Each line graph shows the sales of a region over the period 2005 to 2010. The legend key at the bottom indicates which line represents which region.

This chart was created within the Data node, which is the parent of the Region nodes (refer to XML file above). The data selection is as shown in the screenshot below.

Note the following points about this data selection:

- The Z-Axis (Series Axis) selects the name of the region (Region/@id).
- The X-Axis selects the names of the years (Region/Year/@id) and the Y-Axis selects the sales for each year (content of the Region/Year element).

What the data selection above does is this: For each Region element, it selects a series name (the value of the Region element's id attribute), then generates the X-Axis for the Region (using the sequence obtained with the values of the Year/@id attributes). It then generates the Y-Axis values (using the sequence obtained with the content of the Year elements). This is done for all three Region elements, in sequence, generating the line graphs shown above.

For more information about data selection for the various axes, see the section Rules for Chart Data Selection 225.

    Chart Data Selection: Flexible 225
```

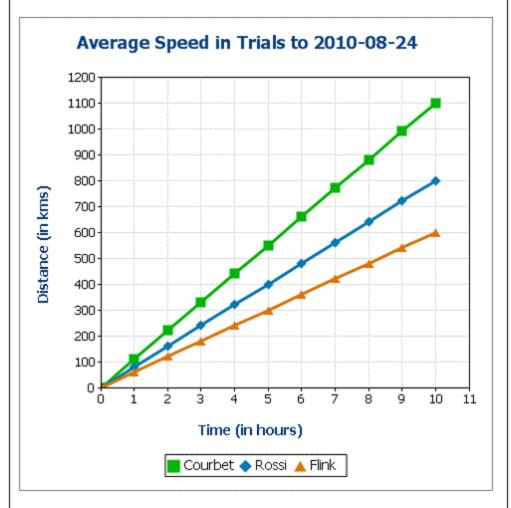

5.9.9 Example: Value Line Charts

The difference between value line graphs and category line graphs is that, in the former, the X-Axis takes numeric values that are the domain of the function whose range is represented on the Y-Axis. For example, for the function y=3x, the Y-Axis plots values that are three times the value of corresponding X-Axis values, for example: (-1, -3) (0,0) (1, 3) (2,6). Category line graphs on the other hand take X-Axis values that are text values and their Y-Axis values are not functions of X-Axis values.

The value line chart examples in this section are located in the (My) Documents folder (33), C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts. In the first example (see screenshot below), TeamTrials.sps (using TeamTrials.xsd and TeamTrials.xml), the X-Axis show time in hours. The Y-Axis values show distance traveled in time and they are a function of X-Axis values: distance travelled = speed * time.

Team Trials

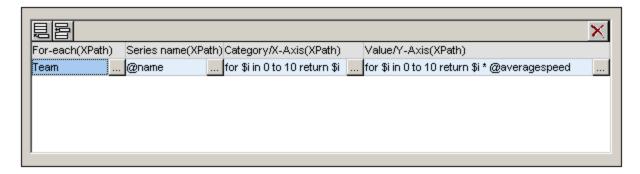

The y-axis value is a function of the x-axis value. For each participating team: y = speed * (x). In the table below, you can modify the speed for each team to see the effect on the chart.

Team 5	Speed (km/h)	After 10 hours				
		Kms Done	From Courbet	From Rossi	From Flink	
Courbet	110	1100	0	300	500	
Rossi	80	800	-300	0	200	
Flink	60	600	-500	-200	0	

The XML file contains the speeds of the various teams. The context node for the chart is the TeamTrials element in the XML document. The Z-Axis (Series Axis) selects the names of the teams (Team/@name). The X-

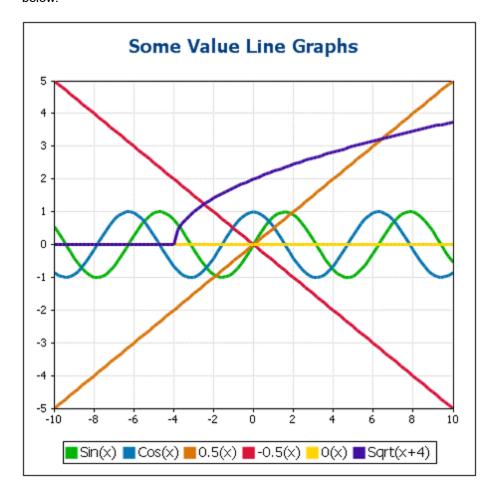

Axis is a sequence of integers generated by an XPath expression. The Y-Axis value of each graph (one per team) is derived by multiplying the X-Axis value (hours) by the speed of that team (Team/@averagespeed). The screenshot below shows the XPath expressions that were used to select data for the three axes.

More value line graphs

The second example, ValueLineGraphs.sps (using ValueLineGraphs.xsd and ValueLineGraphs.xml), contains more line graphs (screenshot below).

The XPath expressions (flexible) to select values for the various graphs are shown in the second screenshot below.

Context	Series name	Category/X-Axis	Value/Y-Axis	
	'Sin(x)'	for \$i in -50 to 50 return \$i div 5	for \$i in -50 to 50 return clitype:System.Math.Sin(\$i div 5)	
for \$i in -50 to 50 return \$i div 5	'Cos(x)'		java:java.lang.Math.cos(.)	
for \$i in -50 to 50 return \$i div 5	'0.5(x)'		0.5 * .	
for \$i in -50 to 50 return \$i div 5	'-0.5(x)'		-0.5 * current()	
for \$i in -50 to 50 return \$i div 5	'0(x)'		0*.	
for \$i in -50 to 50 return \$i div 5	'Sqrt(x+4)'		java:java.lang.Math.sqrt(.+4)	

Note the following points about the XPath expressions shown above:

- For the first graph, the X-Axis values are generated with the XPath expression for the X-Axis (Category) data selection.
- For all the other graphs except the first graph, the X-Axis values are generated with an XPath expression that outputs the context node.
- Java functions are called with java:java.lang.Math. We have used two Java functions: cos() and sqrt().
- .NET functions are called with clitype:System.Math. We have used one .NET function: Sin().
- The X-Axis and Y-Axis ticks have been set manually (in the Change Appearance dialog) at intervals of 2 units and 1 unit, respectively.

```

5.9.10 Example: Area Charts

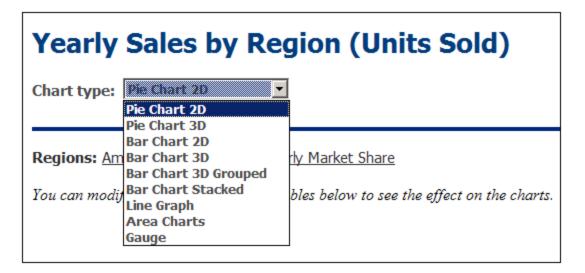

In this section, we discuss the area charts contained in the SPS file YearlySales.sps. The SPS design is based on the XML Schema YearlySales.xsd and it uses YearlySales.xml (screenshot below) as its Working XML File. All three files are located in the (My) Documents folder (Charts and Settings\susername>\My Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

```
■ XML file used in charts example: YearlySales.xml
```

```
<?xml version="1.0" encoding="UTF-8"?>
<Data xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="YearlySales.xsd">
        <ChartType>Pie Chart 2D</ChartType>
        <Region id="Americas">
              <Year id="2005">30000</Year>
              <Year id="2006">90000</Year>
              <Year id="2007">120000</Year>
              <Year id="2008">180000</Year>
              <Year id="2008">140000</Year>
              <Year id="2009">140000</Year>
```

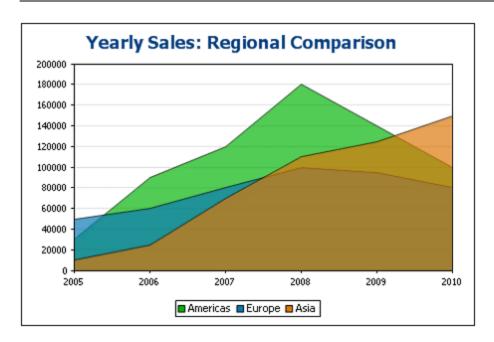

```
<Year id="2010">100000
      </Region>
      <Region id="Europe">
            <Year id="2005">50000</year>
            <Year id="2006">60000</year>
            <Year id="2007">80000</year>
            <Year id="2008">100000
            <Year id="2009">95000</year>
            <Year id="2010">80000
      </Region>
      <Region id="Asia">
            <Year id="2005">10000</year>
            <Year id="2006">25000</year>
            <Year id="2007">70000</year>
            <Year id="2008">110000
            <Year id="2009">125000
            <Year id="2010">150000
      </Region>
</Data>
```

After opening the SPS file in StyleVision, switch to Authentic Preview, and, in the *Chart Type* combo box (*screenshot below*), select Area Charts to see the two kinds of area chart: (i) standard overlay, and (ii) stacked.

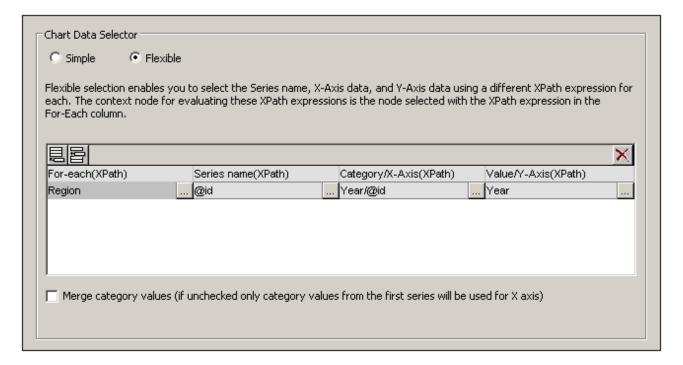

Selecting data for area charts

If we have the years on the X-Axis and the unit sales on the Y-Axis, then the yearly sales of each region can be plotted as an area, with each subsequent area overlaying the previous areas (*screenshot below*). Area charts are selected via the Change Type dialog For area charts in which some areas overlay parts of other areas, it is advisable to set transparency for the areas—an option available for area charts via their Chart Settings For are

The data selection for area charts is done as follows: For the Series Name Axis, we select the names of the three regions. To do this, we create the chart, not within a Region element, but one level higher (within the Data element; refer to XML document above), so that we can target all three Region elements easily. Our XPath expressions for the three axes would be as in the screenshot below.

Note the following points about this data selection:

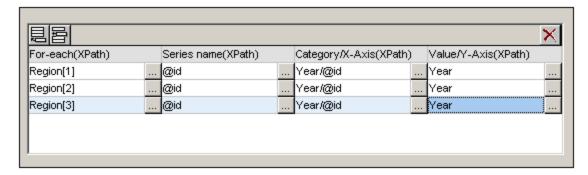

- The context node of the chart is one level higher than the Region element: It is the Data element.
- The for-each iteration is created on the Region element.
- The Z-Axis (Series Name Axis) selects the name of the region (Region/@id).

As with the bar charts showing regional yearly sales, the X-Axis selects the names of the years
 (Region/Year/@id) and the Y-Axis selects the sales for each year (content of the Region/Year element).

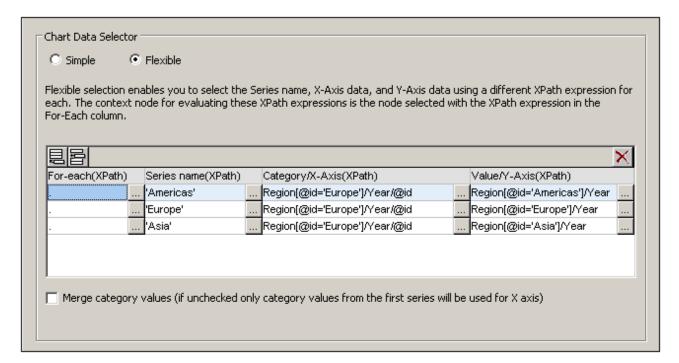

What the data selection above does is this: For each Region element, it selects a series name (the value of the Region element's id attribute), then generates the X-Axis for the Region (using the sequence obtained with the values of the Year/@id attributes). It then generates the Y-Axis values (using the sequence obtained with the content of the Year elements). This is done for all three Region elements, in sequence, generating the chart shown above.

For more information about data selection for the various axes, see the section Rules for Chart Data Selection 31.

The same effect is obtained with the data selection shown in the screenshot below. In this data selection, each region and its axes are selected individually, with one region following on another. Note that, since the X-Axis items of the second and third series will be ignored, it is safe to leave these fields in the dialog box empty.

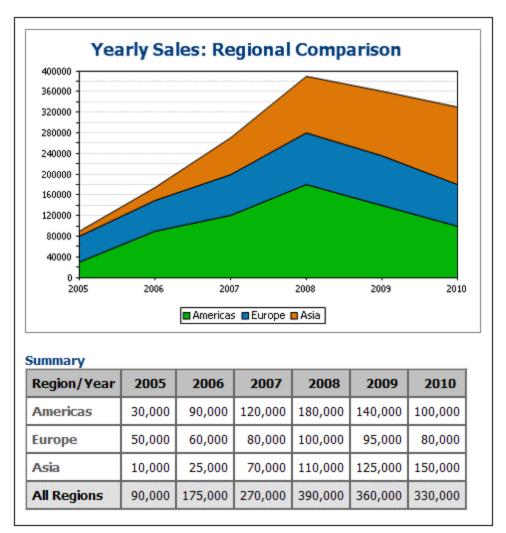

Yet another way to select the same data would be with the XPath expressions in the screenshot below.

Notice that the X-Axis expression in all three data selection rows is identical. What is required is that the XPath data selection returns the correct sequence of items. The sequence can also be entered directly in the XPath expression. For example: "2005, 2006, 2007, 2008, 2009, 2010". Something similar has actually been done for the Series Axis.

Stacked area charts

Stacked area charts (*screenshot below*) use the same data selection principles as for the standard overlay area charts. All three axes are selected exactly as described above. However, instead of areas being superimposed on the same coordinate grid, the areas are stacked along the Y-Axis so that Y-Axis values are cumulative (*screenshot below*).

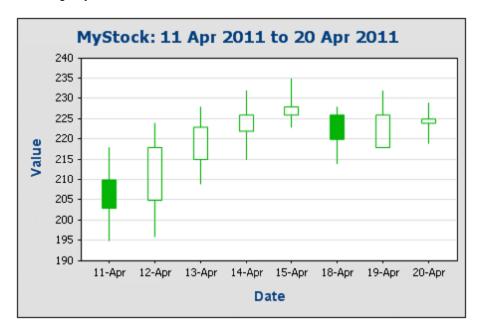

Stacked area charts enable multiple areas to be compared. For example, in the screenshot above, the sales of the three regions (Americas, Europe, and Asia) can be can be visually compared by observing the sizes of their areas over a particular period. In the chart, notice that the plotted Y-Axis value of a series in a given year is the sum of that series' original Y-Axis value plus the Y-Axis values of all the series plotted below it. So Europe in

2005 is plotted at 80,000 (50,000 + 30,000 (of Americas)) while Asia is plotted at 90,000 (10,000 + 50,000 (Europe) + 30,000 (Americas)).

5.9.11 Example: Candlestick Charts

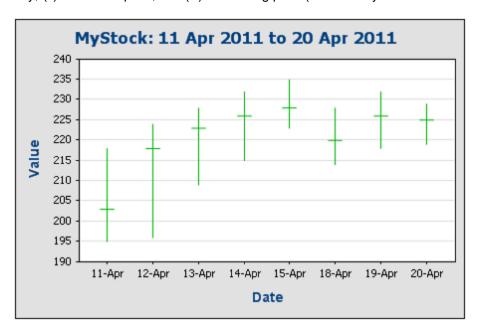

Candlestick charts (*screenshot below*) are most commonly used to show the movement of stock prices. They provide at-a-glance information about the opening and closing prices, and the highest and lowest prices during a trading day.

The screenshot above, for example, shows candlesticks of the share prices of a fictitious company, MyStock, for the trading days from 11 April 2011 to 20 April 2011. The highest and lowest points of the vertical line in each candlestick indicates the day's highest and lowest trading prices, respectively (see table below for prices). A color-filled candlestick body indicates a drop in the price over the day's trading, from the opening price to the closing price, an unfilled body indicates a price rise. So, on 11 April, we see that the price dropped from 210 to 203, whereas on 12 April the price rose from 205 to 218.

Wook	Vone	Month	Data	ID (YYYYMMDD)	Open	High	Low	Close
week	Tear	Month	Date	עטוייווייו און די	Open	nigii	LOW	Ciose
14	2011	Apr	11	20110411	210	218	195	203
14	2011	Apr	12	20110412	205	224	196	218
14	2011	Apr	13	20110413	215	228	209	223
14	2011	Apr	14	20110414	222	232	215	226
14	2011	Apr	15	20110415	226	235	223	228

A second type of candlestick chart (*screenshot below*) shows three values: (i) the highest price traded on the day, (ii) the lowest price, and (iii) the closing price (indicated by the short horizontal line).

Candlestick chart example files

Files for the candlestick chart example discussed in this section are located in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts. The SPS file Candlestick.sps (see screenshot below) uses Candlestick.xsd and Candlestick.xml. In Authentic View (screenshot below), the user can select what should be displayed in the candlestick chart. The selection options are: (i) the company (from two companies); (ii) the period for which prices are to be displayed; (iii) the extent of the Y-Axis; and (iv) the interval of Y-Axis ticks. Furthermore, the table below the chart allows new trading data to be entered for the two companies (right-click in a row and append or insert a Day element).

Stock Prices

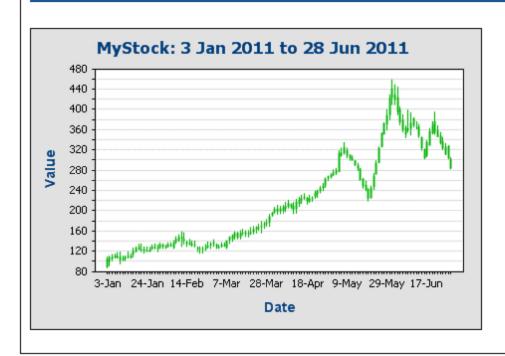

Select the stock you wish to view and the period for which you wish to view its price movement. You can also modify the value-range of the Y-Axis.

Stock: MyStock ▼
Start date: 2011-Jan-03 ▼

Start date: 2011-Jan-03 ▼
End date: 2011-Jun-28 ▼

Y-Axis start: 80 (Lowest value in selected period: 88)
Y-Axis end: 480 (Highest value in selected period: 460)

Y-Axis tick interval: 20 ■

Notice that the top part of the design contains combo boxes and input fields in which the Authentic user can specify the parameters of the chart that is displayed below. These input specifications are stored within the XML file and are used to calculate some key chart settings.

XML file

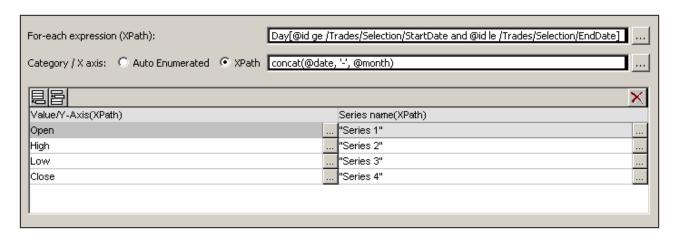

The allowed structure of the XML document is as shown in the listing below. The document element Trades contains one Selection element and an unlimited number of Stock elements. Each Stock element can contain an unlimited number of Day elements.

```
<Trades xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
        xsi:noNamespaceSchemaLocation="Candlestick.xsd">
       <Selection>
              <Stock>Nanonull</Stock>
              <StartDate>20110103</StartDate>
              <EndDate>20110112</EndDate>
              <YAxisStart>80</YAxisStart>
              <YAxisEnd>180</YAxisEnd>
              <YAxisTickInterval>20</YAxisTickInterval>
              <WeekToView>25</weekToView>
       </selection>
       <Stock name="MyStock">
              <Day id="20110103" year="2011" month="Jan" week="01" date="03">
                     <0pen>90</0pen>
                     <High>110</High>
                     <Low>88</Low>
                     <Close>105</Close>
              </Day>
              <Day id="20110104" year="2011" month="Jan" week="01" date="04">
                     <0pen>100</0pen>
                     <High>112</High>
                     <Low>92</Low>
                     <Close>109</Close>
              </Day>
              . . .
       </Stock>
       <Stock/>
         . . .
       <Stock/>
</Trades>
```

The <code>Selection</code> element contains information supplied by the Authentic user and this information is used to select what data is displayed in the chart. The data selection for the chart is therefore based on information in the <code>Selection</code> element. The exact details are explained in the <code>next</code> section. The data about the price movements of each stock on a given day is contained in the <code>Stock/Day</code> element of that stock on that given day.

Data selection for the candlestick chart

The data selection for the chart is specified in the <u>Chart Configuration dialog</u> (see screenshot below), which is accessed by right-clicking the chart and selecting **Edit Chart Settings**. The data selection was done using the *Simple* method.

The settings are made as follows:

- In the design, the chart is inserted within a <code>Stock</code> element. This <code>Stock</code> element has a filter to select the <code>Stock</code> element with an <code>@id</code> attribute equal to the content of the <code>Selection/Stock</code> element. So the context node within which the chart is created is the <code>Stock</code> element that the Authentic user selects in the <code>Stock</code> combo box.
- The For-Each XPath expression selects all Day elements that have an @id attribute which is greater than or equal to the StartDate that the Authentic user specifies and is less than or equal to the user's EndDate. This ensures that data for the dates selected by the Authentic user will now be processed. The context node for all the other XPath expressions used for data selection in this dialog will therefore be the Day element (see example structure below).

- On the X-Axis of the chart, we wish to show the dates. So we use the XPath expression: concat (@date, '-' @month). This expression serves to collect the date from the attributes of the respective Day elements.
- The Y-Axis plots the stock prices. We use four series for our candlestick chart: (i) the opening prices, (ii) the highest price of the day, (iii) the lowest price of the day, and (iv) the closing price. For each of these series, we identify, respectively, the <code>Day/Open</code>, <code>Day/High</code>, <code>Day/Low</code>, and <code>Day/Close</code> elements.

Important: The order in which the series are specified is important, and must be as follows:

- Four-series charts: (i) Open, (ii) High, (iii) Low, (iv) Close.
- Three-series charts: (i) High, (ii) Low, (iii) Close.

The nodes that contain the values that will be used for the various series may have any valid XML name (they need not be called Open, High, etc) but these nodes must contain number values.

Other settings in the example file

Some other crucial chart settings were obtained as explained below. Many were obtained dynamically from the XML file and needed to be set using Dynamic XPath settings (191).

• Since the name of the chart needs the Authentic user's date specifications, the chart title is <u>set</u> <u>dynamically</u> ¹⁹¹.

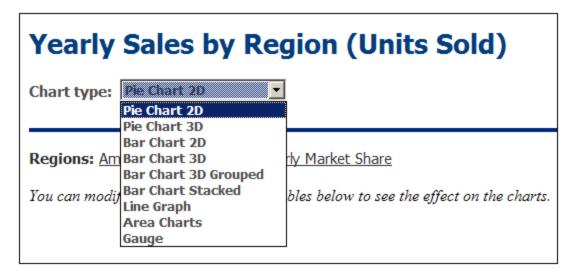

• The Y-Axis range and interval is also determined by the user and therefore requires <u>dynamic XPath</u> settings 191.

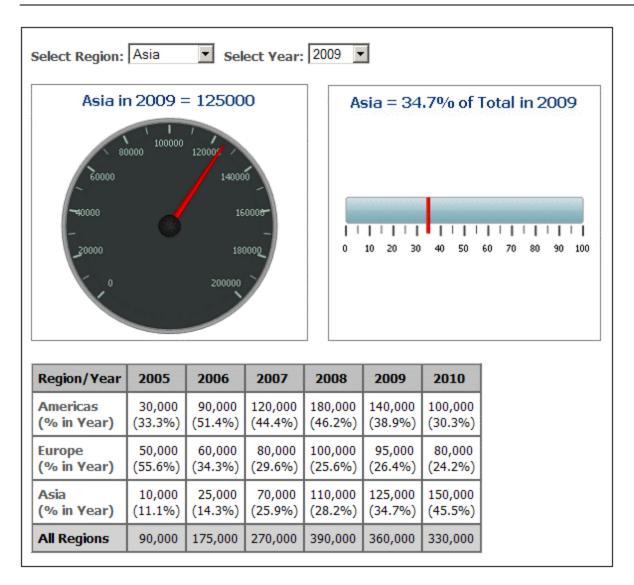

5.9.12 Example: Gauge Charts

In this section, we discuss the gauge charts contained in the SPS file YearlySales.sps. The SPS design is based on the XML Schema YearlySales.xsd and it uses YearlySales.xml as its Working XML File. All three files are located in the (My) Documents folder (C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

After opening the SPS file in StyleVision, switch to Authentic Preview, and, in the *Chart Type* combo box (*screenshot below*), select Gauge to see the gauge charts.

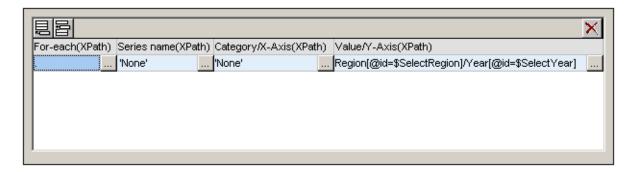

On the gauge charts (*screenshot below*), selecting options in the *Select Region* and *Select Year* combo boxes causes the needle in each of the two gauges (round and bar) to point to the correct value on the gauge scale. The screenshot below shows sales in Asia in 2009, as an absolute value (125000) and as a percentage of total sales in that year (34.7%).

The settings for both charts are similar. Here we consider the first gauge chart: the round gauge chart. To generate a gauge chart a single value is needed, and this is provided by the Y-Axis entry. In the round gauge chart this value is the yearly sales of a user-selected region in a user-selected year. The Y-Axis must accordingly select this data. The X-Axis and Series Name Axis entries are ignored. The XPath expression to select the required data is created as follows:

- 1. The user-selected region is stored in an <u>editable variable for Authentic 410</u> (\$SelectRegion), and the user-selected year is stored in an <u>editable variable for Authentic 410</u> (\$SelectYear).
- 2. These two editable variables are used in predicates to filter which Region element and then which of its Year child elements is selected as the data for the Y-Axis (see the XPath expression in the screenshot below).

3. The following gauge settings (accessed by right-clicking the chart in the design, then selecting **Edit Chart Settings | All Settings | Gauge**) were modified. The scale was changed to a maximum of 200000, and the major and minor ticks, were set, respectively to 20000 and 10000. Major and minor ticks are the major and minor divisions on the scale (see screenshot above).

Note: The scale must be set to the correct range and ticks must be suitably adjusted in order for gauge charts to display correctly.

For more information about data selection for the various axes, see the section Rules for Chart Data Selection 225.

5.9.13 Example: Overlay Charts

Overlay charts (*screenshot below*) enable you to combine multiple charts of different types. The following charts can be combined:

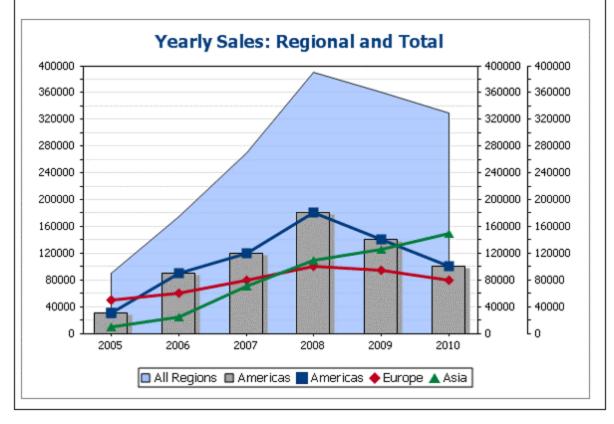

- 2D bar charts and stacked bar charts 237
- Line charts 243
- Area charts and stacked area charts ²⁴⁹
- Candlestick charts ²⁵⁴

Yearly Sales by Region (Units Sold)

		_
Chart type:	Overlay Chart	•

The chart below has three layers. The bottom layer is an area chart showing the total sales of all three regions (Americas, Europe, Asia). The next layer is a bar chart layer which shows the sales of the region selected in the combo box. The third and topmost layer is a layer with three line graphs, showing the sales of each of the three regions seaparately. The three Y-Axes, starting from left, correspond to the three chart layers starting from the bottom layer. In Authentic View, you can modify values in the regional tables below (not the summary table) to see the effect on the chart.

Region to be displayed in bar chart: Americas

An overlay chart (shown in the screenshot above) is contained in the SPS file YearlySales.sps. The SPS design is based on the XML Schema YearlySales.xsd and it uses YearlySales.xml as its Working XML File. All three files are located in the (My) Documents folder (Charts and Settings\\u00e4username>\My Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/Charts.

After opening the SPS file in StyleVision, switch to Authentic Preview, and, in the *Chart Type* combo box (*screenshot below*), select Overlay Charts to see the overlay chart shown above.

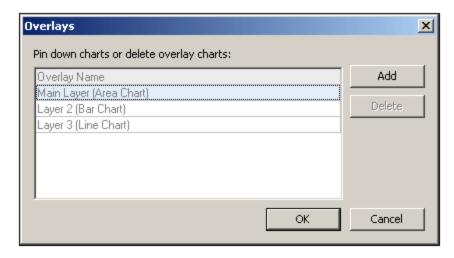

Creating the overlay chart

An overlay chart is created by selecting the *Multiple Layers* radio button in the <u>Chart Configuration dialog</u> (see screenshot below). A main layer is automatically created. You can select the <u>type of chart</u> for the main layer and then make the <u>chart settings</u> and <u>data selection</u> in the usual way.

Managing the layers of the overlay chart

You can add new layers to an overlay chart and delete layers. To do this, click the **Manage** button in the Chart Configuration dialog (see screenshot above). This pops up the Overlays dialog (screenshot below). Click **Add** to add a new layer. To delete a layer, select a layer and click **Delete**.

You should note that when a layer is placed over another, it will obscure the layers beneath it. Since only area charts can be made transparent, some layer arrangements might not be optimal. For example a bar chart that is layered over a line chart would obscure parts of the lines. You should keep this in mind when planning the layering order.

Data selection for the various charts

The data selection for each chart depends on the chart type and is done in the usual ways for each chart type. See the sections, <u>Chart Data Selection: Simple</u> and <u>Chart Data Selection: Flexible</u> for an overview of chart data selection, and the respective example sections for details about chart data selection for individual chart types.

The following general points relating to overlay charts are important and should be noted:

The X-Axis for all chart layers is common and is the X-Axis specified in the main layer. If this X-Axis
definition cannot be evaluated for another chart, then that chart will not be drawn. X-Axes specified in
chart definitions of other layers are ignored.

• The Y-Axes series for each chart are selected separately. The Y-Axes of each layer is drawn parallel to each other, starting from the left for the bottom-most layer (the main layer) and proceeding to right with each layer. Note that a label can be specified for each Y-Axis, in its chart settings.

Important chart settings

The following chart settings are relevant:

- The title of the chart is specified in the Chart Title setting of the main layer.
- X-Axis settings are specified in the settings for the main layer.
- Y-Axis labels can be set for each chart separately.
- Y-Axis start points (minimum) and end points (maximum), as well as the tick intervals, can be specified for each chart separately. This enables axes to be calibrated relative to each other.
- The colors of series in each chart can be selected separately.

5.10 Form Controls

Nodes in the XML document can be created as data-entry devices (such as input fields and combo boxes). Data-entry devices are intended for easier editing in Authentic View. For example, an input field makes it clear to the Authentic View user that input is expected in this location while a combo box lists, as well as restricts, the values a user can enter. When data is entered into a data-entry device, the data is inserted into the XML document as element content or as an attribute's value. In the HTML, Text, RTF, PDF, and Word 2007+ output, the data-entry device is rendered as an object that is the same as that displayed in Authentic View, or a near-equivalent. Note that data-entry devices accept input to the XML document and, therefore, will not work in the HTML output.

General mechanism

Given below is a list of the data-entry devices available in StyleVision, together with (i) an explanation of how data is entered in the XML document for each device and (ii) how the data-entry devices will be output in plain text format.

Data-Entry Device	Data in XML File	Output to Plain Text Format
Input Field (Text Box)	Text entered by user	Text entered by user
Multiline Input Field	Text entered by user	Text entered by user
Combo box	User selection is mapped to a value.	Selected value
Check box	User selection is mapped to a value.	[] (unselected); [x] (selected)
Radio button	User selection is mapped to a value.	() (unselected); (o) (selected)
Button	User selection is mapped to a value.	Button text

The text values entered in the input fields are entered directly into the XML document as XML content. For the other data-entry devices, the Authentic View user's selection is mapped to a value. StyleVision enables you to define the list of options the user will see and the XML value to which each option is mapped. Typically, you will define the options and their corresponding values in a dialog.

General usage

To create a data-entry device, do the following:

- 1. Drag a node from the Schema Tree window into Design View and drop it at the desired location.
- 2. From the context menu that appears, select the data-entry device you wish to create the node as.
- 3. For some data-entry devices, a dialog pops up. In these cases, enter the required information in the dialog, and click OK.

To **reopen and edit** the properties of a data-entry device, select the data-entry device (not the node containing it), and edit its properties in the Properties sidebar.

Note:

- Data can be entered in data-entry devices only in Authentic View.
- Data-entry devices can also be created by changing the current component type of a node to a dataentry device. To do this right-click the node and select **Change to**.

• In the HTML, RTF, PDF, and Word 2007+ output, the entry selected by the user is displayed in the output. Changing the value of a data-entry device in the HTML document does not change the text value in either the XML document or HTML document.

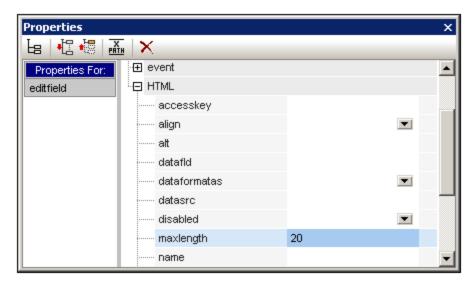

• In the case of some data-entry devices, such as check boxes, where the device cannot correctly be rendered in print, an alternative rendition is implemented.

5.10.1 Input Fields, Multiline Input Fields

You can insert an Input Field or a Multiline Input Field in your SPS when you drop a node from the Schema Sources window into Design View. The text that the Authentic View user enters into these fields is entered into the XML node for which the field was created. The content of that node is displayed in the input field or multiline input field.

Editing the properties of input fields

You can modify the HTML properties of input fields by selecting the input field and then modifying its *HTML* properties in the Properties sidebar (*see screenshot below*).

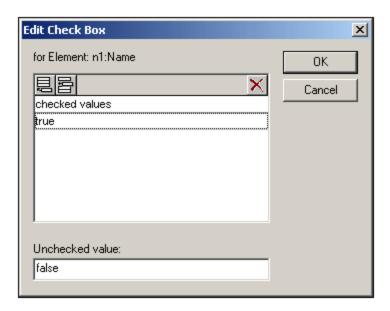

For example, with the input field selected, in the Properties window select editfield, select the *HTML* group of properties and the maxlength property. Then double-click in the Value field of maxlength and enter a value.

Note: CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). CDATA sections can only be entered within elements that are displayed in Authentic View as text content components.

5.10.2 Check Boxes

You can create a check box as a data-entry device. This enables you to constrain user input to one of two choices. In the Edit Check Box dialog (*shown below*), you specify the XML values to map to the checked and unchecked events.

In the above screenshot, an element called Name has been created as a check box. If the Authentic View user checks the check box, a value of true will be entered as the value of the element Name. If the value is unchecked, then the value false is entered as the XML value of Name (as defined in the dialog).

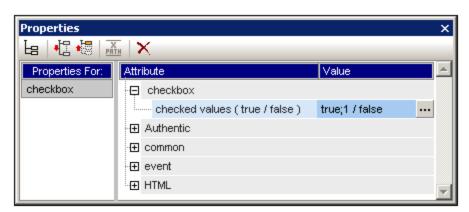

Note: When a new Name (or check box) element is created in Authentic View, its XML value is empty (it is not the Unchecked Value). The Unchecked Value is entered only after the check box has first been checked, and then unchecked. To have a default value in a node, create a Template XML file that contains the default value.

Note: Check boxes in Text output are displayed as square brackets: [] for unselected check boxes; [x] for selected check boxes.

Accessing the Edit Check Box dialog

If you are creating a new check box, when you create the node as a check box, the Edit Check Box dialog pops up. To access the Edit Check Box dialog afterwards, do the following:

- 1. Select the check box in the design.
- 2. In the Properties sidebar, select the checkbox item and then the *checkbox* group of properties (see screenshot below).

3. Click the Edit button of the check values property. This pops up the Edit Check Box dialog.

Note: You can modify the HTML properties of a check box by selecting it and then modifying its HTML properties in the Properties sidebar.

5.10.3 Combo Boxes

A combo box presents the Authentic View user with a list of options entries in a dropdown list. The selected option is mapped to a value that is entered in the XML document. The mapping of drop-down list entry to XML value is specified in the SPS.

Mappings can be made in the Edit Combo Box dialog in one of three ways:

- From the schema enumerations for the selected node. In this case, the visible entry (in the dropdown list) will be the same as the XML value.
- From a list defined in the Edit Combo Box dialog. You enter the visible entry and the corresponding XML value, which may be different.
- From the result sequence of an XPath expression relative to the current node. The items in the result sequence are displayed as the entries of the drop-down list, and the list entry selected by the Authentic View user is entered as the value of the node. This is a powerful method of using dynamic entries in the combo box. The node that you create as the combo box is important. For example, say you have a NameList element that may contain an unlimited number of Name elements, which themselves have First and Last children elements. If you create the Name element as a combo box, and select the Last child element for the list values, then, in Authentic View, you will get as many combo boxes as there are Name elements and each combo box will have the Last child as its dropdown menu entry. In order to get a single combo box with all the Last elements in the dropdown menu list, you must create the single NameList element as the combo box, and select the Last element in the XPath expression.

Accessing the Edit Combo Box dialog

If you are creating a new combo box, when you create the node as a combo box, the Edit Combo Box dialog pops up. You can also insert a combo box with the (Insert | Insert Form Controls | Combo Box) menu command. To access the Edit Combo Box dialog afterwards, do the following:

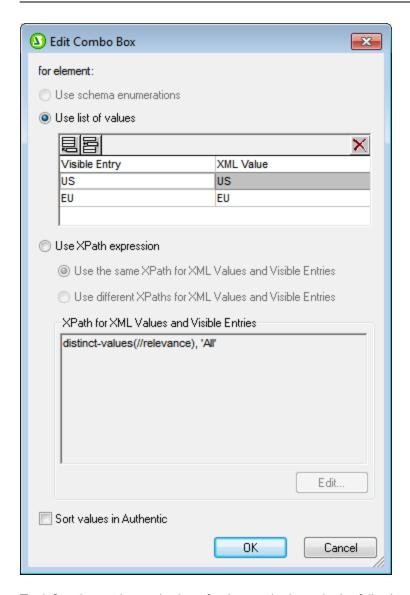

- 1. Select the combo box in the design.
- 2. In the Properties sidebar, select the combo box item and then the *combo box* group of properties (*see screenshot below*).

3. Click the Edit button of the the content origin property. This pops up the Edit Combo Box dialog.

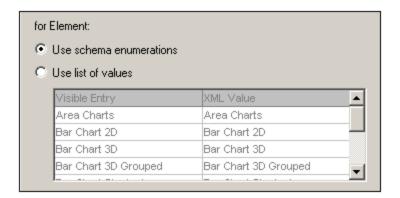

Using the Edit Combo Box dialog

The Edit Combo Box dialog is shown below.

To define the entries and values for the combo box, do the following:

- 1. Select the method with which you wish to define the entries and values by clicking the appropriate radio button: (i) schema enumerations, (ii) list of values, or (iii) XPath expressions to select values.
- 2. If you select *Schema Enumerations*, the enumerations assigned to that node in the schema are entered automatically as (i) the visible entries of the drop-down list of the combo box, and (ii) the corresponding XML values (*screenshot below*). Visible Entries are the entries in the drop-down list of the combo box. Each drop-down list entry has a corresponding XML value. The XML value corresponding to the visible entry that the Authentic user selects will be the XML value that is entered in the XML file. Both visible entries and XML values are grayed out in the list of values because they are both obtained from the schema enumerations and cannot be edited.

If you select *Use List of Values*, you can insert, append, edit, and delete any number of entries for the drop-down list of the combo box as well as for the corresponding XML values. These edits are carried out in the pane below the *Use List of Values* radio button. You could also use an XPath expression to create the visible entries and XML values. The items in the sequence returned by the XPath expression will be used for visible entries and XML values. You can specify: (i) that the same XPath expression be used for visible entries and XML values, or (ii) that different XPath expressions be used. In the latter case, a one-to-one index mapping between the items of the two sequences determines the correspondence of visible entry to XML value. If the number of items in the two sequences are not equal, an error is reported.

- 3. If you wish to have the items that appear in the drop-down list of the combo box in Authentic View sorted, check the *Sort Values in Authentic* check box.
- 4. Click **OK** to finish.

<u>Note</u>

- Using an XPath expression to select the items of the combo box drop-down list enables you to create combo boxes with dynamic entries from the XML file itself.
- If the items in the drop-down list of the combo box are obtained from schema enumerations, they will be sorted alphabetically by default. If the items are obtained from an XML data file, they will appear in document order by default. If the items are obtained from a DB, the DB schema must be set as the main schema. If items are obtained from a DB that is not the main schema, a template for the DB row targeted by the XPath expression must be included in the design, even if the template must be empty. Additionally, in such cases, make sure that all instances of the targeted row are fetched.
- Combo boxes in Text output displayed the selected value.

5.10.4 Radio Buttons, Buttons

There are two types of button: radio buttons and buttons. Radio buttons allow the Authentic View user to enter data into the XML file. Buttons **do not allow** data-entry in Authentic View, but are useful for triggering events in the HTML output.

Radio buttons

Inserting radio buttons in the SPS allows you to give the user a choice among multiple alternatives. Each radio button you insert maps to one XML value. The user selects one radio button. The radio buttons for a node are mutually exclusive; only one may be selected at a time, and the associated XML value is entered as the value of the node. The way to use this feature is to create the node for which the data-entry is required multiple times as a radio button. For each radio button enter (i) some static text to indicate its value to the user, and (ii) an XML value for each radio button. To edit the XML value of a radio button, in the Properties sidebar, select the

radio button item, then click the Edit button of the *radio button* property. This pops up the Edit Radio Button dialog.

Buttons

The button option allows you to insert a button and specify the text on the button. This is useful if you wish to associate scripts with button events in the generated HTML output. Note, however, that a button does not map to any XML value and does not allow data entry in Authentic View. However, the <u>value of the parent node of a button can be selected by the Authentic View user</u> (551), and the SPS can be designed to modify presentation based on what the Authentic View user selects.

Note: You can modify the HTML properties of a radio button or button by selecting it and then modifying its HTML properties in the Properties sidebar.

Note: Radio buttons in Text output are displayed as parentheses: () for unselected radio buttons; (o) for selected radio buttons. Buttons generate only the button text in Text output.

SPS Content Links 273

5.11 Links

Links (or hyperlinks) can be created to bookmarks located in the document as well as to external resources like Web pages. Links can also be created to dynamically generated anchors. StyleVision offers considerable flexibility in the way target URIs for hyperlinks can be built.

The section, <u>Bookmarks and Hyperlinks</u> 440, describes how to create static and dynamic bookmarks in the document and how to link to bookmarks as well as to external documents.

Note: Links are not rendered in Text output.

5.12 Barcodes

The Barcode design element is supported in **XSLT 2.0 or XSLT 3.0 mode** (not XSLT 1.0) and enables barcodes (*screenshot below*) to be generated in the output document. At the location in the design document where you wish to enter the barcode, <u>insert the Barcode design element</u> and specify its <u>properties</u>.

Important: For barcodes to work, a Java Runtime Environment must be installed. This must be version 1.4 or later in a bit version that corresponds to the bit version of the StyleVision package installed on your system: 32-bit or 64-bit.

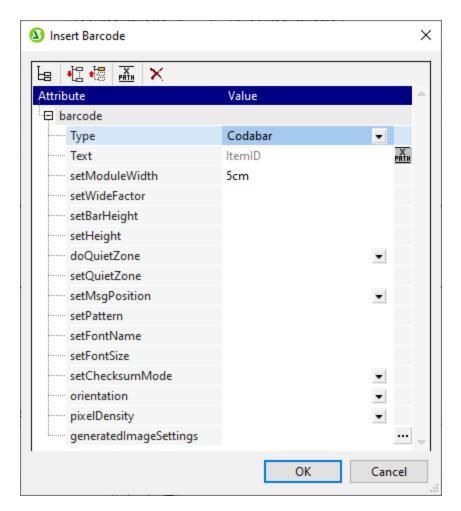

Important: For barcodes to be generated in the output, you must use Altova's XSLT processor to generate the output. This is because the barcodes in an SPS are generated by calling special Java extension functions that are not part of the XSLT standard. Altova's XSLT processors support these specific extension functions, whereas other XSLT processors very probably do not. As a result, barcodes will not be generated if processed with a non-Altova XSLT processor. The Altova XSLT processor is packaged with StyleVision, and is automatically called when you generate output via the **Generate** commands in the **File** menu. Alternatively, you can use RaptorXML Server, which is a Altova's standalone XSLT processor.

Note: Barcodes are not rendered in Text output.

Inserting a barcode

To insert a barcode in your design, do the following:

1. At the location where you wish to insert the barcode, right-click and select the command **Insert Barcode**. Alternatively, select the command **Insert | Insert Barcode** or click the Barcode icon in the toolbar and click the location in the design where you wish to insert the barcode. You can also drag and drop an element from the Schema Tree into the Design View and then select 'Create Barcode'. The Insert Barcode dialog pops up (*screenshot below*).

- 2. Two properties, *Type* and *Text*, are mandatory; the others are optional and/or have appropriate default values. The *Type* property, the value of which can be selected from a dropdown list (see screenshot above), specifies the type of the barcode, for example EAN-13 (which includes ISBN barcodes) and UPC-A. The *Text* property specifies the value that will generate the barcode, for example, an ISBN number. The various barcode properties are described below other properties that you want. Note that, if you wish to use a value in the XML file as the value of a property, you can enter an XPath expression to locate the XML node you wish to access. Do this as follows: Select the property, toggle on the XPath button in the toolbar of the Properties dialog, and then enter the XPath expression in the Edit XPath Expression dialog. The XPath expression will be evaluated within the current context node.
- 3. After setting the properties, click **OK**. The barcode image will be inserted. The generated barcode (*see screenshot below*) can be immediately viewed in any of the output previews.

Note: Barcode images are generated as PNG files.

Barcode properties

The following barcode properties can be specified. The *Type* and *Text* properties must be set; the other properties are optional. Note that different properties are available for different barcode types.

- Type: The barcode system under which the message will be interpreted, such as EAN and UPC.
- *Text:* The value that will be used to generate the barcode pattern.
- SetModuleWidth: The width of the bars in the code.
- SetBarHeight: The height of the bars.
- SetHeight: The height of the barcode graphic.
- DoQuietZone: Yes or No values determine whether the "quiet zone" (or padding) around the barcode, which is specified in the SetQuietZone and SetVerticalQuietZone properties, will be implemented.
- SetQuietZone: Sets the "quiet zone" (or padding) around the barcode. In the case of one-dimensional barcodes, the value specified here is applied to the horizontal dimension. In the case of two-dimensional barcodes, the value is applied to both horizontal and vertical dimensions. The value of the vertical dimension can be overridden by the value specified in the SetVerticalQuietZone property. A length unit of millimeters (mm) is required. Example: 2mm.
- SetVerticalQuietZone: Sets the "quiet zone" (or padding) for the vertical dimension on two-dimensional barcodes. A length unit of millimeters (mm) is required. Example: 2mm.
- SetMsgPosition: Specifies where the message text appears relative to the barcode. Values are top, bottom, and none (no mesage is generated).
- SetPattern: Sets a pattern for the message text so that the text is readable. A long string of numbers, for example, would be difficult to read. The syntax for patterns is given below.
- SetFontName: The font in which text should appear.
- SetFontSize: The font-size in which text should appear.
- SetChecksumMode: The following values are available: (i) Add: the checksum is automatically added to the message; (ii) Check: the checksum is checked while rendering the barcode (assumes the checksum is present); (iii) Ignore: no checksum processing is done; (iv) Auto: enables the barcode type's default behaviour.
- Orientation: Whether the barcode should be rotated. The options are in steps of 90 degrees counterclockwise.
- *PixelDensity:* Specifies the density of the pixels in the barcode image. Higher pixel density provides sharper images.
- GeneratedImageSettings: Enables you to set a name for the generated barcode image file. If no name is specified, a name is generated automatically by StyleVision.

Pattern syntax

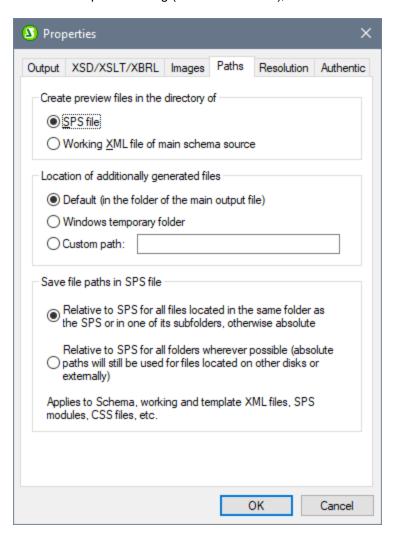

Patterns are used to make the input message string more readable in the barcode. In the pattern, each character of the input message text is represented by the underscore "_". Any other characters included in the pattern are inserted at the corresponding locations in the output message text. The backslash "\" is an escape symbol. So, the combination of '\?' will insert the character '?' in the output message text, where '?' can be any character. The character '#' can be used to delete a character from the original message. These points of pattern syntax are illustrated with the examples below.

Input message text	Pattern	Output message text
123456		12 34 56

15032011094655	_\\::UTC	15\03\2011 09:46:55 UTC
15-03-2011	#/#/	15/03/2011

Generating output files

The barcode image files that are generated for the output are saved to locations that are specified in the Paths tab of the Properties dialog (*screenshot below*), which is accessed with the menu command **File | Properties**.

Barcode image files for previews may be created in the same directory as the SPS file or as the Working XML File. These are temporary files, which are deleted when the SPS is closed. Barcode image files that are created when output is generated using the **File | Save Generated File** command can be created at any location. Their target location is specified in the pane, *Location of Additionally Generated Files* (see screenshot above).

5.13 Layout Modules

Layout Modules are objects containing a layout. The module as a whole is inserted in the SPS design and occurs as a block within the document flow. Within a Layout Module, multiple Layout Boxes, each containing standard SPS design elements, can be placed according to design requirements. Using Layout Modules, therefore, designers can create a layout just as they would using an artboard-based graphical design application.

The steps for creating a Layout Module are as follows:

- 1. Insert a <u>Layout Container</u> 278. The Layout Container can occupy the entire width of a page or can have any other dimensions you want. It can contain a blueprint of the design to serve as design guide and it can be formatted (in the Styles sidebar) using styles for the Layout Container.
- 2. Insert one or more Layout Boxes 233 in the Layout Container. Layout Boxes can contain multiple design elements (including static text, schema nodes, Auto-Calculations, images, lists, etc), and they can be formatted (in the Styles sidebar) using styles for the Layout Box. Layout Boxes can also be moved relative to each other within the Layout Container and can be positioned in front of or behind each other.
- 3. <u>Lines</u> can be drawn, formatted, positioned and moved to the front or back of the stack of layout objects (Layout Boxes and other Lines).

Note: Layout Modules are not rendered in Text output.

Form-based designs

When you <u>create a new SPS</u> ⁽⁹⁴⁶⁾ you are offered the choice of creating a free-flowing design or a form-based design. A form-based design is essentially an SPS design consisting of a Layout Container.

Note: Layout Modules are supported in Authentic View only in the Enterprise Editions of Altova products.

5.13.1 Layout Containers

A Layout Container has the following properties:

- It can be <u>inserted</u> within the flow of a document, that is, within a template. Or it can be inserted as the container within which the document design is created.
- It can have the same dimensions as the page dimensions defined for that section (the Auto-Fit to Page property of Layout Containers). Or it can have any other dimensions you specify. See the <u>Layout Container size</u> section below for details.
- A <u>layout grid</u> and a <u>zoom feature</u> make the positioning of objects in the Layout Container easier.
- It can have <u>style properties</u> 280, such as borders, background colors, font-properties for the whole container, etc.
- It can <u>contain Layout Boxes and Lines</u> but no other design element. (All design elements must be placed within Layout Boxes.)
- It can contain a <u>blueprint</u> which is an image placed on the artboard to serve as a reference template for the designer. The design can then be built to match the blueprint exactly.

Note: Layout Containers are supported in Authentic View only in the Enterprise Editions of Altova products.

Inserting a Layout Container

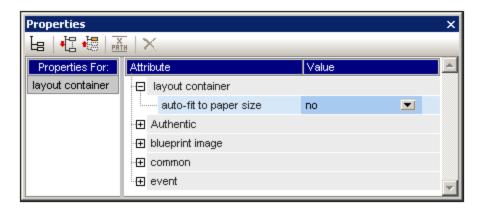

To insert a Layout Container, click the **Insert Layout Container** icon in the <u>Insert Design Elements toolbar</u> and click the location in the design where the Layout Container is to be inserted. A dialog appears asking whether you wish to auto-fit the Layout Container to the page. If you click **Yes**, the Layout Container will have the same size as the page dimensions defined in the page layout properties of that particular document section. If you click **No**, then a Layout Container with a default size of 3.5in x 5.0in is created.

Note that a Layout Container can also be created at the time you create an SPS.

Layout Container size

There are two sets of properties that affect the size of the Layout Container:

• The Auto-Fit Page Size property (Properties sidebar, screenshot below) can be set to yes to create a Layout Container having the same dimensions as those specified for pages in that document section. A value of no for this property creates a Layout Container with a customizable size.

• The *height* and *width* properties of the Details group of Layout Container styles (in the Styles sidebar) specify the dimensions of the Layout Container. The dimensions can also be modified directly in the design by dragging the right and bottom margins of the Layout Container. Note that the *height* and *width* properties will take effect only when the *Auto-Fit Page Size* property has a value of no.

Layout Container Grid

The Layout Container has a grid to aid in spacing items in the layout. The following settings control usage of the grid:

- Show/Hide Grid: A toggle command in the Insert Design Elements toolbar switches the display of the grid on and off.
- Grid Size: In the Design tab of the Options dialog (<u>Tools | Options</u>) units for horizontal and vertical lengths can be specified. Note that if very large length units are selected, the grid might not be clearly visible.
- Snap to Grid: A toggle command in the Insert Design Elements toolbar enables or disables the Snap to Grid function. When the Snap to Grid feature is enabled, the top and left edges of Layout Boxes and the endpoints of Layout Lines align with grid lines and points, respectively.

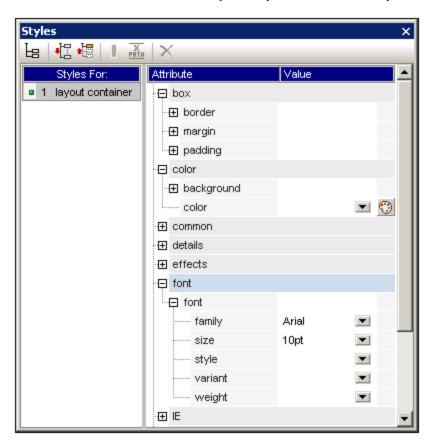

Zooming

To help position objects more accurately, you can magnify the view. Do this by changing the Zoom factor in the Zoom combo box (in the Standard toolbar), or by pressing the **Ctrl** key and scrolling with the mouse.

Layout Container style properties

There are two types of style properties that can be applied to Layout Containers:

- Those applied to the Layout Container alone and which are not inheritable, such as the *border* and *background-color* properties.
- Those that are inheritable by the Layout Boxes in the Layout Container, such as font properties.

The style properties of a Layout Container are set in the *Layout Container* styles in the Styles sidebar (*screenshot above*).

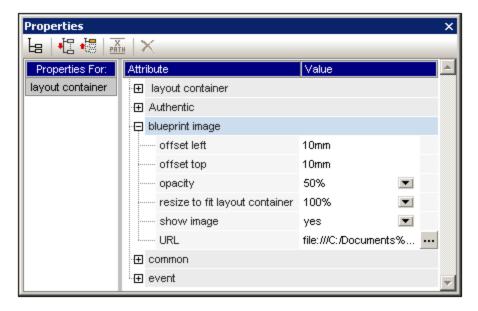

Layout Container contents

The only design items that can be contained in a Layout Container are Layout Boxes and Lines. Additionally, a blueprint (which is not a design element) can be placed in the Layout Container as a design aid. All design elements must be placed in a Layout Box.

Blueprints

One blueprint can be placed in a Layout Container at a time to aid the designer in creating the SPS. The blueprint is an image file that can be placed to exactly fit the size of the Layout Container. Alternatively, if the blueprint image is smaller than the Layout Container, it can be offset to the desired location in the design (see Blueprint image *properties screenshot below*). The designer can use the blueprint by reproducing the SPS design over the blueprint design. In this way the designer will be able to place design elements in the layout exactly as in the blueprint. The blueprint will appear only in Design View, but **not** in any output view: this is because its purpose is only to aid in the design of the SPS.

The blueprint's properties can be controlled via the *Blueprint image* group of properties of the Layout Container properties (in the Properties sidebar, *screenshot below*).

The opacity of the blueprint in the Layout Container can be specified so that the blueprint does not interfere with the viewing of the design. The display of the blueprint image can also be switched off with the *Show Image* property if required.

5.13.2 Layout Boxes

Every design element in a layout (such as static text, schema nodes, Auto-Calculations, images, lists, etc) must be placed in a Layout Box. The Layout Boxes containing design elements are laid out as required in the Layout Container. Note that a design element cannot be placed directly in a Layout Container; it must be placed in a Layout Box.

This section describes how Layout Boxes are used and is organized into the following sub-sections:

- Inserting Layout Boxes 282
- Selecting and moving Layout Boxes 282
- Modifying the size of the Layout Box ²⁸²
- Defining Layout Box style properties

- Inserting content in the Layout Box 283
- Stacking order of Layout Boxes ²⁸

Inserting a Layout Box

A Layout Box can be inserted only in a <u>Layout Container</u>. To add a Layout Box, first click the Insert Layout Box icon in the <u>Insert Design Elements</u> toolbar, then click on the location inside the Layout Container where you wish to insert the Layout Box. A Layout Box will be inserted, with its top left corner positioned at the point where you clicked. The box will be transparent, will have no borders, and will have default text.

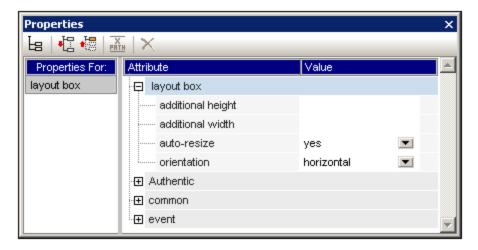

Selecting and moving a Layout Box

To select a Layout Box, place the cursor over the left border or top border of the Layout Box so that the cursor becomes a crossed double arrow. When this happens, click to select the Layout Box. If you keep the mouse button depressed, you can move the Layout Box to another location within its Layout Container. You can also move a Layout Box left, right, up, or down by selecting it, and then pressing the cursor key for the required direction. When the Layout Box is selected, its properties and styles are displayed in the respective sidebars.

Layout Box size

Each Layout Box has a property called *Auto-Resize* (see screenshot below). When the value of this property is set to yes, the Layout Box automatically resizes to exactly accommodate any static content (including markup) that is inserted in it in the Design View. When the value of Auto-Resize is set to no, the size of the Layout Box does not automatically change when content is inserted in it.

To change the size of the Layout Box manually, drag its right border and bottom border. You can also the change the size of a Layout Box by using the cursor keys to move the right and bottom borders of the box. To do this first select the Layout Box . Then do the following: (i) to move the right border, keep the **Shift** key depressed and press the right or left cursor key till the required size is obtained; (ii) to move the bottom border, keep the **Shift** key depressed and press the top or bottom cursor key.

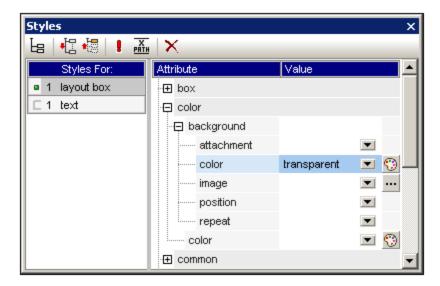

The Additional Height and Additional Width properties give the lengths that are additional to the optimal dimensions as determined by auto-resizing. The additional lengths are obtained when a Layout Box is manually resized. Conversely, by changing the values of these two properties, the size of the Layout Box can be changed.

Note: In a Layout Box a linefeed is obtained by pressing the **Enter** key. This is significant, because if content is added that does not contain a linefeed, then the length of the current line increases, thus increasing the optimal width of the Layout Box and—incidentally—affecting the *Additional Width* value, which is calculated with reference to the optimal width.

Layout Box style properties

The style properties of a Layout Box are set in the *Layout Box* styles in the Styles sidebar (*screenshot below*). The styles are displayed when the Layout Box is selected, and can then be edited.

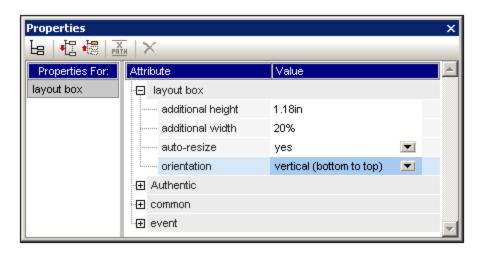

Note: The *background-color* value of transparent can be selected in the dropdown list of the property's combo box (it is not available in the color palette). The significance of this value in a situation where the Layout Box is part of a stack is explained below.

Inserting content in a Layout Box

Any type of design element can be inserted in a Layout Box, and is inserted just as it normally would be in an SPS. Note, however, that neither a <u>Layout Container</u> nor a <u>Layout Line</u> can be inserted in a Layout Box. The following points should be noted:

- When design elements are inserted that require a context node, the current node will be taken as the context node. The current node is the node within which the Layout Module has been created.
- Text content in a layout box can be rotated 90 degrees clockwise or anti-clockwise, so that the text is
 vertical, reading from top-to-bottom or bottom-to-top, respectively. To do this, in the design, select the
 text that is to be rotated and, in the Properties sidebar (*screenshot below*), select LayoutBox. In the
 Layout Box group of properties, select the required value for the Orientation property.

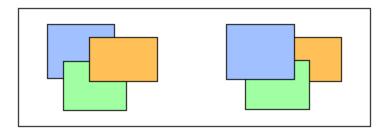

Note the following points:

- The rotation will be applied to the output, but will not be be displayed in the design.
- This property can also be applied to text in <u>table cells</u> 160.

Stacking order of Layout Boxes

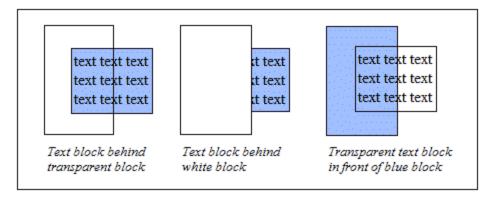

Layout Boxes can be placed one over the other. When one Layout Box is placed on top of another, then, if it is opaque, it hides that part of the Layout Box which it covers. This behavior can be extended to a stack of several Layout Boxes. In such a stack, only the topmost Layout Box will be fully visible; the others will be partially or fully covered.

Layout Boxes can be sent backward or brought forward using the **Order** menu commands in the context menu of the selected Layout Box. Using these commands a Layout Box can be ordered: (i) relative to its nearest neighbor on the stack (the **Bring Forward** and **Send Backward** commands), or (ii) relative to the entire stack (the **Bring to Front** and **Send to Back** commands). In the screenshot above, the stacking order from front to back is as follows:

- Left stack: orange, green, blue
- Right stack: blue, green, orange

Note that Layout Boxes with transparent backgrounds (the default background of Layout Boxes) might appear to not move relative to each other, especially if more than one box in the stack is transparent and if boxes have no borders. The screenshot below presents some ways in which transparency affects stacking.

Note: Layout Lines can also be added to a stack of Layout Boxes, and each Line can be moved relative to other items in the stack.

5.13.3 Lines

Lines can be <u>inserted in a Layout Container</u> (but not in Layout Boxes), then <u>selected, re-sized and moved</u> around within the Layout Container, <u>assigned properties</u>, and <u>moved backwards and forwards in a stack of layout items</u> consisting of Layout Boxes and other Lines.

Inserting a Line

To add a Line to a Layout Container, do the following:

- 1. Click the Insert Line icon in the Insert Design Elements (940) toolbar.
- 2. Click on the location inside the Layout Container where you wish to locate the start point of the line.
- 3. Without releasing the mouse button, draw the line from the start point to the desired end point. Then release the mouse button.

A black line will be inserted, with a dot at each end indicating the start and end points respectively.

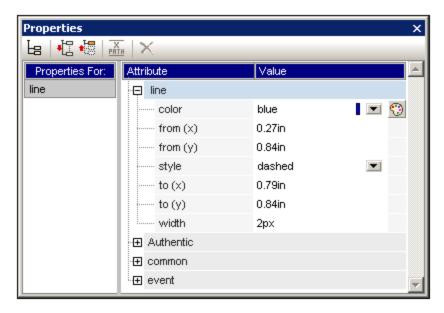

Selecting, moving, and sizing a Line

In the Main Window, you can carry out the following-drag-and-drop functions:

- To select a Line, click any part of the Line (the cursor becomes a crossed double arrow when it is over the Line). Once a Line is selected, its properties are displayed in the Properties sidebar and can be edited there (see below).
- To move a Line, select it and drag it to the desired location. You can also move a line left, right, up, or down by selecting it, and then pressing the cursor key for the required direction.
- To graphically re-size or re-orient a Line, select either the start point or end point and re-position it to obtain a new size and/or orientation. You can also re-size or re-orient a Line by pressing **Shift** and the cursor keys: the right and left cursor keys move the right-hand endpoint right and left, the up and down cursor keys move the right-hand endpoint up and down, respectively.

Line properties

When a Line is selected its properties are displayed in the Properties sidebar (*screenshot below*), and the properties (listed below) can be edited in the sidebar. You can also right-click a Line to pop up the Properties sidebar with the properties of the Line in it.

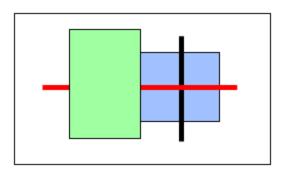

The following Line properties can be edited in the Properties sidebar:

- Color: Specifies a color for the Line. The default is black.
- Size and position: The location of the start and end points of the Line can be specified using an x-y (horizontal-vertical) coordinate system. The reference frame is created with the top left corner of the Layout Container having the coordinates (x=0, y=0).
- Width: Specifies the thickness of the Line.

Lines and stacking order

When a Line is in a stack consisting of Layout Boxes and other Lines, it can be sent backward or brought forward using the **Order** menu commands in the context menu of the selected Line. Using these commands a Line can be ordered: (i) relative to its nearest neighbor on the stack (the **Bring Forward** and **Send Backward** commands), or (ii) relative to the entire stack (the **Bring to Front** and **Send to Back** commands).

In the screenshot above, the stacking order from front to back is as follows: green box, red line, black line, blue box.

5.14 The Change-To Feature

The **Change-To** feature is available when a template or the contents of a template are selected, and enables you to change: (i) the node for which that template applies, or (ii) how the node is created in the design.

What can be changed with the Change-To feature

Either a node or its contents can be changed. In the image below left, the node is selected. In the image at right, the node's contents are selected.

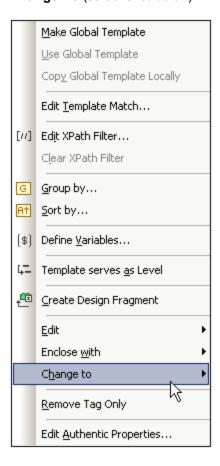

The n1:Name element in the screenshot above has been created as (contents), and so the node's contents are represented by the (contents) placeholder. Alternatively, the node could have been created as another type of content, for example, as an input field or combo box. Other types of content can also be selected.

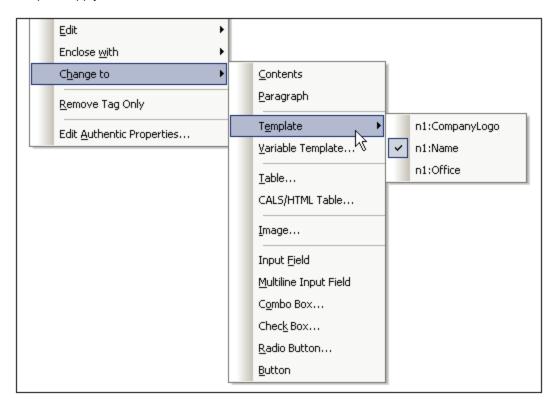

The Change-To command

Access the change to comannd by right-clicking your selection. In the context menu that pops up, select **Change To** (*screenshot below*).

Changing template matches

If a template is selected, you can change the node for which that template applies. This is useful if, for instance, the name of an element has been changed in the schema. When you mouse over the Change To command and select Template from the sub-menu that pops up, you are presented with a list off all the nodes that may be inserted as a child of the selected node's parent element. Click one of these nodes to make the template apply to that node.

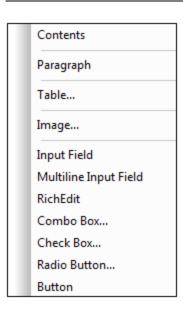

If the selected node has a content model that does not match that described in the template, there will be structural inconsistencies. Such inconsistencies are errors and are indicated with red strikethroughs in the tags of nodes that are invalid.

You can also change the template-match to match, not a node, but a <u>variable template</u> 352.

Changing the content type of the node

If a template or its contents are selected, then you can change the type of content the node is created as. On hovering over the Change To command in the context menu, the type of content that the selected node can be changed to is displayed as options in the sub-menu that pops up (*screenshot below*).

The screenshot above has been taken with a combo box selected.

SPS Structure 291

SPS Structure 6

The structure of an SPS document is both input- as well as output-driven, and it is controlled by:

- Schema sources 293 Modular SPSs 330
- Templates and Design Fragments 344

Input-driven structure: schemas and modular SPS files

By input-driven, we mean that the source schemas of SPS files specify the structure of the input document/s and that this structure is the structure on which the SPS document is based. For example, if a source schema specifies a structure that is a sequence of Office elements, then SPS design could have a template for the Office element. At processing time this template will be applied in turn to each Office element in the source data document.

Another example of how the source document structure drives the design of the SPS file can be seen in the use of tables. Say that an Office element contains multiple Person element children, and that each Person element contains a set of child elements such as Name, Address, Telephone, etc. Then a template in the form of a table can be created for the Person element. Each Person element can be presented in a separate row of the table (screenshot below), in which the columns are the details of the Person (the child elements of the Person element).

First	Last	Title (sorted by)
Loby	Matise	Accounting Manager
Frank	Further	Accounts Receivable
Vernon	Callaby	Office Manager

Such a template is possible because of the structure of the Person element and because the Person elements are siblings. In the table template a single row is designed for the Person element, and this processing (the row design) is applied in turn to each Person element in the source document, creating a new row for each Person element, with the child elements forming the columns of the table.

How to use various kinds of schema sources is described in the section, Schema Sources 233.

Additionally, StyleVision allows SPSs to be re-used as modules within other SPSs. In this way, modules can be included within a structure and can modify it. However, a schema structure contained in a module must fit in with the structure of the underlying schema of the containing SPS. How to work with modular SPSs is described in the section, Modular SPSs 330.

Output-driven structure: templates and design fragments

While the schema sources provide the structure of the input data document, the actual design of the output document is what is specified in the SPS document. This design is contained in one document template called the main template. The main template typically contains several component templates and can reference global templates. Templates are described in the section, <u>Templates and Design Fragments</u> 344.

This composability (of multiple templates) is further enhanced by a StyleVision feature called Design Fragments, which enables specific processing to be assigned to a document fragment that can be re-used. A Design Fragment is different than a global template in that: (i) it can be composed of multiple templates; and (ii) identical content with different processing can be created in separate design fragments, either of which can be used in a template according to the situation. For example, in some processing situations, an Email node might be required as a link that opens an empty email; in other cases the Email element could be required in bold and in red. Two separate design fragments could provide the respective processing, and both can be reused as required.

Design fragments are described in detail in the section, <u>Design Fragments</u> 356.

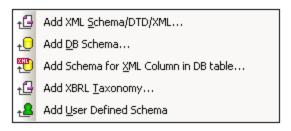

6.1 Schema Sources

The schema sources are the starting point of the design, and design structure can be influenced by: (i) choices you make during schema selection, and (ii) the root elements you select in the schema.

Schema selection

The selection of the schema for a new SPS file can be done in the following ways:

- 1. Click **File | New** and directly select a schema source to add via one of the methods (except **New** (empty)) available in the menu that pops up.
- Click File | New, select New (empty) from the menu that pops up. After the new SPS is created and displayed in the GUI, in the <u>Design Overview sidebar</u> 45, select the Add New Schema command. This pops up a a menu listing the methods you can use to add different types of schemas (*screenshot below*). Each command in this menu is described in the sub-sections of this section.

The schema source can be selected from a file, from a DB, or be an XBRL taxonomy or user-defined. An important point to consider is whether you will be using global templates, and whether elements you wish to create as global templates are defined as global elements in the schema. When adding a DTD from file, remember that all elements defined in the DTD are global elements. When adding an XML Schema from file, it is worth checking what elements are defined as global elements and, should you wish to make any change to the schema, whether this is permitted in your XML environment. When a DB is selected, during the import process, you can select what tables from the DB to import. This selection determines the structure of the XML Schema that will be generated from the DB.

Note: You can select multiple schemas, of which one schema is designated the <u>main schema</u> (right-click the schema in the Design Overview sidebar and select Set As Main Schema). The <u>document node</u> of the <u>main schema</u> is the entry point of the <u>main template</u>. The selection and presence of subsidiary schemas in the schema sources enable nodes from these schemas to be included in the design.

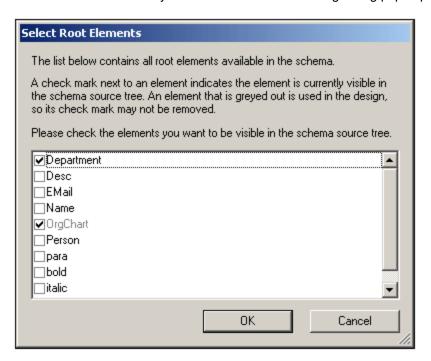

Note: If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Root elements

If a schema source has multiple global elements (document elements (document elements (document elements)) can be selected for use in the design. This enables the SPS design to have templates that match multiple document elements. The advantage of this is that if an SPS, say UniversalSPS.sps, based on UniversalSchema.xsd has one template each for its two root elements, Element-A and Element-B, then this one SPS can be used with an XML instance document which has Element-A as its document element as well as with another XML instance document which has Element-B as its document element. For each XML instance, the relevant template is used, while the other is not used. This is because for the document element of each XML instance document, there is only one template in the SPS which matches that document element.

For example, the document element /Element-A will be matched by the template which selects /Element-A but not by that which selects /Element-B. In this connection, it is important to remember that if multiple global elements are defined in the schema, an XML document with any one of these global elements as its document element is valid (assuming of course that its substructure is valid according to the schema).

To set up the SPS to use multiple root elements (<u>document elements</u> 30), click the button to the right of the /Root elements entry of the schema. The following dialog pops up.

The dialog lists all the global elements in the schema. Select the global elements that you wish to use as root elements (document elements (document elements and will be displayed in the Root Elements list. A template can now be created for each of these document elements. Each of these templates serves as an alternative root element template. When an XML document is processed with this SPS, only one of the alternative root element templates will be used: the one that matches the root (or document) element of the XML document.

So, when an XML document having <code>Element-A</code> as its document element is processed with this SPS, then the root template in the SPS that matches <code>Element-A</code> is triggered, while all the other root element templates in the SPS are ignored. If an XML document having <code>Element-B</code> as its document element is processed, then the root template in the SPS that matches <code>Element-B</code> is triggered, while all other root element templates in the SPS are ignored. In this way a single SPS can be used to process two or more XML documents, each of which has a different root (or document) element.

6.1.1 DTDs and XML Schemas

An SPS can be based on an XML Schema or DTD or have one or more XML Schemas or DTDs among its schema sources. An XML Schema or DTD can be created as a schema source in one of the following ways:

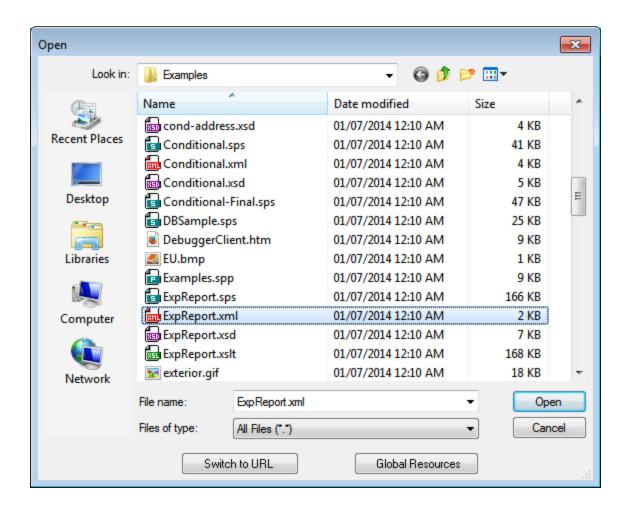

The XML Schema or DTD is is created as a schema source directly when the SPS is created (File | New | New from XML Schema / DTD / XML).

• The XML Schema or DTD is added to an empty SPS or to an SPS with existing schema sources (in the <u>Design Overview sidebar</u> 45).

The respective commands prompt you to browse for the XML Schema or DTD. If the schema is valid, it is created as a schema source in the Schema Sources tree of the Schema Tree sidebar. Alternatively, an XML file can be selected. If an XML Schema (.xsd) or DTD file is associated with the XML file, then the XML Schema or DTD file is loaded as the source schema and the XML file is loaded as the Working XML File. If no schema is associated with the XML file, a dialog pops up asking whether you wish to generate an XML Schema based on the structure and contents of the XML file or browse for an existing schema. If you choose to generate a schema, the generated schema will be loaded as the source schema, and the XML file will be loaded as the Working XML File.

Selecting and saving files via URLs and Global Resources

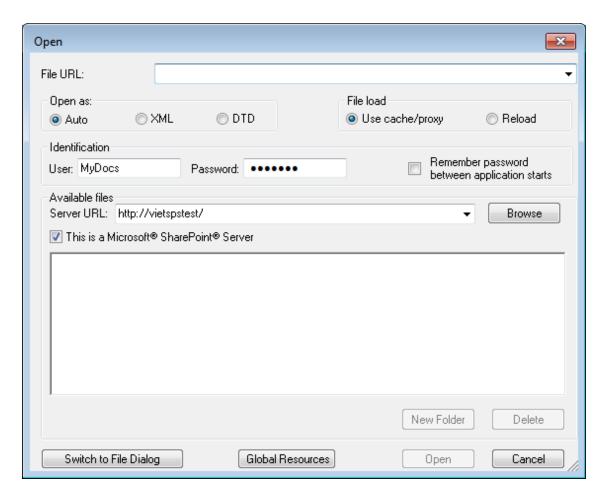

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Click **Switch to URL** or **Global Resource** to go to one of these selection processes.

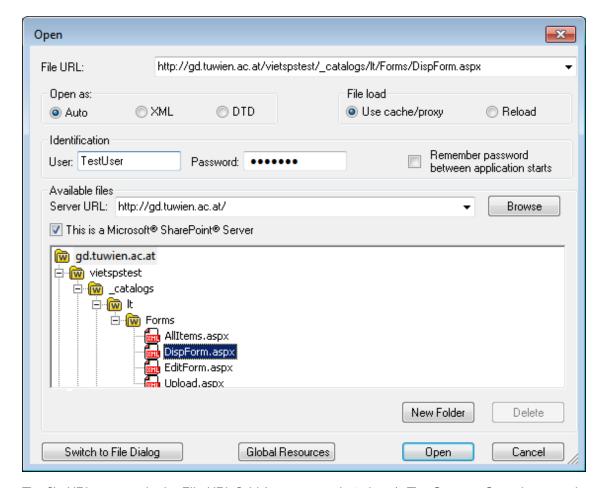

Selecting files via URLs

To select a file via a URL (either for opening or saving), do the following:

1. Click the **Switch to URL** command. This switches to the URL mode of the Open or Save dialog (the screenshot below shows the Open dialog).

- 2. Enter the URL you want to access in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.
- 3. If the server is password protected, enter your User-ID and password in the *User* and *Password* fields
- 4. Click **Browse** to view and navigate the directory structure of the server.
- 5. In the folder tree, browse for the file you want to load and click it.

The file URL appears in the File URL field (see screenshot above). The **Open** or **Save** button only becomes active at this point.

6. Click **Open** to load the file or **Save** to save it.

Note the following:

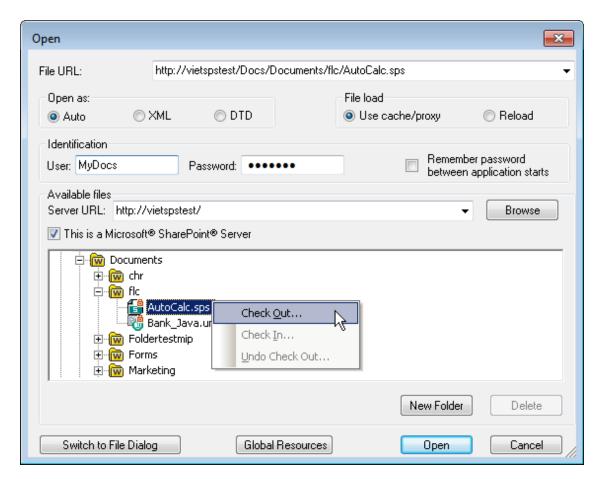

- The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.
- To give you more control over the loading process when opening a file, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

Microsoft® SharePoint® Server Notes

Note the following points about files on Microsoft® SharePoint® Servers:

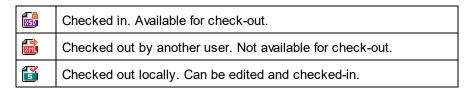

• In the directory structure that appears in the Available Files pane (*screenshot below*), file icons have symbols that indicate the check-in/check-out status of files.

© 2019-2025 Altova GmbH

Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

The various file icons are shown below:

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot
 above), or via the context menu that pops up when you right-click the file tab in the Main Window
 of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out

command in the context menu. This has the effect of returning the file unchanged to the server.

• If you check out a file in one Altova application, you cannot check it out in another Altova application. The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: Check In and Undo Check Out.

Opening and saving files via Global Resources

To open or save a file via a global resources, click **Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, <u>Using Global Resources</u>

For a general description of Global Resources, see the <u>Global Resources</u>

Section in this documentation.

The anyType datatype of XML Schema

If an element in the XML Schema has been assigned the <code>anyType</code> datatype of XML Schema or if it has not been assigned any datatype, then the schema tree in the Schema Tree will show this element as having all the global elements of that schema as possible children. For example, if an element called <code>email</code> has not been assigned any datatype, then it will be displayed in the schema tree with all global elements as possible children, such as, for example: <code>person</code>, <code>address</code>, <code>city</code>, <code>tel</code>, etc. To avoid this, assign the <code>email</code> element a datatype such as <code>xs:string</code>.

6.1.2 DB Schemas

An SPS can be based on a schema that is generated from a DB or have a DB-based schema (DB schema) as one of its schema sources. A DB schema can be created as a schema source in one of the following ways:

- The DB schema is generated for a new SPS when the SPS is created directly from a DB (File | New | New from DB or File | New | New from XML Column in DB Table).
- The DB schema is added to a new empty SPS that has no schema sources or to an SPS with existing non-DB schema sources (in the <u>Design Overview sidebar</u> 45).

The respective DB-schema-generation commands generate a temporary XML Schema from the selected DB and creates the schema as a schema source in the Schema Tree sidebar 48, or the command loads a DB-based schema (DB schema) from an XML DB. An element extraneous to the DB, called DB, is created as the document element, and the DB structure is created within this document element. During the schema creation process, you will be prompted to select which tables or data from the database you wish to import. These database tables will be created in the XML Schema as children of the DB element and also as items in the Global Templates list.

Creating the XML Schema from a DB

Creating the XML Schema from a DB consists of two steps:

Connecting to a Database 633. This consists essentially of browsing for the DB file (if it is a MS Access DB), or building a connection string (all other DBs except MS Access).

• <u>DB Data Selection</u> In this step, the table or data structure from the database is selected. In the case of non-XML DBs, the temporary XML Schema that is generated and the XML file that is created will be based on the selected data tables.

After the schema source appears in the Schema Tree window, you can start designing the SPS. A temporary XML File is created each time an output preview tab is clicked. The XML file is structured according to the generated XML Schema and contains data from the selected DB tables.

6.1.3 XBRL Taxonomy

An XBRL taxonomy can be used as a schema source in the following ways:

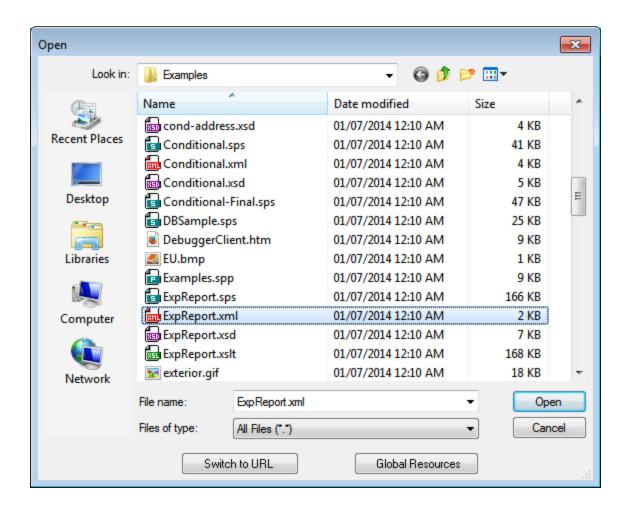

- A new SPS file can be created with an XBRL taxonomy as its schema source via the File | New | New from XBRL Taxonomy.
- In the Design Overview sidebar, clicking the Add Schema Source link pops up a menu in which you select the option **Add XBRL Taxonomy**. The taxonomy can be added to an empty SPS file (that is, one with no schema source) or to one already containing one or more schema sources.

On clicking either of these two commands, a file open dialog pops up, in which you can browse for the XBRL taxonomy. The taxonomy can also be selected via a URL or a global resource; how to do this is described below. Select the taxonomy and click **Open**. A dialog appears asking whether you wish to assign a Working XBRL file to the schema source. Browse for the file or global resource, or select **Skip** to not assign a Working XBRL File. (You will need a Working XBRL File in order to preview your output in the Output Views.)

The XBRL taxonomy will be loaded and will be available in the Schema Tree sidebar for dragging into the design. The Working XBRL file will be loaded and will provide the data for output previews.

Selecting and saving files via URLs and Global Resources

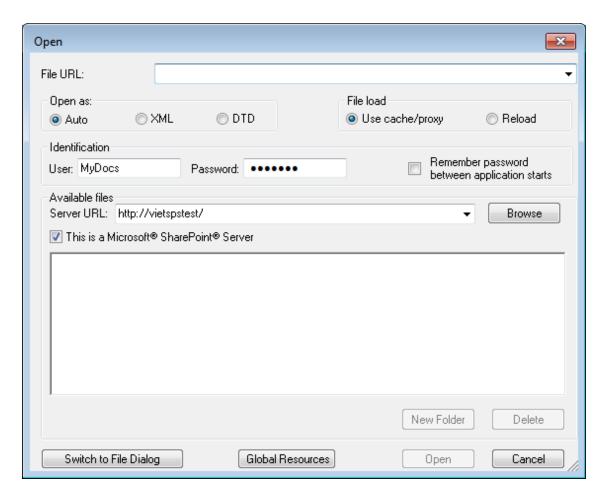

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Click **Switch to URL** or **Global Resource** to go to one of these selection processes.

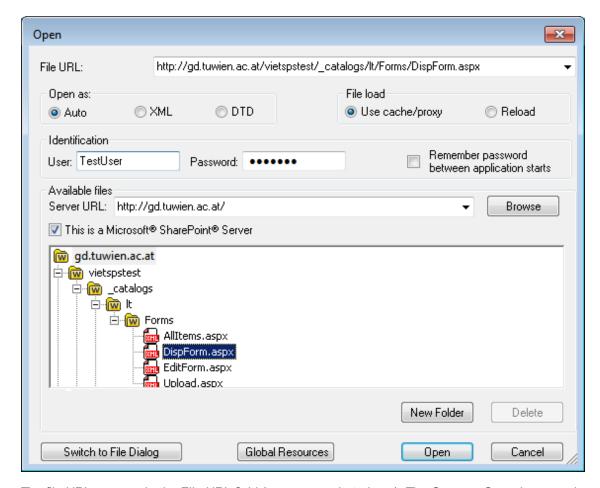

Selecting files via URLs

To select a file via a URL (either for opening or saving), do the following:

1. Click the **Switch to URL** command. This switches to the URL mode of the Open or Save dialog (the screenshot below shows the Open dialog).

- 2. Enter the URL you want to access in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.
- 3. If the server is password protected, enter your User-ID and password in the *User* and *Password* fields
- 4. Click **Browse** to view and navigate the directory structure of the server.
- 5. In the folder tree, browse for the file you want to load and click it.

The file URL appears in the File URL field (see screenshot above). The **Open** or **Save** button only becomes active at this point.

6. Click **Open** to load the file or **Save** to save it.

Note the following:

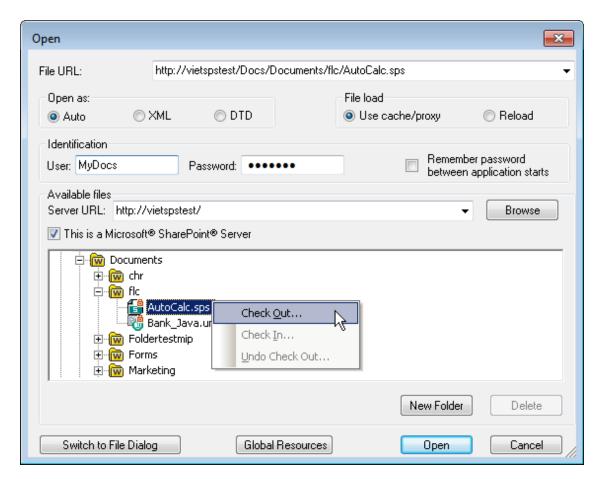

- The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.
- To give you more control over the loading process when opening a file, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

Microsoft® SharePoint® Server Notes

Note the following points about files on Microsoft® SharePoint® Servers:

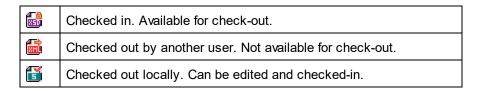

• In the directory structure that appears in the Available Files pane (*screenshot below*), file icons have symbols that indicate the check-in/check-out status of files.

© 2019-2025 Altova GmbH

Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

• The various file icons are shown below:

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot
 above), or via the context menu that pops up when you right-click the file tab in the Main Window
 of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out

- command in the context menu. This has the effect of returning the file unchanged to the server.
- If you check out a file in one Altova application, you cannot check it out in another Altova application. The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: Check In and Undo Check Out.
- Opening and saving files via Global Resources

To open or save a file via a global resources, click **Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, <u>Using Global Resources</u>

For a general description of Global Resources, see the <u>Global Resources</u>

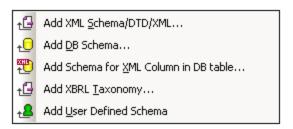

Section in this documentation.

6.1.4 User-Defined Schemas

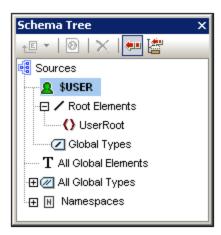

You can quickly create a user-defined schema in the <u>Schema Tree sidebar</u> ⁴⁸. This is useful if you have an XML document that is not based on any schema and you wish to create an SPS for this XML document.

To add and create a user-defined schema, in the Schema Tree sidebar, do the following:

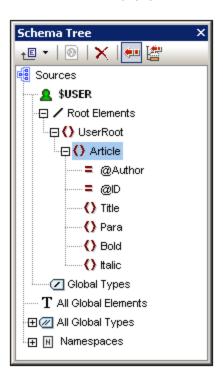

1. In the <u>Design Overview sidebar</u> 45, click the **Add New Source** command (under the Sources heading), and select **Add User-Defined Schema** (*screenshot below*).

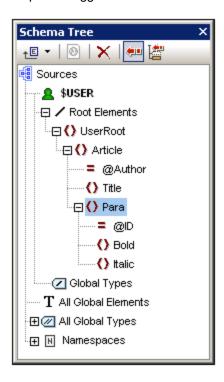

The new schema is created and is indicated with the parameter \$USER (screenshot below).

- 2. In the Root Elements tree, there is a single root element (document element) 30 called UserRoot.
- 3. Double-click UserRoot and rename it to match the document element of the XML document for which you are building this schema.
- 4. To assign a child element or an attribute to the document element, select the document element (UserRoot), and click, respectively, (i) the drop-Append New Element icon in the toolbar of the Schema Tree sidebar (ii) the dropdown arrow of the Append New Element icon the Append New Attribute command. Alternatively, you can right-click and select the required command from the context menu. When an element is selected, appending and inserting an element, adds the new element as a sibling element, respectively, after and before the selected element. You can also add a child element and a child attribute. When an attribute is selected, you can append or insert another attribute, respectively, after and before the selected attribute. After the new element or attribute is added to the tree, type in the desired name. You can also drag nodes to the desired location (described in the next step). In the screenshot below, the Article element is the document element. The elements Title, Para, Bold, and Italic, and the attributes ID and Author have been added at the child level of Article.

5. To move the elements Bold and Italic, and the attribute ID to the level of children of Para, select each individually and drag to the Para element. When a bent downward-pointing arrow appears, drop the dragged node. It will be created as a "child" of Para (screenshot below).

6. When any element other than the document element is selected, adding a new element or attribute adds the new node at the same level as the selected element. Drag a node (element or attribute) into an element node to create it as a "child" of the element node.

Editing node names and deleting nodes

To edit the name of an element or attribute, double-click in the name and edit the name. To delete a node, select it and click the Remove icon in the toolbar. Alternatively, select **Remove** from the context menu.

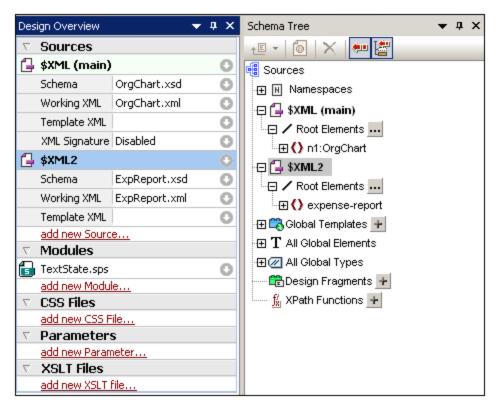

6.1.5 Multiple Schema Sources

You can use multiple schema sources in your SPS. This enables you to combine data from different XML documents in the output. For example, in one XML document you can have the structure of an organization, with its various departments. In another XML document you can have the listing of personnel in the various departments. In the output, the organizational structure data (first XML document) and the personnel data (second XML document) can be combined.

Note: If, across the multiple schemas used, there are two or more global elements that have the same expanded QName, there will be a naming conflict and one or more of the involved schema documents will be rendered invalid. You must therefore ensure that no two global elements across the multiple schemas have the same expanded QName. Local elements across multiple schemas may have the same expanded QName as other local elements, and will not cause any naming conflict.

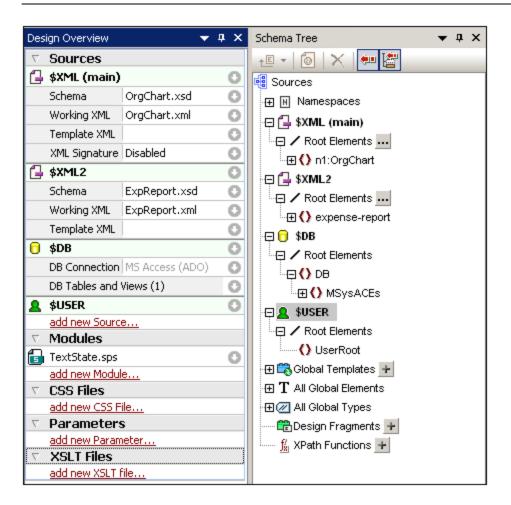

Adding multiple schemas

In order to combine the dynamic XML data from different documents, you first add to the SPS the different schemas that are involved. You do this in the <u>Design Overview sidebar</u> (screenshot below). This creates a tree for each schema in the <u>Schema Tree sidebar</u> (screenshot below). You can choose the <u>Working XML File</u> 1, and <u>Root elements</u> 1, and <u>Root elements</u> 1, and <u>Root elements</u> 2, and are available for creation as <u>global templates</u> 3.

Note that XML signatures 605 can only be enabled for the main source.

Each schema source is identified by a parameter of the form \$xml1 (DTD or XML Schemas) or \$DB1 (DB-based schema) or \$USER1 (user-defined schema). These three kinds of schemas can be combined in a single SPS (see screenshot below). Note, however, that, while any number of DTDs and/or XML Schemas can be added to an SPS, only one each of a DB-based schema and a user-defined schema can be added.

Selecting the main schema

Of all the schemas added to the SPS, one can be designated as the <u>main schema</u> ³⁰, and, in both the Design Overview and Schema Tree sidebars, this is indicated with the the word **(main)** next to the main schema. The <u>document node</u> ³⁰ of the XML document corresponding to the main schema will be the starting point of the transformation. To select the main schema, right-click the schema in the <u>Design Overview sidebar</u> ⁴⁵, and select **Set as Main Schema**.

Adding nodes from different schemas to the design

Within the <u>main template</u> ³⁰, nodes from different schemas are added to the design by dragging the nodes from their respective schema trees into the main template. A <u>global template</u> ³⁰ is created in the same way as with a single schema. It can be copied or used by a <u>local template</u> ³⁰, or used instead of the built-in template when invoked via a <u>rest-of-contents instruction</u> ¹³⁶ from the main template.

Using schema parameters in external transformations

Each schema added to the SPS is identified by a parameter. For example, \$XML (for DTDs or XML Schemas) or \$DB (DB-based schema) or \$USER (user-defined schema). In StyleVision, the Working XML File that is associated with each schema is known to the application, so the correct document nodes are accessed, thus enabling the display of data from the XML sources in Authentic View and output previews. However, when you generate XSLT stylesheets from the SPS, no XML file associations are contained in the stylesheet. In order to associate an XML file with each schema in the XSLT stylesheet, you must pass the location of each XML file

as the value of the corresponding schema parameter. For example, the schema parameter, \$xml, according to the screenshot above, would have a value of "[path]NanonullOrg.xml".

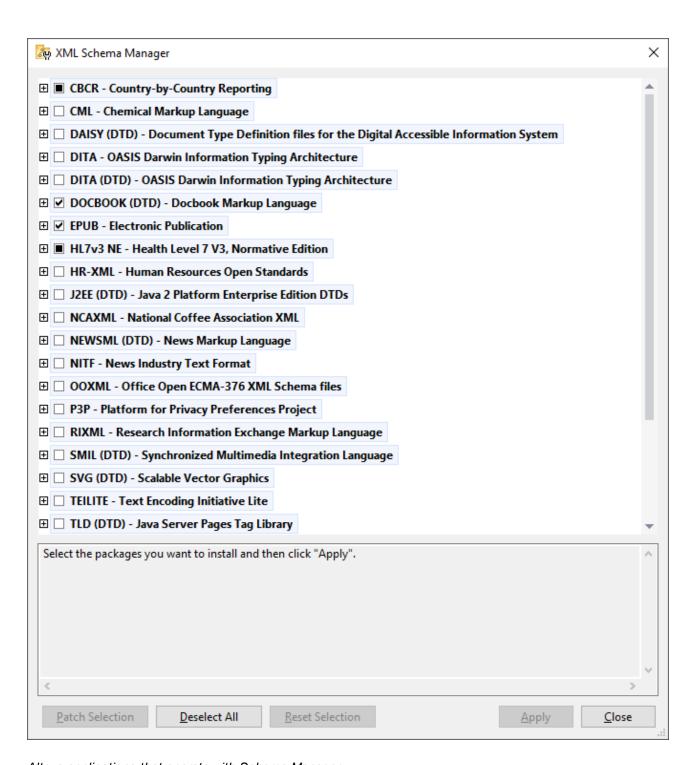

Note: The following points should be noted.

- For DB-based schemas, it is the XML file generated from the DB (via File | Save Generated Files) that should be passed as the value of the \$DB parameter.
- Any value passed for the main schema parameter will be ignored. The XSLT stylesheet will use as its starting point the document node of the XML document that is being transformed.

6.1.6 Schema Manager

XML Schema Manager is an Altova tool that provides a centralized way to install and manage XML schemas (DTDs for XML and XML Schemas) for use across all Altova's XML-Schema-aware applications, including StyleVision.

- On Windows, Schema Manager has a graphical user interface (*screenshot below*) and is also available at the command line. (Altova's desktop applications are available on Windows only; *see list below*.)
- On Linux and macOS, Schema Manager is available at the command line only. (Altova's server applications are available on Windows, Linux, and macOS; see list below.)

Altova applications that operate with Schema Manager

Desktop applications (Windows only)	Server applications (Windows, Linux, macOS)
XMLSpy (all editions)	RaptorXML Server, RaptorXML+XBRL Server

MapForce (all editions)	StyleVision Server
StyleVision (all editions)	
Authentic Desktop Enterprise Edition	

Installation and de-installation of Schema Manager

Schema Manager is installed automatically when you first install a new version of Altova Mission Kit or of any of Altova's XML-schema-aware applications (see table above).

Likewise, it is removed automatically when you uninstall the last Altova XML-schema-aware application from your computer.

Schema Manager features

Schema Manager provides the following features:

- Shows XML schemas installed on your computer and checks whether new versions are available for download.
- Downloads newer versions of XML schemas independently of the Altova product release cycle. (Altova stores schemas online, and you can download them via Schema Manager.)
- Install or uninstall any of the multiple versions of a given schema (or all versions if necessary).
- An XML schema may have dependencies on other schemas. When you install or uninstall a particular schema, Schema Manager informs you about dependent schemas and will automatically install or remove them as well.
- Schema Manager uses the XML catalog mechanism to map schema references to local files. In the
 case of large XML schemas, processing will therefore be faster than if the schemas were at a remote
 location
- All major schemas are available via Schema Manager and are regularly updated for the latest versions.
 This provides you with a convenient single resource for managing all your schemas and making them readily available to all of Altova's XML-schema-aware applications.
- Changes made in Schema Manager take effect for all Altova products installed on that machine.
- In an Altova product, if you attempt to validate on a schema that is not installed but which is available via Schema Manager, then installation is triggered automatically. However, if the schema package contains namespace mappings, then there will be no automatic installation; in this case, you must start Schema Manager, select the package/s you want to install, and run the installation. If, after installation, your open Altova application does not restart automatically, then you must restart it manually.

How it works

Altova stores all XML schemas used in Altova products online. This repository is updated when new versions of the schemas are released. Schema Manager displays information about the latest available schemas when invoked in both its GUI form as well as on the CLI. You can then install, upgrade or uninstall schemas via Schema Manager.

Schema Manager also installs schemas in one other way. At the Altova website (https://www.altova.com/schema-manager) you can select a schema and its dependent schemas that you want to install. The website will prepare a file of type altova_xmlschemas for download that contains information about your schema selection. When you double-click this file or pass it to Schema Manager via the CLI as an argument of the install command, Schema Manager will install the schemas you selected.

Local cache: tracking your schemas

All information about installed schemas is tracked in a centralized cache directory on your computer, located here:

Windows	C:\ProgramData\Altova\pkgs\.cache
Linux	/var/opt/Altova/pkgs\.cache
macOS	/var/Altova/pkgs

This cache directory is updated regularly with the latest status of schemas at Altova's online storage. These updates are carried out at the following times:

- Every time you start Schema Manager.
- When you start StyleVision for the first time on a given calendar day.
- If StyleVision is open for more than 24 hours, the cache is updated every 24 hours.
- You can also update the cache by running the update 325 command at the command line interface.

The cache therefore enables Schema Manager to continuously track your installed schemas against the schemas available online at the Altova website.

Do not modify the cache manually!

The local cache directory is maintained automatically based on the schemas you install and uninstall. It should not be altered or deleted manually. If you ever need to reset Schema Manager to its original "pristine" state, then, on the command line interface (CLI): (i) run the reset command, and (ii) run the initialize command. (Alternatively, run the reset command with the --i option.)

6.1.6.1 Run Schema Manager

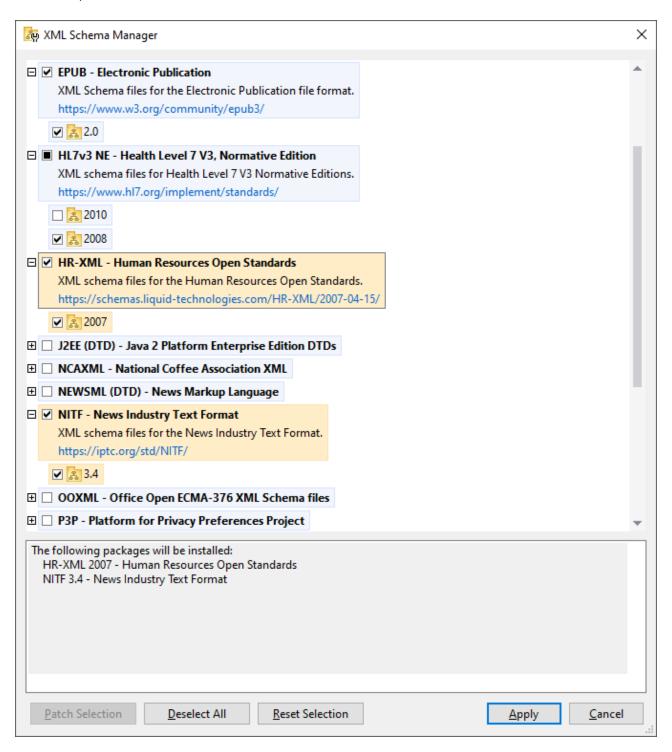

Graphical User Interface

You can access the GUI of Schema Manager in any of the following ways:

- During the installation of StyleVision: Towards the end of the installation procedure, select the check box Invoke Altova XML-Schema Manager to access the Schema Manager GUI straight away. This will enable you to install schemas during the installation process of your Altova application.
- After the installation of StyleVision: After your application has been installed, you can access the Schema Manager GUI at any time, via the menu command **Tools | XML Schema Manager**.
- Via the .altova_xmlschemas file downloaded from the Altova website: Double-click the downloaded file to run the Schema Manager GUI, which will be set up to install the schemas you selected (at the website) for installation.

After the Schema Manager GUI (*screenshot below*) has been opened, already installed schemas will be shown selected. If you want to install an additional schema, select it. If you want to uninstall an already installed schema, deselect it. After you have made your selections and/or deselections, you are ready to apply your changes. The schemas that will be installed or uninstalled will be highlighted and a message about the

upcoming changes will be posted to the Messages pane at the bottom of the Schema Manager window (see screenshot).

When you click **Apply**, the progress of the installation is displayed. If there is an error (for example, a connection error), then an error message is displayed. In this case, click the **Advanced** button that appears in the dialog, check the schema selection and retry with **Apply**.

Command line interface

You can run Schema Manager from a command line interface by sending commands to its executable file, xmlschemamanager.exe.

The xmlschemamanager.exe file is located in the following folder:

- On Windows: C:\ProgramData\Altova\SharedBetweenVersions
- On Linux or macOS (server applications only): %INSTALLDIR%/bin, where %INSTALLDIR% is the program's installation directory.

You can then use any of the commands listed in the <u>CLI command reference section</u> ³²⁰.

To display help for the commands, run the following:

- On Windows: xmlschemamanager.exe --help
- On Linux or macOS (server applications only): sudo ./xmlschemamanager --help

6.1.6.2 Status Categories

Schema Manager categorizes the schemas under its management as follows:

- Installed schemas. These are shown in the GUI with their check boxes selected (in the screenshot below the checked and blue versions of the EPUB and HL7v3 NE schemas are installed schemas). If all the versions of a schema are selected, then the selection mark is a tick. If at least one version is unselected, then the selection mark is a solid colored square. You can deselect an installed schema to uninstall it; (in the screenshot below, the DocBook DTD is installed and has been deselected, thereby preparing it for de-installation).
- Uninstalled available schemas. These are shown in the GUI with their check boxes unselected. You can select the schemas you want to install.

• Upgradeable schemas are those which have been revised by their issuers since they were installed. They are indicated in the GUI by a icon. You can **patch** an installed schema with an available revision.

Points to note

- In the screenshot above, both CBCR schemas are checked. The one with the blue background is already installed. The one with the yellow background is uninstalled and has been selected for installation. Note that the HL7v3 NE 2010 schema is not installed and has not been selected for installation.
- A yellow background means that the schema will be modified in some way when the Apply button is clicked. If a schema is unchecked and has a yellow background, it means that it will be uninstalled when the Apply button is clicked. In the screenshot above the DocBook DTD has such a status.
- When running Schema Manager from the command line, the <u>list</u> 322 command is used with different options to list different categories of schemas:

xmlschemamanager.exe list	Lists all installed and available schemas; upgradeables are also indicated
xmlschemamanager.exe list	Lists installed schemas only; upgradeables are also indicated
xmlschemamanager.exe list	Lists upgradeable schemas

Note: On Linux and macOS, use sudo ./xmlschemamanager list

6.1.6.3 Patch or Install a Schema

Patch an installed schema

Occasionally, XML schemas may receive patches (upgrades or revisions) from their issuers. When Schema Manager detects that patches are available, these are indicated in the schema listings of Schema Manager and you can install the patches quickly.

In the GUI

Patches are indicated by the icon. (Also see the previous topic about status categories are available, the **Patch Selection** button will be enabled. Click it to select and prepare all patches for installation. In the GUI, the icon of each schema that will be patched changes from to it, and the Messages pane at the bottom of the dialog lists the patches that will be applied. When you are ready to install the selected patches, click **Apply**. All patches will be applied together. Note that if you deselect a schema marked for patching, you will actually be uninstalling that schema.

On the CLI

To apply a patch at the command line interface:

- 1. Run the <u>list -u</u> command. This lists any schemas for which upgrades are available.
- 2. Run the upgrade 325 command to install all the patches.

Install an available schema

You can install schemas using either the Schema Manager GUI or by sending Schema Manager the install instructions via the command line.

Note: If the current schema references other schemas, the referenced schemas are also installed.

In the GUI

To install schemas using the Schema Manager GUI, select the schemas you want to install and click Apply.

You can also select the schemas you want to install at the <u>Altova website</u> and generate a downloadable <u>.altova_xmlschemas</u> file. When you double-click this file, it will open Schema Manager with the schemas you wanted pre-selected. All you will now have to do is click **Apply**.

On the CLI

To install schemas via the command line, run the install command:

```
xmlschemamanager.exe install [options] Schema+
```

where schema is the schema (or schemas) you want to install or a .altova_xmlschemas file. A schema is referenced by an identifier of format <name>-<version>. (The identifiers of schemas are displayed when you run the list command.) You can enter as many schemas as you like. For details, see the description of the install command.

Note: On Linux or macOS, use the sudo ./xmlschemamanager command.

Installing a required schema

When you run an XML-schema-related command in StyleVision and StyleVision discovers that a schema it needs for executing the command is not present or is incomplete, Schema Manager will display information about the missing schema/s. You can then directly install any missing schema via Schema Manager.

In the Schema Manager GUI, you can view all previously installed schemas at any time by running Schema Manager from **Tools | Schema Manager**.

6.1.6.4 Uninstall a Schema, Reset

Uninstall a schema

You can uninstall schemas using either the Schema Manager GUI or by sending Schema Manager the uninstall instructions via the command line.

Note: If the schema you want to uninstall references other schemas, then the referenced schemas are also uninstalled.

In the GUI

To uninstall schemas in the Schema Manager GUI, clear their check boxes and click **Apply**. The selected schemas and their referenced schemas will be uninstalled.

To uninstall all schemas, click Deselect All and click Apply.

On the CLI

To uninstall schemas via the command line, run the uninstall 324 command:

xmlschemamanager.exe uninstall [options] Schema+

where each schema argument is a schema you want to uninstall or a .altova_xmlschemas file. A schema is specified by an identifier that has a format of <name>-<version>. (The identifiers of schemas are displayed when you run the list command.) You can enter as many schemas as you like. For details, see the description of the uninstall command.

Note: On Linux or macOS, use the sudo ./xmlschemamanager command.

Reset Schema Manager

You can reset Schema Manager. This removes all installed schemas and the cache directory.

- In the GUI, click **Reset Selection**.
- On the CLI, run the reset 323 command.

After running this command, make sure to run the <u>initialize</u> 321 command in order to recreate the cache directory. Alternatively, run the <u>reset</u> 323 command with the -i option.

Note that $\underline{reset} - \underline{i}$ are stores the original installation of the product, so it is recommended to run the \underline{update} command after performing a reset. Alternatively, run the \underline{reset} command with the $-\underline{i}$ and $-\underline{u}$ options.

6.1.6.5 Command Line Interface (CLI)

To call Schema Manager at the command line, you need to know the path of the executable. By default, the Schema Manager executable is installed here:

```
C:\ProgramData\Altova\SharedBetweenVersions\XMLSchemaManager.exe
```

Note: On Linux and macOS systems, once you have changed the directory to that containing the executable, you can call the executable with sudo ./sudo indicates that the executable is in the current directory. The prefix sudo indicates that the command must be run with root privileges.

Command line syntax

The general syntax for using the command line is as follows:

```
<exec> -h | --help | --version | <command> [options] [arguments]
```

In the listing above, the vertical bar I separates a set of mutually exclusive items. The square brackets II indicate optional items. Essentially, you can type the executable path followed by either --h, --help, or --version options, or by a command. Each command may have options and arguments. The list of commands is described in the following sections.

6.1.6.5.1 help

This command provides contextual help about commands pertaining to Schema Manager executable.

Syntax 1 4 1

```
<exec> help [command]
```

Where [command] is an optional argument which specifies any valid command name.

Note the following:

- You can invoke help for a command by typing the command followed by -h or --help, for example: <exec> list -h
- If you type -h or --help directly after the executable and before a command, you will get general help (not help for the command), for example: <exec> -h list

Example

The following command displays help about the list command:

```
xmlschemamanager help list
```

6.1.6.5.2 info

This command displays detailed information for each of the schemas supplied as a schema argument. This information for each submitted schema includes the title, version, description, publisher, and any referenced schemas, as well as whether the schema has been installed or not.

Syntax

```
<exec> info [options] Schema+
```

- The schema argument is the name of a schema or a part of a schema's name. (To display a schema's package ID and detailed information about its installation status, you should use the 1ist122122<a href="command
- Use <exec> info -h to display help for the command.

Example

The following command displays information about the latest DocBook-DTD and NITF schemas:

```
xmlschemamanager info doc nitf
```

6.1.6.5.3 initialize

This command initializes the Schema Manager environment. It creates a cache directory where information about all schemas is stored. Initialization is performed automatically the first time a schema-cognizant Altova application is installed. You would not need to run this command under normal circumstances, but you would typically need to run it after executing the reset command.

Syntax 1 4 1

```
<exec> initialize | init [options]
```

Options

The initialize command takes the following options:

silent,s	Display only error messages. The default is false.
verbose,v	Display detailed information during execution. The default is false.
help,h	Display help for the command.

Example

The following command initializes Schema Manager:

```
xmlschemamanager initialize
```

6.1.6.5.4 install

This command installs one or more schemas.

Syntax

```
<exec> install [options] Schema+
```

To install multiple schemas, add the schema argument multiple times.

The schema argument is one of the following:

- A schema identifier (having a format of <name>-<version>, for example: cbcr-2.0). To find out the schema identifiers of the schemas you want, run the list command. You can also use an abbreviated identifier if it is unique, for example docbook. If you use an abbreviated identifier, then the latest version of that schema will be installed.
- The path to a .altova_xmlschemas file downloaded from the Altova website. For information about these files, see Introduction to SchemaManager: How It Works

Options

The install command takes the following options:

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Example

The following command installs the CBCR 2.0 (Country-By-Country Reporting) schema and the latest DocBook DTD:

```
xmlschemamanager install cbcr-2.0 docbook
```

6.1.6.5.5 list

This command lists schemas under the management of Schema Manager. The list displays one of the following

- All available schemas
- Schemas containing in their name the string submitted as a schema argument
- Only installed schemas
- Only schemas that can be upgraded

Syntax

```
<exec> list | ls [options] Schema?
```

If no schema argument is submitted, then all available schemas are listed. Otherwise, schemas are listed as specified by the submitted options (see example below). Note that you can submit the schema argument multiple times.

<u>Options</u>

The list command takes the following options:

```
--installed, --i List only installed schemas. The default is false.

--upgradeable, --u List only schemas where upgrades (patches) are available. The default is false.

--help, --h Display help for the command.
```

Examples

- To list all available schemas, run: xmlschemamanager list
- To list installed schemas only, run: xmlschemamanager list -i
- To list schemas that contain either "doc" or "nitf" in their name, run: xmlschemamanager list doc nitf

6.1.6.5.6 reset

This command removes all installed schemas and the cache directory. You will be completely resetting your schema environment. After running this command, be sure to run the initialize command to recreate the cache directory. Alternatively, run the reset command with the -i option. Since reset -i restores the original installation of the product, we recommend that you run the update command after performing a reset and initialization. Alternatively, run the reset command with both the -i and -u options.

Syntax

```
<exec> reset [options]
```

Options

The reset command takes the following options:

```
--init, --i Initialize Schema Manager after reset. The default is false.

--update, --u Updates the list of available schemas in the cache. The default is false.
```

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Examples

- To reset Schema Manager, run: xmlschemamanager reset
- To reset Schema Manager and initialize it, run: xmlschemamanager reset -i
- To reset Schema Manager, initialize it, and update its schema list, run: xmlschemamanager reset -i
 -u

6.1.6.5.7 uninstall

This command uninstalls one or more schemas. By default, any schemas referenced by the current one are uninstalled as well. To uninstall just the current schema and keep the referenced schemas, set the option --k.

Syntax

```
<exec> uninstall [options] Schema+
```

To uninstall multiple schemas, add the schema argument multiple times.

The schema argument is one of the following:

- A schema identifier (having a format of <name>-<version>, for example: cbcr-2.0). To find out the schema identifiers of the schemas that are installed, run the list-i command. You can also use an abbreviated schema name if it is unique, for example docbook. If you use an abbreviated name, then all schemas that contain the abbreviation in its name will be uninstalled.
- The path to a .altova_xmlschemas file downloaded from the Altova website. For information about these files, see Introduction to SchemaManager: How It Works311.

Options

The uninstall command takes the following options:

```
--keep-references, --k

Set this option to keep referenced schemas. The default is false.

--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Example

The following command uninstalls the CBCR 2.0 and EPUB 2.0 schemas and their dependencies:

```
xmlschemamanager uninstall cbcr-2.0 epub-2.0
```

SPS Structure Schema Sources 325

The following command uninstalls the eba-2.10 schema but not the schemas it references:

```
xmlschemamanager uninstall --k cbcr-2.0
```

6.1.6.5.8 update

This command queries the list of schemas available from the online storage and updates the local cache directory. You should not need to run this command unless you have performed a reset and initialize 321.

Syntax

```
<exec> update [options]
```

Options

The update command takes the following options:

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Example

The following command updates the local cache with the list of latest schemas:

```
xmlschemamanager update
```

6.1.6.5.9 upgrade

This command upgrades all installed schemas that can be upgraded to the latest available *patched* version. You can identify upgradeable schemas by running the list - u command.

Note: The upgrade command removes a deprecated schema if no newer version is available.

Syntax

```
<exec> upgrade [options]
```

Options

The upgrade command takes the following options:

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.
```

326 SPS Structure Schema Sources

--help, --h

Display help for the command.

6.2 Merging XML Data from Multiple Sources

XML data from multiple source XML files can be merged when XSLT 2.0 or 3.0 is used as the XSLT version of the SPS.

Typically, the merging of data will be based on a common piece of data, such as an ID. For example, an employee in a company, who is identified by a personal ID number, can have his or her personal data stored in multiple XML files held by the personnel department: (i) personal details, (ii) payroll, (iii) work and leave, (iv) courses attended, etc. Data from these different files can be merged in a single output document using the personal ID number as a key.

Note: The Enterprise Edition enables you to include multiple schema sources, so XML nodes from other schemas can be selected using the parameter name for the corresponding schema (as is the case in the example below). In the Professional and Basic Editions, the doc() function of XPath 2.0 can be used to locate the required XML file and the XML node within that file. The doc() function of XPath 2.0 provides access to the document root of external XML documents, and thus enables node content from external XML documents to be inserted in the output. An Auto-Calculation that uses the doc() function can, therefore, also be used to merge XML data (see example below).

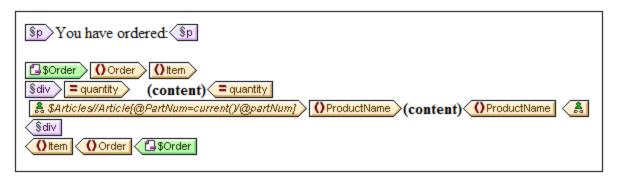

Example

The (My) Documents folder 33, C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2025\StyleVisionExamples, contains an example SPS file
(MergeData_2_Files.sps) that shows how data from different source XML files can be merged. The SPS selects data from an order (MergeOrder.xml, listed below) that a fictitious customer places.

The value of the <code>/Order/Item/@partNum</code> attribute in this file (see above) is used to select the ordered products from the catalog of articles stored in another file, <code>MergeArticles.xml</code> (see listing below).

```
<ProductName>Uncut diamond
     <Price>79.90</Price>
  </Article>
  <Article PartNum="238-KK">
     <ProductName>Amber ring</ProductName>
     <Price>89.90</Price>
  </Article>
  <Article PartNum="229-OB">
     <ProductName>Pearl necklace
     <Price>4879.00</Price>
  </Article>
  <Article PartNum="128-UL">
     <ProductName>Jade earring</productName>
     <Price>179.90</Price>
</Article>
</Articles>
```

The way the merging of the data is done is to set up a <u>User-defined template</u> within the <code>/Order/Item</code> template (see screenshot below) that selects the corresponding <code>Article</code> element in the <code>MergeArticles.xml</code> file by using the part number of the ordered item to identify the article. The XPath expression (which is in the <code>/Order/Item context</code>) is: <code>SArticles//Article[@PartNum=current()/@partNum]</code>

This template will produce output something like that shown in the screenshot below.

You have ordered:

3 Amber ring
1 Diamond heart
1 Pearl necklace
2 Lapis necklace

Notice that while the quantity ordered of each item is taken from the file MergeOrder.xml, the name of the ordered article is taken from the file MergeArticles.xml. Also notice how the ProductName node is selected within the context of the /Articles/Article template.

The same result as that obtained above could also be achieved using an Auto-Calculation (see screenshot below). Drag the quantity attribute from the Schema Tree window and create it as contents. Then add an Auto-Calculation as shown in the screenshot and give the Auto-Calculation an XPath expression as described below.

```
$\sumsetem \text{You have ordered: \sumsetem p} \\ \text{$\sumsetem \text{Order} \text{Ottem}} \\ \text{$\sumsetem \text{Sorder}} \\ \text{$\text{Ottem} \text{Order}} \\ \text{$\text{Ottem} \text{Order}} \\ \text{$\text{Calc}} \text{$\text{Sdiv}} \\ \text{$\text{Quantity}} \\ \text{$\text{Ottem} \text{$\text{Order}}} \\ \text{$\text{Calc}} \\ \text{$\text{Sdiv}} \\ \text{$\text{Calc}} \\ \text{$\text{Calc}} \\ \text{$\text{Sdiv}} \\ \text{$\text{Calc}} \\
```

The XPath expression of the Auto-Calculation could target the required node using either the parameter of another schema source or the doc() function:

```
$Articles//Article[@PartNum=current()/@partNum]/ProductName

or

doc('MergeArticles.xml')//Article[@PartNum=current()/@partNum]/ProductName
```

Notice that, while the first XPath expression above uses a parameter to refer to another XML Schema (a feature available only in the Enterprise Edition), the second expression uses the doc() function of XPath 2.0 (a feature available in the Professional and Basic editions as well).

6.3 Modular SPSs

The global templates of an SPS, as well as Design Fragments, JavaScript functions, and page layout items can be used in the design of another SPS. This enables:

1. The re-use of global templates and other components across multiple SPSs, the main advantages of which are single-source editing and consistency of output.

2. SPSs to be modularized, and thus to be more flexibly structured.

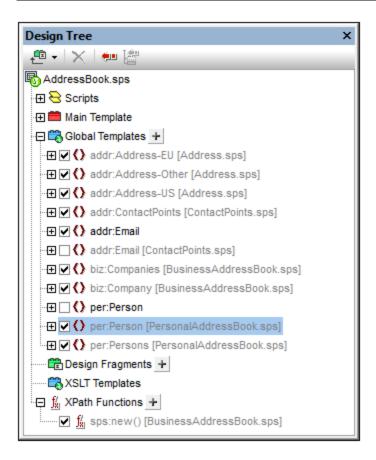

In any given SPS, one or more SPSs can be added as modules. Some types of components (or objects) in these modules are then available to the importing (or referring) SPS.

Available module objects

The section, <u>Available Module Objects</u> (33), not only describes the extent to which, and conditions under which, the various components of an SPS are available to an importing SPS. It also lists those components that are not available to the importing SPS. You should note that if an added module itself contains modules, then these are added recursively to the referring SPS. In this way, modularization can be extended to several levels and across a broad design structure.

Creating a modular SPS

To build a modularized SPS, first add the required SPS to the main SPS as a module. All the JavaScript functions, global templates, Design Fragments, and XPath functions in the added module are available to the referring SPS. Each of the available objects is listed in the Design Tree, under its respective heading (screenshot below), and can be activated or deactivated, respectively, by checking or unchecking its check box.

These objects can then be re-used in the referring SPS according to their respective inclusion mechanisms. Global templates typically would need merely to be activated in order for them to be applied in the referring SPS. Design fragments have to be dragged from the Design Tree to the required location. JavaScript functions are assigned via the Property window as event handlers for the selected design component. And available (activated) XPath functions can be used in Xpath expressions.

How to create and work with a modular SPS is described in the section, Creating a Modular SPS (334).

Terminology

When an SPS is used within another module it is said to be added to the latter, and we call the process adding. The two SPSs are referred to, respectively, as the added SPS module and the referring SPS module. When an SPS module is added, its objects are added to the referring SPS module. These objects are called module objects, and are of the following types: global templates; Design Fragments; JavaScript functions; and page layout items.

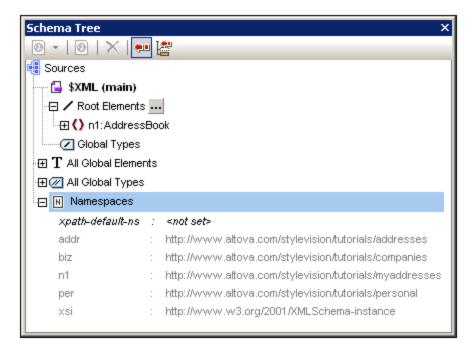

6.3.1 Available Module Objects

This section lists the objects in <u>added SPS modules</u> that are available to the <u>referring SPS module</u>. The listing explains in what way each object is available to the referring SPS module and how it can be used there. For a step-by-step approach to creating modular SPSs, see the next section, <u>Creating a Modular SPS</u>. The section ends with a list of objects in the added SPS that are not available to the referring SPS module; this will help you to better understand how modular SPSs work.

- Namespace declarations
 332
- Global templates
- Design fragments 333
- Added modules 333
- Scripts 334
- CSS styles 334
- Page layouts 334
- Unavailable module objects 334

Namespace declarations

Each SPS stores a list of namespace URIs and their prefixes. When an SPS is added as a module, the namespaces in it are compared to the namespaces in the schema source/s of the referring SPS. If a namespace URI in the added SPS matches a namespace URI in the schema source/s of the referring SPS, then the prefix used in the schema source of the referring SPS is adopted as the prefix for that namespace in the added SPS. If a namespace URI in the added SPS cannot be matched with any namespace URI in the schema source/s of the referring SPS, then an error message indicating this is displayed.

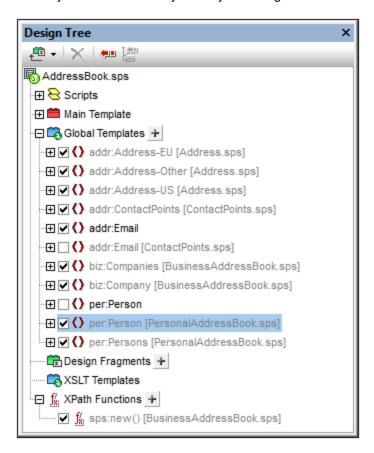

The screenshot above shows the various namespaces in an SPS, together with their prefixes, in the Schema Tree sidebar. These namespaces come from the source schema/s and cannot be edited.

Global templates

The global templates of the added SPS module are available to the referring SPS module and are displayed in the Design Tree sidebar (screenshot below). They are, by default, activated or deactivated (checked or unchecked), according to the respective activation status in the added module. If you wish to create a global template to override a global template from an added module, create the new global template by clicking the icon next to the Global Templates entry. In the Add New Global Template that pops up, select an element or attribute for which you wish to create the global template. Alternatively, enter an XPath expression that selects the required node in the schema. On clicking **OK**, you will be prompted as to whether the new global

template should be activated in preference to the global template in the added module. The response you select activates either the newly created global template or the global template in the added module. You can switch your selection at any time by checking the other of the two global templates.

Note that the main template of added modules are not available. This means that if you plan to re-use a template via the modular approach, you must create it as a global template. If no global template is defined for a particular element and processing is invoked for that element, then the default processing for that element (XSLTs built-in templates) will be used.

Design fragments

<u>Design fragments</u> in the added SPS module are available to the referring SPS and are displayed in the <u>Design Tree sidebar</u> (*screenshot above*). When inserting a design fragment in the design, care should be taken to place the design fragment within the correct context node in the design.

Added modules

Each added SPS module also makes available to the referring SPS its own added modules, and their added modules, and so on. In this way, adding one module recursively makes available all modules that have been added to it, down multiple levels. Needless to say, these modules must together construct a content model that is valid according to the source schema/s of the referring SPS module. Modules are displayed and can be managed in the Design Overview sidebar and their added modules, and so on. In this way, adding one module recursively makes available all modules that have been added to it, down multiple levels. Needless to say, these modules must together construct a content model that is valid according to the source schema/s of the referring SPS module. Modules are displayed and can be managed in the Design Overview sidebar and their added modules, and their added modules, and their added modules are displayed and can be managed in the Design Overview sidebar and their added modules are displayed and can be managed in the Design Overview sidebar and their added modules are displayed and can be managed in the Design Overview sidebar and their added modules are displayed and can be managed in the Design Overview sidebar and their added modules are displayed and can be managed in the Design Overview sidebar and their added modules are displayed and can be sidebar and their added modules are displayed and can be sidebar and their added modules are displayed and can be sidebar and their added modules are displayed and can be sidebar and their added modules

Scripts

The scripts in all the added SPS modules are available for use in the referring SPS and are displayed in the Design Tree sidebar 599. In effect, the scripts of all the added modules are collected in a library that is now—in the referring SPS—available for selection in the Properties dialog.

CSS styles

The global styles present in added SPS modules are carried over to the referring SPS as global styles and the style rules are displayed in the <u>Style Repository sidebar</u> 460. The CSS files are also listed in the <u>Design</u> Overview sidebar 450. Similarly, external CSS files that were available to the added SPS module, are available to the referring SPS module.

Page layouts

The page layouts of an added module are available to the referring SPS and are displayed in the <u>Design Tree</u> sidebar ⁵¹.

Module objects that are not available to the referring SPS

The following objects of the added module are not available to the referring SPS:

- Parameter definitions: are ignored.
- Schema sources: The schema source on which the added SPS is based is ignored. Bear in mind that the content model of the document element of the added SPS must be contained within the content model of the referring SPS; otherwise it would not be possible to correctly use the added SPS as a module. If you wish, you could always add a secondary schema or a user-defined schema to the referring SPS. The additional schema could accommodate the content model of the added global template/s.
- Working XML File and Template XML File: References to these files are ignored. The referring SPS uses its own Working XML and Template XML Files.
- **XPath default namespaces:** If they have been set on a module that is imported then they are not carried through to the importing SPS.

6.3.2 Creating a Modular SPS

Creating a modular SPS consists of four broad parts:

- 1. Design and save the <u>SPS module to be added</u> 334.
- 2. Add the module 335 to the SPS in which it is to be used (that is, to the referring SPS module).
- 3. Activate or deactivate the added object/s 337 as required.
- 4. Apply the required object wherever required.

The SPS module to be added

There are two points to bear in mind when creating an SPS that will be added to another:

1. The templates that can be used in the <u>referring SPS module</u> (331) can only be <u>global templates</u> (345). This means that the templates you wish to re-use must be created as global templates in the <u>SPS module</u> that is to be added (331).

2. The document structure defined in the SPS module to be added must be valid within the content model defined by the <u>source schema/s of the referring SPS</u> ³³⁴. If an added template is not contained in the content model defined by the main schema of the SPS, its content model, however, can still be defined in a secondary schema or a user-defined schema.

When creating the SPS module to be added, the schema on which you base the SPS could be one of the following:

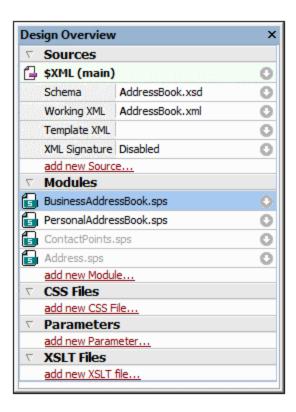

- The main source schema of the referring SPS. In this case, when the SPS is added, the added global templates will be part of the content model of the referring SPS's main schema. The output of these global templates in Authentic View is, therefore, editable.
- A schema which defines a content model that is part of the content model defined by the main schema
 of the referring SPS. In this case, when the global templates are added, they will fit into the content
 model of the main schema of the referring SPS. The output of these global templates is editable in
 Authentic View.
- A schema which defines a content model that is **not** part of the content model defined by the main schema of the referring SPS. When this SPS module is added, its global templates will not be part of the content model of the main schema of the referring SPS. They can, however, be used to produce output if a secondary schema or a user-defined schema is used that defines a content model that contains the content model of the global template/s. In Authentic View, however, the output of these global templates cannot be edited.

When defining the content models in your schemas, you should pay close attention to the <u>namespaces</u> used since these determine the expanded names of nodes.

You could use a <u>Working XML File</u> to test the output of the SPS module to be added. The reference to this Working XML File will be <u>ignored by the referring SPS</u> 334.

Adding the SPS module

To add a module to an SPS, in the <u>Design Overview</u> (screenshot below), click the Add New Module command, browse for the required SPS file in the dialog that appears, select it, and click **Open**.

The module is added to the SPS and is listed under the Modules heading in the Design Overview. In the screenshot above, the <code>BusinessAddressBook.sps</code> and <code>PersonalAddressBook.sps</code> modules have been added to the <code>AddressBook.sps</code> module (the active SPS). All the added module objects are listed in the Design Tree sidebar; added CSS files, though, are also also listed in the Design Overview. If the added modules themselves refer to modules, these latter, indirectly imported modules are listed under the Modules heading, but in gray. Information about which modules import an indirectly imported module is available in a pop-up that appears when you mouseover the indirectly imported module.

To open one of the added modules or indirectly imported modules quickly in StyleVision, right-click that module, and select **Open Defining Module** from the context menu that pops up.

Order of added modules

The order in which modules are added and listed is significant for the prioritizing of CSS styles. In keeping with the CSS cascade order, CSS style rules in a relatively later module (lower down the list) have priority over style rules defined in a relatively earlier module (higher up the list). CSS styles in the referring SPS module have priority over those in any added module. To change the relative position of an added module, right-click it in the Design Overview and click, as required, the **Move Up** or **Move Down** command in the context menu.

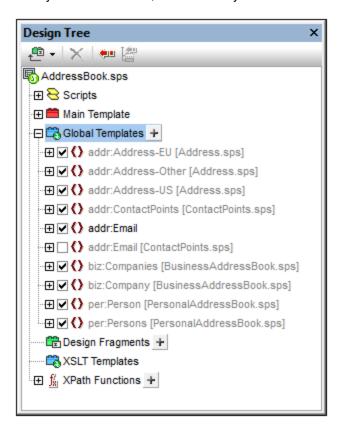

The module order is not significant for resolving conflicts among scripts, global templates, design fragments, and page layout items.

File modification alerts

If any added file (whether an SPS module, schema, or Working XML File) is modified after the referring SPS module has been opened, then a file modification pop-up will alert you to the change and ask whether the referring SPS module should be refreshed with the changes.

Activating/deactivating the added object

All module objects in all added modules (whether added directly or indirectly) are added to the referring SPS and are listed under the corresponding headings in the Design Tree: Scripts; Global Templates; Design Fragments; XSLT Templates; and XPath Functions. Next to each of these objects is a check box (see screenshot below), which you can check or uncheck to, respectively, activate or deactivate that object. When an object is deactivated, it is effectively removed from the SPS.

In the screenshot above, all the global templates used in the <code>AddressBook.sps</code> module are listed under the Global Templates heading. Those that have been added via other modules (whether directly or indirectly) are displayed in gray. Those that have been created directly in <code>AddressBook.sps</code> are displayed in black. The screenshot shows that only one global template, <code>addr:Email</code>, has been created in <code>AddressBook.sps</code> itself. All the other global templates have been added via other modules, and the file in which each of these is defined is listed next to its name.

Notice that there are two global templates for addr:Email, one created in the referring SPS (AddressBook.sps) itself, and the other created in the added module ContactPoints.sps. If more than one global template has the same (namespace-) expanded name, then only one of these will be active at a time. You can select which one by checking its check box. (Alternatively, you activate the global template from its context menu in Design View.) This mechanism is useful if you: (i) wish to override an added global template with one that you create in the referring SPS module, or (ii) wish to resolve a situation where a global template for one element is defined in more than one added module.

A global template that has been defined in the current SPS can be deleted by selecting it and clicking the **Remove** button. However, global templates that have been defined in an added module cannot be removed

from the referring SPS. They must be removed by opening the added SPS and removing the global template there

Individual scripts, Design Fragments, and page layout items can be activated and deactivated in the same way.

Applying or using modular objects

In the <u>referring SPS module</u> (331), you design your templates as usual. Each different type of added object is used or applied differently. You should, of course, ensure that each module object you wish to apply has been activated (337).

Global templates

When you wish to use a <u>global template</u> from any of the added SPS modules, you must make sure that this global template is indeed applied. This can be done in one of two ways, according to which one is appropriate for your design:

- In the main template, specify that the element template either uses the global template for that element or copies that global template locally. These two commands are available in the context menu that appears when you right-click the element tag in the design.
- In the main template, the contents or rest-of-contents placeholders cause templates to be applied, leading to the relevant global templates being processed.

<u>Design Fragmen</u>ts

To use a Design Fragment, drag it from the Design Tree to the desired location in the main template or a global template. Make sure that the location where the Design Fragment is dropped is the correct context node for that Design Fragment. For details, see <u>Design Fragments</u> 350.

Scripts

All JavaScript functions (whether in an added module or created in the referring SPS) are available as event handlers, and can be set for a particular event via the Properties sidebar ⁶⁹⁵.

6.3.3 Example: An Address Book

The (My) Documents folder (33), C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\ModularSPS, contains examples of modular SPSs. The example files in this folder comprise a project in which an address book containing business and personal contacts is modularized. The example not only demonstrates the mechanisms in which modularization is implemented, but also illustrates the main reasons why one would modularize.

- The complete address book is composed of two modules: (i) a business address book, and (ii) a
 personal address book, each of which has a separate SPS defining different designs. The two modules
 together make up the composite address book. Modularization in this case is used to compose: the
 modules are the components of a larger unit.
- Although the content model of each module (business and personal address books) differs slightly from
 the other, both have a common module, which is the ContactPoints module, consisting of the core
 contact details: address, telephone, fax, and email. The ContactPoints module can therefore be shared
 between the two address books (business and personal). Modularization in this case enables a single
 module to be used as a common unit within multiple other units.
- Further, the ContactPoints module can be modularized to provide more flexibility. In the example project, we have created a separate Address module to contain the postal address, which may have

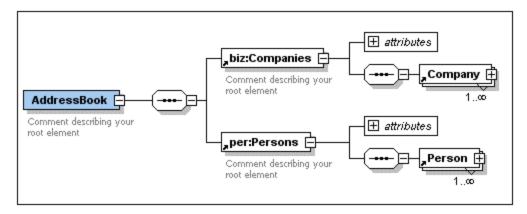

one of three content models, depending on whether the address is in the EU, US, or elsewhere. The output for all three content models is defined in a single SPS. However, they could have been defined in separate SPSs, which would have provided finer granularity. In this case, modularization would provide more flexibility as modules could be re-used more easily.

The description of this project is organized into the following parts:

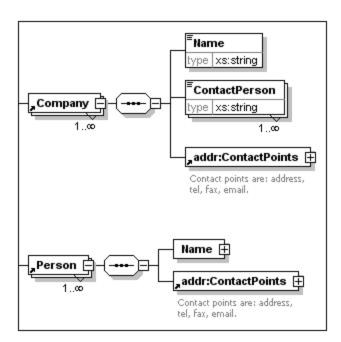

- The schema files (339)
 The XML data sources (340)
- The SPS files 341

The schema files

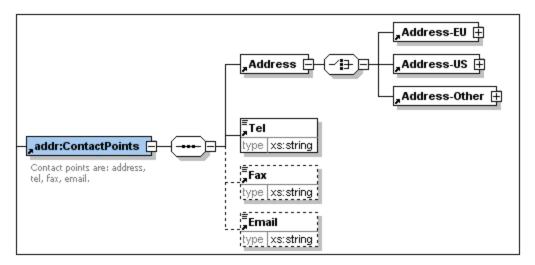

When creating schemas for modular SPSs, the most important thing to bear in mind is to create the elements that you wish to re-use as global elements. The schema for the address book is AddressBook.xsd. This schema has been constructed by importing the schemas for the business address book (BusinessAddressBook.xsd) and personal address book (PersonalAddressBook.xsd). The BusinessAddressBook.xsd schema provides a content model for companies, while the PersonalAddressBook.xsd schema provides a content model for persons (see screenshot below).

Both schemas import the ContactPoints.xsd schema (see screenshot below), which defines a content model for contact details.

Finally, the ContactPoints.xsd schema (screenshot below) includes the Address.xsd schema, which defines the three address-type content models: for EU, US, and other addresses.

Imports are used when the imported schema belongs to a different namespace than the importing schema. Includes are used when the included schema belongs to the same namespace as the including schema.

Note: The screenshots above are of the schema in the Schema View of Altova's XMLSpy.

The XML data sources

The XML data is contained in the file AddressBook.xml. This file is structured so that the AddressBook element contains the companies and persons elements as its children. The content models of these two elements are defined in the schema files, BusinessAddressBook.xsd and PersonalAddressBook.xsd, respectively.

There are two additional XML data files, which correspond to the BusinessAddressBook.xsd and PersonalAddressBook.xsd schemas. These two XML files, BusinessAddressBook.xml and PersonalAddressBook.xml, are used as the Working XML Files of the corresponding SPS files.

The three XML files are the Working XML Files of the following SPS modules:

- AddressBook.xml => AddressBook.sps, ContactPoints.sps, Address.sps
- BusinessAddressBook.xml => BusinessAddressBook.sps
- PersonalAddressBook.xml => PersonalAddressBook.sps

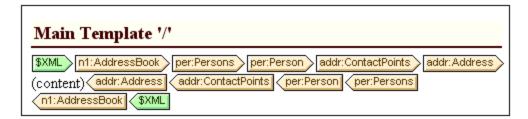

The SPS modules

The description of the SPS modules starts with the most basic module (Address.sps) and progresses in compositionally incremental steps to the complete address book (AddressBook.sps). All the SPS modules use AddressBook.xsd as its schema.

Address.sps

The key points to note are the use of the schema and the Working XML File.

- Address.sps uses AddressBook.xsd as its schema, but the schema could equally well have been Address.xsd, ContactPoints.xsd, BusinessAddressBook.xsd, Or PersonalAddressBook.xsd—since the Address element is present in all these schemas and would be available as a global element. When the SPS module is added to another SPS module, the schema of the imported module is ignored, so which one is used is not important when the SPS is added as a module.
- The Working XML File is AddressBook.xml. Note that the main template in Address.sps specifies that only the Address element should be processed, and that global templates for Address-EU, Address-US, and Address-Other have been defined.

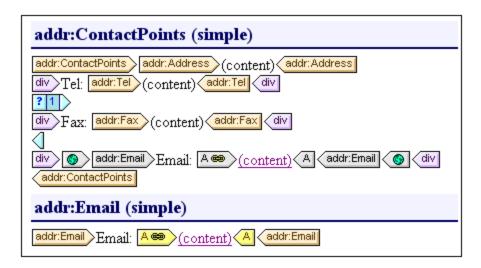

Because only the Address element is processed, the output previews show only the output of Address. When Address.sps is used as a module, the global templates are added and the main template is ignored.

ContactPoints.sps

This SPS imports one module. Note the use of global templates within other global templates and the main template.

- ContactPoints.sps uses AddressBook.xsd as its schema and AddressBook.xml as its Working XML File.
- Address.sps is added as a module, thus making the global templates of the Address-EU, Address-US. and Address-Other elements available.
- Global templates for the ContactPoints and Email elements are defined. Note that the ContactPoints definition uses the global template of Email (screenshot below).

• The main template—required for the previews—uses the global template of the ContactPoints element, thus enabling previews of the ContactPoints output.

BusinessAddressBook.sps and PersonalAddressBook.sps

These SPSs each import one module, which in turn imports another. Note that the main template simply applies global templates.

- Each of these two modules uses AddressBook.xsd as its schema. The Working XML Files are, respectively, BusinessAddressBook.xml and PersonalAddressBook.xml.
- ContactPoints.sps is added as a module. This causes Address.sps to be indirectly imported. All the global templates in these two modules are available to the referring SPS module.
- In BusinessAddressBook.sps, global templates are defined for the Companies and Company elements.

 Note that the Company definition uses the global template of ContactPoints.
- In PersonalAddressBook.sps, global templates are defined for the Person and Persons elements.

 The Person definition uses the global template of ContactPoints.

AddressBook.sps

There are two global templates for the Email element; any one can be activated..

- AddressBook.sps uses AddressBook.xsd as its schema. The Working XML File is AddressBook.xml.
- BusinessAddressBook.sps and PersonalAddressBook.sps are added as modules, and this causes ContactPoints.sps and Address.sps to be indirectly imported.
- A global template is defined for the Email element. This means that there are now two global templates for Email, one in ContactPoints.sps and the other in AddressBook.sps (see screenshot below).

• In the Global Templates list in the Design Tree (*screenshot above*), you can select which of the two global templates should be active. StyleVision allows only one to be active at a time. Whichever is active is used within the ContactPoints global template.

• The main template contains some static content for the output header.

6.4 Templates and Design Fragments

The design document is composed of templates, and it is important to recognize the various types of templates that can be used.

- *Main templates and global templates:* The design document consists of one <u>main template</u> and, optionally, one or more <u>global templates</u> Global templates can be referenced via the main template.
- *Node-templates and variable iterators:* These are the templates that constitute the main template and global templates. A <u>node-template</u> matches a node in a schema source.
- Design fragments: These are templates that are designed separately and re-used in various parts of the design (main template or global templates).

In this section, we describe the role that templates and design fragments play in the structure of the design. We are not concerned here with the <u>presentation properties</u> in the design, only the structure. In this section, we also do not consider additional structural items for paged media, such as cover pages, headers and footers. These are described in the section, <u>Designing Print Output</u> [494].

Note: In Design View, the SPS can have several templates: the main template, global templates, page layout templates, and Design Fragments. You can control which of these template types is displayed in Design View by using <u>Template Display Filters</u> , which are available as <u>toolbar icons</u>. These display filters will help you optimize and switch between different displays of your SPS.

6.4.1 Main Template

The <u>main template</u> determines the structure of the output. This means that the sequence in which the main template is laid out in the design is the sequence in which Authentic View and the output is laid out. In programming jargon, this is procedural processing. Processing starts at the beginning of the template and proceeds in sequence to the end. Along the way, nodes from the XML document are processed. The templates which process these nodes are called <u>local templates</u>. After a local template is processed, the processor moves to the next component in the main template, and so on. Occasionally, a node may reference a <u>global template</u> for its processing. In such cases, after the global template is executed for that node, the processor returns to the position in the main template from which it branched out and continues in sequence from the next component onwards.

The entry point for the main template is the <u>document node</u> of the main schema. The <u>main schema</u> is the schema designated by you as such (right-click the schema in the <u>Design Overview sidebar</u> and select Set As Main Schema Source). StyleVision offers the option of selecting multiple root elements (<u>document elements</u>). This means that within the main template, there can be <u>local templates</u> for each of the active document elements. The one that is executed during processing will be that for the element which is the document element of the XML instance document being processed.

6.4.2 Global Templates

A global template can be defined for any node or type in the schema, or for a node specified in an XPath pattern.

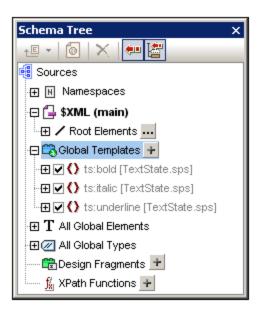

A global template specifies instructions for the selected node or type, and it is invoked by a call from the main template , design fragments , or other global templates. The processing model is similar to that of declarative programming languages, in that a single template is defined and invoked multiple times. In this way a single definition can be re-used multiple times. Global templates are invoked in two situations:

- When a node or type in the <u>main template</u> and has been set to reference its global template (done by right-clicking the component in the design and selecting Make Global Template).
- When a <u>(contents)</u> (131) or <u>(rest-of-contents)</u> (136) is inserted within an element or type in a <u>local template</u> (30), and the rest of the content of that element or type includes a node or type for which a <u>global template</u> (30) exists.

Global templates are useful if a node (or type) occurs within various elements or in various locations, and a single set of instructions is required for all occurrences. For example, assume that a para element must be formatted the same no matter whether it occurs in a chapter, section, appendix, or blockquote element. An effective approach would be to define a global template for para and then ensure, that in the main template the global template for the para element is processed wherever required (for example, by including //chapter/para in the main template and specifying that para reference its global template; or by including //chapter/title and then including (contents) or (rest-of-contents) so that the rest of the content of the chapter element is processed with the available global templates and default templates). Also, a global template can be defined for a complex type (for example, one that defines an address model) or even for a simple type (for example, xs:decimal). In such cases, all occurrences of the type (complex or simple) that invoke the global template for that type will be processed according to the rules in the global template.

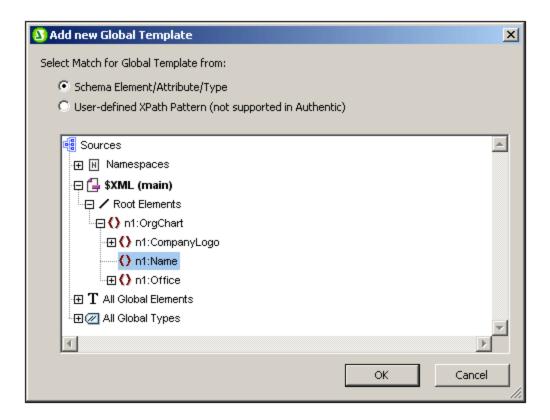

Creating a global template

Global templates can be created for any node or type in the schema, or for a node specified in an XPath pattern., and are created from the Schema Tree sidebar (*screenshot below*).

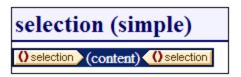

A global template can be created in any of the following ways:

• Click the Add New Global Template button located at the right of the Global Templates item in the Schema Tree (see screenshot above). This pops up the Add New Global Template dialog (screenshot below). You can select an element, an attribute, or a type from the schema tree shown in the dialog, or you can enter an XPath pattern. (Note that global templates created for nodes selected with an XPath pattern are not supported in Authentic.) This selects the node that must be created as the global template. Click OK to finish. The template will be created and appended to the already existing templates in Design View and can then be edited. In the Schema Tree, the schema node or type will be marked with a plus sign icon in front of it.

- Right-click the schema node or type component in the Schema Tree (under Root Elements, All Global Elements, or All Global Types, as appropriate), and select the command Make/Remove Global Template. The template will be created and appended to the already existing templates in Design View and can then be edited. In the Schema Tree, the schema node or type will be marked with a plus sign icon in front of it.
- Global templates can also be created from templates in the main template in Design View. Right-click
 the template (either in Design View or the Schema Tree sidebar) and select the command Make
 Global Template. A global template is created from the selected template (it is appended to the
 templates in Design View) and the template in the main template is automatically defined to use this
 global template (see below for an explanation of how global templates are used).

A global template is located in Design View below the main template. It is indicated by a mauve bar containing the name of the node for which the global template has been created, followed by its type: (simple) or (complex). A global template is shown in the screenshot below.

Note that the processing of the global template is user-defined and could include both static and dynamic components, as well as the whole range of processing options available for processing of the main template.

Using a global template

After a global template has been created, it can be used when a node having the same qualified name is inserted into the document (When the node is dropped in the design, select the command **Use Global**

Template from the menu that pops up.) by dropping. Alternatively, if a local template is present in the design and a global template exists for a node having the same qualified name, then the global template can be used instead of the local template. To use a global template for a local template, right-click the local template in Design View and select the command **Use Global Template**. When a global template is used, its processing instructions are called and used by the local template at runtime.

Wherever a global template is used in the design, an XPath pattern can be created on the global template to filter the nodeset it addresses. To create such a filter, right-click the global template tag in the design, and select **Edit XPath Filter** in the context menu that appears. This pops up the **Edit XPath Expression** dialog of the in the required expression can be entered.

Recursive global templates

Global templates can be recursive, that is, a global template can call itself. However, to guard against an endless loop in Authentic View, a property to limit the call-depth can be set. This property, the *Maximum Template-Call-Depth* property, is available in the Authentic tab of the Properties dialog of the SPS (File | Properties (File | Properties)). It specifies the maximum number of template calls that may be made recursively when processing for the Authentic View output. If the number of template calls exceeds the number specified in the *Maximum Template-Call-Depth* property, an error is returned.

Copying a global template locally

After a global template has been created, its processing instructions can be copied directly to a template of the same qualified name in the main template. To do this, right-click the local template and select the command **Copy Global Template Locally**. Copying the global template locally is different than using the global template (at runtime) in that the processing instructions are merely copied in a one-time action. The global template has no further influence on the local template. Either, or both, the global template and local template can subsequently be modified independently of each other, without affecting the other. On the other hand, if it is specified that a global template should be *used* (at runtime) by a local template, then any modifications to the global template will be reflected in the local template at runtime.

Activating and deactivating global templates

A global template can be activated by checking its entry in the global templates listing in the Schema Tree sidebar. It can be deactivated by unchecking the entry. If a global template has been activated (the default setting when the global template was created), it is generated in the XSLT stylesheet. If it has been deactivated, it is not generated in the XSLT stylesheet but is still saved in the SPS design.

Any local template that uses a deactivated global template will then—since it is not able to reference the missing global template—fall back on the default templates of XSLT, which have the collective effect of outputting the contents of descendant text nodes.

The advantages of the activation/deactivation feature are: (i) Global templates do not have to be deleted if they are temporarily not required; they can be reactivated later when they are required; (ii) If there are name conflicts with templates from imported stylesheets, then the global template that is not required can be temporarily deactivated.

Removing a global template

To remove a global template, right-click the global template to be removed, either in Design View or the Schema Tree sidebar, and select the command **Make/Remove Global Template**.

Simple global templates and complex global templates

Global templates are of two types: simple and complex. Complex global templates are available for reasons of backward-compatibility. If a global template in an SPS created with a version of StyleVision prior to version 2006 contains a table or list, then that global template will typically be opened in StyleVision 2006 and later versions as a complex global template.

A complex global template is different than a simple global template in the way the node for which the global template was created is processed. When the first instance of the node is encountered in the document, the complex global template processes all subsequent instances of that node immediately afterwards. A simple global template, on the other hand, processes each node instance only when that node instance is individually encountered.

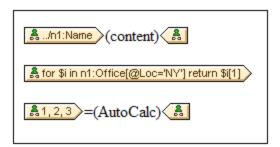

It is important to note that a simple global template will be automatically converted to a complex global template if a <u>predefined format</u> or newline is created **around** the element node for which the global template was created. This will result in the processing behaviour for complex global templates (described in the previous list item). To revert to the simple global template, the <u>predefined format</u> should be removed (by dragging the node outside the predefined format and then deleting the predefined format), or the newline should be removed (by deleting the item in the <u>Design Tree sidebar</u>), as the case may be. To avoid the automatic conversion from simple global template to complex global template, make sure that the <u>predefined format</u> or newline is added within the node tags of the element for which the simple global template was created.

Global templates in modular SPSs

When an <u>SPS module is added to another SPS module</u> 330, the global templates in the added module are available for use within the referring SPS. For more information about using modular SPSs, see the section Modular SPSs 330.

6.4.3 User-Defined Templates

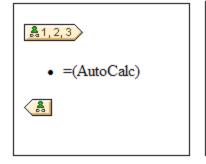

User-Defined Templates are templates for items generated by an XPath expression you specify. These items may be atomic values or nodes. In the screenshot below, which shows three User-Defined Templates, note the User-Defined Template icon on the left-hand side of the tags (a green person symbol). User-Defined Templates are very useful because they provide extraordinary flexibility for creating templates. Note, however, that content generated by User-Defined Templates cannot be edited in Authentic View.

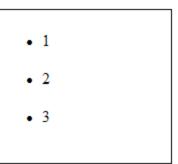

The XPath expression of each of the three User-Defined templates shown in the screenshot above do the following:

Selects a node in a source schema. By using an XPath expression, any node in any of the schema

- sources can be reached from within any context node. If StyleVision can unambiguously target the specified node, the template will be changed automatically from a User-Defined Template to a normal template, enabling Authentic View editing. If it is a User-Defined Template, this will be indicated by the green User-Defined Template icon on the left-hand side of the template tags.
- Selects a node that fulfills a condition specified by the for construct of XPath 2.0 and XPath 3.0. Such
 templates can never resolve to normal templates (but will remain User-Defined Templates) because the
 for construct does not allow StyleVision to unambiguously resolve the target from only the schema
 information it currently has at its disposal.
- Selects a sequence of atomic values {1, 2, 3}. While it is allowed to create a template for an atomic value, you cannot use the contents placeholder within such a template. This is because the xsl:apply-templates instruction (which is what the contents placeholder generates) can only be applied to node items (not atomic values). You could, however, use an Auto-Calculation in combination with some design element such as a list. For example, the User-Defined Template at left would generate the output at right.

Note: If the SPS uses XSLT 1.0, then the XPath expression you enter must return a node-set. Otherwise an error is reported.

Advantage of using XPath to select template node

The advantage of selecting a schema node via an XPath expression (User-Defined Templates) is that the power of XPath's path selector mechanism can be used to select any node or sequence of items, as well as to filter or set conditions for the node selection. As a result, specific XML document nodes can be targeted for any given template. For instance, the XPath expression //Office/Department[@Location="NY"] will select only those Department nodes that have a Location attribute with a value of NY. Also see the other examples in this section.

Note: If an XPath expression contains multiple location path steps, then it is significant—especially for grouping and sorting—whether brackets are placed around the multiple location path steps or not. For example, the XPath expression <code>/Org/Office/Dept</code> will be processed differently than <code>(/Org/Office/Dept)</code>. For the former expression (without brackets), the processor loops through each location step. For the latter expression (with brackets), all the <code>Dept</code> elements of all <code>Office</code> elements are returned in one undifferentiated nodeset.

Brackets	Underlying XSLT Mechanism	Effect
No	<pre><xsl:for-each select="Org"> <xsl:for-each select="Office"></xsl:for-each></xsl:for-each></pre>	Each Office element has its own Dept population. So grouping and sorting can be done within each Office.

Yes	<pre><xsl:for-each select="/Org/Office/Dept"></xsl:for-each></pre>	The Dept population extends over all Office elements and across Org.
	<pre></pre>	

This difference in evaluating XPath expressions can be significant for grouping and sorting.

Inserting a User-Defined Template

To insert a User-Defined Template, do the following:

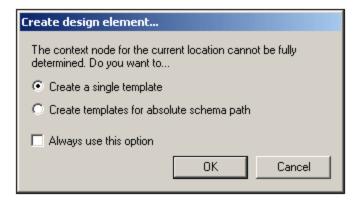

- Click the Insert User-Defined Template icon in the Insert Design Elements toolbar and then click the
 design location where you wish to insert the template. Alternatively, right-click the design location
 where you wish to insert the template and, from the context menu that appears, select the Insert
 User-Defined Template command.
- 2. In the Edit XPath Expression dialog that pops up, enter the XPath expression you want, and click OK. Note that the context node of the XPath expression will be the node within which you have clicked. An empty node template will be created. Sometimes a joined node is created. When a node is joined, the targeted instance nodes are selected as if at a single level, whereas if a node is not joined (that is if it is split into multiple hierarchic levels), then the node selection is done by looping through each instance node at every split level. The nodeset returned in both cases of selection (joined and split) is the same unless a grouping or sorting criterion is specified. For a discussion of the effect joined nodes have on the grouping and sorting mechanisms, see Node-Template Operations.

Editing a Template Match

The node selection of any node template (user-defined or normal) can be changed by using an XPath expression to select the new match expression. To edit the template match of a node template, right-click the node template, then select the **Edit Template Match** command. This pops up the Edit XPath Expression dialog, in which you enter the XPath expression to select the new node. Then click **OK**.

Adding nodes to User-Defined Templates

If a node from the schema tree is added to a User-Defined Template, the context for the new node will not be known if the User-Defined Template has been created for a node or sequence that cannot be placed in the context of the schema source of the SPS. You will therefore be prompted (*screenshot below*) about how the new node should be referenced: (i) by its name (essentially, a relative path), or (ii) by a full path from the root of the schema source.

Prompting for advice on how to proceed is the default behavior. This default behavior can be changed in the Design tab of the Tool | Options dialog (033).

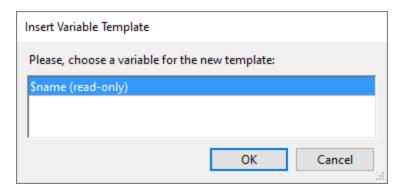

6.4.4 Variable Templates

A **Variable Template** is a template that targets a variable and, by default outputs its content. It is inserted with the **Insert | Variable Template** or **Enclose with | Variable** command, which inserts, at the cursor insertion point, a template for a variable defined in the SPS. The variable template (*screenshot below*) contains a content placeholder by default, and this serves to output the contents of the variable. You can insert additional content (static as well as dynamic) in the variable template as required, or modify it as you would any other template. A variable template is indicated with a dollar symbol in its start and end tags.

To insert a variable template, do the following:

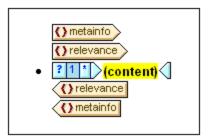

- 1. Place the cursor in the design at the location where the template is to be inserted.
- 2. Right-click and select the **Insert | Variable Template** command. This pops up the Insert Variable Template dialog (*screenshot below*).

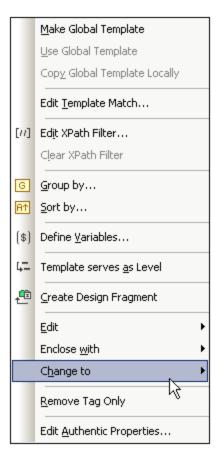

- 3. The dialog contains a list of all the <u>user-declared parameters and variables</u> defined in the SPS. Select the variable for which you wish to add a variable template.
- 4. Click **OK** to finish.

6.4.5 Node-Template Operations

A node-template is a template in the design that specifies the processing for a node. In the design, node-templates are displayed with beige start and end tags (*screenshot below*). The type of node is indicated by a symbol inside the tags (For example: angular brackets for element nodes and equal-to signs for attribute nodes). The screenshot below contains two node-templates, both for elements: metainfo and relevance. *Also see, Nodes in the XML document* [913].

The operations that can be carried out on a node-template are accessible via the context menu of that node-template (accessed by right-clicking either the start or end tag of a node-template, see screenshot below).

The commands in this context menu are described below:

- Global templates 354
- <u>Template match</u> 354
- XPath filters 354
- Group by, Sort by, Define variables, Template serves as level 355
- Create Design Fragment 355
- Remove Tag Only 355
- Edit, Enclose with, Change to 355
- Authentic properties 356

These menu commands are described below. Note that for a given node-template, some commands might not be available; these are grayed out in the context menu.

Global templates: make, use, copy locally

A node-template in the main template can be changed to or associated with a global template via the following commands:

- Make global template: This option is available if the node-template represents an element that is
 defined as a global element in the schema. A global template will be created from the node-template.
 The node-template in the main template will use this global template and its tags will then be displayed
 in gray (indicating its use of the global template).
- Use global template: If a global template of the same qualified name as the node-template has been defined, the node-template will use the processing of the global template. The tags of the node-template will become gray.
- Copy global template locally: The processing instructions of a global template of the same qualified
 name as the node-template are copied physically to the node-template. The node-template is
 independent of the global template. Subsequently, both it and the global template can be modified
 independently of each other. Since the node-template does not reference a global template, it retains
 its beige color.

For more information, see the section Global Templates 45.

Editing the template match

The node for which a template has been created can be changed by using this command. The Edit Template Match command pops up the Edit XPath Expression dialog 917, in which you can enter an XPath expression that selects another node in the schema. You can also enter any XPath expression to change the template to a User-Defined Template 143.

Edit/Clear XPath Filter

An XPath filter enables you to filter the nodeset on which a node-template is applied. XPath filters can also be applied to global templates 345.

By default, a node-template will be applied to nodes (elements or attributes) corresponding to the node for which the node-template was created (having the same name and occurring at that point in the schema hierarchy). For example, a node-template for the <code>/Personnel/Office</code> node will select all the <code>/Personnel/Office</code> elements. If an XPath filter with the expression 1 is now created on the <code>Office</code> element (by right-clicking the <code>Office</code> element and editing its XPath Filter), this has the effect of adding a predicate expression to the <code>Office</code> element, so that the entire XPath expression would be: <code>/Personnel/Office[1]</code>. This XPath expression selects the first <code>Office</code> child of the <code>Personnel</code> element, effectively filtering out the other <code>Office</code> elements.

A filter can be added to any node-template and to multiple node-templates in the design. This enables you to have selections corresponding to such XPath expressions

as: /Personnel/Office[@country='US']/Person[Title='Manager'] to select all managers in the US offices of the company. In this example, a filter each has been created on the Office and on the Person node-templates, respectively.

Wherever a global template is used—that is, called—an XPath filter can be applied to it. So, for every instance of a global template that is used, an XPath filter can be applied to the global template in order to restrict the targeted nodeset.

To add an XPath Filter to a node-template, right-click the node-template and select **Edit XPath Filter**. Enter the XPath filter expression without quotes, square brackets, or delimiters of any kind. Any valid XPath expression can be entered. For example:

- •
- @country='US'
- Title='Manager'

After an XPath Filter has been created for a node-template, this is indicated by a filter symbol in the start tag of the node-template. In the screenshot below, the synopsis node-template has a filter.

Note: Each node-template supports one XPath Filter.

Group by, Sort by, Define variables, Template Serves as Level

The mechanisms behind these commands are described in detail in their respective sections:

- The **Group by** command enables instances of the node represented by the selected node-template to be grouped. The grouping mechanism is described in the section, <u>Grouping</u> 339.
- The **Sort by** command enables instances of the node represented by the selected node-template to be sorted. The sorting mechanism is described in the section, <u>Sorting</u> ⁽³⁹⁷⁾.
- The **Define Variables** command enables you to define variables that are on scope on the selected node-template. How to work with variables is described in the section, <u>Variables</u> (408).
- The **Template Serves as Level** command is a toggle command that creates/removes a level on the node-template. Levels can be specified at various levels in order to structure the document into a hierarchy. This structure can then be used to generate a table of contents (TOC), automatic numbering, and text references. These features are described in detail in the section, <u>Table of Contents</u> (TOC) and <u>Referencing</u> (418).

Create Design Fragment

Creates a Design Fragment template from the selected template. The resulting Design Fragment template is added to the Design Fragment templates at the bottom of the design, and added to the Design Tree and Schema Tree. The Design Fragment is also applied at that point in the design where it was created.

Remove (Template or Formatting) Tag Only

This command removes the selected template or formatting tag only. It does not remove any descendant nodes or formatting tags. This command is useful for removing a formatting tag or a parent element tag without removing all that is contained within the tag (which is what would happen if the **Delete** operation is carried out with a tag selected). Note, however, that removing a parent element might render descendant nodes of the deleted element invalid. In such cases, the invalid nodes are indicated with a red strike-through.

Edit, Enclose with, Change to

These commands are described below:

• Edit: Pops out a submenu with the familiar Windows commands: cut, copy, paste, and delete.

- Enclose with: The node-template can be enclosed within the following design components, each of which is described in a separate section of this documentation: paragraph (131), special paragraph (133), Bullets and Numbering (171), Hyperlink (440), Condition (331), TOC Bookmark and Level (413).
- Change to: The Change-To feature enables you to change: (i) the node for which that template applies, or (ii) how the node is created in the design. It is described in detail in the section, The Change-To Feature
 288.

Edit Authentic Properties

Selecting this command pops up the Properties sidebar, in which certain properties (Authentic Properties) of the instantiated node in Authentic View can be defined. Authentic Properties are described in detail in the section, <u>Authentic Node Properties</u> ⁵⁵⁹.

6.4.6 Design Fragments

Design Fragments are useful for creating parts that can be re-used at different locations in the document, similar to the way functions are re-used. The usage mechanism is as follows:

- 1. Create the Design Fragment in the design 356
- 2. Fill out the contents of the Design Fragment 357
- 3. Insert the Design Fragment at a location in a template 358.

Creating a Design Fragment

To create a Design Fragment do the following:

1. In the Design Tree or Schema Tree, click the Add New Design Fragment icon , which is located to the right of the Design Fragments item in the tree (see screenshot below). This adds a Design Fragment item in the Design Fragments list of the tree. (Also see note below.)

Notice that a Design Fragment template is created in the SPS design. This template is appended to the templates already in the design and indicated with a green header. (If you wish to see only the Design Fragments that are in the design, hide the main template and global templates by clicking their Show/Hide cons in StyleVision's Design Filter toolbar.) Additionally, the Design Fragment templates are also listed in the schema tree for ready access from there.

2. Double-click the Design Fragment item (either in the design tree or the schema tree) so as to edit its name. Name the Design Fragment as required and press **Enter**. The edited name is entered in the Design Tree (*screenshot below*) and in the template in the design.

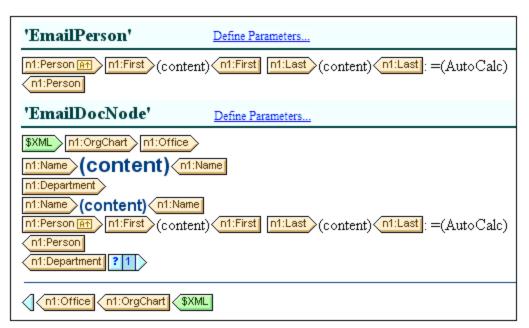

In the design, create the contents of the Design Fragment template. How to do this is described in the next section.

Note: If you wish to create a Design Fragment from an already existing template, right-click that template and select the command **Create Design Fragment** from the context menu that pops up. This creates a Design Fragment template from the selected template at that point in the design. The Design Fragment template is also appended to the existing Design Fragment templates at the bottom of the design and added to the Design Tree and Schema Tree. Creating a Design Fragment in this way also applies it directly at the point where it was created, there is no need to insert it from the Design Tree or Schema Tree.

Creating the contents of a Design Fragment

The contents of the Design Fragment template are created <u>as for any other template</u> ¹³⁰. To insert static content, place the cursor in the Design Fragment template and insert the required static content. To insert dynamic content, drag the required schema node into the Design Fragment template.

When dragging a node from the schema source you can drag the node either: (i) from the Global Elements tree, or (ii) from the Root Elements tree. The difference is significant. If a node is dragged from the Global Elements tree, it is created without its ancestor elements (in the screenshot below, see the EmailPerson Design Fragment) and, therefore, when used in a template, it will have to be used within the context of its parent. On the other hand, if a node is dragged from the Root Elements tree, it is created within a structure starting from the document node (in the screenshot below, see the EmailDocNode Design Fragment), and can therefore be used anywhere in a template.

The screenshot above shows two Design Fragment templates that produce identical output for the Person element. In the EmailPerson Design Fragment template, the Person node has been created by dragging the global element Person into the EmailPerson template. In the EmailDocNode Design Fragment template, the Person node has been dragged from the Root Elements tree, and is created with an absolute path (from \$XML, the document node).

When these Design Fragment templates are inserted in the main template, care must be taken that the EmailPerson template is called from within a context that is the parent of the Person node. You can experiment with these Design Fragments. They are in the example file Email.sps, which is in the (My) Documents folder 33, C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\DesignFragments.

You can also define a parameter with a default value on the Design Fragment. The parameter can be assigned a different value in every Design Fragment instance. See <u>Parameters for Design Fragments</u> for details.

After you have completed the design, notice that the components of the design are also graphically depicted in the Design Tree.

Inserting a Design Fragment in a template

To insert a Design Fragment, drag the Design Fragment from the Design Tree or Schema Tree to the required location. The location at which the Design Fragment is dropped should be such that it provides a correct context. If the contents of the Design Fragment were created from a global element, then the correct context in the main template would be the parent of the node dragged into the Design Fragment. See <u>Creating the contents of a Design Fragment</u> shove.

Alternatively, right-click at the location where the Design Fragment is to be inserted and select **Insert Design Fragment** from the context menu.

Note: If a Design Fragment is referenced in the main template and if the name of the Design Fragment is changed subsequently, then the reference in the main template will no longer be correct and an XSLT error will result. In order to correct this, delete the original reference in the main template and create a fresh reference to the newly named Design Fragment.

Recursive design fragments

Design fragments can be recursive, that is, a design fragment can call itself. However, to guard against an endless loop in Authentic View, a property to limit the call-depth can be set. This property, the *Maximum Call-Depth* property, is available in the Authentic tab of the Properties dialog of the SPS (File | Properties properties). It specifies the maximum number of template calls that may be made recursively when processing for the Authentic View output. If the number of template calls exceeds the number specified in the *Maximum Call-Depth* property, an error is returned.

Deleting a Design Fragment

To delete a Design Fragment, select it in the Design Tree and click the **Remove** toolbar icon of the Design Tree

Design Fragments in modular SPSs

When an <u>SPS module is added to another SPS module</u> 330, the Design Fragments in the added module are available for use within the referring SPS. For more information about using modular SPSs, see the section Modular SPSs 330.

Example file

For an example SPS, go to the (My) Documents folder 33, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\DesignFragments.

360 SPS Structure XSLT Templates

6.5 XSLT Templates

XSLT files can be imported into an SPS, and XSLT templates in them will be available to the stylesheet as global templates. If, during the processing of the XML document, one of the XML nodes matches a node in an imported XSLT template, then the imported XSLT template is applied to that node. If the imported XSLT file contains named templates, these are available for placement in the design.

Note the following points:

- Imported XSLT templates cannot be modified in StyleVision.
- XSLT templates are not supported in Authentic View.

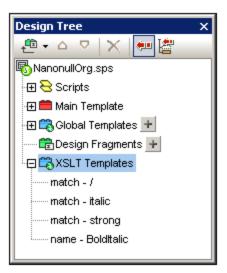

Importing the XSLT file

To import an XSLT File, do the following:

1. In the Design Overview sidebar (screenshot below), click the Add New XSLT File link.

2. In the Open dialog that appears, browse for the required XSLT file, select it, and click **Open**. The XSLT file is imported. An xsl:import statement is added to the XSLT stylesheet, and, in the Design Tree sidebar (*screenshot below*), the XSLT Templates contained in the imported XSLT file are displayed under the XSLT Templates heading.

SPS Structure XSLT Templates 361

There are two types of imported XSLT templates: (i) match templates (indicated by *Match*), and (ii) named templates (indicated by *Name*). In the Design Tree, these two types are listed with (i) the value of the select attribute of match templates, and (ii) by the value of the name attribute of named templates, respectively.

Match templates

Match templates will be used when a template, in the course of processing, applies templates to a node in the XML document instance, and the match template is selected to be applied. This will happen when the qualified name of the XML node matches the qualified name of the imported match template. If a global template has been created in the SPS that has the same qualified name, then it has precedence over an imported template and will be used. If there are several imported XSLT files, the file imported first (and listed first in the XSLT code) has the lowest precedence, followed by the second lowest precedence for the file imported second, and so on.

Named templates

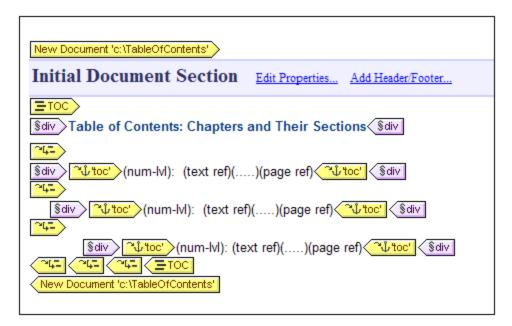

A named template can be dragged from the Design Tree to any location in the design. At this location, it will be created as an xsl:call-template element (screenshot below) that calls the named template.

The effect of this in the output is to implement the named template at that location in the design. This can be useful for inserting content that is independent of both the XML instance document as well as of the XSLT stylesheet.

6.6 Multiple Document Output

You can design an SPS to produce multiple output-documents: a main output-document and one or more additional documents. This is particularly useful if you wish to modularize the output. Output-documents are created in the design by inserting a New Document template (see screenshot below). Content for each output-document is placed within its New Document template.

New Document templates can be created anywhere in the document design, thus allowing the output to be modularized at any level. So, for example, a report about the various branch offices of a global organization can have separate output-documents at each of the following levels: (i) world, (ii) continent, (iii) country, (iv) state, and/or (v) branch office. Each branch office, for example, can be presented in a separate output-document or all the branch offices in a country can appear together in a single country report. In the design, a New Document template would have to be created at each of the hierarchical levels for which separate output-documents are required. How to set up the correct document structure is described in the section, New Document Templates and Design Structure

The multiple output-document feature is available in all formats: HTML, RTF, PDF, Word 2007+, and Text. In Authentic View, which is intended as an editing view, content is displayed in a single document.

This description of multiple output-documents is organized into the following sub-sections:

- Inserting a New Document Template 363
- New Document Templates and Design Structure

 364

 364
- URLs of New Document Templates 364
- Preview and Output Document Files
- Document Properties and Styles 369

6.6.1 **Inserting a New Document Template**

A New Document template can be placed in an SPS design in one of two ways:

- A new output-document template can be inserted at any location in the design. In this case the content of the New Document is added to the template after inserting the template. To insert a New Document template, place the cursor at the desired location in the design and select the command Insert | Insert New Document or right-click the location and, from the context menu that pops up, select Insert New Document.
- A new output-document can be placed in the design by **enclosing content** with a New Document template. The New Document template will, in this case, contain the enclosed content when it is created. You can add to or modify this content in the design. To place a New Document template so that it encloses content, highlight the content to be enclosed and then select the command Enclose With | New Document. Alternatively, you can select the content to be enclosed, then right-click it, and, from the context menu that pops up, select the command Enclose With | New Document.

A New Document template with content is shown in the screenshot below.

Notice the following from the screenshot above:

- 1. The New Document template tags contain the URL (path and name) of the output-document it will generate. The filename suffix will be generated automatically according to the file type of the output format. For example, for the HTML output format, the filename suffix .html will be appended to the filename in the URL. Issues relevant to the assigning of URLs are discussed in the section, URLs of New Document Templates 364.
- 2. The New Document Template contains one Initial Document Section. Additional document sections can be added to the initial document section as described in the section, <u>Document Sections</u>

6.6.2 New Document Templates and Design Structure

When creating multiple output-documents, you must create the different New Document templates on the appropriate nodes of the source document. Therefore, you must consider both the <u>output structure</u> as well as the <u>input (source XML document) structure</u> when designing multiple output-documents.

Main output document and additional output documents (output structure)

When the first New Document template is added to the design, all design content outside this New Document template is automatically assigned to a separate document. This separate document is considered to be the main output document, and, in the output previews of StyleVision, it is referred to as Main Output Document.

In the generated output-documents (created using the command **File | Save Generated Files**), the name of the main output document will be the name you assign it when generating the output-document files using the **Save Generated Files** command. The names of the additional output-document files will be the names assigned in the URLs of the respective New Document templates.

New Document templates and source document structure

When a New Document template is created, the hierarchical location where it is created is significant. Two possibilities exist:

- 1. The node within which the New Document template is created is processed only once. In this case the New Document template is also processed only once. The filename in the URL property of the New Document template can therefore be a static name.
- 2. The node within which the New Document template is created is processed multiple times. As a result, the New Document template will be processed as many times as the node is processed. An example of such a situation would be the following. An Office element has multiple Department element children (for its various departments). If a New Document template is created within the Department node in the design, then, since the Department node will be processed multiple times (for all the different Department elements in that Office element), the New Document template also will be processed multiple times, once for each Department element in the source XML document. The filename in the URL property of the New Document template must therefore be a dynamic name. Otherwise, the output-documents created for the Department elements will each have the same filename.

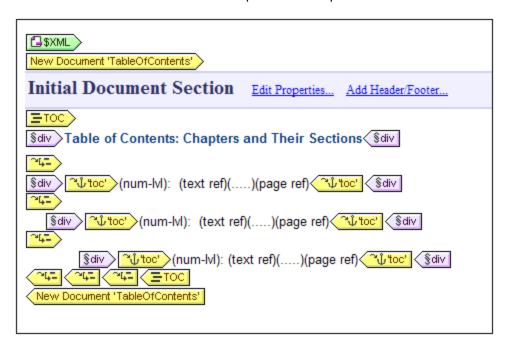

6.6.3 URLs of New Document Templates

In this section we describe how the <u>URLs of New Document templates relate to design structure</u> 364, how <u>URLs</u> are edited 366, and how multiple output-documents can be linked 366 among each other.

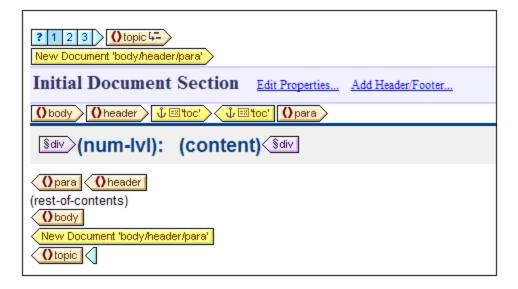

URLs of New Document templates

If the New Document template is processed only once (see <u>preceding section</u>), then the template's *URL* property can be a static URL. In the screenshot below, since the New Document template is immediately within the document element (\$XML), it will be processed only once. The URL has been given a static value of TableOfContents. This value will therefore be the filename of the output-document. Since no path has been prefixed to the filename, the file will be generated in the same directory as the Main Document File (see

Multiple Document Outputs and Previews (366) for details). Alternatively, if the URL contained a path, the output-document will be saved to the location specified in the path.

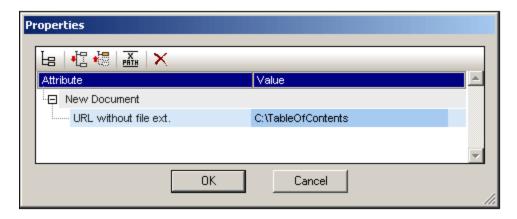

If, on the other hand, a New Document template will be processed multiple times to generate multiple output-documents (see <u>preceding section</u>), then the template's *URL* property must be a dynamic URL that is selected with an XPath expression. In the screenshot below, the URL of the New Document template is the XPath expression: <code>body/header/para</code>. The New Document template is within the <code>topic</code> element, so it will be processed each time the <code>topic</code> element is processed. On every iteration through the <code>topic</code> element, the content of that <code>topic</code> element's <code>body/header/para</code> element will be assigned as the URL of the New Document template. This creates a new document for every <code>topic</code> element. Each of these documents has a different name, that of its <code>body/header/para</code> element (which is the text of the topic's header).

Editing the URL

When a New Document template is added to the design, it is created with a default URL. This is a static text string: <code>DocumentX</code> (where <code>X</code> is an integer). If you wish to edit the URL, right-click the New Document template and select the command **Edit URL**. This pops up the Properties dialog (*screenshot below*), in which you can edit the Value field of the *URL without file ext* property.

If you wish to enter a static URL, edit the Value field to contain the required URL text. If you wish to enter a dynamic URL, click in the Value field, click the XPath button in the toolbar of the Properties dialog, and enter the XPath expression you want. Note the following: (i) The context node for the XPath expression is the node within which the New Document template has been inserted. (ii) To prefix a path to the XPath location expression, use the <code>concat()</code> function of XPath. For example: <code>concat('C:\MyOutput\', body\header\para)</code>. This example expression will generate the URL string: <code>C:\MyOutput\filename</code>. The appropriate file extension will be generated automatically according to the output format.

Linking the documents

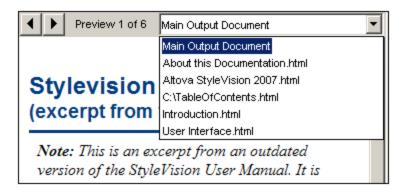

Multiple output-documents can be linked to one another using bookmarks and hyperlinks 440. A bookmark can be placed at the head of a New Document Template or anywhere within the New Document Template. Hyperlinks 442 can then be created in other documents to link back to the bookmark. If bookmarks are required on a node that is processed multiple times, then make sure that the name of the bookmark is generated dynamically. Otherwise (if a static bookmark name is given) multiple nodes in the output will have the same bookmark name.

A <u>Table of Contents (TOC)</u> (413) can also be used to link documents. The TOC could be in a separate document (for example, the main document) and link to the various output-documents, while the output-documents could link back to the TOC.

Note: Links to external documents are supported in the FO spec but might not be supported by the FO processor you are using. You should check support for this feature in your FO processor if you are planning to use links to external documents in your PDF output documents.

6.6.4 Preview Files and Output Document Files

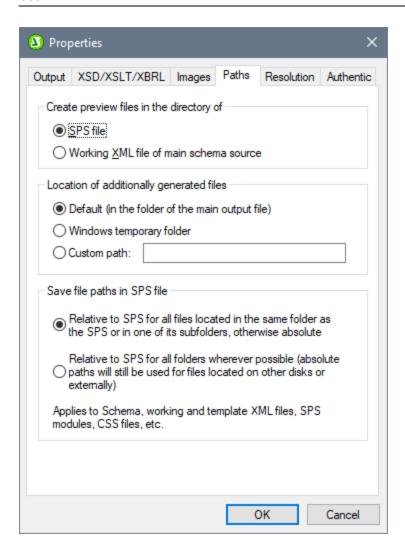

The output previews of a design document show each of the multiple output-documents that have been specified in the design as separate documents (*see screenshot below*).

The screenshot above shows the HTML Preview of an SPS document that has been designed to generate multiple output-documents. Each output document can be called up in the view window by either: (i) navigating through the available documents using the arrow buttons at top left, or (ii) selecting the required document from the dropdown list of the combo box (see screenshot above). Notice that the items of the dropdown list show the entire URL (path plus filename).

Location of preview files

The preview files are created by default in the directory in which the SPS file is created. This default setting can be changed in the Paths tab of the SPS file's Properties dialog (*screenshot below*), which is accessed with the **File | Properties** command. In this tab you can specify the directory of the Working XML File as an alternative location. If the URL of a New Document template contains a path, the location specified in this path will be used as the location of the respective preview files. If the location cannot be found, an error is returned. You should be aware of where the output-documents will be saved if you are setting up output-documents to link to each other.

In the Paths tab of the Properties dialog (see screenshot above), you can also specify where temporary additional files for previews, such as output-document files, and image and chart-image files, will be saved. Note that, if the URL of a New Document template contains a path, then the location specified in this path will be used.

Generating output (paths etc)

To generate the output-document files, do the following:

- 1. Mouse over the menu command File | Save Generated Files and click the required output format.
- 2. In the Save Generated File dialog that pops up browse for the folder in which you wish to save the generated file.
- 3. Enter the name of the Main Document File and click **Save**.

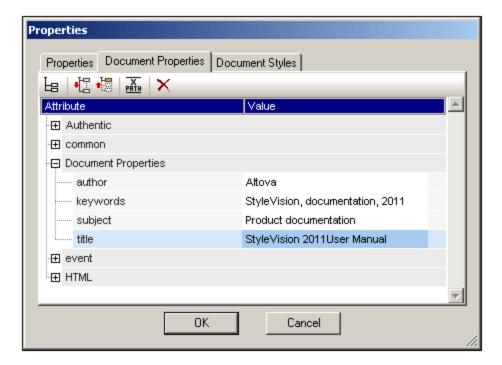

The location of all output-document files as well as other additionally generated files, such as image files and chart-image files, will be displayed in a pop-up window for your information.

The Main Document File will be saved to the folder location you selected in the Save Generated File dialog. All the multiple output-documents that were created with New Document templates and whose URLs have no path information will be saved to the same folder as the Main Document File. If a path was prefixed to the filename in

a New Document template's URL, the output document will be saved to the location specified in the URL. If that folder location does not exist an error will be generated.

6.6.5 Document Properties and Styles

In an SPS design, you can split the output into multiple documents. Each of these documents can be assigned separate document properties and document styles. These are specified in the *Document Properties* and *Document Styles* tabs, respectively (see screenshot below), of the Properties dialog of the document's Initial Document Section. To access the Properties dialog, click the *Edit Properties* link in the title bar of the Initial Document Section of the document for which you wish to set these properties. Document properties and document styles apply to the entire output document.

In the Document Properties tab, the Document Properties group of properties enable meta-information to be entered for the document. This meta-information will be saved to the respective output document and to the respective properties according to output format. For example, in the HTML output format, the properties are stored in the respective META tags of the HEAD element.

Document styles are described in the section <u>Setting CSS Property Values</u> 474.

7 Advanced Features

How to create the basic content and structure of the SPS design is described in the sections, SPS File Content and SPS File Structure and SPS File SPS Fil

Given below is a list of StyleVision's SPS file advanced features:

- <u>Auto-Calculations</u> ³⁷¹. Auto-Calculations are a powerful XPath-based mechanism to manipulate data and (i) present the manipulated data in the output as well as (ii) update nodes in the XML document with the result of the Auto-Calculation.
- <u>Conditions</u> 331. Processing of templates and the content of templates can be conditional upon data structures or values in the XML, or upon the result of an XPath expression
- <u>Grouping</u> 339. Processing can be defined for a group of elements that are selected with an XPath expression.
- Sorting 397. A set of XML elements can be sorted on multiple sort-keys.
- Parameters and Variables 403. Parameters are declared at the global SPS level with a default value. These values can then be overridden at runtime by values passed to the stylesheet from the command line. Variables can be defined in the SPS and these variables can be referenced for use in the SPS.
- Table of Contents (TOC) and Referencing ⁴¹³. Tables of Contents (TOCs) can be constructed at various locations in the document output, for all output formats. The TOC mechanism works by first selecting the items to be referenced in the TOC and then referencing these marked items in the TOC. Other features which use referencing are: (i) Auto-Numbering (repeating nodes in the document can be numbered automatically and the numbers formatted); (ii) Text-References (text in the document can be marked for referencing and then referenced from elsewhere in the document); and (iii) Bookmarks and Hyperlinks (bookmarks mark key points in the output document, which can then be targeted by hyperlinks. Hyperlinks can also link to external resources using a variety of methods to determine the target URI (static, dynamic, a combination of both, and unparsed entity URIs).) All these referencing mechanisms are described in this section.

7.1 Auto-Calculations

The **Auto-Calculation** feature (i) displays the result of an XPath evaluation at any desired location in the output document, and (ii) optionally updates a node in the main XML document (the XML document being edited in Authentic View) with the result of the XPath evaluation.

The Auto-Calculation feature is a useful mechanism for:

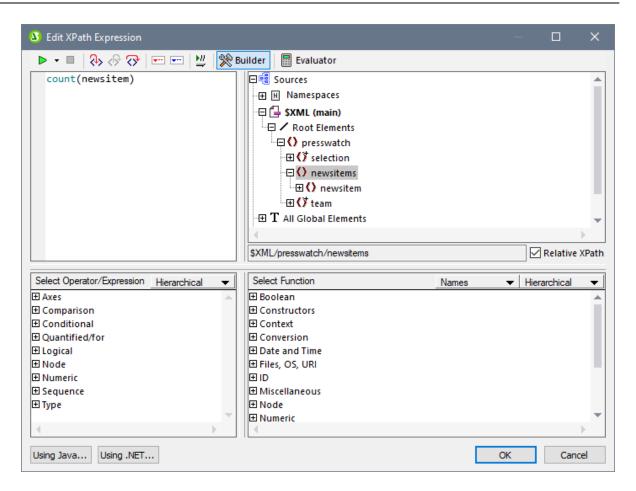

- Inserting calculations involving operations on dynamic data values. For example, you can count the number of Employee elements in an Office element (with count (Employee)), or sum the values of all Price elements in each Invoice element (with sum (Price)), or join the FirstName and LastName elements of a Person element (with concat (FirstName, '', LastName)). In this way you can generate new data from dynamically changing data in the XML document, and send the generated data to the output.
- Displaying information derived from the structure of the document. For example, you can use the position() function of XPath to dynamically insert row numbers in a dynamic table, or to dynamically number the sections of a document. This has the advantage of automatically generating information based on dynamically changing document structures.
- Inserting data from external XML documents. The doc() function of XPath 2.0 provides access to the document root of external XML documents, and thus enables node content from the external XML document to be inserted in the output.
- Updating the value of nodes in the main XML document. For example, the node Addressee could be updated with an XPath expression like concat (Title, '', FirstName, '', LastName).
- Presenting the contents of a node at any location in the design.

7.1.1 Editing and Moving Auto-Calculations

Creating Auto-Calculations

To create an Auto-Calculation, do the following:

1. Place the cursor as an **insertion point** at the location where the Auto-Calculation result is to be displayed and click **Insert | Auto-Calculation**. In the submenu that appears, select Value if the result is to appear as plain text, select Input Field if it is to appear within an input field (i.e. a text box), or select Multiline Input Field if it is to appear in a multiline text box. (Note that the output of the Auto-Calculation is displayed as a value, or in an Input Field. It is an output in Authentic View, and cannot be edited there.) The Edit XPath Expression dialog pops up (*screenshot below*).

- 2. In the *Expression* pane, enter the XPath expression for the Auto-Calculation via the keyboard. Alternatively, enter the expression by double-clicking nodes, operators, and/or functions in the respective panes of the dialog. It is important to be aware of the context node at the insertion point; the context node is highlighted in the schema source tree (in the screenshot above the context node, newsitems, is highlighted). If you have selected XSLT 1.0 as the version of the XSLT language for your SPS, then you must use XPath 1.0 expressions; if you have selected XSLT 2.0 or XSLT 3.0, then you must use, respectively, XPath 2.0 or XPath 3.0 expressions. For a detailed description of the Edit XPath Expression dialog, see the section Edit XPath Expression
- 3. Optionally, if you wish to copy the value of the Auto-Calculation to a node in the XML document, you can select that node via an XPath expression. How to update nodes with the result of the Auto-Calculation is described in the section, <u>Updating Nodes with Auto-Calculations</u> 374.

Click the **OK** button finish. In the Design tab, the Auto-Calculation symbol is displayed. To see the result of the Auto-Calculation, change to Authentic View or an Output View.

Java and .NET functions

Java and .NET functions can be used in the XPath expressions of Auto-Calculations. Here are examples of XPath expressions containing Java and .NET functions:

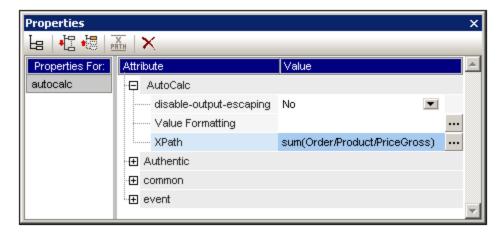

- Java: java.util.Date.toString(java:java.util.Date.new())
- .NET: clitype:System.Math.PI()

See the Appendices (1266) for more information about these extension functions.

Note: Java and .NET functions in Auto-Calculations are supported only in the Enterprise editions of Authentic Desktop and Authentic Browser.

Editing Auto-Calculations

To edit the XPath expression of the Auto-Calculation, select the Auto-Calculation and, in the Properties sidebar, click the **Edit** button of the XPath property in the AutoCalc group of properties (screenshot below). This pops up the Edit XPath Expression dialog (screenshot above), in which you can edit the XPath expression.

Formatting Auto-Calculations

You can apply predefined formats and CSS styles to Auto-Calculations just as you would to normal text: select the Auto-Calculation and apply the formatting. Additionally, <u>input formatting</u> of an Auto-Calculation that is a numeric or date datatype can be specified via the Input Formatting property in the AutoCalc group of properties in the Properties window.

Note also that you can include carriage returns and/or linefeeds (CR/LFs) in the XPath expression. If the Auto-Calculation is enclosed in the pre special paragraph type, the output of a CR/LF will produce a new line in the output (except in the RTF output). An example of such an XPath expression is:

translate('a;b;c', ';', codepoints-to-string(13))

Moving Auto-Calculations

You can move an Auto-Calculation to another location by clicking the Auto-Calculation (to select it) and dragging it to the new location. You can also use cut/copy-and-paste to move/copy an Auto-Calculation. Note, however, that the XPath expression will need to be changed if the context node in the new location is not the same as that in the previous location.

Summary of important points

Note the following points:

- An Auto-Calculation can be inserted anywhere in the Design Document.
- The point at which you insert the Auto-Calculation determines the context node for the XPath evaluation.

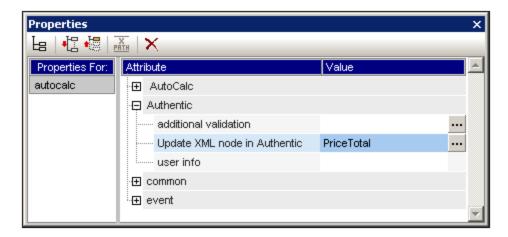

• In Authentic View, an Auto-Calculation is re-evaluated each time any value relevant to the calculation (that is, any node included in the XPath expression) changes.

- An Auto-Calculation result is non-editable in Authentic View or any other output view.
- Any node in the XML document can be updated with the result of the Auto-Calculation.

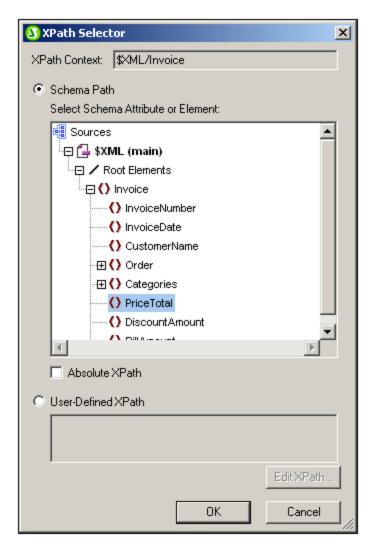

7.1.2 Updating Nodes with Auto-Calculations

You can copy the value (or result) of an Auto-Calculation to a node in the main XML document (the document being edited in Authentic View). You do this as follows:

- 1. Create the Auto-Calculation as described in Editing and Moving Auto-Calculations 371.
- 2. Select the Auto-Calculation and, in the Properties sidebar, click the **Edit** button of the Update XML node in Authentic property in the *Authentic* group of properties (*screenshot below*).

3. In the XPath Selector dialog that pops up (*screenshot below*), select the node to update and click **OK** to finish. If you wish the XPath expression to be absolute (that is, starting at the document root), check the Absolute XPath check box.

Alternatively, if you select the User-Defined XPath radio button, you can enter any XPath expression you like to select the node to be updated.

The XPath expression must select **a single node**. If the XPath expression selects multiple nodes, no node will be updated.

IMPORTANT!

Only nodes in the XML file of the main schema source will be updated. Nodes in the XML files of additional schemas will not be updated. For a node in the main XML document to be updated two conditions must be fulfilled:

- 1. The XPath expression for the Auto-Calculation must include at least one value that is related to an XML node, i.e. a dynamic value. For example, Price*1.2. This expression involves the element Price, and is therefore dynamic. If the XPath expression contains a static value (for example, string("Nanonull, Inc.")), then the Update XML Node feature will not work.
- 2. Any one of the nodes used in the XPath expression must be modified in Authentic View. So, if the XPath expression is Price*1.2, and the Auto-Calculation is set to update the VATPrice node, then the Price element must be modified in Authentic View in order for the VATPrice node to be updated.

Changing the node to update, cancelling the update

To change the node to update, click the **Edit** button of the <code>Update XML Node</code> property in the *Authentic* group of properties of the Auto-Calculation (in the Properties window) and then select the required node from the Schema Selector dialog box that pops up. To delete the <code>Update XML Node</code> property, click the **Remove** button in the toolbar of the Properties window.

Should you use the Auto-Calculation or the updated node contents for display?

If there are no conditional templates involved, you can use either the Auto-Calculation or the contents of the updated node for display. It is immaterial which one you choose because the node update happens immediately after the Auto-Calculation is evaluated and there is no factor to complicate the update. You should, however, be aware that there is a different source for the content displayed in each of the two cases.

Hiding the Auto-Calculation

You may find yourself in the situation where you wish to use an Auto-Calculation to make a calculation in order to update a node with the value of the Auto-Calculation. In this case, one of the following scenarios arises:

- You wish to display the result just once. You cannot hide the Auto-Calculation since it would then not be evaluated. If there is no conditional template involved, it is best to display the Auto-Calculation and not display the contents of the updated node.
- You wish not to display the result, merely to update the node. The best way to handle this scenario is to apply text formatting to the Auto-Calculation, so that it is invisible on the output medium (for example, by applying a white color to an Auto-Calculation on a white background).

7.1.3 Auto-Calculations Based on Updated Nodes

If you wish to create an Auto-Calculation (second Auto-Calculation) that uses a node updated by another Auto-Calculation (first Auto-Calculation), there are two possible situations:

- The two Auto-Calculations are in the same template.
- The two Auto-Calculations are in different templates.

Auto-Calculations in the same template

When two Auto-Calculations are in the same template, the SPS applies the following procedure:

- 1. A node used in the XPath expression of the first Auto-Calculation is modified.
- 2. All node values in the XML document are read and all Auto-Calculations are executed.
- 3. Assuming that the first Auto-Calculation is executed correctly, it updates the specified XML node (call it Node-A). The second Auto-Calculation, which is based on Node-A, will be executed but will use the value of Node-A before Node-A was updated. This is because the value of Node-A was read before it was updated, and has not been read since then.
- 4. If the document is now edited in any way or if document views are changed (from and to Authentic View), then the values of nodes are read afresh and Auto-Calculations are executed.
- 5. The second Auto-Calculation is now carried out. (If this Auto-Calculation is intended to update a node, then, as is usual for node updates, a node used in the XPath expression will have to be changed before the update takes place.)

The time lag between the updating of Node-A and the evaluation of the second Auto-Calculation with the updated value of Node-A could be confusing for the Authentic View user. To ensure that this situation does not occur, it is best that the XPath expression of the second Auto-Calculation contain the XPath expression of the first Auto-Calculation—not the updated node itself. As a result, the second Auto-Calculation will execute with the input to the first Auto-Calculation and perform that Auto-calculation as part of its own Auto-Calculation. This enables it to be evaluated independently of the contents of Node-A.

Example

The first Auto-Calculation calculates the VAT amount of a product using the nodes for (i) the net price, and (ii) the VAT rate; it updates the VAT-amount node. The second Auto-Calculation calculates the gross price, which is the sum of net price and VAT amount; it updates the gross price node.

- The Auto-Calculation to calculate the VAT amount is: NetPrice * VATRate div 100. When the VAT rate of the product is entered, the Auto-Calculation is executed and updates the VATAmount node.
- If the Auto-Calculation to calculate the gross price is: NetPrice + VATAmount, then the Auto-Calculation will execute with the value of VATAmount that was read in before VATAmount was updated.
- If, however, the Auto-Calculation to calculate the gross price is: NetPrice + (NetPrice * VATRate div 100), then the Auto-Calculation will execute with the value of VATRate and will update the GrossPrice node. The updated VatAmount node has been left out of the second Auto-Calculation.

For a detailed example, see **Example**: An Invoice 377.

Auto-Calculations in different templates

When two Auto-Calculations are in different templates, a node updated by the first Auto-Calculation can be used by the second Auto-Calculation. This is because Auto-Calculations are calculated and nodes updated for each template separately. For an example of how this would work, see Example: An Invoice

7.1.4 Example: An Invoice

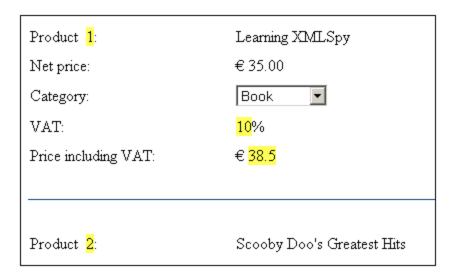

The Invoice.sps example in the (My) Documents folder 33, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Auto-Calculations\, demonstrates how Auto-Calculations can be used for the following purposes:

- Counting nodes
- Selecting a node based on input from the Authentic View user
- Updating the content of a node with the result of an Auto-Calculation
- Using the result of one Auto-Calculation in another Auto-Calculation

In the example file, the Auto-Calculations have been highlighted with a yellow background color (see screenshot below).

Counting nodes

In the Invoice example, each product in the list is numbered according to its position in the list of products that a customer has ordered (Product 1, Product 2, etc). This numbering is achieved with an Auto-Calculation (screenshot below).

In this particular case, the XPath expression <code>position()</code> would suffice to obtain the correct numbering. Another useful way to obtain the position of a node is to count the number of preceding siblings and add one. The XPath expression would be: <code>count(preceding-sibling::Product)+1</code>. The latter approach could prove useful in contexts where using the <code>position()</code> function is difficult to use or cannot be used. You can test this Auto-Calculation in the example file by deleting products, and/or adding and deleting new products.

Selecting a node based on user input

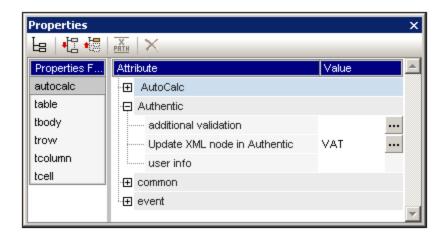

In the Invoice example, the user selects the category of product (Book, CD, DVD, or Electronics) via a combo box. This selection is entered in the //Product/Category node in the XML document. An Auto-Calculation then uses this value to reference a "lookup table" in the XML document and identify the node holding the VAT percentage for this product category. The XPath expression of this Auto-Calculation is:

```
for $i in Category return /Invoice/Categories/Category[. = $i]/@rate.
```

The VAT percentage is displayed at the Auto-Calculation location in the output. In the Invoices example, the lookup table is stored in the same XML document as the invoice data. However, such a table can also be stored in a separate document, in which case it would be accessed using the doc() function of XPath 2.0. To test this Auto-Calculation, change the product type selection in any product's Category combo box; the VAT value will change accordingly (Book=10%; CD=15%; DVD=15%; Electronics=20%).

Updating content of a node with the result of an Auto-Calculation

The VAT percentage obtained by the Auto-Calculation from the lookup is dynamic and stored temporarily in memory (for use in Authentic View). The result of the Auto-Calculation can, however, be stored in the VAT node in the XML document. This has two advantages: (i) the content of the VAT node does not have to be entered by the user; it is entered automatically by the Auto-Calculation; (ii) each time the lookup table is modified, the changes will be reflected in the VAT node when Invoice.xml is opened in Authentic. To cause an Auto-Calculation to update a node, select the Auto-Calculation in Design View, and in the Properties window (screenshot below), click the Authentic | Update XML Node button. In the dialog that pops up, select the VAT node, and then click **OK**.

In Authentic View, when the user selects a different product category in the combo box, the Auto-Calculation obtains the VAT percentage by referencing the lookup table, displays the VAT percentage, and updates the VAT node.

Using an Auto-Calculation-updated node in another Auto-Calculation

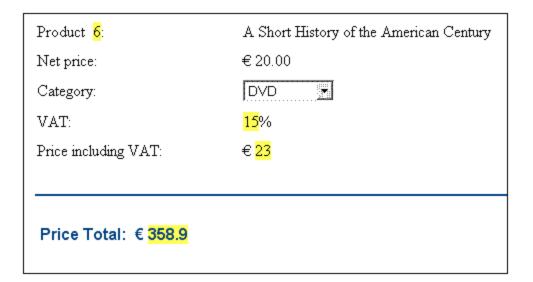

The VAT percentage, obtained by the Auto-Calculation described above, is required to calculate the gross price (net price + VAT amount) of each product. The formula to use would be derived as follows:

```
Gross Price = Net Price + VAT-amount
Since VAT-amount = Net Price * VAT-percentage div 100
Gross Price = Net Price + (Net Price * VAT-percentage div 100)
```

The net price of a product is obtained from the PriceNet node. The VAT percentage is calculated by an Auto-Calculation as described above, and this Auto-Calculation updates the VAT node. The content of the VAT node can now be used in an Auto-Calculation to generate the gross price. The XPath expression to do this would be:

```
PriceNet + (PriceNet * (VAT div 100))
```

The XPath expression can be <u>viewed and edited in the Properties window</u> You can test the Auto-Calculation for the gross price by changing either the price or product category of any product. Notice that the gross price (price including VAT) of the product also changes.

In the Invoice SPS, the gross price Auto-Calculation updates the PriceGross node in the XML document.

The updated PriceGross nodes can now be used in an Auto-Calculation that sums up the prices of all purchased products. The XPath expression would be: sum(Order/Product/PriceGross). In the Invoice SPS, this Auto-Calculation updates the PriceTotal node. You can test this Auto-Calculation by modifying the prices of individual products and seeing the effect on the price total.

An Auto-Calculation Exercise

Now add two Auto-Calculation components to the SPS yourself.

- 1. Create an Auto-Calculation that calculates a volume discount for the entire invoice. If the order amount (price total) exceeds Euro 100, Euro 300, or Euro 600, discounts of 5%, 10%, and 12% apply, respectively. Display the discount amount (see screenshot below) and update the DiscountAmount node in the XML document.
- 2. Create an Auto-Calculation that calculates the discounted bill amount. This amount would be the price total less the discount amount (as calculated in the previous Auto-Calculation). Display the bill amount (see screenshot below) and update the BillAmount node in the XML document.

Set up these components so that the Authentic View output is as shown in the screenshot below.

Price Total:	€	358.90	Volume Discounts
Less Volume Discount:	€	35.89	Over € 100 = 05% Over € 300 = 10%
Bill Amount:	€	323.01	Over € 600 = 12%

You can see these two additional Auto-Calculations in the file InvoiceWithDiscounts.sps, which is in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

 ${\tt Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Auto-Calculations} \ \textbf{folder}.$

7.2 Conditions

You can insert conditions anywhere in the design, in both the main template and global templates. A condition is an SPS component that is made up of one or more branches, with each branch being defined by an XPath expression. For example, consider a condition composed of two branches. The XPath expression of the first branch tests whether the value of the Location attribute of the context node is "US". The XPath expression of the second branch tests whether the value of the Location attribute is "EU". Each branch contains a template —a condition template. When a node is processed with a condition, the first branch with a test that evaluates to true is executed, that is, its condition template is processed, and the condition is exited; no further branches of that condition are evaluated. In this way, you can use different templates depending on the value of a node. In the example just cited, different templates could be used for US and EU locations.

This section consists of the following topics:

- Setting Up the Conditions 381, which describes how to create a condition and its branches.
- Editing Conditions (382), about how to edit the XPath expressions of condition branches after they have been created.
- <u>Conditions for Specific Outputs</u> (385), which shows how conditions are used to produce different output for different output formats.
- <u>Conditions and Auto-Calculations</u> (388), explains usage issues when conditions and Auto-Calculations are used in combination.

7.2.1 Setting Up the Conditions

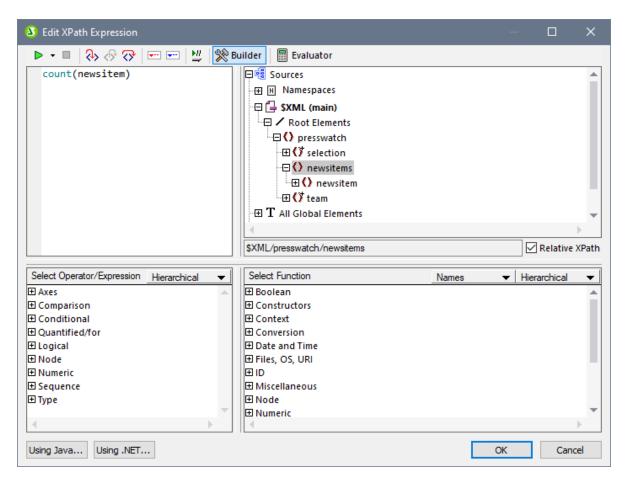

Setting up the condition consists of the following steps:

- 1. Create the condition with its first branch.
- 2. Create additional branches for alternative processing.
- 3. Create and edit the templates within the various branches of the condition.

Creating the condition with its first branch

Set up a condition as follows:

1. Place the cursor anywhere in the design or select a component and then select the menu command Insert | Condition. The Edit XPath Expression dialog pops up (screenshot below).

- 2. In the Expression pane, enter the XPath expression for the condition branch via the keyboard. Alternatively, enter the expression by double-clicking nodes, operators, and/or functions in the panes of the dialog. It is important to be aware of the context node at the insertion point; the context node is highlighted in the schema sources tree when the dialog pops up.
- 3. Click **OK** to finish. The condition is created with its first branch; the XPath expression you entered is the XPath expression of the first branch. If the condition was inserted at a text insertion point, the first branch is empty (there is no template within it; see screenshot below). If the condition was inserted with a component selected, the condition is created around the component, and that component becomes the template of the first branch.

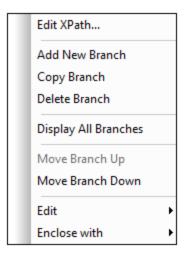

To select the entire condition, click the cell with the question mark. To select the first branch, click the cell with the number one.

After creating a condition with one branch (which may or may not have a template within it), you can create as many additional branches as required.

Creating additional branches

Additional branches are created one at a time. An additional branch is created via the context menu (screenshot below) and can be created in two ways: (i) without any template within it (Add New Branch); and (ii) with a copy of an existing template within the new branch (Copy Branch).

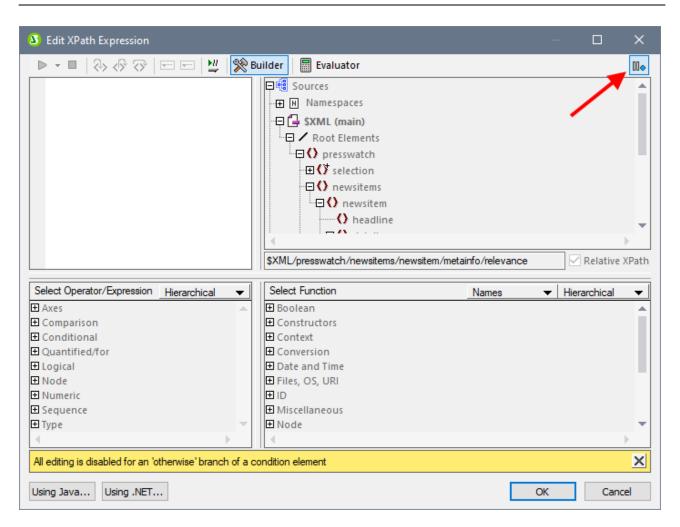

To create a new branch, right-click any branch of the condition and select **Add New Branch** from the context menu. The <u>Edit XPath Expression dialog</u> will pop up. After entering an XPath expression and clicking **OK**, a new empty branch is added to the condition. This is indicated in the design by a new cell being added to the condition; the new cell has a number incremented by one over the last branch prior to the addition.

To create a copy of an existing branch, right-click the branch of the condition you wish to copy and select **Copy Branch**. The <u>Edit XPath Expression dialog</u> will pop up, containing the XPath expression of the branch being copied. After modifying the XPath expression and clicking **OK**, a new branch is added to the condition. The new branch contains a copy of the template of the branch that was copied. The new branch is indicated in the design by a new cell with a number incremented by one over the last branch prior to the addition.

The Otherwise branch

The <code>Otherwise</code> branch is an alternative catch-all to specify a certain type of processing (template) in the event that none of the defined branches evaluate to <code>true</code>. Without the <code>Otherwise</code> branch, you would either have to create branches for all possible eventualities or be prepared for the possibility that the conditional template is exited without any branch being executed.

To insert an otherwise branch, use either the **Add New Branch** or **Copy Branch** commands as described above, and in the <u>Edit XPath Expression dialog</u> or click the *Otherwise* check box (see screenshot below).

Moving branches up and down

The order of the branches in the condition is important, because the first branch to evaluate to true is executed and the condition is then exited. To move branches up and down relative to each other, select the branch to be moved, then right-click and select **Move Branch Up** or **Move Branch Down**.

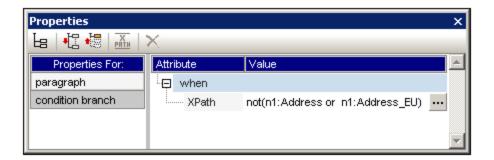

Deleting a branch

To delete a branch, select the branch to be deleted, then right-click and select **Delete Branch**.

7.2.2 Editing Conditions

To edit the XPath expression of a condition branch, do the following:

- 1. Select the condition branch (not the condition).
- 2. In the Properties sidebar, select condition branch in the Properties For column (screenshot below).

3. Click the **Edit** button of the XPath property in the *When* group of properties. This pops up the <u>Edit</u> XPath Expression dialog (917), in which you can edit the XPath expression for that branch of the condition.

7.2.3 Output-Based Conditions

Individual components in the document design can be processed differently for StyleVision's different output formats (Authentic View, RTF, PDF, Word 2007+, Text and HTML). For example, consider the case where you wish to create a link, which, in Authentic View should point to a file on a local system, but in the HTML output should point to a Web page. In this case, you can create one condition to process content for Authentic View output and a second condition to process content for HTML output. Or consider the case where you want some text to be included in the Authentic View output but not in the HTML output. A condition could be created with a branch for processing Authentic View output, and no branch for HTML output.

Note: Conditions for specific output can be placed around individual parts or components of the document, thus providing considerable flexibility in the way the different output documents are structured.

Creating conditions for specific output

To create conditions for specific output, do the following:

- 1. In Design View, select the component (or highlight the document part) which you wish to create differently for different output formats.
- 2. Right-click, and, from the context menu that pops up, select **Enclose with | Output-Based Condition**. This inserts the output condition with six branches, each having the same content (the selected component). Each branch represents a single output (Authentic View, RTF, PDF, Word 2007+, Text, or HTML). To determine which branch represents which output, mouseover the branch tag or check the XPath expression of the selected branch (in the Properties sidebar, in the Condition Branch entry, click the Edit button 334).
- 3. Within each branch, define the required processing. If you wish not to have any processing for a particular output format, then delete the branch for that format (select the branch and press **Delete**, or select the branch and in the (right-click) context menu select **Delete Branch**).

Note: The output-based condition can also be created first and (static and/or dynamic) content for each branch inserted later. First insert the output-based condition at a cursor insertion point in the design. Then within the respective branches, insert the required static and/or dynamic content.

Editing the branches of an Output-Based Condition

The XPath expression of a branch of an output-based condition is \$SV_OutputFormat = 'format', where format is one of the values: Authentic, RTF, PDF, Word 2007+, Text, or HTML. You can edit the XPath expression of a condition branch (in the Properties sidebar, in the Condition Branch entry, click the Edit button 334). For example, you could combine the Authentic View and HTML output formats in one condition branch (using the XPath expression: \$SV OutputFormat = 'Authentic' or \$SV OutputFormat = 'HTML').

You can also (a) delete one or more branches; (b) create an otherwise branch in a condition; and (c) move the branches up or down relative to each other, thus changing the relative priority of the branches. For information on how to carry out these actions, see <u>Setting Up the Conditions</u> and <u>Editing Conditions</u> 334.

Using the \$SV OutputFormat parameter

In the XSLT file generated for each output, \$SV_OutputFormat is created as a global parameter and assigned the value appropriate to that output format (that is, Authentic, RTF, PDF, Word 2007+, Text, or HTML). This parameter can be overridden by passing another value for it to the processor at runtime. This could be useful, if, for example, you wish to create two alternative HTML output options, one of which will be selected at runtime. You could then create condition branches \$SV_OutputFormat = 'HTML-1' and \$SV_OutputFormat = 'HTML-2'. At runtime you could pass the required parameter value (HTML-1 or HTML-2) to the processor.

7.2.4 Conditions and Auto-Calculations

When using Conditions and Auto-Calculations together, there are a few issues to bear in mind. The two most fundamental points to bear in mind are:

- Only Auto-Calculations in visible conditions—that is the branch selected as true—are evaluated.
- Auto-Calculations are evaluated before Conditions.

Here are a few guidelines that summarize these issues.

- 1. If an Auto-Calculation updates a node, and if that node is involved in a Condition (either by being in the XPath expression of a branch or in the content of a conditional template), then keep the Auto-Calculation outside the condition if possible. This ensures that the Auto-Calculation is always visible—no matter what branch of the condition is visible—and that the node will always be updated when the Auto-Calculation is triggered. If the Auto-Calculation were inside a branch that is not visible, then it would not be triggered and the node not updated.
- 2. If an Auto-Calculation must be placed inside a condition, ensure (i) that it is placed in every branch of the condition, and (ii) that the various branches of the condition cover all possible conditions. There should be no eventuality that is not covered by a condition in the Conditional Template; otherwise there is a risk (if the Auto-Calculation is not in any visible template) that the Auto-Calculation might not be triggered.
- 3. If you require different Auto-Calculations for different conditions, ensure that all possible eventualities for every Auto-Calculation are covered.
- 4. Remember that the order in which conditions are defined in a conditional template is significant. The first condition to evaluate to true is executed. The otherwise condition is a convenient catch-all for non-specific eventualities.

Advanced Features Conditional Presence 387

7.3 Conditional Presence

The Conditional Presence feature enables you to create certain design components if a specified condition is fulfilled. The design components that can be created conditionally are:

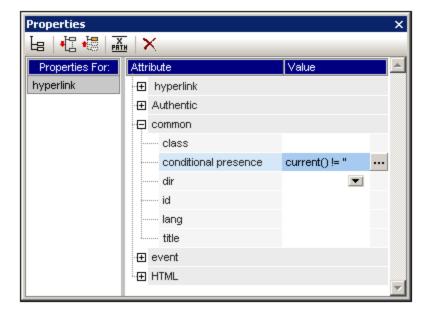

- Hyperlinks 442
- Bookmarks

 440
- New Documents 363
- <u>User-Defined Elements</u> 146
- TOC Levels 416

Specifying conditional presence

To specify that one of these design components be created conditionally and to set the required condition, do the following:

- 1. Select the design component.
- 2. In the *Common* group of properties in the Properties sidebar of that design component (*screenshot below*), click the Edit XPath icon of the *Conditional Presence* property.

- 3. In the <u>Edit XPath Expression dialog</u> that pops up, enter the XPath expression that is required as the condition to be fulfilled in order for the design component to be implemented in the output.
- 4. Click OK to finish.

Note: When the condition is fulfilled, the design component is implemented. Otherwise it is not, but all content of the design component is output—without the presence of that design component. For example, in the screenshot above, a hyperlink is created to be conditionally present. The condition tests whether the current node is not empty. If the node is not empty, then the condition test evaluates to true and the hyperlink is created. The text of the hyperlink text is derived from the content of the Hyperlink design component. (The URL of the hyperlink is specified elsewhere, in the *Hyperlink* group of properties.) If the condition test evaluates to false, then the Hyperlink text (derived from the Hyperlink design component) is output, but as plain text and not as a hyperlink.

388 Advanced Features Conditional Presence

In the same way, in the case of the other design components that can be conditionally created, it is the design component itself that is conditionally created or not. The content of the design component is created in either event (whether the condition test evaluates to true or false).

7.4 Grouping

The grouping functionality is available in **XSLT 2.0 and 3.0** SPSs and for HTML, Text, RTF, PDF, and Word 2007+ output. **Grouping is not supported for Authentic View output.**

Grouping enables items (typically nodes) to be processed in groups. For example, consider an inventory of cars, in which the details of each car is held under a car element. If, for example, the car element has a brand attribute, then cars can be grouped by brand. This can be useful for a variety of reasons. For example:

- All cars of a single brand can be presented together in the output, under the heading of its brand name.
- Operations can be carried out within a group and the results of that operation presented separately for each group. For example, the number of models available for each brand can be listed.

Additionally, a group can be further processed in sub-groups. For example, within each brand, cars can be grouped by model and then by year.

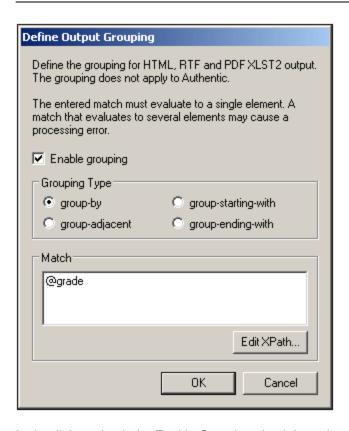

Grouping criteria

Items can be grouped using two general criteria: (i) a grouping key, which typically tests the value of a node, and (ii) the relative position of items. The following specific grouping criteria are available:

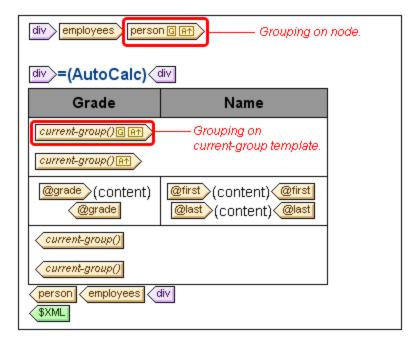

- *group-by*, which groups items on the basis of an XPath-defined key. For example, car elements can be grouped on the basis of their brand attributes. The grouping is set on the car element, and an XPath expression selects the brand attribute.
- **group-adjacent** uses a combination of grouping-key and position criteria. All adjacent items that have the same value for the grouping key are included in one group. If the grouping-key value of an item is different from that of the previous item, then this item starts a new group.
- **group-starting-with** starts a new group when a node matches a defined XPath pattern. If a node does not match the defined XPath pattern, then it is assigned to the current group.
- **group-ending-with** ends a group when a node matches a defined XPath pattern; the matching node is the last in that group. The next node starts a new group. If a node subsequent to that which starts a group does not match the defined XPath pattern it is assigned to the current group.

Creating groups

Groups can be created on either a node or a current-group template via the context menu. To create a group, right-click the node or current-group template, and in the context menu that appears, select the **Group by** command. This pops up the Define Output Grouping dialog (*screenshot below*).

In the dialog, check the Enable Grouping check box, then select the required Grouping Type and, in the Match text box, enter the XPath expression that defines the grouping key (for the *group-by* and *group-adjacent* options) or the desired match pattern (for the *group-starting-with* and *group-ending-with* options). When you click **OK**, a dialog pops up asking whether you wish to sort the group-set alphabetically (in ascending order). You can always sort group-sets subsequently or remove such sorting subsequently. The screenshot below shows nodes and current-group templates which have had grouping added to them.

In the screenshot above, the person node has been grouped and the resulting groups sorted. For example if the person elements have been grouped by department, then the various departments can be sorted in alphabetically ascending order. The groups thus created have been further grouped by creating grouping on the current-group() template. In this way person elements can be grouped, say, first by department, and then by employment grade.

Sorting groups

After confirming a grouping definition, a pop-up asks you to confirm whether the groups should be sorted in ascending order or not. You can set sorting subsequently at any time, or modify or delete, at any time, the sorting set at this stage.

To set, modify, or delete sorting subsequently, right-click the required grouping template and select **Sort by**. This pops up the <u>Define Output Sort Order dialog</u> ³⁹⁷. How to use this dialog is described in the section <u>Sorting</u> ³⁹⁷. The important point to note is that to sort groups on the basis of their grouping-key, you must select the XPath function <code>current-grouping-key()</code> as the sorting key. For examples, see the files described in the following sections.

Viewing and editing grouping and sorting settings

To view and edit the grouping and sorting settings on a template, right-click the template and select Group by or Sort by, respectively. This pops up the respective dialog, in which the settings can be viewed or modified.

User-defined templates

<u>User-defined templates</u> are templates that are applied to items selected by an XPath expression you specify. The nodes selected by the XPath expression of a user-defined template can also be grouped. In this case, the grouping is applied on the user-defined template.

7.4.1 Example: Group-By (Persons.sps)

The Persons.sps example is based on the Persons.xsd schema and uses Persons.xml as its Working XML File. It is located in the (My) Documents folder (33), C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Grouping\Persons\. The XML document structure is as follows: an employees document element can contain an unlimited number of person employees. Each person employee is structured according to this example:

```
<person first="Vernon" last="Callaby" department="Administration" grade="C"/>
```

In the design we group persons according to department. Each department is represented by a separate table and the departments are sorted in ascending alphabetical order. Within each department table, persons are grouped according to grade (sorted in ascending alphabetical order) and, within each grade, persons are listed on in ascending alphabetical order of their last names.

Strategy

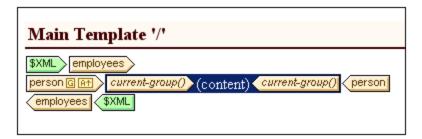

The strategy for creating the groups is as follows. The grouping is created on the person element with the department attribute being the grouping-key. This causes the person elements to be ordered in groups based on the value of the department attribute. (If sorting is specified, then the department groups can be organized in alphabetical order, for example, Administration first, and so on.) Since the departments are to be created as

separate tables, the current-grouping (which is based on the department grouping-key) is created as a table. Now, within this grouped order of Person elements, we specify that each group must be further ordered with the grade attribute as the grouping-key.

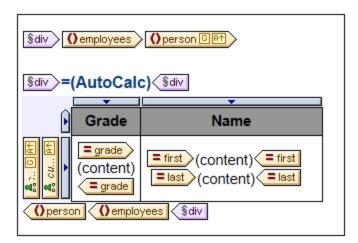

Creating the SPS

The design was created as follows:

- 1. Drag the person element from the schema tree and create it as contents.
- 2. Right-click the person element tag and, in the context menu, select Group by.
- 3. In the Define Output Grouping dialog, select *group-by*, set the XPath expression in the Match text box to @department, and click **Yes**.
- 4. A dialog pops up asking whether the groups should be sorted. Since we wish the groups to be sorted according to the default ascending alphabetical sorting, click **OK**. (Sorting can always be set, modified, or deleted subsequently.)
- 5. Since each group (which is a department) is to be created in a separate table, create the current group as a table. Do this by right-clicking the current-group() tag (screenshot below), and selecting Change to | Table, selecting the child attributes @last and @grade as the columns of the table.

- 6. Re-organize the contents of the columns and cells of the table so that the first column contains <code>@grade</code> and the second column contains the <code>@first</code> and <code>@last</code> nodes (see screenshot below).
- 7. Within the current group, which is grouped by department, we wish to group by grade. So on the current-group() template, create a grouping for the grade attribute. Confirm the default sorting. A new current-group() template is created (see screenshot below).
- 8. Sort this current group (which is the sub-group of persons and grouped by grade), on the last attribute.

9. Set formatting for the table.

10. Above the table provide a heading for the table. Since each table represents a department, the name of the department can be dynamically obtained from the current context by using an Auto-Calculation with an XPath expression that calls the current-grouping-key() function of XPath 2.0/3.0.

11. Repeat the entire process, to create similar output, but this time grouping persons by grade and then by department.

To view or modify the grouping or sorting of a template, right-click that template and select **Group by** or **Sort by** from the context menu. This pops up the respective dialog, in which the settings can be viewed or modified.

7.4.2 Example: Group-By (Scores.sps)

The Scores.sps example is based on the Scores.xsd schema and uses Scores.xml as its Working XML File. It is located in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Grouping\Scores\. The XML document structure is as follows: a results document element contains one or more group elements and one or more match elements. A group element contains one or more team elements, and a match element is structured according to this example:

The design consists of three parts (*screenshot below*): (i) the match results presented by day (grouped on //match/@date); (ii) the match results presented by group (grouped on //match/@group); and (iii) group tables providing an overview of the standings by group (a dynamic table of the group element, with Auto-Calculations to calculate the required data).

Match Results: Day-by-Day

2007-10-12

Brazil - Germany 2 - 1 Italy - Holland 2 - 2

2007-10-13

Argentina - France 2 - 0 England - Spain 0 - 0

Match Results: By Group

Group A

Group Tables

Group A

Team	Р	w	D	L	F	Α	Pts
Brazil	3	2	0	1	4	3	6
Italy	3	1	2	0	5	4	5
Germany	3	0	2	1	4	5	2
Holland	3	0	2	1	4	5	2

Strategy

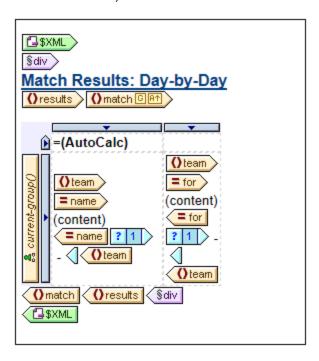

For the two sections containing the match results, we group matches by date and tournament-group. For members of each group (date and tournament group), we create borderless tables (for alignment purposes). So matches played on a single date will be in a separate table, and all the match results of a single tournament

group will be in a separate table (for example, Group A matches). For the group-tables section, the group element is created as a dynamic table, with Auto-Calculations providing the value of the required data.

Creating the SPS

The design was created as follows:

- 1. Drag the /results/match element from the schema tree and create it as contents.
- 2. Right-click the match element tag and, in the context menu, select Group by.
- 3. In the Define Output Grouping dialog, select *group-by*, set the XPath expression in the Match text box to @date, and click **OK**.
- 4. A dialog pops up asking whether the groups should be sorted. Since we wish the groups to be sorted according to the default ascending alphabetical sorting, click **Yes**. (Sorting can always be set, modified, or deleted subsequently.)
- 5. Since each group (which is a date) is to be created in a separate table, create the current group as a table. Do this by right-clicking the current-group() tag, selecting Change to | Table, and then selecting the descendant nodes team/@name and team/@for as the columns of the table (see screenshot below).

- 6. Set a hyphen in each cell that will be output if the match is not the last in the current group. Do this by using a conditional template with a condition set to position() != last(). This provides output such as: Brazil Germany or 2 1.
- 7. Put an Auto-Calculation in the header that outputs the current grouping key for the respective group (XPath expression: current-grouping-key()).
- 8. Format the table as required.
- 9. To group the matches by tournament group, repeat the entire process, but group matches this time on the group attribute of match.
- 10. For the group tables (in the third section of the design), which contain the standings of each team in the group, create the /results/group element as a dynamic table. Add columns as required (using the **Table | Append Column** or **Table | Insert Column** commands). Set up Auto-Calculations in each column to calculate the required output (3 point for a win; 1 point for a draw; 0 points for a loss).

And, finally, sort the table in descending order of total points obtained. To see the XPath expressions used to obtain these results, right-click the Auto-Calculation or sorted template, and select, respectively, the **Edit XPath** and **Sort by** commands.

7.5 Sorting

The sorting functionality is available for HTML, Text, RTF, PDF, and Word 2007+ output. **Sorting is not supported for Authentic View output.**

A set of sibling element nodes of the same qualified name can be sorted on one or more sort-keys you select. For example, all the Person elements (within, say, a Company element) can be sorted on the LastName child element of the Person element. The sort-key must be a node in the document, and is typically a descendant node (element or attribute) of the element node being sorted. In the example mentioned, LastName is the sort-key.

If there are two elements in the set submitted for sorting that have sort-key nodes with the same value, then an additional sort-key could provide further sorting. In the Person example just cited, in addition to a first sort-key of LastName, a second sort-key of FirstName could be specified. So, for Person elements with the same LastName value, an additional sort could be done on FirstName. In this way, in an SPS, multiple sort instructions (each using one sort-key) can be defined for a single sort action.

The template is applied to the sorted set and the results are sent to the output in the sorted order. Sorting is supported in the HTML, Text, RTF, PDF, and Word 2007+ output.

User-defined templates

<u>User-defined templates</u> are templates that are applied to items selected by an XPath expression you specify. The nodes selected by the XPath expression of a user-defined template can also be sorted. In this case, the sorting is applied on the user-defined template.

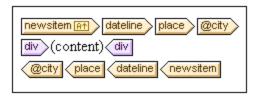

In this section

- The sorting mechanism (397) is described.
- An <u>example</u> ³⁹⁹ demonstrates how sorting is used.

7.5.1 The Sorting Mechanism

Setting up a schema element node for sorting consists of two steps:

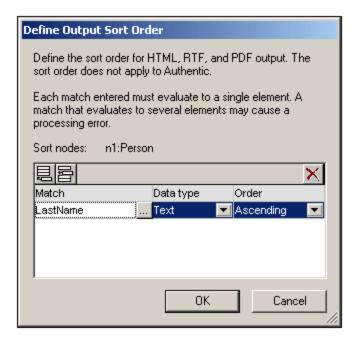

1. In Design View, select the schema element node that is to be sorted. Note that it is the instances of **this** element in the XML document that will be sorted. Often it might not immediately be apparent which element is to be sorted. For example, consider the structure shown in the screenshot below.

Each newsitem has a dateline containing a place element with a city attribute. The @city nodes of all newsitem elements are to be output in alphabetical order. In the design, should the @city node be

selected for sorting, or the place, dateline, or newsitem elements? With @city selected, there will be only the one city node that will be sorted. With place or dateline selected, again there will be just the one respective element to sort, since within their parents they occur singly. With newsitem selected, however, there will be multiple newsitem elements within the parent newsitems element. In this case, it is the newsitem element that should be sorted, using a sort-key of dateline/place/@city.

2. After selecting the element to sort, in the context menu (obtained by right-clicking the element selection), click the **Sort Output** command. This pops up the Define Output Sort Order dialog (*screenshot below*), in which you insert or append one or more sort instructions.

Each sort instruction contains: (i) a sort-key (entered in the Match column); (ii) the datatype that the sort-key node should be considered to be (text or number); (iii) and the order of the sorting (ascending or descending). The order in which the sort instructions are listed is significant. Sorting is carried out using each sort instruction in turn, starting with the first, and working down the list when multiple items have the same value. Any number of sort instructions are allowed.

For an example of how sorting is used, see Example: Sorting on Multiple Sort-Keys 399.

User-defined templates

<u>User-defined templates</u> are templates that are applied to items selected by an XPath expression you specify. The nodes selected by the XPath expression of a user-defined template can also be sorted. In this case, the sorting is applied on the user-defined template.

A note about sort-keys

The XPath expression you enter for the sort-key must select a **single node** for each element instance—not a nodeset (XPath 1.0) or a sequence of items (XPath 2.0 and XPath 3.0); the key for each element should be resolvable to a string or number value.

In an **XSLT 2.0 or 3.0** SPS, if the sort-key returns a sequence of nodes, an **XSLT** processing error will be returned. So, in the Person example cited above, with a context node of Person, an **XP**ath expression such

as: .../Person/LastName would return an error because this expression returns all the LastName elements contained in the parent of Person (assuming there is more than one Person element). The correct XPath expression, with Person as the context node, would be: LastName (since there is only one LastName node for each Person element).

In **XSLT 1.0**, the specification requires that when a nodeset is returned by the sort-key selector, the text value of the first node is used. StyleVision therefore returns no error if the XPath expression selects multiple nodes for the sort-key; the text of the first node is used and the other nodes are ignored. However, the first node selected might not be the desired sort-key. For example, the XPath expression ../Person/LastName of the example described above would not return an error. But neither would it sort, because it is the same value for each element in the entire sort loop (the text value of the first LastName node). An expression of the kind: location/@*, however, would sort, using the first attribute of the location child element as the sort-key. This kind of expression, however, is to be avoided, and a more precise selection of the sort-key (selecting a single node) is advised.

7.5.2 Example: Sorting on Multiple Sort-Keys

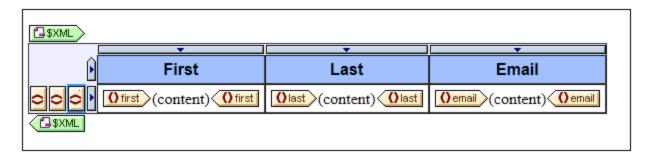

In the simple example below (available in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Sorting\SortingOnTwoTextKeys. sps), team-members are listed in a table. Each member is listed with first name, last name, and email address in a row of the table. Let us say we wish to sort the list of members alphabetically, first on last name and then on first name. This is how one does it.

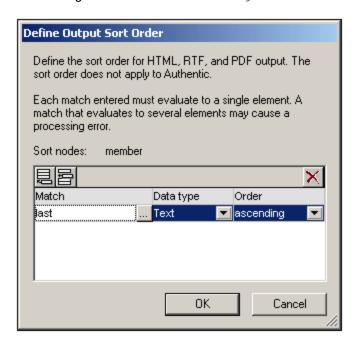

When the list is unsorted, the output order is the order in which the member elements are listed in the XML document (*screenshot below, which is the HTML output*).

First	Last	Email
Andrew	Bentinck	a.bentinck@nanonull.com
Nadia	Edwards	n.edwards@nanonull.com
John	Edwards	j.edwards@nanonull.com
Janet	Ashe	j.ashe@nanonull.com

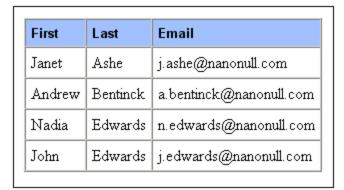

In Design View, right-click the member element (highlighted blue in screenshot below), and from the context menu that appears, select the **Sort Output** command.

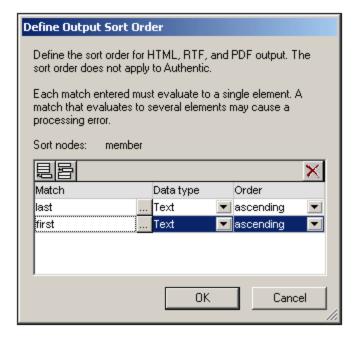

This pops up the Define Output Sort Order dialog (*screenshot below*). Notice that the element selected for sorting, member, is named at the Sort Nodes entry. This node is also the context node for XPath expressions to select the sort-key. Click the Add Row button (at left of pane toolbar) to add the first sort instruction. In the row that is added, enter an XPath expression in the Match column to select the node last. Alternatively, click the Build button to build the XPath expression. The Datatype column enables you to select how the sort-key content is to be evaluated: as text or as a number. The Order column lists the order of the sort: ascending or descending. Select Text and Ascending. Click **OK** to finish.

In Design View, the member tag displays an icon indicating that it contains a sort filter member list, sorted on last name, is shown below. Notice that the two Edwards are not alphabetically sorted (Nadia is listed before John, which is the order in the XML document). A second sort-key is required to sort on first name.

In Design View, right-click the member tag and select the **Sort Output** command from the context menu. The Define Output Sort Order dialog pops up with the last sort instruction listed. To add another sort instruction, append a new row and enter the first element as its sort-key (*screenshot below*). Click **OK** to finish.

In the HTML output, the list is now sorted alphabetically on last name and then first name.

7.6 Parameters and Variables

Parameters and variables can be declared and referenced in the SPS. The difference between the two is that while a variable's value is defined when it is declared, a parameter can have a value passed to it (at run-time via the command line) that overrides the optional default value assigned when the parameter was declared.

In this section, we describe the functionality available for parameters and variables:

- <u>User-Declared Parameters</u> explains how user-defined parameters can be used in an SPS.
- Parameters for Design Fragments describes how parameters can be used with design fragments.
- SPS Parameters for Sources are a special type of parameter. They are automatically defined by StyleVision for schema sources (specifically, the Working XML Files of schemas). Since the name and value of such a parameter are known to the user, the parameter can be referenced within the SPS and a value passed to it at run-time from the command line.
- <u>Variables</u> enable you to: (i) declare a variable with a certain scope and define its value, and (ii) to reference the value of declared variables and create a template on a node or nodes selected by the variable.
- Editable Variables in Authentic 410 allow the Authentic View user to edit variables and consequently to control the display of content in Authentic View.

7.6.1 User-Declared Parameters

In an SPS, user-declared parameters are declared globally with a name and a default string value. Once declared, they can be used in XPath expressions anywhere in the SPS. The default value of the parameter can be overridden for individual XSLT transformations by passing the XSLT stylesheet a new global value via StyleVision Server.

Use of parameters

User-declared parameters are useful in the following situations:

- If you wish to use one value in multiple locations or as an input for several calculations. In this case, you can save the required value as a parameter value and use the parameter in the required locations and calculations.
- If you wish to pass a value to the stylesheet at processing time. In the SPS (and stylesheet), you use
 a parameter with a default value. At processing time, you pass the desired value to the parameter via
 StyleVision Server.

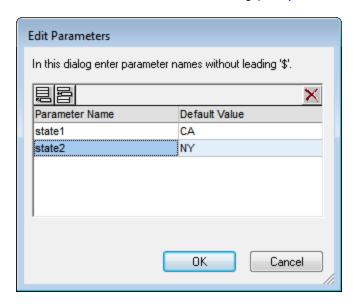

Usage mechanism

Working with user-declared parameters in the SPS consists of two steps:

- 1. <u>Declaring the required parameters</u> 404.
- 2. Referencing the declared parameters 404.

Declaring parameters

All user-defined parameters are declared and edited in the Edit Parameters dialog (*screenshot below*). The Edit Parameters dialog is accessed via: the <u>Edit | Stylesheet Parameters</u> command and the **Parameters** button in the Edit Database Filters dialog (<u>Edit | Edit DB Filter</u> 1048).

Declaring a parameter involves giving it a name and a string value—its default value. If no value is specified, the default value is an empty string.

To declare a parameter, do the following:

- 1. In the Edit Parameters dialog, append or insert a new parameter by clicking the Append or Insert buttons. A new line appears.
- 2. Enter the name of the parameter. Parameter names must begin with a letter, and can contain the characters A to Z, A to A, A to A to A, A to A.
- 3. Enter a default value for that parameter. The value you enter is accepted as a text string.

You can insert any number of parameters and modify existing parameters at any time while editing either the SPS or Authentic View.

Note:

- The Edit Parameters dialog contains all the user-defined parameters in an SPS.
- Parameters can also be declared in the <u>Design Overview sidebar</u> 45.

Referencing declared parameters

Parameters can be referenced in XPath expressions by prefixing a \$ character before the parameter name. For example, you could reference a parameter in the XPath expression of an Auto-Calculation (e.g. concat('www.', \$company, '.com')). If your SPS is DB-based, then you can also use parameters as the values of DB Filter criteria. The DB parameters, however, are declared and edited in the Edit Parameters dialog of DB Filter criteria.

Note: While it is an error to reference an undeclared parameter, it is not an error to declare a parameter and not reference it.

7.6.2 Parameters for Design Fragments

Parameters for Design Fragments enable you to define a parameter on a design fragment you have created and to give this parameter a default value. At each location where this design fragment is used in the design, you can enter a different parameter value, thus enabling you to modify the output of individual design fragments.

For example, a design fragment named EMailAddresses can be created with a parameter named Domain that has a default value of altova.com. Now, say this parameter is used in an Auto-Calculation in the design fragment to generate the email addresses of company employees. For the EU addresses, we could use the design fragment EmailAddresses and edit the value of the Domain parameter to be altova.eu. In the same way, in the template for Japanese employees, we could edit the value of the Domain parameter to be altova.jp. For the US employees of the company, we could leave the parameter value of Domain unchanged, thus generating the default value of altova.com.

Using parameters for design fragments consists of two parts:

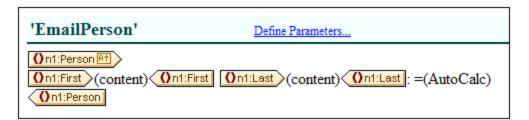

- 1. <u>Defining the parameter</u> 405 with a default value on the design fragment where it is created.
- 2. Editing the parameter value 400 where the design fragment is used.

These parts are explained in detail below.

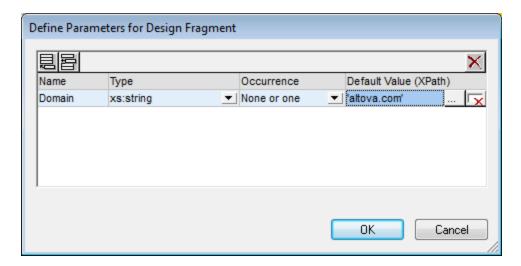

Note: Parameters for Design Fragments are supported in Authentic View only in the Enterprise Editions of Altova products.

Defining the parameter

Each design fragment can be assigned any number of parameters. To do this, click the Define Parameters link in the title bar of the design fragment (see screenshot below).

This pops up the Define Parameters for Design Fragments dialog (*screenshot below*). Click the **Append** or **Insert** icon at top left to add a parameter entry line. Enter or select the name, datatype, number of occurrences, and default value of the parameter. The *Occurrence* attribute of the parameter specifies the number of items returned by evaluating the XPath expression specified as the default value of the parameter. The *Occurrence* attribute is optional and is, by default, none or one. You can add as many parameters as you like.

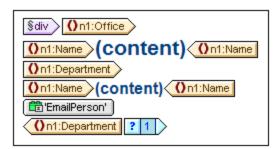

There are two types of **Delete** icon. The Delete icon to the right of each parameter entry deletes the default value of that parameter. The **Delete** icon at the top right of the pane deletes the currently highlighted parameter.

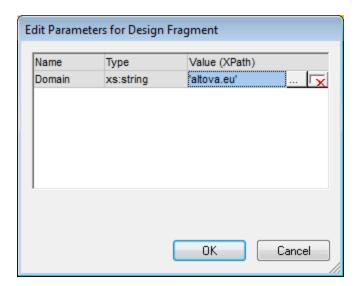

Note: If the SPS uses XSLT 1.0, then the XPath expression you enter must return a node-set. Otherwise an error is reported.

Using the parameter

After a design fragment has been created, it can be inserted at multiple locations in the design (by dragging it from the Design Tree or Schema Tree). The screenshot below shows the design fragment EmailPerson, inserted after the n1:Name element.

If a parameter has been defined for this design fragment, then its value can be edited for this particular usage instance of the design fragment. Do this by right-clicking the design fragment and selecting the command **Edit Parameters**. This pops up the Edit Parameters for Design Fragments dialog (*screenshot below*).

You can edit the value of the parameter in this dialog. Click **OK** to finish. The new parameter value will be used in this usage instance of the design fragment. If the parameter value is not edited, the original (or default) parameter value will be used.

Note: If XSLT 1.0 is being used, then the XPath expression must return a node-set. Otherwise an error is reported.

7.6.3 SPS Parameters for Sources

An SPS can have multiple schema sources, where a schema could be a DTD or XML Schema on which an XML document is based, or an XML Schema that is generated from a DB and on which the DB is based.

In each SPS, there is one main schema, and, optionally, one or more additional schemas. When you add a new schema source, StyleVision automatically declares a parameter for that schema and assigns the parameter a value that is the URI of the Working XML File you assign to that schema. In the case of DBs, StyleVision generates a temporary XML file from the DB, and sets the parameter to target the document node of this temporary XML file.

Referencing parameters for sources

Each SPS parameter for a schema source addresses the document node of an XML file corresponding to that schema. In StyleVision, the XML file for each schema is the Working XML File or the XML file generated from a DB. SPS parameters for sources can therefore be used in two ways:

- 1. In XPath expressions within the SPS, to locate nodes in various documents. The parameter is used to identify the document, and subsequent locator steps in the XPath expression locate the required node within that document. For example, the expression: count (\$XML2//Department/Employee) returns the number of Employee elements in all Department elements in the XML document that is the Working XML File assigned to the schema source designated \$XML2.
- 2. On the command line, the URI of another XML file can be passed as the value of an SPS parameter for sources. Of course, the new XML file would have to be based on the schema represented by that parameter. For example, if FileA.xml and FileB.xml are both valid according to the same schema, and FileA.xml is the Working XML File assigned to a schema \$xml3 used in an SPS, then when an

XSLT transformation for that SPS is invoked from the command line, FileB.xml can be substituted for FileA.xml by using the parameter \$XML3="FileB.xml". You should also note that, on the command line, values should be entered for all SPS parameters for sources except the parameter for the main schema. The XML file corresponding to the main schema will be the entry point for the XSLT stylesheet, and will therefore be the XML file on which the transformation is run.

7.6.4 Variables

Using variables consists of two parts: (i) <u>declaring the variable</u> 408, and (ii) <u>using the variable</u> 410.

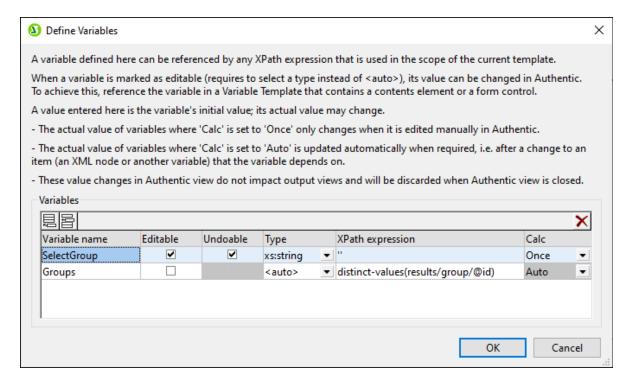

Note: Variables are supported in Authentic View only in the Enterprise Editions of Altova products.

Declaring a variable

A variable can be declared on any template included in the design. It is given a name, a datatype, and a value. Additionally, you can specify whether it is to be editable in the Enterprise editions of Authentic View. The variable will then be in scope on this template and can be used within it. To declare a variable so that it is in scope for the entire document, declare the variable on the root template. A major advantage of declaring a variable only on the template where it is needed is that XPath expressions to locate a descendant node will be simpler.

Declare a variable as follows:

- 1. Right-click the node template on which the variable is to be created and select the command **Define Variables**.
- 2. In the Define Variables dialog that appears (*screenshot below*), click the **Append Variable** icon in the top left of the Variables pane, then enter a variable name. The value of the variable is given via an XPath expression. If you wish to enter a string as the value of the variable (as in the first variable in the screenshot below), then enclose the string in quotation marks. In the screenshot below, the value of the SelectGroup variable is the empty string. Otherwise, the text will be read as a node name or a function-call.

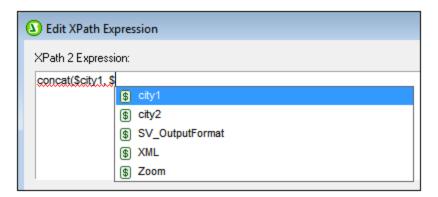

- 3. Setting a variable to Editable (by checking the *Editable* check box) enables the <u>variable to be edited in Authentic View</u> 10. In this case, you must also set the datatype value to the correct type, such as xs:string. When a variable is editable, the original value set by the SPS designer can be edited when the Authentic View user makes changes to the document in Authentic View. Such changes can be the explicit editing of the variable (such as when the variable value is created as editable (contents) or an editable text box and this is edited by the Authentic View user), or when a node or value used in the variable's XPath expression is modified by the Authentic View user.
- 4. If the variable is set to Editable, then two more options relevant to Authentic View are enabled: Undoable and Calc. Checking the Undoable option generates an Undo step for every change made to the variable. The Authentic View user can therefore click through the Undo cycle to retrieve an earlier value of the variable. The Calc value can be either Once or Auto. If this option is set to Once, the variable value is calculated once, when the template containing the variable is evaluated. The value can only be changed when the user explicitly edits the variable (for example, if the variable is created as editable (contents) or an editable text box). On the other hand, if this option is set to Auto, the variable will be re-calculated also each time a node or value used in the variable's XPath expression is modified.
- 5. You can add as many variables as you like, but the name of a variable must not be the name of an already declared in-scope variable. To delete a variable click the **Delete** icon in the top right of the pane.
- 6. Click **OK** when done. The template tag will now have a \$ icon to indicate that one or more variables have been declared on it.

In this way, variables can be created for each node template that is present in the design. Each of these variables will have a name and a value, and will be in scope within the template on which it was declared. To edit a variable subsequently, right-click the node template on which the variable was created and select the command **Define Variables** to access the Define Variables dialog.

Using a variable

For a variable to be used at any location, it must be in scope at that location. This means that a variable can only be used within the template on which it was defined. Variables can also be edited in Authentic View so that users can control the display. The edited value is discarded when the SPS is closed.

A variable can be used in any XPath expression, and is referenced in the XPath expression by prefixing its name with a \$ symbol. For example, the XPath expression \$VarName/Name selects the Name child element of the node selected by the variable named VarName.

When you enter an XPath expression in the <u>Edit XPath Expression dialog</u> in-scope variables appear in a pop-up (*see screenshot above*). Selecting a variable in the pop-up and pressing **Enter** inserts the variable reference in the expression.

7.6.5 Editable Variables in Authentic

Variables that are in scope can be edited in Authentic View by the Authentic View user to control the display in Authentic View. For example, if a very large XML document containing, say the personnel data of several branches of a company, is being used, the Authentic View user can be given the option of selecting one particular company branch. The Authentic View display of the XML document could in this way be restricted to the branch selected by the Authentic View user.

How it works

Three steps are involved in setting up editable variables in Authentic View (also see screenshot below):

- 1. The required variable is defined on the template within which it will be used. This template delimits the scope of the variable. The variable can only be used within the template on which it is in scope.
- 2. A User-Defined Template is created with the name of the variable. The dynamic content of this User-Defined Template will contain the value of the variable. If the (contents) placeholder or an input field is inserted in the design as the content of the User-Defined Template, then the Authentic View user can enter any content as the value of the variable. The options available to the Authentic View user can however be restricted by inserting a form control, such as a combo box, as the content of the User-Defined Template.
- 3. The variable can be used in an XPath expression to control the Authentic View display. For example, the variable can be used in a condition. Depending on the value of each branch of the condition, a

different display can be specified. Another mechanism where a variable can be well used is in a template match expression or template filter.

Note: Note the following points:

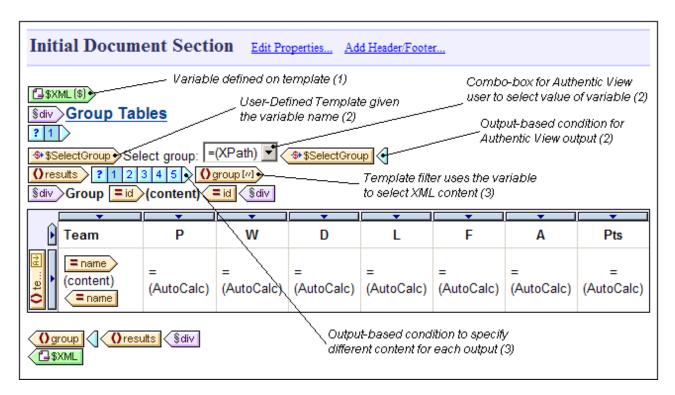

- Since grouping and sorting are not supported in Authentic View, editable variables in Authentic View cannot be used in an SPS containing any of these features.
- Since the editable variables feature applies only to Authentic View, the design for Authentic View will need to be different than that for the other outputs. This can be designed easily using the Output-Based Conditions (38) feature.

Example file

The file Authentic Variables.sps in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Grouping\Scores\, shows how editable variables in Authentic View can be used. The XML file contains the results of matches in a tournament. The teams participating in the tournament are divided into two groups. The editable variable enables the Authentic View user to select the group to be viewed and restrict the display to that group.

The screenshot below displays the entire SPS design. One editable variable is created and the different steps required to set it up are labeled in the screenshot below. A description of the actual steps is given below the screenshot.

The key steps in setting up the editable variable were as follows:

• On the \$xml template (the root template), an editable variable called <code>SelectGroup</code> is defined with a type of <code>xs:string</code>. This variable will be in scope for the entire template

• On the \$XML template, a non-editable variable alled Groups is defined with a type of <auto>. Its purpose is to dynamically collect the distinct values of all the results/group/@id attributes. These distinct values are planned to be displayed in the dropdown list of the combo box [288] from which the Authentic View user will select the group he or she wishes to have displayed.

- A <u>User-Defined Template</u> is created and given the name \$selectGroup (the name of the editable variable). The location of the User-Defined template does not matter as long as it is within the scope of the editable variable.
- Within this <u>User-Defined Template</u> (349), a combo box is inserted. The combo box uses the XPath expression \$Groups, 'All' to select the entry values of the dropdown list. This XPath expression returns the sequence of items contained in the variable \$Groups (which dynamically collects all the available groups), and adds an item All to the sequence returned by \$Groups. The All entry item of the combo box will be used to display all groups.
- The User-Defined Template is enclosed in an <u>output-based conditional template</u> with the output set for Authentic View. This is because the editable variable can only be used in Authentic View.
- The next step is to use the value of the editable variable that the Authentic View user selects. This will be used to filter the display down to the group that the Authentic View user selects. It is done by specifying a filter on the results/group template. The XPath expression of this filter is:

```
if ($SelectGroup != 'All') then @id=$SelectGroup else @id
```

This filter expression sets up a predicate step on the <code>group</code> element. If the <code>\$SelectGroup</code> variable has a value not equal to <code>All</code>, then the predicate step will be <code>[@id=X]</code>, where <code>X</code> is the value of the <code>\$SelectGroup</code> variable (that the Authentic View user selected in the combo box). This filter has the effect of selecting the group that has an <code>id</code> attribute with the value the Authentic View user selected. If the <code>\$SelectGroup</code> variable has a value of <code>All</code>, then the predicate expression will select groups with any <code>id</code> attribute value, that is, all groups.

• The group template is enclosed within an <u>output-based condition</u> (385), each branch of which selects a different output. Only in the Authentic View branch does the group template have the filter applied.

The Authentic View output will look like this:

Notice the entries in the combo box, the combo box selection of Group B, and the display limited to Group B.

7.7 Table of Contents, Referencing, Bookmarks

The Table of Contents (TOC) and other referencing mechanisms work by creating anchors at the required points in the design document and then referring back to these references from TOCs, text references, autonumbering sequences, and hyperlinks.

We will look briefly at the anchoring (or bookmarking) mechanism first and then look at the overall TOC mechanism. We do this because understanding the bookmarking mechanism first will provide a better understanding of the overall TOC mechanism.

The bookmarking mechanism

Two types of bookmarking mechanism are used: simple and complex. The complex bookmarking mechanism is the one used for creating TOCs.

- A simple bookmark is created at a point in the design document. The bookmark is given a unique name which is used as the target of links that point to it. This simple bookmarking mechanism is the mechanism used for the <u>Bookmarks and Hyperlinks</u> feature. (Note that hyperlinks can additionally point to URLs outside the document.)
- For more complex referencing, such as for TOCs and for the auto-numbering of document sections, building the bookmark involves two parts.
 - 1. The design document is structured into a hierarchy of levels required for the TOC. These levels are known as TOC levels. The structuring is achieved by assigning TOC levels to different points in the document structure. TOC levels can be nested within other TOC levels so as to give the document a hierarchical TOC structure. (For example, a TOC level can be assigned to a book chapter, and another TOC level can be assigned within that level to the sections of the chapter.)
 - 2. TOC bookmarks are created within the various TOC levels. These TOC bookmarks identify the document sections at various levels that are to go into the TOC. Additionally, each TOC bookmark must be defined to provide the text that will appear in the referencing component.

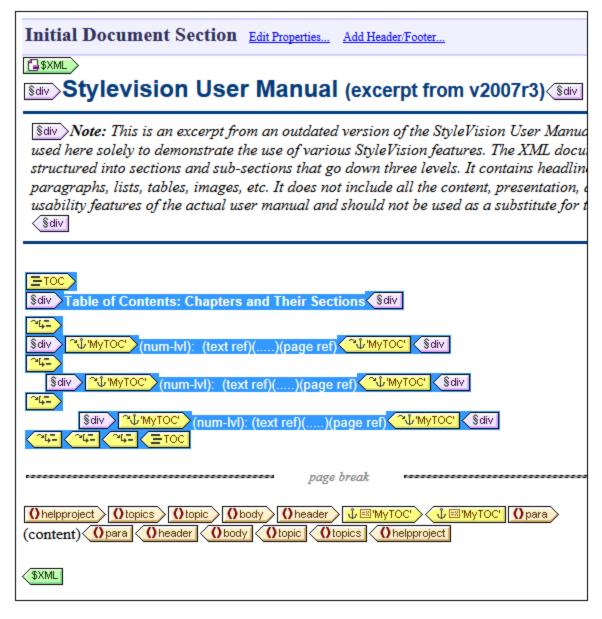

After the TOC levels and the TOC bookmarks' reference texts have been defined, the TOC template containing the referencing components can be designed.

The overall TOC mechanism is broadly described below, under <u>The TOC mechanism</u> 413. The various referencing features are explained in detail in the rest of this section.

The TOC mechanism

If you have selected XSLT 2.0 or XSLT 3.0 (not XSLT 1.0) as the XSLT version of your SPS, you can create a table of contents (TOC)—essentially a template for the TOC—at any location in the design.

- It is recommended that the items from the design that are to be included in and linked to from the TOC are bookmarked in the design first. These items can be static content or dynamic content. In the bottom half of the screenshot below, yellow TOC bookmark tags with the header tag indicates that the header item has been bookmarked (for inclusion in the TOC template).
- A <u>template is created for the TOC</u> (highlighted in screenshot below). The TOC template contains the design of the TOC; it can be located anywhere in the design. In the example shown in the screenshot below, the TOC template is located near the top of the document.

Note: Either of these two parts can be created first, or both parts can be created concomitantly. We recommend, however, that the TOC bookmarks are created before the TOC template.

The TOC is displayed in Authentic View and in the HTML, Text, RTF, PDF, and Word 2007+ output. Also note that: (i) TOCs can be created with a flat or a hierarchical structure (with corresponding numbering), and (ii) multiple TOCs can be created within a design. As a result, a stylesheet designer can create a document with, say, one (hierarchical) TOC at the book level and others (also hierarchical) at the chapter level, plus (flat) lists of figures and tables.

Procedure for creating TOCs

Given below is one step-by-step way of creating a TOC. Items are first bookmarked for inclusion. The TOC template is constructed after that. (Alternatively, you can create the TOC template first, and then bookmark items for inclusion. Or you can create the TOC template and select items for inclusion in parallel.)

- 1. Make sure that XSLT 2.0 110 is the selected XSLT version.
- 2. <u>Structure the document in TOC levels</u> If the TOC is to have multiple levels, structure the document design in a hierarchy of nested TOC levels. If the TOC is to have a flat structure (that is, one level only), then create at least one TOC level (in the document design) that will enclose the TOC bookmarks.
- 3. <u>Create one or more TOC bookmarks</u> within each level in the document design. The TOC bookmarks identify the components within each TOC level that are to appear in the TOC.
- 4. <u>Create a TOC template containing TOC level references (levelrefs)</u> The TOC template should have the required number of TOC level references (levelrefs). In the case of a multi-level TOC, the levelrefs in the TOC template should be nested (see screenshot above).
- 5. <u>Create TOC references (TOCrefs) in the TOC template</u> 120. In the TOC template, set up a TOCref for each levelref. Each TOCref will reference, by name, the TOC bookmarks within the corresponding TOC level in the document. Alternatively, the TOCref can reference TOC bookmarks in other levels.
- 6. Format the TOC items (423). Each text item in the TOC output is generated by a TOCref in the TOC template. TOCref definitions can specify item numbering (including hierarchical), the TOC item text, a leader, and, for paged media, a page number. Each TOCref and its individual parts can be formatted separately as required. (Note that automatic numbering can also be defined within a TOC bookmark in the main body of the document. See the section, Auto-Numbering (335), for details.)

Updating TOC page numbers in DOCX and RTF documents

When a user edits a DOCX or RTF output document in MS Word in such a way that the page count changes, it may happen that the TOC is not updated with the new page references. This is an MS Word issue. To update the page references in the TOC, press **Ctrl+A** to select everything, and then press **F9**. For more information, see here.

Terminology

The names of the main TOC-related components used in the interface are given in the table below. Components have been put in two different columns according to where they occur: in the **document body**, or in the **TOC template** (which is the template that specifies the design of the actual Table of Contents and typically occurs at the beginning of the document).

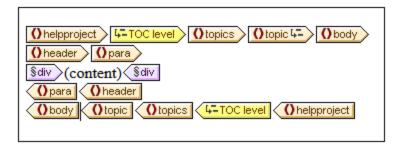

- The **TOC** components in the document body mark out items that will be used in the TOC template.
- The **TOC components in the TOC template** reference the marked items in the document body. Components in the TOC template have the word *'reference'* in their names.

Document body	TOC template
TOC level: The TOC levels structure the document in a nested hierarchy.	Level references (levelrefs): Correspond to the TOC-level structure defined in the document body. Enables TOCrefs in a given level to target TOC bookmarks at the corresponding level.
TOC bookmark: Has a name, with which it identifies a node in the document as a TOC item.	TOC references (TOCrefs): References a TOC bookmark by its name.

7.7.1 Bookmarking Items for TOC Inclusion

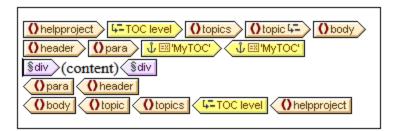

Bookmarking an item in the design for inclusion in a TOC consists of two steps, which can be done in any order:

1. Structuring the design document in a hierarchy of nested TOC levels 417. A TOC level can be created in the design either on a template or around a design component. In the screenshot below, a TOC level has been created on the topic template Otopic 4-2.

When a level is created on a template, this is indicated by the level icon inside the start tag of the template, for example, the level is created around a component it is indicated by TOC level tags template component is enclosed by a level. The difference between the two ways of marking levels is explained in the section structuring the Design in Levels the TOC template is created to the levels you have created in the design. Even for TOCs with a flat structure (one level), the design must have a corresponding level.

2. <u>Creating a TOC bookmark</u> ⁽⁴²⁰⁾ in the design with a name and TOC-item text. The TOC bookmark can either enclose or not enclose a design component; in the latter case it is empty. In the screenshot below, the TOC bookmark does not enclose a design component.

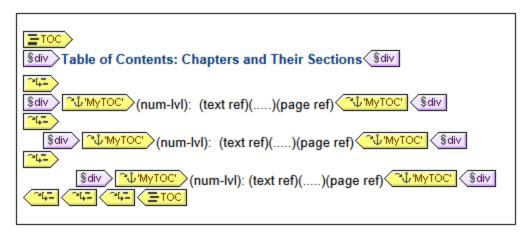

The TOC bookmark serves as an anchor in the document. In the screenshot above, the TOC bookmark (and anchor) is located at the start of para element instances. The TOC bookmark has two attributes: (i) a name that will be used to reference the TOC bookmark when creating the TOC item in the TOC template, and (ii) a text string that will be used as the text of the corresponding TOC item. How these two attributes are assigned is described in the section, Creating TOC Bookmarks

How bookmarked items are referenced in the TOC template

The <u>TOC template</u> is structured in nested levels (called level references (levelrefs) to differentiate them from the levels created in the main body of the design template). Within each levelref , a TOC reference (TOCref) is inserted (see screenshot below). The TOCref within a levelref references TOC bookmarks using the TOC bookmark's name. Each TOC bookmark with that name and in the corresponding

level in the XML document will be created as a TOC item at this level in the TOC. For example, the TOCref indicated with the tag references all TOC bookmarks named chapters in the corresponding level in the XML document (when the scope of the TOCref has been set to current). The text attribute of the respective instantiated TOC bookmarks will be output as the text of the TOC item.

In the screenshot above of a TOC template, there are three nested levelrefs, within each of which is a TOCref that contains the template for the TOC item of that level. For example, in the first levelref, there is a TOCref that references TOC bookmarks that have a name of MYTOC . As a result, all TOC bookmarks in the first level (as structured in the design) and named MYTOC will be accessed for output at this level in the TOC. The TOCref within the second levelref also references TOC bookmarks having a name of MYTOC. As a result, all TOC bookmarks in the second level of the document and that are named MYTOC will be used for second-level items in the TOC. The third levelref works in the same way: TOC bookmarks named MYTOC that occur within the document's third level are referenced for third-level items in the TOC.

In the sub-sections of this section, we describe: (i) how the design is structured into levels 417, and (ii) how bookmarks are created 420. How the TOC template is created 423 is described in the section, Creating the TOC Template 423.

7.7.1.1 Structuring the Design in TOC Levels

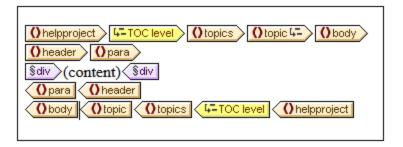

The hierarchical structure you wish to design for the TOC is specified as a set of **nested levels**. As such it is a hierarchical structure which, although related to the XML document structure, is separate from it. This structure is specified in the SPS document design. The TOC template that you construct will use a structure corresponding to this hierarchical structure. In the case of a TOC with a flat structure (one level only), the design document must have at least one level. If more than one level exists in the document, a flat TOC can then be created for any of these levels or for multiple levels (aggregated together as one level).

In the design, levels can be created in the main template, in global templates, or in a combination of main template and global templates. The important thing to note is that, wherever created, these levels must together, in combination, define a clear hierarchical structure.

Creating levels

Each level in the design is created separately. A level can be created on a template or around a component. In the screenshot below, one level has been created on the topic template (indicated by template (indicated by

another around the topics element (indicated by Li-Toc level). The essential difference between these two ways of creating levels is that the enclose-within-a-level option enables levels to be created around components other than templates.

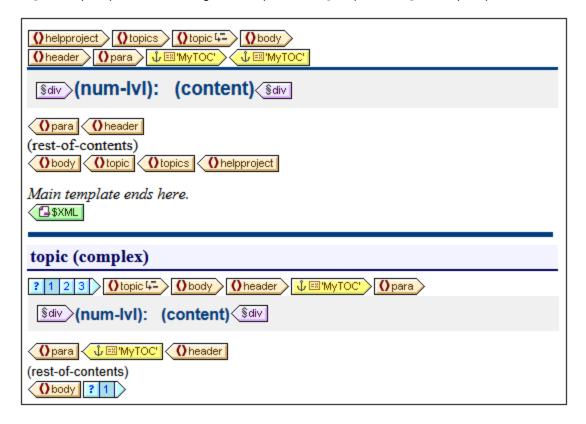

To create a level, do the following:

- 1. Select the component (template or other).
- 2. Right-click, and from the context menu select **Template Serves As Level** (enabled when a template is selected) or **Enclose With | TOC Level**. Both these options are also available in the **Insert | Insert Table of Contents** menu: **TOC Level** or **Template Serves** as **Level**.

Levels in global templates

Levels can also be set in global templates. In these cases, care must be taken to ensure that the levels created in various global templates, as well as those in the main template, **together** define a hierarchical structure when the SPS is executed. The screenshot below shows two levels, one in the main template (on the topic template) and one in the global template for topic (on the topic template).

In the content model represented by the screenshot above, <code>topic</code> is a recursive element, that is, a <code>topic</code> element can itself contain a descendant <code>topic</code> element. In the main template (the end of which is indicated by the **TML* tag), a level has been set on the first level of <code>topic**</code>. The <code>rest-of-contents</code> instruction in the main template specifies that templates will be applied for all child elements of <code>topic/body</code> except header. This means that the global template for <code>topic</code> children of <code>topic/body</code> will be processed.

In the global template for topic, a level has been set on the topic template (indicated by Otopic 1). This second level of the TOC hierarchy, which occurs on the second level of topic elements, is nested within the first level of the TOC hierarchy. Since this global template also has a rest-of-contents instruction, the global template for topic will be applied to all recursive topic elements, thus creating additional nested levels in the TOC hierarchy: third level, fourth level, and so on.

As a designer, you should be aware of the number of levels created in the design, because when the TOC template is constructed, you will need to explicitly specify how TOC items for each level will be selected and formatted.

Levels in flat TOCs

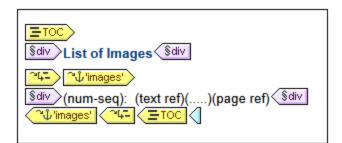

In a flat TOC hierarchy, TOC items will be output at a single level: for example, a simple list of the images in a document.

A flat hierarchy can be obtained in a number of ways.

- The design document can be structured with just a single TOC level. The TOC template will then have a single levelref with a single TOC reference (TOCref) within it.
- If the design document has more than one TOC level, then the TOC template could have a number of levelrefs equal to the sequential position of the TOC level being referenced. The levelref corresponding to the targeted TOC level will contain the single TOCref in the TOC template.
- If the design document has more than one TOC level, then the single TOCref in the TOC template must have a scope that covers all the targeted document levels, which, in effect, will be flattened into a single level.

Let us say that we wish to gather all the images in a document in a single flat-hierarchy TOC. The document design must therefore contain at least one level, and this level must contain all the required TOC bookmarks. In the TOC template, the images to be listed are referenced in the usual way: (i) by creating a corresponding number of levelrefs; and (ii) creating a TOCref within the levelref corresponding to the targeted TOC level. The TOCref will have the name of TOC bookmarks in the targeted TOC level.

In the TOC template shown below, there is one levelref containing a TOCref that references TOC bookmarks named <code>images</code>. The scope of the TOCref has been set to *Current level and below*. As a result, all TOC bookmarks named <code>images</code> in the first level and below (that is, in the whole document) will be referenced.

If the design contains more than one level, and a flat TOC is required, say, for items in the second level, then the TOC template could have two levelrefs with a TOCref only within the second level (no TOCref within the first level). Alternatively, the scope property of TOCrefs can be used to specify what level/s in the design document should be looked up for bookmarks of a given name.

7.7.1.2 Creating TOC Bookmarks

TOC bookmarks are created within a TOC level in the document design. They can be created in the main template and/or in global templates. A TOC bookmark serves two purposes:

- It marks a (static or dynamic) component in the design with a static name you assign. It can either enclose or not enclose a design component; in the latter case it is empty. In the output, the TOC bookmark is instantiated as an anchor identified by a name. This named anchor can be referenced by items in the TOC (template).
- A TOC bookmark also defines the text string that will be used as the text of a TOC item. This text string can be the content of child elements of the node where the marker is located, or it can be the output of an XPath expression.

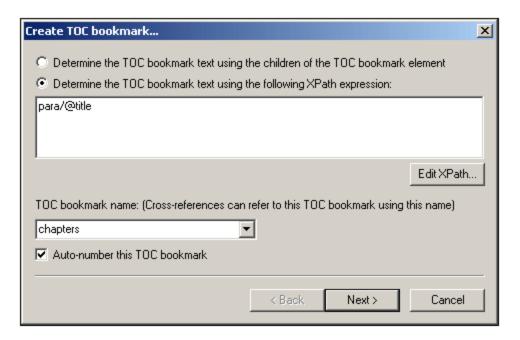

You can create a TOC bookmark in two ways:

- By using the <u>Create TOC Bookmark Wizard</u> 420, which enables you to specify the TOC bookmark's name, its text entry, whether auto-numbering should be used, and the level within which it appears.
- By inserting an empty TOC bookmark 422, the properties of which will be defined subsequently.

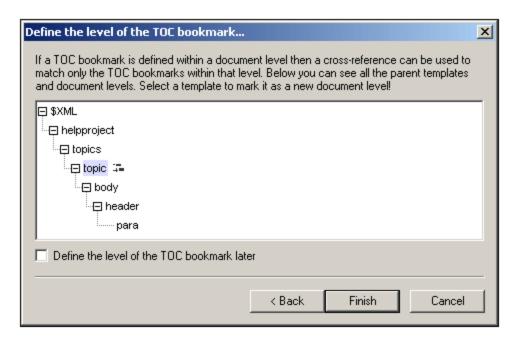

Creating the TOC bookmark with the Create TOC Bookmark Wizard

To create a TOC bookmark using the TOC Bookmark Wizard, do the following:

- 1. Place the cursor at the point in the design where you wish to insert the TOC bookmark. Alternatively, select the design component around which you wish to insert the TOC bookmark.
- From the context menu (obtained by right-clicking) or from the Insert menu, select Insert Table of Contents | TOC Bookmark (Wizard). If you are enclosing an a node with a TOC Bookmark, use the command Enclose with | TOC Bookmark (Wizard). This pops up the Create Marker Wizard (screenshot below).

- 3. In the wizard's first screen (*screenshot above*) you: (i) define the text for the TOC item; (ii) set the TOC bookmark name; and (iii) specify whether this TOC bookmark should be numbered in the output. For the text entry you can select whether the text of child elements should be used, or an XPath expression. For the name of the TOC bookmark, you can enter text directly or select from a dropdown list containing the names of already specified TOC bookmark names. When you are done, click **Next**.
- 4. In the wizard's second screen (*screenshot below*), you can create a TOC level on a template if you wish to do so. Ancestor templates of the insertion point location are shown in a tree. If a template has already been created as a TOC level, this is indicated with a symbol. In the screenshot below, the symbol next to the topic template indicates that it has already been created as a level. If you wish to create an additional level on any of the ancestor templates, select that template. Alternatively, you can choose to define the level later by checking the *Define Level Later* check box. When you have completed making your selection, click **Finish**. (Note that, if a TOC level already exists on a template, selecting such a template and clicking **Finish** will not create a new TOC level on that template.)

On clicking **Finish**, a TOC bookmark will be created at the insertion point and, if it was specified in the second screen of the wizard, a TOC level will be created on one template. The TOC bookmark that has been created will be in the TOC level that immediately contains it. For example, if that TOC level is the third TOC level in the TOC level hierarchy, then the inserted TOC bookmark will be in the third TOC level.

Creating a TOC bookmark

To create a TOC bookmark without attributes (TOC bookmark name, TOC item text, etc), do the following:

- 1. Place the cursor at the point in the design document where you wish to insert the TOC bookmark, or select the design component around which you wish to insert the TOC bookmark.
- 2. From the context menu (obtained by right-clicking) or from the **Insert** menu, select **Insert Table of Contents | TOC Bookmark**. A TOC bookmark is inserted. This TOC bookmark has neither a name nor a text entry. These can be defined subsequently using the **Edit commands** (see below).

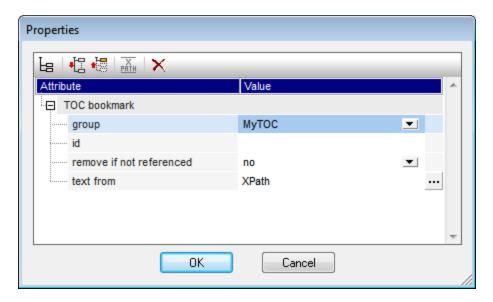

Inserting hierarchical or sequential numbering for a component

Hierarchical or sequential numbering within the main body of the output document (not within the TOC) can be inserted within (but also outside) a TOC bookmark's tags. Right-click at the location where you wish to insert the numbering, then select **Insert Table Of Contents | Hierarchical Numbering / Sequential Numbering**. For example, an auto-numbering TOC bookmark that is placed around the chapter heading template will generate numbering for all the chapter headings generated by the chapter heading template.

Note that numbering is based on the structure of TOC levels. So, for example, if a chapter heading element is in the first TOC level, then the fourth chapter heading will be numbered 4 because it is the fourth instance of a chapter heading within the first TOC level. If the sections of a chapter occur within the second TOC level, then the third section of the fourth chapter will be numbered 4.3. This is because, within the first (chapter) TOC level, it is the fourth instance of a chapter, and within the second (section) TOC level (of the fourth chapter), it is the third instance of a section.

Editing the name and text entry of a TOC bookmark

The name and text entry of the TOC bookmark can be edited in the Properties window (*screenshot below*). To edit these properties, select the TOC bookmark, and either directly edit the property in the <u>Property window</u> or right-click the TOC bookmark and select the property you wish to edit.

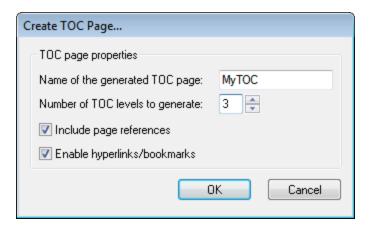

The TOC bookmark has the following properties: (i) the name of the TOC bookmark group (*Group*); (ii) a unique ID; (iii) an option to remove the bookmark if it is not referenced; and (iv) an option (*Text From*) to specify the text entry, which could come from the bookmark's content or from an XPath expression.

7.7.2 Creating the TOC Template

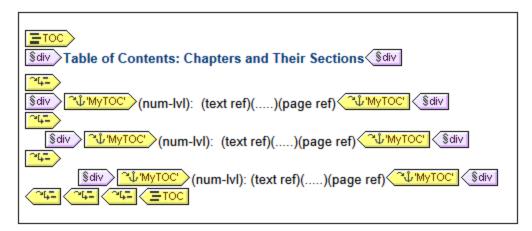

The TOC template is the template that produces the table of contents in the output. It can be created anywhere within the SPS design, and multiple TOC templates can be created in a single SPS design.

The steps to create a TOC template are as follows:

- 1. Place the cursor at the location where the TOC template is to be inserted.
- 2. Click the menu command Insert | Insert Table of Contents | Table of Contents. This pops up the Create TOC Page dialog (*screenshot below*). (Alternatively, this command can be accessed via the context menu, which appears when you right-click.)

- 3. Enter the information requested in the dialog: (i) The name of the generated TOC page is the (TOCref) name that will be used to reference the TOC bookmarks in the design document. If you select multiple levels for the TOC (level references, to be more accurate; next option), the same TOCref name will be used in all level references (though individual TOCref names can be edited subsequently will be used in all level references (though individual TOCref names can be edited subsequently level.). (ii) The number of TOC level references (levelrefs) specifies how many level references the TOC is to have. (iii) For printed media, the option to output page references (i.e. page numbers) is available. (iv) The text entries in the TOC can be used as links to the TOC bookmarks.
- 4. Click **OK** to finish. The TOC template is created with the specified number of levelrefs (*screenshot below, the formatting of the TOC template has been modified from that which is created initially*).

Within each levelref is a TOCref having a name that identifies TOC bookmarks that are to be the TOC items for that levelref. Within each TOCref is a default template for the TOC item, which you can edit at any time 420.

Editing the TOC template

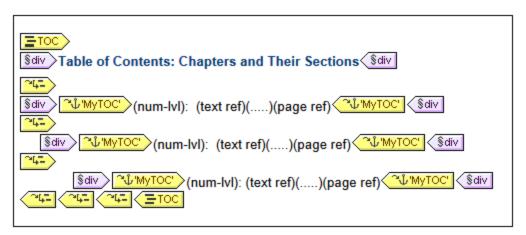

The following editing options are available:

- The TOC template can be dragged to another location in the SPS. Note, however, that a change of context node could affect XPath expressions within the TOC template.
- <u>Levelrefs</u> 425 can be added to or deleted from the structure of the TOC template.
- The <u>properties of individual TOC references</u> (TOCrefs) can be edited. The name and scope of a TOCref can be changed, and you can choose whether the TOC item corresponding to the TOCref is created as a hyperlink or not.

- TOCrefs 426 can be added to or deleted from any levelref in the TOC template.
- The <u>TOC item</u> 426 within a TOCref can be formatted with CSS properties using the standard <u>StyleVision</u> mechanisms 465.
- Standard SPS features (such as images, Auto-Calculations, and block-formatting components) can be inserted anywhere in the TOC template.

7.7.2.1 Levelrefs in the TOC Template

The <u>TOC template</u> is structured in **level references** (or levelrefs); see screenshot below. These levels are initially created when the TOC template is created, and the number of levelrefs are the number you specify in the <u>Create TOC Page dialog</u> 423.

Notice that the levelrefs are nested. For the purposes of the TOC design there is a one-to-one correspondence between the levelrefs in the TOC template and the levels in the SPS design. Thus, the first levelref of the TOC template corresponds to the first level in the SPS design, the second levelref in the TOC template to the second level in the SPS design, and so on. The TOCrefs within a given levelref of the TOC template identify TOC bookmarks within a specified scope to the SPS design. For example, a TOCref can specify that the TOCref target TOC bookmarks in the corresponding document level, or target TOC bookmarks in all document levels, or those in the current document level and lower document levels.

Inserting and removing levelrefs

Levelrefs can be inserted in or deleted from the TOC template after the TOC template has been created.

To insert a levelref around content, select the content in the TOC template around which the levelref is to be created, then, from the context menu or via the menu bar, select the command **Enclose With | TOC Level Reference**. You can also insert an empty levelref at the cursor insertion point with the menu command **Insert | Insert Table of Contents | TOC Level Reference** (also available in the context menu).

To remove a levelref from the TOC template, select the levelref to be removed and either press the **Delete** key or select **Remove** from the context menu. Note that only the levelref will be removed—not its contents.

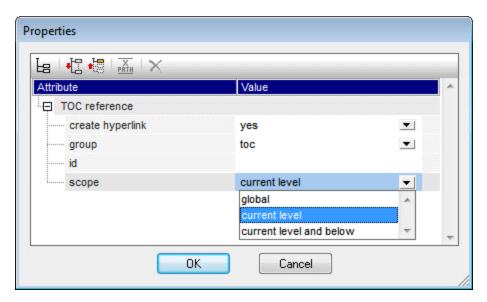

7.7.2.2 TOC References: Name, Scope, Hyperlink

TOC references (TOCrefs) occur within level references (levelrefs) and have four properties (see screenshot below):

- A *hyperlink* property which can be toggled between yes and no to specify whether the corresponding TOC items are created as hyperlinks or not.
- A *group* property, which is the name of the TOCref and identifies TOC bookmarks of the same name that occur within the specified scope (*see below*). The TOC bookmarks so identified provide the items to be included at that levelref of the TOC.
- An id to uniquely identify the TOCref.
- A scope, which specifies to which corresponding levels in the SPS design the TOCref applies. Three
 options are available: (i) global, (ii) current level, (iii) current level and descendant levels (see
 screenshot below).

To insert a TOCref, place the cursor within a levelref and, from the **Insert** menu or context menu, select **Insert Table of Contents | TOC Reference**.

To edit a TOCref property, right-click the TOCref tag in the TOC template and select the property you wish to edit (*Create Hyperlink*, *Edit ID*, *Edit Group*, or *Edit Scope*). This pops up the Properties window with the specified property selected for editing (*screenshot below*).

Alternatively, with the TOCref tag selected, go directly to the required property in the Properties window (*TOC reference* group of properties).

7.7.2.3 Formatting TOC Items

The TOC item can contain up to four standard components, plus optional user-specified content. The four standard components are (see also screenshot below):

the text entry of the TOC item, indicated in the TOC template by (text ref)

- the leader between the text entry and the page number (for paged media output), indicated by (.....)
- the page reference of the TOC item (for paged media output), indicated by (page ref)
- hierarchical or sequential numbering, indicated by (num-lvl) and (num-seq), respectively

When the TOC template is initially created, the text entry is automatically inserted within TOCrefs. If the Include Page Reference option was selected, then the leader and page reference components are also included. Subsequently, components can be inserted and deleted from the TOC item. To insert a component, place the cursor at the desired insertion point within the TOC item, and in the context menu, select Insert Table Of Contents | TOC Reference | Entry Text / Leader / Page Reference or Insert Table Of Contents | Hierarchical Numbering / Sequential Numbering as required. (Hierarchical numbering should be inserted when the design is structured into nested levels, sequential numbering when there is no hierarchy, that is, just one flat TOC level. See the note below on flat TOCs) To delete a component, select it and press the Delete key.

Additionally, you can insert static content (e.g. text) and dynamic content (e.g. Auto-Calculations) within the TOC item.

Levels in flat TOCs

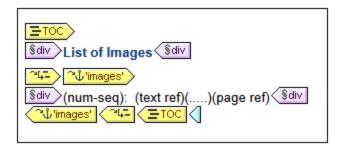

In a flat TOC hierarchy, TOC items will be output at a single level: for example, a simple list of the images in a document.

A flat hierarchy can be obtained in a number of ways.

- The design document can be structured with just a single TOC level. The TOC template will then have a single levelref with a single TOC reference (TOCref) within it.
- If the design document has more than one TOC level, then the TOC template could have a number of levelrefs equal to the sequential position of the TOC level being referenced. The levelref corresponding to the targeted TOC level will contain the single TOCref in the TOC template.
- If the design document has more than one TOC level, then the single TOCref in the TOC template must have a scope that covers all the targeted document levels, which, in effect, will be flattened into a single level.

Let us say that we wish to gather all the images in a document in a single flat-hierarchy TOC. The document design must therefore contain at least one level, and this level must contain all the required TOC bookmarks. In the TOC template, the images to be listed are referenced in the usual way: (i) by creating a corresponding number of levelrefs; and (ii) creating a TOCref within the levelref corresponding to the targeted TOC level. The TOCref will have the name of TOC bookmarks in the targeted TOC level.

In the TOC template shown below, there is one levelref containing a TOCref that references TOC bookmarks named <code>images</code>. The scope of the TOCref has been set to *Current level and below*. As a result, all TOC bookmarks named <code>images</code> in the first level and below (that is, in the whole document) will be referenced.

If the design contains more than one level, and a flat TOC is required, say, for items in the second level, then the TOC template could have two levelrefs with a TOCref only within the second level (no TOCref within the first level). Alternatively, the scope property of TOCrefs can be used to specify what level/s in the design document should be looked up for bookmarks of a given name.

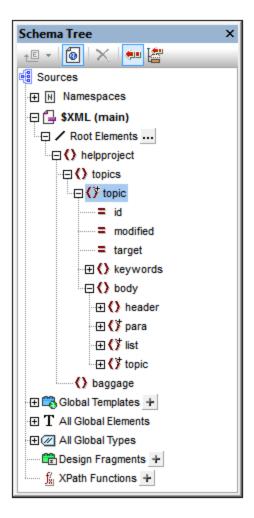

Formatting the TOC item

The TOC item can be formatted with <u>CSS styles</u> 465 via the <u>Styles sidebar</u> 172. Individual TOC item components can be separately formatted by selecting the component and assigning it <u>style properties</u> in the Styles sidebar.

7.7.3 Example: Simple TOC

An example SPS file to demonstrate the basic use of TOCs, called ChaptersSimple.sps, is in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Toc. This SPS is based on a schema that defines the content model of a large chapter-based document. The schema structure is shown in the screenshot below and can be viewed in the Schema Tree window of StyleVision when you open ChaptersSimple.sps. (A more complex TOC example based on the same schema is described in the next section of this documentation, Example: Hierarchical and Sequential TOCs (39).)

The document element is helpproject, which contains a child topics element. The topics element can contain an unlimited number of topic elements, each of which can in turn contain descendant topic elements. The first level of topic elements can be considered to be the chapters of the document, while descendant topic elements are sections, sub-sections, and so on.

This SPS creates a TOC, located at the top of the document, which lists the names of each chapter (the first-level topics). Creating the TOC involves three steps:

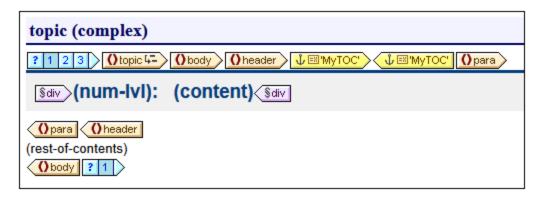

- 1. Structuring the design in TOC levels (417): One or more levels are inserted in the design document to structure the (output) document hierarchically. This hierarchic structure will be the one that the TOC reflects. In our current example, to keep things simple, only one TOC level has been created—on the Topic template. Because there is only one level in the design, the TOC template—when it is created subsequently—can have only one level in its structure (i.e. one level reference).
- 2. Creating TOC bookmarks (420): A **TOC bookmark** is created within the TOC level that was created in Step 1 (in the design document). This enables TOC references in the TOC template (which will be created in the next step) to point back to this TOC bookmark. The TOC bookmark also specifies the text that will appear in the TOC item that points to it.
- 3. <u>Creating the TOC template</u> This is the template that creates the TOC in the document. It is structured into **level references** (**levelrefs**), which must correspond to the structure of TOC levels in the design document. For example if there are three nested levelrefs in the TOC template, then the design document must have at least three nested levels. In this example we have a single levelref to

correspond to the single TOC level in the design document. It is within the levelref that the **TOC reference (TOCref)** is placed. It is this TOCref that generates the TOC items for this level in the TOC.

SPS structure and levels

Look at the structure of the design in the SPS. Notice that the main template (with the green \$xml tags) contains the TOC. The rest of the main template specifies, through the rest-of-contents instruction, that global and default templates are to be applied. The rest of the SPS design—outside the main template and after it—consists of global templates.

The TOC definitions (TOC levels and TOC bookmarks in the design) are in the global template for <code>topic</code> (screenshot below). In this global template a condition has been inserted to separate <code>topic</code> elements according to how many ancestor <code>topic</code> elements each has, thus providing separate processing (within different conditional branches) for chapters, sections, and sub-sections.

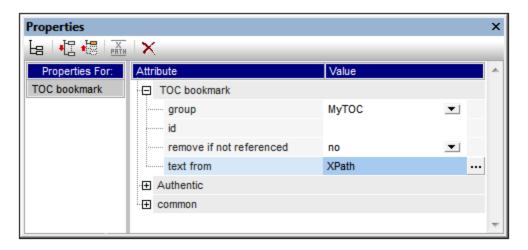

The screenshot above shows the contents of the first conditional branch, for first-level, chapter-type topic elements. Note that a TOC level has been created on the template start-tag of this topic element. In the other two conditional branches no TOC level has been created on the topic template. As a result, the document has been assigned only one TOC level, and this is at the level of the first-level (chapter-type) topic element.

Creating the TOC bookmark

A TOC bookmark (yellow tags in screenshot below) has been created within the header descendant element of topic (but outside the para element). This TOC bookmark serves as an anchor for every top-level, chapter-type topic element..

The properties of the TOC bookmark can be edited in the Properties sidebar (screenshot below).

The *Group* property sets the TOC bookmark group (and is the name of the TOC bookmark). In our example, we have specified the value M_YTOC for this property. The bookmark group will be referenced in the TOC when it is created, and it enables different TOC groups to be specified within the same level. The *ID* property enables unique IDs to be specified for the bookmark instances created. The *Remove if not referenced* property is an option to remove the bookmark if it is not referenced. The *Text From* property specifies the text entry that will be used as the text of the TOC item in the TOC. The text could come from the bookmark's content (the content between the start and end tags of the bookmark in the design) or from an XPath expression. In our example, an XPath expression is used which returns the header text, respectively, of each first-level topic element.

TOC template

Inside the TOC template (*screenshot below*), a single Level Reference (levelref) has been inserted. This levelref corresponds to the TOC Level assigned on the first-level, chapter-type topic element in the design (*see 'SPS Structure and Levels' above*).

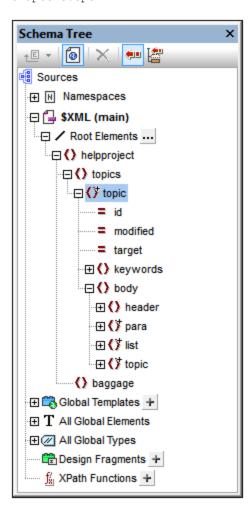

Within this levelref, a TOC reference (TOCref) has been inserted. This TOCref has been set to select bookmarks (i) that are in the bookmark group named MyToC (see 'Creating the TOC bookmark' above), and (ii) that are within the scope of the current level only. These settings can be made in the Properties sidebar when the TOCref is selected, or by right-clicking the TOCref in the design and selecting the relevant editing command from the context menu..

The appearance of the TOC item is specified within the TOCref tags of the TOC. The numbering format, the text, the leader, and the page reference can be inserted by right-clicking within the TOCref tags and selecting the component to insert from the context menu. Each of these components can be edited by selecting it in the design and modifying its properties in the Properties sidebar.

7.7.4 Example: Hierarchical and Sequential TOCs

An example SPS file to demonstrate the use of TOCs, called Chapters.sps, is in the (My) Documents folder 33, C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\TOC. This SPS is based on a schema that defines the content model of a large chapter-based document. The schema structure is shown in the screenshot below and can be viewed in the Schema Tree window of StyleVision when you open Chapters.sps.

The document element is helpproject, which contains a child topics element. The topics element can contain an unlimited number of topic elements, each of which can in turn contain descendant topic elements. The first level of topic elements can be considered to be the chapters of the document, while descendant topic elements are sections, sub-sections, and so on.

The SPS contains three TOCs, located at the top of the document, in the following order:

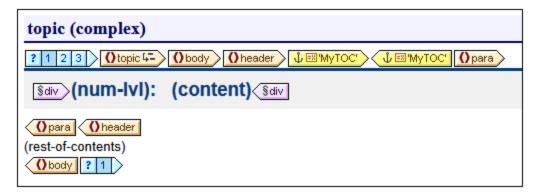

- 1. Chapters at a glance 433, which lists the names of each chapter (the first-level topics).
- 2. <u>Chapters and their sections</u> (334), which lists each chapter with its descendants sections (first-level topics, plus each topic's hierarchy of sub-topics down to the lowest-level topic, which in the accompanying XML document, chapters.xml, is the third-level topic)

3. <u>List of images</u> 434, which is a flat list of all images in the document (except the first), listed by file name.

SPS structure

Before considering the TOCs in detail, take a look at the structure of the design. Notice that the main template (with the green \$XML tags) contains the TOCs. The rest of the main template specifies, through the rest-of-contents instruction, that global and default templates are to be applied.

The TOC definitions are in the global templates for topic and image. In the global template for topic (screenshot below), a TOC level has been created on the topic element, and a TOC bookmark has been created within the header child element (but outside the para element).

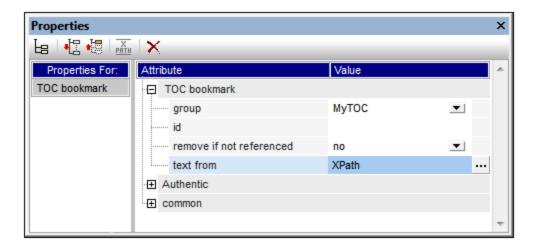

Since the topic element is recursive, the TOC level and the TOC bookmark will also recurse. This means that, at the first recursion, a new hierarchically subordinate TOC level and and a new TOC bookmark is created. This process continues for each descendant topic, thus creating a hierarchy of descendant TOC levels, each with a corresponding TOC bookmark. Since the formatting of the header (the topic title) for each TOC level is to be different, we have enclosed each level within a separate branch of a condition with three branches. Each branch tests for the TOC level at which a topic occurs: first, second, or third level.

Notice that hierarchical numbering (num-lvl) has been inserted within the level. This is done by right-clicking at the required location and selecting **Insert Table of Contents | Hierarchical Numbering**. The effect is to insert the correct hierarchical number before each topic title in the **document's text flow**, for example, 3.1 or 4.2.3.

TOC descriptions

Given below is a brief description of each TOC and the points to note about them.

Chapters at a glance: Select the TOC bookmark in the global template for topic. In the Properties sidebar (screenshot below), notice that the entry text has been set to be constructed using an XPath expression. When you click the Edit button in the value field of the Text from property, you will see that the XPath expression has been defined as para. This means that the contents of the para child of header (since the TOC bookmark has been inserted within the header element) will be used as the text of the TOC item.

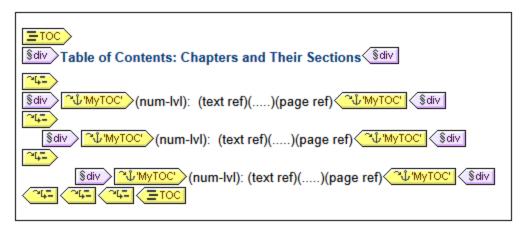

The TOC template itself (*screenshot below*) contains one level reference (levelref) , and the TOCref within that levelref has been set to select TOC bookmarks named MyTOC within the scope of the current level only—which is the first level. As a result, TOC items will be created only for first-level topics.

Notice also that the numbering has been defined as hierarchical numbering.

Chapters and their sections: In this TOC (screenshot below), notice that three nested levelrefs have been defined, each containing a TOCref for which the scope is the current level.

Since each TOC item is contained in a div block, formatting properties (including indentation) can be set for the block.

List of images: The list of images is a flat list. First of all, consider within which levels images will occur in the instantiated document. The image element is a child of the para element. Since levels have been created on

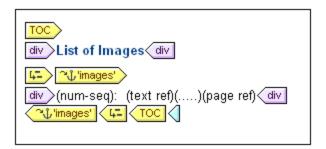

topic elements, image elements will occur within the first, second, and/or third levels of the document. There is therefore no need to create any level for the image element.

In the global template for image, the condition (see screenshot below) enables separate processing for (i) the first image (which is presented in this example), and (ii) the other images (which, for purposes of economy, are not presented in this example).

Notice that the TOC bookmark is placed only within the second branch of the condition; this means that the images selected in the first branch are not bookmarked. Also, the sequential numbering (num-seq) of the images, inserted with Insert Table of Contents | Sequential Numbering, will start with the second image (because the first image is selected in the first branch of the condition). Another feature to note is that the numbering can be formatted, as has been done in this case. To see the formatting, right-click (num-seq), and select Edit Format. In the dialog box that pops up, you will see that the formatting has been set to 01, indicating that a 0 will be inserted in front of single-digit numbers.

In the TOC template for images (*screenshot below*), notice that there is a single TOCref identifying bookmarks named <code>images</code>, and that this TOCref is within a single levelref. The scope of the TOCref (editable in the Properties window when the TOCref is selected) has been set to: <code>current level</code> and <code>below</code>. The current level, determined by the levelref, is the first level. The levels below will be the second, third, and so on. In this way, all images from the first level downward are selected as items in the TOC.

Since the selected numbering is sequential, the images are numbered sequentially in a flat list.

7.7.5 Auto-Numbering in the Document Body

Repeating instances of a node can be numbered automatically in the main body of the document using the Auto-Numbering feature. For example, in a Book element that contains multiple Chapter elements, each Chapter element can be numbered automatically using the Auto-Numbering feature. This is an easy way to insert numbering based on the structure of the XML document.

Note: The Auto-Numbering feature refers to numbering within the main body of the document. It **does not** refer to numbering within tables of contents (TOCs), where numbering is considered to be a property of the TOC item.

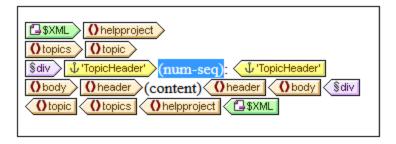

Auto-Numbering can be either sequential (flat) or hierarchical. Sequential numbering provides ordinary numbering on a single level. Hierarchical numbering is based on the TOC-level hierarchy created in the document and creates numbering according to the element's position in the TOC-level hierarchy.

A wide variety of formatting is available for the numbers. In the case of hierarchical numbers, individual number tokens can be formatted separately. For example, a three-token number could be given the format: A.1.i., where each of the three tokens has a different number format. Number formatting is assigned differently for sequential and hierarchical numbering, and therefore have separate descriptions, each in their respective sections below.

Sequential numbering (num-seq)

Sequential (or flat) numbering can be inserted within a <u>TOC Bookmark</u> in the document design (see screenshot below). Create sequential numbering as follows:

- 1. Place the cursor within the node that has to be numbered and create the TOC bookmark (right-click, and select Insert Table of Contents | TOC Bookmark). The TOC bookmark will be created. In the screenshot below, we wish to number the topic element, so the TOC bookmark has been created within the topic element. The exact location within the topic element depends on where in the layout you want the numbering. (In the screenshot below, the numbering is placed immediately to the left of the chapter header (title).)
- 2. Place the cursor within the tags of the TOC bookmark, right-click, and select **Insert Table of Contents | Sequential Numbering**. This inserts the Auto-Numbering placeholder for sequential numbering, (num-seq) (highlighted within the TOC bookmark 'TopicHeader' in the screenshot below).

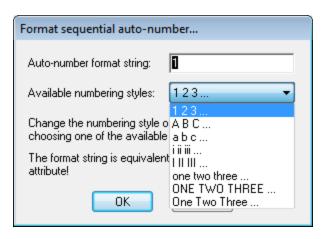

3. If the TOC bookmark is going to be referenced from within a TOC template, then you can enter TOC bookmark properties as required. However, if the TOC bookmark is going to be used only for sequential numbering, there is no need to name it. If you wish to name it, right-click it and select the **Edit Group** command.

In the example shown in the screenshot above, sequential numbering has been set on the topic node. The result is that each topic element receives a sequential number, as shown in the screenshot below. Note that the numbering is essentially the position of each topic element within the sequence of all sibling topic elements at that level of the XML document hierarchy.

- 1: Altova StyleVision 2007
- 2: About this Documentation
- 3: Introduction
- 4: User Interface

Note: If sequential numbering must be continued on another set of nodes, then use a TOC bookmark with the same name on both nodesets.

To format the sequential numbering, right-click the num-seq placeholder and select the **Edit Format** command. This pops up the Format Sequential Auto-Number dialog (*screenshot below*).

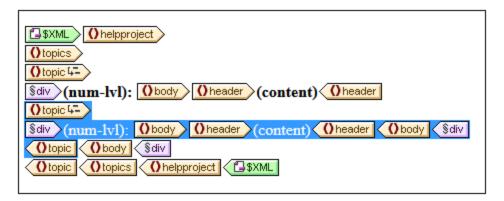

Select the format you want from the dropdown box of the *Available numbering styles* combo box (see screenshot above) and click **OK** to apply the selected format.

Hierarchical numbering (num-lvl)

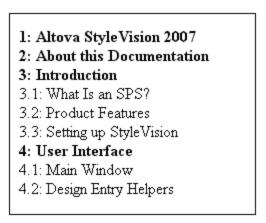

Hierarchical numbering can be inserted within a <u>TOC level in the design</u> To create hierarchical numbering in a document, you must therefore first structure the document in TOC levels. Do this as described in the section Structuring the Design in Levels To the following points should be borne in mind:

- Levels must be created either on the node to be numbered or within it.
- Levels must be nested according to the hierarchy of the numbering required (see screenshot below).
- The hierarchical numbering placeholder must be inserted within the corresponding level in the design (see screenshot below).

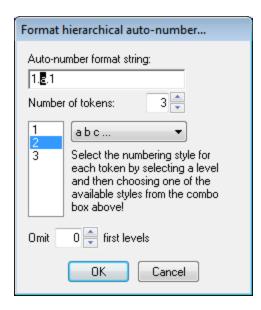

In the screenshot above, there are two levels. The <code>topic</code> element is recursive, and a level has been created on two <code>topic</code> elements (by right-clicking the node tag and selecting **Template Serves as Level**). One <code>topic</code> element (highlighted in the screenshot above) is nested within the other. As a result, the levels also are nested. Within each level, a hierarchical numbering placeholder (num-lvl) has been inserted (right-click within the level and select **Insert Table of Contents | Hierarchical Numbering**).

The result of the design shown in the screenshot above will look like this.

The first level is shown in bold, the second in normal.

To format hierarchical numbering, right-click the num-lvl placeholder and select the **Edit Format** command. This pops up the Format Hierarchical Auto-Number dialog (screenshot below).

First select the number of tokens in the Token combo box. This number should be the same as the number of TOC levels in the document. Each token can then be separately formatted. In the lower of the two display boxes, select the token to be formatted. (In the screenshot above, the second token has been selected.) Next, in the Formatting combo box, select the formatting style you want. In the screenshot above, lowercase formatting has been selected for the second token, and this is reflected in the display box at the top of the dialog. Additionally, levels can be omitted by entering the required number of levels to be omitted in the Omit Levels box.

Note that formatting is defined on hierarchical numbering one level at a time. So the hierarchical numbering placeholder num-lvl at each level must be separately formatted.

Click **OK** when done.

7.7.6 Cross-referencing

A cross-reference is a reference to another part of the document. In an SPS a cross-reference is created in two parts: First, by setting the target of the cross-reference. Second, by defining the link to the target. Setting a target consists of creating a TOC bookmark within a TOC level. The link to the target is a Text Reference within a TOC reference (TOCref). The Text Reference generates the output text and serves as the link. Building a cross-reference therefore consists of the following three steps:

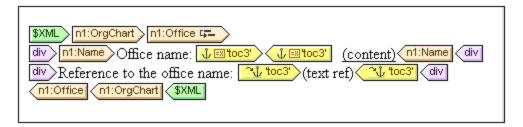

Step 1: Levels

The document is structured into TOC levels as described in the section <u>Structuring the Design in Levels 417</u>. TOC levels will be used during referencing to specify the scope of the referencing. Only those TOC bookmarks having the specified name and falling within the specified scope will be targeted. In the screenshot below, a level has been created on the n1:office element.

Step 2: Creating TOC bookmarks

Within a level, a TOC bookmark is created by placing the cursor at the required location, right-clicking, and selecting **Insert Table of Contents | TOC Bookmark**. The TOC bookmark is given a name and an XPath expression that generates the output text. The XPath expression will typically identify a node in the document, the contents of which is the required text.

In the screenshot below, the TOC bookmark within the n1:Name element within the n1:Name element and an XPath expression that locates the current node. This means that the output text will be the contents of the n1:Name node.

When the XML document is processed, an anchor is created for every n1:Name element. This anchor will have a text reference (the text of the cross-reference) that is the value of the n1:Name element.

Step 3: Creating TOC references

A TOC reference (TOCref) is inserted (context menu, **Insert Table of Contents | TOC Reference**) to create a link to the anchors generated by a TOC Bookmark.

In the screenshot above, the TOCref named toc3 (screenshot above) is within the same TOC level as the TOC bookmark it references (the Office level). You must also specify the scope of the TOCref. The scope specifies what TOC levels must be searched for TOC bookmarks of the same name as the TOCref. In the example shown above, the scope is the current level. This means that TOC bookmarks within the current level that have a name of toc3 are targeted by this reference.

The screenshot above shows an n1:Office template. When an n1:Office node is processed, an anchor is created with output text that is the content of the n1:Name node. This is because the TOC bookmark specifies in an XPath expression (via the *Text from* property of the TOC bookmark) that the contents of this node will be the output text. The TOCref in the next line identifies the anchor with the name toc3, and the Text reference component generates the output text of the link to the anchor (*purple text in the screenshot below*). The output will look something like this:

Office name: Nanonull, Inc.

Reference to the office name: Nanonull, Inc.

Office name: Nanonull Europe, AG

Reference to the office name: Nanonull Europe, AG

In the example above, the scope was set to the current level. There are two other possibilities for the scope: (i) a global scope, (ii) scope for the current level and below. With these options, it is possible to also target TOC Bookmarks in other levels of the design.

7.7.7 Bookmarks and Hyperlinks

In the SPS document, bookmarks can be inserted anywhere within the design. These bookmarks are transformed into anchors in the output, which can be linked to from hyperlinks. Hyperlinks can not only link to bookmarks, but also to external resources like Web pages. StyleVision offers considerable flexibility in the way target URIs for hyperlinks can be built.

In this section, we describe:

- How bookmarks 440 can be inserted in the SPS.
- How hyperlinks 442 can be inserted in the SPS and how they link to the target pages.

Note: Links to external documents are supported in the FO spec but might not be supported by the FO processor you are using. You should check support for this feature if you are planning to use it.

7.7.7.1 Inserting Bookmarks

A bookmark (or anchor) can be inserted anywhere in the SPS, at a cursor insertion point or around an SPS component.

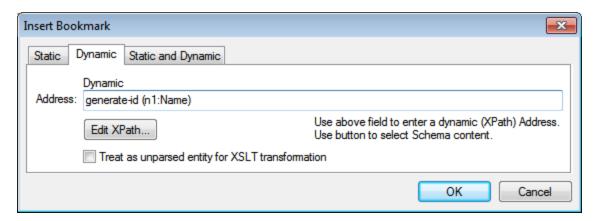

Bookmarks are created in the SPS via the Insert Bookmark dialog (*screenshot below*). In this dialog you define the name of the bookmark. The name can be a static name, or it can be a dynamic name that is (i) derived from XML document content, or (ii) generated arbitrarily with an XPath expression.

Creating a bookmark

To insert a bookmark, do the following:

1. Place the cursor at the location where you wish to create the bookmark.

- 2. Select the menu command Insert | Insert Bookmark (011), or right-click and select Insert | Bookmark.
- 3. In the Insert Bookmark dialog (*screenshot below*), select a tab according to whether the name of the bookmark should be static (Static tab), dynamically obtained from the XML document or arbitrarily generated from an XPath expression (Dynamic), or composed of both static and dynamic parts (Static and Dynamic). In the screenshot below a dynamic bookmark is created, which has a name that is a unique ID for each Name child of the context node.

4. Click **OK**. The bookmark is defined.

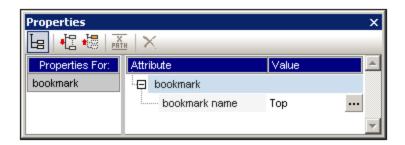

After a bookmark has been created, it can be linked to by a hyperlink 442.

Note: Bookmarks are created at the location specified in the design. If that location is within an element that repeats, a bookmark is created within each instance of that repeating element. If a static name is given, then each bookmark will have the same name. Therefore, it is better in such cases (of repeating elements) to give a dynamic name, which can be, for example, the name of a child element of the context node (the element within which the bookmark is created). If the node selected for the dynamic name might have the same content across multiple instances, then the uniqueness of the bookmark name can be ensured by using the generate-id() function to generate the name (see screenshot above). To reference such a bookmark, the same ID can be generated as the href value of a hyperlink (10 location). In this case make sure you use the fragment-identifier # in front of the generate-id() function. The XPath expression would be: concat('#', generate-id(nodeXXX)).

Modifying a bookmark

After a bookmark has been created, its name can be modified via the Edit Bookmarks dialog. This dialog is accessed as follows:

- 1. Select the bookmark in the design.
- 2. In the Properties sidebar, click the **Edit** button of the Bookmark Name property (*screenshot below*) in the *Bookmark* group of properties. This pops up the Edit Bookmark dialog, which is identical to the Insert Bookmark dialog described above (*see screenshot above*).

3. In the Edit Bookmark dialog, edit the name of the bookmark in either the Static, Dynamic, or Static and Dynamic tab.

Deleting a bookmark

To delete a bookmark, select it in the design and press the **Delete** key.

7.7.7.2 Defining Hyperlinks

Hyperlinks can be created around SPS components such as text or images. The targets of hyperlinks can be: (i) bookmarks in the SPS design, or (ii) external resources, such as web pages or email messages. In this section, we first discuss the content of the hyperlink (text, image, etc) and then the target of the hyperlink.

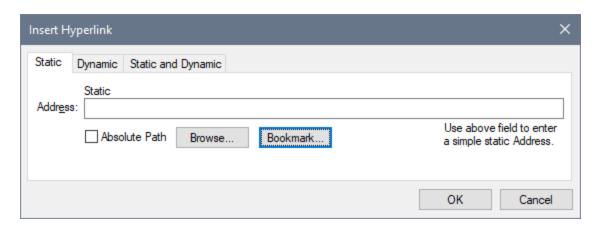

Creating hyperlinks

A hyperlink can be created in the following ways:

- Around text (static or dynamic), nodes, images, conditional templates, Auto-Calculations, and blocks of content or nodes; it cannot be created around a data-entry device such as an input field or combo box—though it can be created around a node or conditional template in which that data-entry device is. This is the content of the link, which, when clicked, jumps to the target of the link. To create a hyperlink around a component in the SPS, select that component and use the Enclose With | Hyperlink menu command.
- A new hyperlink can be inserted via the **Insert | Hyperlink** menu command. The content of the link will need to be subsequently added within the tags of the newly created hyperlink.

Defining the target of the hyperlink

The target of the hyperlink is created in the Insert Hyperlink dialog (*screenshot below*), which is accessed via the **Enclose With | Hyperlink** or **Insert | Hyperlink** 012.

The target of a link can be either:

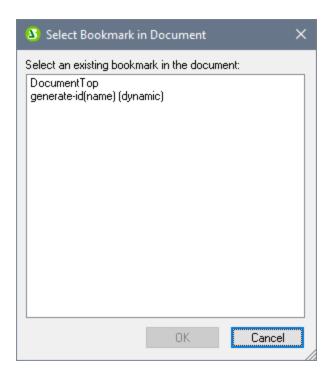

- A bookmark 43 in the same SPS design (in which case the target URI must be a fragment identifier),
- <u>Dynamically generated</u> 445 to match bookmark anchors (these URIs are also fragment identifiers),
- An <u>external resource</u> An <u>external resource</u> the URI can be static (directly entered), dynamic (taken from a node in an XML document), a combination of static and dynamic parts, or the value of an unparsed entity.

How these targets are defined is explained below. After the URI has been defined in the Insert/Edit Hyperlink dialog, click **OK** to finish.

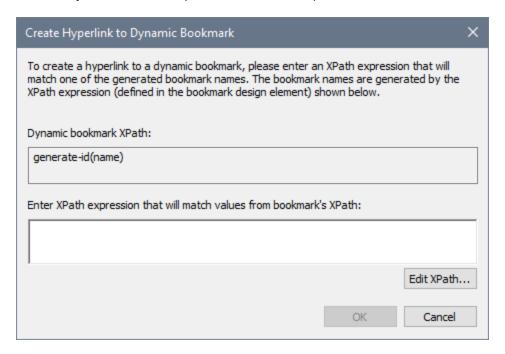

Linking to bookmarks

To link to a bookmark, do the following:

1. In the Static tab of the Insert Hyperlink dialog, click the **Bookmark** button. This pops up the Select Bookmark in Document dialog (*screenshot below*). The screenshot below shows two bookmarks: one static, one dynamic.

2. To select a static bookmark as the target URI, double-click the static bookmark and click **OK**. If you double-click a dynamic bookmark, you will be prompted to enter an XPath expression to match the selected dynamic bookmark (see screenshot below).

The <u>dynamic bookmark</u> is actually an XPath expression that generates the name of the bookmark; it is not itself the name of the bookmark. The Create Hyperlink to Dynamic Bookmark dialog, displays the XPath expression of the dynamic bookmark and enables you to construct an XPath expression that will generate a name to match that of the targeted bookmark. Click **OK** when done.

Linking to dynamically generated ID bookmarks

Bookmarks can have <u>dynamically generated ID anchors</u> 440. If one wishes to link back to such a bookmark, the problem then is this: Since the names of dynamically generated anchors are generated at runtime and therefore unknown at design time, how is one to set the href value of a <u>hyperlink</u> that targets such an anchor? The answer is to use the generate-id() function once again, this time within the href value of the <u>hyperlink</u> 1012. The key to understanding why this works lies in a property of the generate-id() function. In a single transformation, each time the generate-id() function is evaluated for a specific node, it always generates the same ID. Because of this the IDs generated in the bookmark and the hyperlink will be the same.

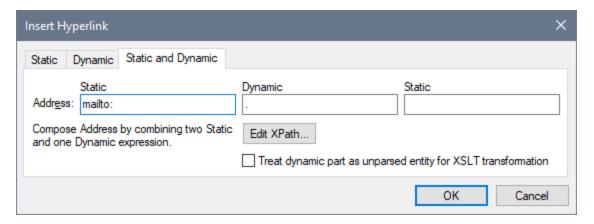

Two points should be borne in mind:

- Since the <code>generate-id()</code> function must be evaluated as an XPath expression, use the Dynamic tab of the Insert Hyperlink dialog (see <code>screenshot below</code>) to set the target of the hyperlink.
- The evaluated value of the href attribute must start with # (the fragment identifier). Consequently the XPath expression will be: concat('#', generate-id(nodeXXX)). Alternatively, in the Static and Dynamic tab, enter # in the static part of the address and generate-id(nodeXXX) in the dynamic part.

Linking to external resources

URIs that locate external resources can be built in the following ways:

- By entering the URI directly in the Static tab of the Insert Hyperlink dialog. For example, a link to the Altova home page (http://www.altova.com) can be entered directly in the Address input field of the Static tab.
- By selecting a node in the XML document source in the Dynamic tab of the Insert Hyperlink dialog. The node in the XML source can provide a text string that is either: (i) the URI to be targeted, or (ii) the name of an <u>unparsed entity</u> which has the required URI as its value. For example, the Altova website address can be contained as a text string in a node.
- By building a URI that has both static and dynamic parts in the Static and Dynamic tab of the Insert Hyperlink dialog. This can be useful for adding static prefixes (e.g. a protocol) or suffixes (e.g. a domain name). For example, email addresses could be created by using a static part of mailto: and a dynamic part that takes the string content of the //contact/@email node (the screenshot below creates a link on the contents placeholder of the //contact/@email node, which is why the abbreviated self::node() selector has been used). The Edit XPath button opens the Edit XPath Expression dialog to help you build the dynamic part of the hyperlink.

How to use unparsed entities is described in the section <u>Unparsed Entity URIs</u> 5500.

Note: While linking to external documents is supported in the FO specification, an FOP limitation could result in external links not working in PDF documents created with FOP.

Authentic View modification of parent node's content

The <u>value of the parent node of a hyperllink can be selected by the Authentic View user</u> . The SPS can be designed to modify presentation based on what the Authentic View user selects.

Editing hyperlink properties

To edit a hyperlink, right-click either the start or end hyperlink (A) tag, and select **Edit URL** from the context menu. This pops up the Edit Hyperlink dialog (*screenshot above*). The Edit Hyperlink dialog can also be accessed via the URL property of the *Hyperlink* group of properties in the Properties window.

Removing and deleting hyperlinks

To delete a hyperlink, select the hyperlink (by clicking either the start or end hyperlink (A) tag), and press the **Delete** key. The hyperlink and its contents are deleted.

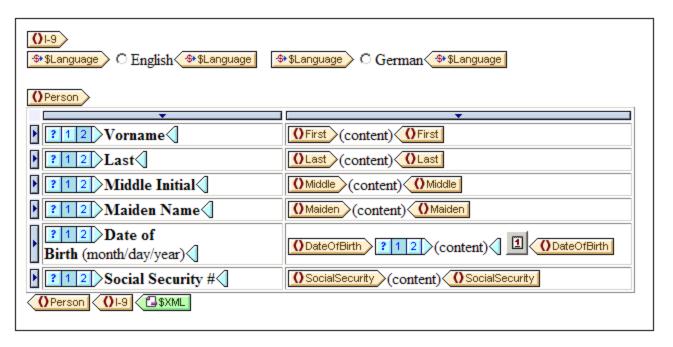

7.8 Example: Multiple Languages

Very often, documents and Authentic Forms will need to contain content in multiple languages or will require the user to choose a preferred language. StyleVision offers a range of features that can be used to achieve these goals. Given below are some possibilities, all of which which are demonstrated in the *Multiple Language* examples in the <code>Examples</code> project delivered with StyleVision. (The <code>Examples</code> project should load automatically by default when you first start StyleVision. It can also be loaded by selecting the menu command **Project |**Open, and then browsing for the <code>Examples.svp</code> file in the folder: <code>C:\Documents</code> and

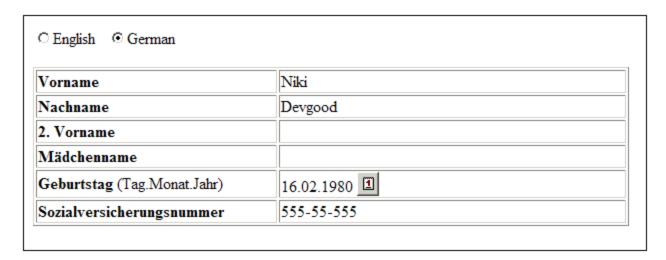

Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples.)

Using variables and conditions

The user's preferred language is entered in an <u>editable variable</u> (410). A <u>condition</u> (381) with multiple branches maps each language to the correct language content. The user's language choice is used to select the correct conditional branch.

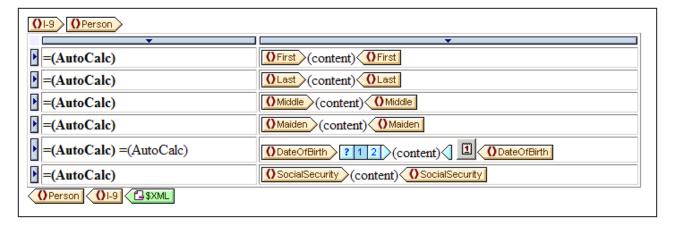

In the screenshot above, notice that the user's choice is entered as the value of the editable variable. The conditions in the table have two branches for the two language choices and test for the value of the editable variable. The Authentic View output is as in the screenshot below.

The above strategy is well-suited for forms in which the user selects the required language. For details, see the file, MultiLangByCondition.sps, which is in the Examples project.

Using parameters and Auto-Calculations

Another scenario would be one in which the same data is required to be output in different languages. A possible strategy for this requirement would be to use a <u>parameter</u> 403, the value of which triggers the required language output. The appropriate language output can be determined, for example, by means of an <u>Auto-Calculation</u> 371. The Auto-Calculation could output the appropriate content according to the value of the parameter.

In the screenshot above, the Auto-Calcs have XPath expressions of the form:

```
if ( $Language = 'E' ) then 'First' else
if ( $Language = 'G' ) then 'Vorname' else ''
```

The value of the \$Language global parameter can be modified in the SPS design or can be supplied via the command line at runtime. Multiple transformation runs can be made to output the same data in multiple languages.

For details, see the file, MultiLangByAutoCalcs.sps, which is in the Examples project.

Example files

For more examples, open the Examples project file, Examples.svp, which is in the folder: C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2025\StyleVisionExamples.

8 Presentation and Output

In the SPS design, a single set of styling features is defined for components. These styles are converted to the corresponding style markup in the respective outputs (*Authentic View, HTML, RTF, PDF, Word 2007+ and Text in the Enterprise Edition; Authentic View, HTML, RTF, and Text in the Professional Edition; HTML in the Basic Edition*). Some presentation effects, notably interactive Web presentation effects (such as combo boxes and JavaScript event handlers), will by their nature not be available in paged media output (RTF, PDF and Word 2007+). In these cases, the paged media will use a suitable print rendition of the effect. For print output, however, StyleVision offers essential page definition options (354). These paged media options (454), such as page size, page layout, and headers and footers, are defined additionally to the styling of components, and will be used for RTF, PDF and Word 2007+ output alone.

Note: Since plain text cannot be formatted, text styling properties and page layouts in the design will be ignored when generating Text output.

Styling of SPS components

All styling of SPS components is done using CSS2 principles and syntax. Styles can be defined in external stylesheets, globally for the SPS, and locally on a component. The cascading order of CSS2 applies to the SPS, and provides considerable flexibility in designing styles. How to work with CSS styles is described in detail in the Working with CSS Styles sub-section of this section.

The values of style properties can be entered directly in the Styles or Properties sidebars, or they can be set via XPath expressions. The benefits of using XPath expressions are: (i) that the property value can taken from an XML file, and (ii) that a property value can be assigned conditionally according to a test contained in the XPath expression.

Additionally, in the SPS design, certain HTML elements are available as markup for SPS components. These predefined formats are passed to the HTML output. The formatting inherent in such markup is therefore also used to provide styling to SPS components. When CSS styles are applied to predefined formats, the CSS styles get priority over the inherent style of the predefined format. Predefined formats are described in the Predefined Formats sub-section of this section. Note that the inherent styles of predefined formats are converted to equivalent markup for RTF, PDF and Word 2007+ output.

Note: When defining CSS styles for an SPS component be aware that some styles may not, by their nature, be applicable to paged media output (RTF, PDF and Word 2007+). Also, when HTML selectors are used (in external stylesheets and global style rules), these will not be applicable to paged media output (RTF, PDF and Word 2007+). When such selectors are used, a comment is displayed next to the selector to the effect that the style will not be applied to Text, RTF, PDF and Word 2007+ output.

Designing for paged media output

For StyleVision's paged media support (RTF, PDF and Word 2007+ outputs and XSLT stylesheets for RTF, PDF and Word 2007+), page definition and layout options are available. These options are used additionally to the component styling mechanism, and are described in the <u>Designing Print Output</u> sub-section of this section.

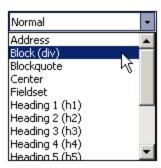

8.1 Predefined Formats

StyleVision provides a number of pre-defined formats, each of which corresponds to an HTML element (*screenshot below*). When you apply a Predefined Format to a component in the Design, that component is marked up as a component having the corresponding HTML semantics. This has two effects:

- Formatting inherent to the selected predefined format is applied.
- The component is contained in the component type, *paragraph*, which <u>makes it available for local styling</u> by component type.

Assigning Predefined Formats

Predefined formats can be assigned by clicking **Insert | Special Paragraph**, and then the required format, or by selecting the required format from the Format drop-down list in the Toolbar (shown below).

Inherent styles

The predefined formats used in StyleVision have either one or both of the following two styling components:

- a text-styling component
- a spacing component.

For example, the predefined para (p) format has a spacing component only; it puts vertical space before and after the selected component, and does not apply any text styling. On the other hand, the predefined Heading 1 (h1) format has both a text-styling component and a spacing component.

The following styling points about predefined formats should be noted:

- The spacing component of a predefined format applies for any type of SPS component, but the text styling only if it can be applied. For example, if you select an image and apply a predefined format of Heading 1 (h1) to it, then the spacing component will take effect, but the text-styling component will not.
- The text-styling component of predefined formats does not apply to data-entry devices.
- Only one predefined format applies to a component at any given time.
- The Preformatted predefined format (pre) applies formatting equivalent to that applied by the pre tab of HTML: linebreaks and spacing in the text are maintained and a monospaced font (such as Courier) is used for the display. In the case of run-on lines with no linebreaks, such as in a paragraph of text, the Preformatted (pre) predefined format will display lines of text without wrapping. If you wish to wrap the text, use the predefined format Preformatted, wrapping (pre-wrap).

Defining additional styling for a predefined format

Styles additional to the inherent styling can be defined for a predefined format by selecting it and applying a <u>local style via the Styles sidebar</u> 472.

The Return key and predefined formats

In Authentic View, when the **Return** key is pressed within the contents of an element having a predefined format, the current element instance and its block are terminated, and a new element instance and block are inserted at that point. This property is useful, for example, if you want the Authentic View user to be able to create a new element, say a paragraph-type element, by pressing the **Return** key.

8.2 Output Escaping

A character in a text string is said to be escaped when it is written as a character reference or entity reference. Both types of references (character and entity) are delimited by an ampersand at the start and a semicolon at the end. For example:

- the hexadecimal (or Unicode) character reference of the character A is A
- the decimal character reference of the character A is A
- the HTML (and XML) entity reference of the character & is & amp;
- the hexadecimal (or Unicode) character reference of the character & is & #x26;
- the decimal character reference of the character & is &
- the HTML (and XML) entity reference of the character < is <

Output escaping

Output escaping refers to the way characters that are **escaped in the input** are represented in the output. A character is said to be output-escaped when it is represented in the output as a character or entity reference. Note that a character can only be output-escaped when it is escaped in the input (*see table below for examples*). In an SPS, output-escaping can be enabled or disabled for:

- Fragments of static text,
- The contents placeholder, and
- Auto-Calculations

This is done with the <code>disable-output-escaping</code> attribute of the *Text* group of properties. The default value of this property is <code>no</code>, which means that output-escaping will not be disabled. So characters that are escaped in the input will be escaped in the output by default (see table below for examples).

To disable output escaping, do the following:

- 1. Select the (i) static text, or (ii) fragment of static text, (iii) contents placeholder, or (iv) Auto-Calculation for which you wish to disable output escaping.
- 2. In the Properties sidebar, select the *Text* group of properties for the *Text* item, and set the disable-output-escaping attribute to yes for the various outputs individually or for all outputs. The available values are:
 - For HTML (to set disable-output-escaping to yes for HTML output).
 - For Authentic (to set disable-output-escaping to yes for Authentic output). Note that disabling output escaping for Authentic View is enabled only in Enterprise editions of Authentic View (that is, in the Enterprise editions of StyleVision, Authentic Desktop, Authentic Browser, and XMLSpy).
 - For RTF (to set disable-output-escaping to yes for RTF output).
 - For PDF (to set disable-output-escaping to yes for PDF output).
 - For Word 2007+ (to set disable-output-escaping to yes for Word 2007+ output).
 - For all (to set disable-output-escaping to yes for all outputs except Text).

Note: Output escaping does not apply to Text output. (It is neither enabled or disabled.)

When output escaping is disabled for a particular output format (for example, HTML output), the selected text will not be escaped in that output format, but will be escaped in the other output formats.

Given below are some examples of text with output escaping disabled and/or enabled.

Static text	disable-output-escaping	Output text
&	no	%amp;
&	yes	&
&	no	&
&	yes	&
<	no	<
<	yes	<
A	no	A ;
A	yes	А
<	no	<
<	yes	<
<	yes	<
&<	yes	&<

Note: Disable-Output-Escaping is supported in Authentic View only in the Enterprise Editions of Altova products.

Using disabled output-escaping across output formats

If output-escaping is disabled, the text string can have significance in one output but no significance at all in another output. For example, consider the following input text, which has escaped characters (highlighted):

```
<b&gt;This text is bold.&lt;/b&gt;
```

If output-escaping is disabled, this text will be output as:

```
<b>This text is bold.</b>
```

If output-escaping is disabled for HTML output and this output is viewed in a browser (as opposed to a text editor), the markup will be significant for the HTML browser and the text will be displayed in bold, like this:

```
This text is bold.
```

However, if viewed in another output format, such as PDF, the markup that was significant in HTML will not necessarily be of significance in this other output format. In the particular case cited above, the unescaped text (output escaping disabled) will be output in PDF format as is, like this:

```
<br/>
<br/>
text is bold.</b>
```

As the example above demonstrates, the output text obtained by disabling output-escaping might be interpretable as code in one output format but not in another. This should be clearly borne in mind when using the Disable-Output-Escaping property.

Value Formatting (Formatting Numeric Datatypes) 8.3

Value Formatting enables the contents of numeric XML Schema datatype nodes (see <u>list below 455</u>) to be displayed in a format other than the lexical representation of that datatype. (For example, the lexical representation of an xs:date datatype node is YYYY-MM-DD, with an optional timezone component, such as +02:00.) The Value Formatting is displayed in Authentic View and, depending on the formatting definition, may also be available for display in the HTML, Txet, RTF, PDF and Word 2007+ output. Value Formatting can also be used to format the result of an Auto-Calculation if the result of the Auto-Calculation is in the lexical format of one of the numeric datatypes (see <u>list below</u> 455) for which Value Formatting is available.

In the sub-sections of this section, we describe:

- how the <u>Value Formatting mechanism works</u> ⁴⁵⁵, and
- the syntax 458 for defining the Value Formatting.

Note: Value Formatting does not change the format in which the data is stored in the XML document. In the valid XML document, the data is always stored in the lexical format appropriate to the datatype of the node. Value Formatting is applied to the display in Authentic View and, optionally (if available), to the display in the output.

Numeric datatypes for which Value Formatting is available

Value Formatting is available for the following datatypes:

- xs:decimal; xs:integer; the 12 built-in types derived from xs:integer
- xs:double and xs:float when values are between and including 0.000001 and 1,000,000. Values outside this range are displayed in scientific notation (for example: 1.0E7), and cannot have Value Formatting applied to them.
- xs:date; xs:dateTime: xs:duration
- xs:gYear; xs:gYearMonth; xs:gMonth; xs:gMonthDay; xs:gDay

8.3.1 The Value Formatting Mechanism

Value Formatting can be applied to:

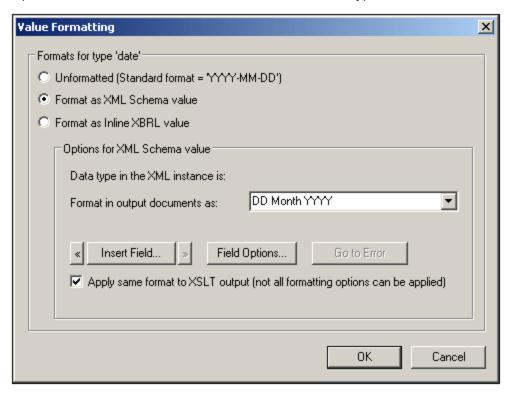

- A <u>numeric datatype node</u> 455, such as xs:decimal or xs:date that is present in the SPS as contents or an input field.
- An Auto-Calculation that evaluates to a value which has the lexical format of a <u>numeric_datatype_455</u>.

Defining Value Formatting

To define Value Formatting for a node or Auto-Calculation in the SPS, do the following:

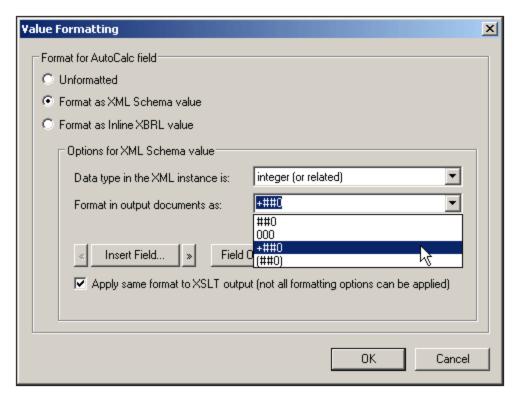

- 1. Select the contents placeholder or input field of the node, or the Auto-Calculation.
- 2. In the Properties sidebar, select the item, and then the Content group (or AutoCalc group) of properties. Now click the Edit button of the Value Formatting property. Alternatively, right-click

and select **Edit Value Formatting** from the context menu. The Value Formatting dialog appears (*screenshot below*). It is different according to whether the selected component was a node or an Auto-Calculation. If the selected component was a node, then a dialog like the one below appears. The node represented in the screenshot below is of the xs:date datatype.

Note that the screenshot above contains the line: Formats for type 'date' and that the standard format for the xs:date datatype is given alongside the Unformatted check box. For a node of some other datatype, this information would be correspondingly different.

If the selected component was an Auto-Calculation, the following dialog appears.

- 3. You now specify whether the display of the component's value is to be unformatted or formatted. If you wish to leave the output unformatted, select the *Unformatted* radio button. Otherwise select the *Format as XML Schema Value* radio button. (If the value is unformatted, the output has the standard formatting for the datatype of the selected node or the datatype of the Auto-Calculation result. If you specify *Formatting as XML Schema Value* for an Auto-Calculation, you have to additionally select (from a dropdown list) the datatype of the expected Auto-calculation result.
- 4. Enter the Value Formatting definition. This definition can be entered in three ways: (i) by selecting from a dropdown list of available options for that datatype (see the 'Format in Output Documents' input field in the screenshots above); (ii) by entering the definition directly in the input field; and (iii) by using the Insert Field and Field Options buttons to build the definition correctly. See <u>Value Formatting</u>
 Syntax
 459 for a full description of the various formatting options.

Errors in syntax

If there is an error in syntax, the following happens:

- The definition is displayed in red.
- An error message, also in red, is displayed below the input field.
- The **OK** button in the Value Formatting dialog is disabled.
- The **Go to Error** button in the Value Formatting dialog is enabled. Clicking it causes the cursor to be placed at the point in the format definition where the syntax error is.

Mismatch of data and datatype formats

If the data entered in an XML node does not match the lexical format of that node's datatype, or if the result of an Auto-Calculation does not match the lexical format of the expected datatype, then the formatting will be undefined and will not be displayed correctly in the output.

Applying Value Formatting to the output

The Value Formatting that you define applies to Authentic View, which is supported in the Enterprise and Professional editions.

Some Value Formatting definitions—not all—can also, additionally, be applied to HTML, Text, RTF, and PDF output. To do this, check the Apply Same Format to XSLT Output check box. If this option is not checked, or if it is not available, then only Authentic View will display the Value Formatting, while the output will display the value in the standard format for the datatype of the component (the lexical format).

8.3.2 Value Formatting Syntax

The syntax for Value Formatting is:

where

prefix character/s and suffix character/s are optional specifiers used to control
alignment and the display of positive/negative symbols;

field can be any datatype-specific formatting or text; and

{field-option(s)} is an optional qualifier, that enables additional formatting options.

Explanation of definition syntax

The Value Formatting definition is constructed as follows:

- The definition is composed of one or more fields. For example, the definition DD Month YYYY has three fields.
- Fields can be run together, or they can be separated by the following characters: space, hyphen, comma, colon, period, or by a text string in single or double quotes. For example, in the definition: DD-Month' in the year 'YYYY, the fields DD and Month are separated by a hyphen, and the fields Month and YYYY are separated by a text string enclosed in single quotes.
- A field can have optional prefix and/or suffix character/s. For example: <+###, ##0.00.
- A field can have one or more optional field-options. The field-option/s for each field must be contained in a single set of curly braces, and must follow the field without any intervening space. Multiple field-options for a single field are separated by "," (comma). For example, in the definition: DD Month{uc,ro} YYYY, the curly-brace-enclosed uc and ro are field-options for the field Month.

Examples

Example of Value Formatting for an xs:decimal datatype:

```
"$"(##0.00)
```

Examples of the output would be:

```
$ 25.00
```

\$ 25.42

\$267.56

Example of Value Formatting for an xs:date datatype:

```
DD Month {uc, ro} YYYY
```

where uc and ro are field-options for making the Month field uppercase and read-only, respectively

An example of the output would be:

24 SEPTEMBER 2003

Field types

A field type represents a component of the data and the way that component is to be formatted. The formatting inherent in the field type can be modified further by prefix and suffix modifiers as well as by field options. The following tables list the available field types. Note that, in the drop-down menu of the Value Formatting dialog, there are type-specific and field-only Value Formatting definitions. You can select one of these and modify them as required by adding prefix modifiers, suffix modifiers, and/or field options.

Field Type	Explanation
#	Space if no digit at position
0	Zero if no digit at position
	Decimal mark
,	Digit group separator
Υ	Year
у	year (base = 1930); see Note below
ММ	Month, must have length of 2
DD	Day, must have length of 2
W	Week number
d	Weekday number (1 to 7)
i	Day in the year (1 to 366)
hh	Hour (0 to 23), must have length of 2
НН	Hour (1 to 12), must have length of 2
mm	Minute, must have length of 2
ss	Second, must have length of 2
АМ	AM or PM
am	am or pm
AD	AD or BC

ad	ad or bc
CE	CE or BCE
се	ce or bce

Field Type	Explanation
Weekday	Weekday (Sunday, Monday)
WEEKDAY	Weekday (SUNDAY, MONDAY)
weekday	Weekday (sunday, monday)
Wkd	Weekday (Sun, Mon)
WKD	Weekday (SUN, MON)
wkd	Weekday (sun, mon)
Month	Month (January, February)
MONTH	Month (JANUARY, FEBRUARY)
month	Month (january, february)
Mon	Month (Jan, Feb)
MON	Month (JAN, FEB)
mon	Month (jan, feb)

Notes on field length and entry length

The following points relating to the length of data components should be noted:

Length of date fields: When fields such as MM, DD, HH, hh, mm, and ss are used, they must have a length of 2 in the definition. When the y or y fields are used, the number of y or y characters in the definition determines the length of the output. For example, if you specify yyy, then the output for a value of 2006 would be 006; for a definition of yyyyyy, it would be 002006. See also Base Year below.

Extending field length: The * (asterisk) symbol is used to extend the length of a non-semantic numeric field (integers, decimals, etc). In the case of decimals, it can be used on either or both sides of the decimal point. For example, the Value Formatting *0.00* ensures that a number will have zeroes as specified in the formatting if these digit locations are empty, as well as any number of digits on both sides of the decimal point.

Entry lengths in Authentic View: The display in Authentic View of the contents of a node is based on the Value Formatting definition for that node. Therefore, the Authentic View user will not be able to insert more characters than are allowed by the Value Formatting definition. This is a useful way to restrict input in Authentic View. Note, however, that if the length of a **pre-existing** value in the XML document exceeds the length specified in the formatting definition, then the entire value is displayed.

Note: If a field does not render any text, this might be because of your region setting in Windows. For example, Windows returns an empty string for the AM/PM field if the regional language setting is German.

Prefix and suffix modifiers

Prefix and suffix modifiers are used to modify the textual alignment and positive/negative representations of fields. The following table lists the available prefix and suffix modifiers.

Prefix	Suffix	Explanation
<		Left aligned; default for text. For numbers, which are aligned right by default, this is significant if there are a fixed number of leading spaces.
>		Right aligned; default for numbers.
?		Minus symbol adjacent to number if negative; nothing otherwise. This is the default for numbers.
</td <td></td> <td>Minus symbol left-aligned if negative; nothing otherwise. Number left-aligned, follows minus sign.</td>		Minus symbol left-aligned if negative; nothing otherwise. Number left-aligned, follows minus sign.
		Minus symbol left-aligned if negative; nothing otherwise. Number right-aligned.
-	-	Minus symbol adjacent to number if negative; space otherwise. Located before number (prefix), after number (suffix).
<-	>-	Minus symbol if negative; space otherwise. Number and sign adjacent. Left-aligned (prefix); right-aligned (suffix).
<->		Minus symbol left-aligned if negative; space otherwise. Number right-aligned.
+	+	Plus or minus sign always, located adjacent to number; before number (prefix), after number (suffix).
<+	>+	Plus or minus sign always, located adjacent to number; left-aligned (prefix), right-aligned (suffix).
<+>		Plus or minus sign always, left-aligned; number right-aligned.
()	Parentheses if negative; space otherwise. Adjacent to number.
<(Parentheses if negative; space otherwise. Adjacent to number. Left-aligned.
<(>		Parentheses if negative; space otherwise. Left parentheses left-aligned; number and right parentheses adjacent and right-aligned.
[]	Parentheses if negative; nothing otherwise. Adjacent to number.
*	*	Extendable number of digits to left (prefix) or to right (suffix)
_	_	Space
۸	٨	Fill character (defined in options)
	th	Ordinality of number in EN (st, nd, rd, or th)
	TH	Ordinality of number in EN (ST, ND, RD, or TH)

Field options

Field options enable advanced modifications to be made to fields. The following options are available:

Option	Explanation
uc	Make uppercase
Ic	Make lowercase
left	Left aligned
right	Right aligned
ro	Read (XML) only; no editing allowed
edit	The field is editable (active by default)
dec= <char></char>	Specify a character for the decimal point (default is point)
sep= <char></char>	Specify a character for the digit separator (default is comma)
fill= <char></char>	Specify fill character
base= <year></year>	Base year for year fields (see note below)
pos	Show only positive numbers; input of negative numbers allowed

Field options should be used to generate number formatting for European languages, which interchange the commas and periods of the English language system: for example, 123.456,75.

The Value Formatting to use to obtain the formatting above would be: ###, ###.## {dec=, , sep=.}

Notice that the field retains the English formatting, while it is the field options dec and sep that specify the decimal symbol and digit separator. If the decimal symbol and digit separator are not specified, these characters will default to decimal symbol and digit separator of the regional settings of the Windows OS (Control Panel | All Items | Region | Format).

Note on Base Year

When using **short year formats** (such as yy and yy), the base year specifies a cut-off for a century. For example, the base year field option could be used in the definition $DD-MM-YY\{base=1940\}$. If the user enters a value that is equal to or greater than the last two digits of the base year, which are considered together as a two-digit positive integer, then the century is the same as that of the base year. If the value entered by the user is less than the integer value of the last two digits, then the century is the century of the base year plus one. For example if you set base=1940, then if the Authentic View user enters 50, the value entered in the XML document will be 1950; if the user enters 23, the value entered in the XML document will be 2023.

Note the following points:

- Although two digits are commonly used as the short year format, one-digit and three-digit short year formats can also be used with a base year.
- Datatypes for which short year formats can be used are: xs:date, xs:dateTime, xs:gYear, and xs:gYearMonth.
- If the Value Formatting is being set for an Auto-Calculation component, make sure that the correct datatype is selected in the Value Formatting dialog. (The selected date datatype should be that of the result to which the Auto-Calculation evaluates.)

- If the yy field type is used, the default base year is 1930. Explicitly setting a base year overrides the
 default
- If the YY field type is used without any base year being set, then the Authentic View user will be able to modify only the last two digits of the four-digit year value; the first two digits remain unchanged in the XML document.

8.4 Working with CSS Styles

The SPS design document is styled with CSS rules. Style rules can be specified:

- In <u>external CSS stylesheets</u> 466. External CSS stylesheets can be added via the <u>Design Overview</u> 45 sidebar and via the <u>Style Repository</u> 54 sidebar.
- In <u>global styles</u> ⁴⁷⁰ for the SPS, which can be considered to be defined within the SPS and at its start. (In the HTML output these global styles are defined within the style child element of the head element.) Global styles are defined in the <u>Style Repository</u> ⁵⁴ sidebar.
- Locally 472, on individual components of the document. In the HTML output, such rules are defined in the style attribute of individual HTML elements. Local style rules are defined in the Styles 57 sidebar.

Each of the above methods for creating styles is described in detail in the sub-sections of this section (*links above*).

Note: Since CSS styles cannot be applied to plain text, they will not be applied to Text output.

Terminology

A CSS stylesheet consists of one or more style rules. A rule looks like this:

```
H1 { color: blue }

or

H1 { color: blue;
    margin-top: 16px; }
```

Each rule has a selector (in the examples above, H1) and a declaration (color: blue). The declaration is a list of properties (for example, color) with values (blue). We will refer to each property-value pair as a style definition. In StyleVision, CSS styles can be defined in the Styles of Styles (local styles) and Style Repository sidebar (global styles).

Cascading order

The cascading order of CSS applies. This means that precedence of rules are evaluated on the basis of:

- 1. *Origin.* External stylesheets have lower precedence than global styles, and global styles have lower precedence than local styles. External stylesheets are considered to be imported, and the import order is significant, with the latter of two imported stylesheets having precedence.
- 2. **Specificity.** If two rules apply to the same element, the rule with the more specific selector has precedence.
- 3. **Order.** If two rules have the same origin and specificity, the rule that occurs later in the stylesheet has precedence. Imported stylesheets are considered to come before the rule set of the importing stylesheet.

CSS styles in modular SPSs

When an SPS module is added to another SPS, then the CSS styles in the referring SPS have priority over those in the added module. When multiple modules are added, then CSS styles in those modules located

relatively lower in the module list have priority. For more information about modular SPSs, see the section, Modular SPSs 330.

CSS support in Internet Explorer

Versions of Internet Explorer (IE) prior to IE 6.0 interpret certain CSS rules differently than IE 6.0 and later. As a designer, it is important to know for which version of IE you will be designing. IE 6.0 and later offers support for both the older and newer interpretations, thus enabling you to use even the older interpretation in the newer versions (IE 6.0 and later). Which interpretation is used by IE 6.0 and later is determined by a switch in the HTML document code. In an SPS, you can specify whether the HTML and Authentic View output documents should be styled according to Internet Explorer's older or newer interpretation 111. You should then set CSS styles according to the selected interpretation. For more details, see Properties: CSS Support 973.

Note: For more information about the CSS specification, go to http://www.w3.org/TR/REC-CSS2/.

8.4.1 External Stylesheets

This section describes how external CSS stylesheets can be managed from within the StyleVision GUI. It consists of the following parts:

- Adding an external CSS stylesheet to the SPS
- Viewing the contents of an external CSS stylesheet and modifying the media applicability 467
- Changing the precedence 468
- Switching between the full CSS stylesheet set and a single CSS stylesheet
 468

External CSS stylesheets can be managed from two sidebars: the <u>Style Repository sidebar</u> and the <u>Design Overview sidebar</u>. If an aspect of the external stylesheets is viewable in both sidebars (for example, the relative precedence of multiple stylesheets), then changes made in one sidebar will automatically be reflected in the other.

Adding an external CSS stylesheet to the SPS

To assign an external CSS stylesheet to the SPS, do the following:

1. In Design View, select the External item in the Style Repository window (screenshot below).

- 2. Click the **Add** button at the top left of the Style Repository toolbar (see screenshot above).
- 3. In the Open dialog that pops up, browse for and select the required CSS file, then click **Open**. The CSS file is added to the External item as part of its tree structure (see tree listing and screenshot below).
- 4. To add an additional external CSS stylesheet, repeat steps 1 to 3. The new CSS stylesheet will be added to the External tree, below all previously added external CSS stylesheets.

Note: You can also add an external CSS stylesheet via the <u>Design Overview</u> sidebar.

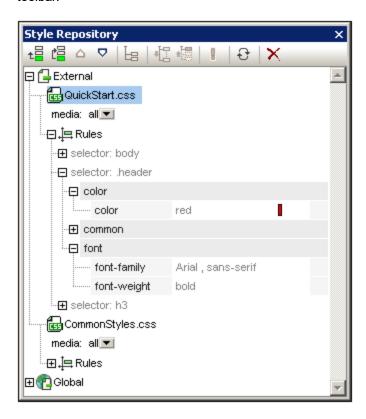

Viewing and modifying the tree of external CSS stylesheets

The tree of external CSS stylesheets is structured as follows (also see screenshot below):

```
- CSS-1.css (File location appears on mouseover)
- Media (can be defined in Style Repository window)
- Rules (non-editable; must be edited in CSS file)
- Selector-1
- Property-1
- ...
- Property-N
- ...
- Selector-N
+ ...
+ CSS-N.css
```

The media to which that particular stylesheet is applicable can be edited in the Style Repository window. Do this by clicking the down arrow to the right of the item and selecting the required media from the dropdown list. The rules defined in the external CSS stylesheet are displayed in the Style Repository window, but cannot be edited. The Stylesheet, Rules, and individual Selector items in the tree can be expanded and collapsed by clicking the + and - symbols to the left of each item (see screenshot below).

To delete an external stylesheet, select the stylesheet and click the **Reset** button in the Style Repository toolbar.

Changing the precedence of the external CSS stylesheets

The external CSS stylesheets that are assigned in the Style Repository window will be imported into the HTML output file using the @import instruction. In the HTML file, this would look something like this:

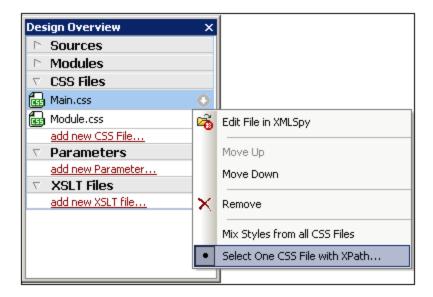

```
<html>
<head>
<style>
<!--
@import url("ExternalCSS-1.css");
@import url("ExternalCSS-2.css")screen;
@import url("ExternalCSS-3.css")print;
-->
</style>
</head>
<body/>
</html>
```

The order in which the files are listed in the HTML file corresponds to the order in which they are listed in the External tree of the Style Repository and in the CSS Files tree of the Design Overview sidebar. To change the order of the CSS stylesheets in the Style Repository, select the stylesheet for which the precedence has to be changed. Then use the Move Up or Move Down buttons in the Style Repository toolbar to reposition that stylesheet relative to the other stylesheets in the tree. In the Design Overview sidebar, click the Edit button of a CSS stylesheet and select the Move Up or Move Down command as required.

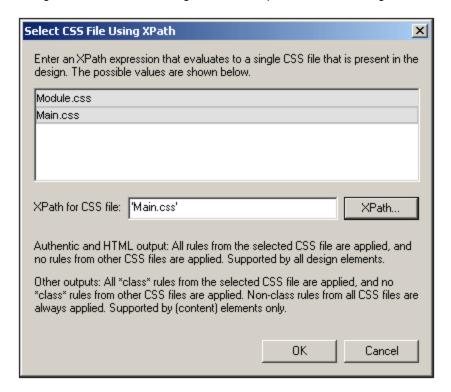

Important: Note that it is the lowermost stylesheet that has the highest import precedence, and that the import precedence decreases with each stylesheet higher in the listing order. The order of import precedence in the listing shown above is: (i) ExternalCSS-3.css; (ii) ExternalCSS-2.css; (iii) ExternalCSS-1.css. When two CSS rules, each in a different stylesheet, use the same selector, the rule in the stylesheet with the higher import precedence applies.

Switching between all CSS files and a single CSS file

You can choose to either: (i) let rules in all CSS files apply with the cascading rules determining precedence, or (ii) let rules in a single selected CSS file apply. You can select the option you want in the Design Overview sidebar (see screenshot below). Click the **Edit** button of any of the listed CSS files and select either the **Mix Styles** command or **Select One** command. This option is also available in the Style Repository (on any of the external stylesheets).

If you click the **Select One CSS File with XPath** command, a dialog pops up in which you can enter the XPath expression (*screenshot below*). The XPath expression must evaluate to the name of one of the CSS files in the SPS, exactly as these names are listed in the top pane of the dialog. If you enter the filename as a string, note that, like all strings in XPath expressions, the string must be entered within single quotes.

Note the following:

When a single CSS file is selected: In the Authentic and HTML outputs, all rules from the selected
CSS file are applied and these rules are supported on all design components. In the RTF, PDF, and
Word 2007+ outputs, only class selector rules from the selected CSS file are applied. Non-class rules
are applied from all CSS files, with conflicts being resolved on the basis of the priority of the CSS file.

In the RTF, PDF, and Word 2007+ outputs, these rules can be applied to the following design components: Auto-Calculations 371, the (contents) placeholder 1311, paragraph (block) components 133, and table cells 149.

When styles are mixed from all CSS files: In the Authentic and HTML outputs, all rules from all the
CSS file are applied and are supported on all design components. Conflicts are resolved on the basis of
the priority of the CSS file. In the RTF, PDF, and Word 2007+ outputs, only non-class selector rules
are applied, with conflicts being resolved on the basis of priority.

8.4.2 Global Styles

Global styles are defined for the entire SPS design in the Style Repository and are listed in the Style Repository under the Global heading. They are passed to Authentic View and the HTML output document as CSS rules. In the HTML document, these CSS rules are written within the /html/head/style element.

In the Style Repository, a global style is a single CSS rule consisting of a selector and CSS properties for that selector. Creating a global style, therefore, consists of two parts:

- Adding a new style and declaring the CSS selector for it
- Defining CSS properties for the selector

Supported selectors

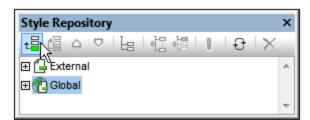

The following selectors are supported:

- Universal selector: written as *
- Type selectors: element names, such as h1
- Attribute selectors: for example, [class=maindoc]
- Class selectors: for example, .maindoc
- ID selectors: for example, #header

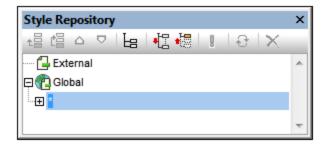

Adding a global style

To add a global style to the SPS design, do the following:

1. In Design View, select the Global item in the Style Repository window (screenshot below).

- 2. Click the **Add** button at the top left of the Style Repository toolbar (see screenshot above). A global style is inserted in the Global tree with a * selector (which selects all HTML elements); the universal selector is the default selector for each newly inserted global style.
- 3. To change the selector from the default universal selector, double-click the selector and edit it.

- 4. Now set the CSS property values for the selector. How to do this is explained in the section <u>Setting Style Values</u> 474.
- 5. To add another global style, repeat steps 1 to 4. The new global style will be added to the Global tree, below all previously added global styles.

Note:

- Global styles can also be inserted before a selected global style in the Global tree by clicking the
 Insert button in the Style Repository window. The Add and Insert buttons are also available via the
 context menu that appears when you right-click a global selector.
- A global style with a selector that is an HTML element can be inserted by right-clicking an item in the Global tree, then selecting **Add Selector | HTML | HTMLElementName**.

Editing and deleting global styles

Both a style's selector as well as its properties can be edited in the Style Repository window.

- To edit a selector, double-click the selector name, then place the cursor in the text field, and edit.
- For information about defining and editing a style's property values, see <u>Setting Style Values</u> (The style properties can be displayed in three possible views. These views and how to switch between them are described in <u>Views of Definitions</u> 57.

To delete a global style, select the style and click the **Reset** button in the Style Repository toolbar.

Changing the precedence of global styles

Global styles that are assigned in the Style Repository window are placed as CSS rules in the /html/head/style element. In the HTML file, they would look something like this:

```
</style>
</head>
<body/>
</html>
```

The order in which the global styles are listed in Authentic View and the HTML document corresponds to the order in which they are listed in the Global tree of the Style Repository. The order in Authentic View and the HTML document has significance. If two selectors select the same node, then the selector which occurs lower down the list of global styles has precedence. For example, in the HTML document having the partial listing given above, if there were an element <h1 class="green">, then three global styles match this element: that with the h1 selector and the two .green class selectors. The color property of the .green selector with the color lime will apply because it occurs after the .green selector with the color green and therefore has a higher precedence. (Class selectors always have a higher precedence than node selectors, so both .green selectors will have a higher precedence than the h1 selector regardless of their respective positions relevant to the h1 selector.) The font-size of the h1 style will, however, apply to the <h1> element because there is no selector with a higher precedence that matches the <h1> element and has a font-size property.

To change the precedence of a global style, select that style and use the **Move Up** and **Move Down** buttons in the Style Repository toolbar to reposition that global style relative to the other global styles in the tree. For example, if the .green global style were moved to a position before the .red style, then the color property of the .red style would have precedence over that of the .green style.

Note, however, that class selectors always have precedence over type selectors. So, if the selector order were changed to .red .green h1 h2, then h1 and h2 would still be green.

8.4.3 Local Styles

When styles are defined locally, the style rules are defined directly on the component. These local rules have precedence over both global style rules and style rules in external CSS stylesheets that select that component. Locally defined styles are CSS styles and are defined either via the Format toolbar or in the styles sidebar. (This is as opposed to global styles, which are defined in the Style Repository sidebar.)

Local styles via the Format toolbar

You can select content in the design and apply local styles via the Format toolbar (screenshot below).

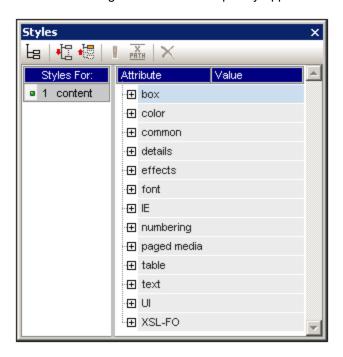

You can apply predefined HTML formatting (such as div, h1, pre, etc), text styling, background color, text alignment, lists, and hyperlinks. See the section, Format toolbar (336), for details.

Local styles via the Styles sidebar

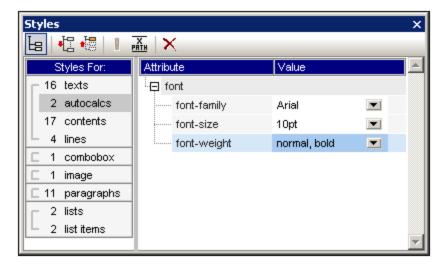

Defining a style locally via the Styles sidebar consists of three parts:

1. The component to be styled is selected in Design View. Any component in the design except node tags can be styled. The component selected in Design View then appears in the *Styles-For* column of

the Styles sidebar (see screenshot below). In the screenshot below, a content component was selected in Design View and consequently appears in the Styles-For column.

Very often, the component selected in Design View might contain other components. In this case all the components in the selection are displayed, organized by component-type, in the *Styles-For* column of the Styles sidebar. The screenshot below shows the different component-types contained in the Design View selection. To the left of each component-type is the number of instances of that component-type in the selection. For example, in the screenshot below, there are 16 text components and two Auto-Calculation components (among others) in the Design View selection. You can also select a range of components by keeping the **Shift** key pressed while selecting the second, end-of-range component.

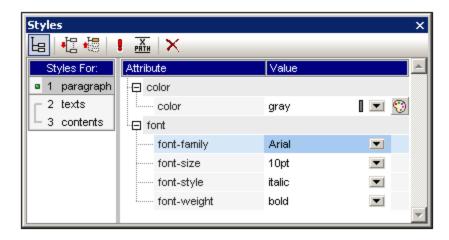

2. After making the selection in Design View, you select, in the *Styles-For* column, the **component-type** you wish to style. If there is more than one instance of the component-type you select, then the styles you define will be applied to all these instances. So, for example, if you select the *16-texts* item of the

screenshot above, then the styles you define (see Step 3 below) will be applied to all 16 text components. If you wish to style, say, four of these text components differently, then you must select and style each of the four components separately. If two components of the same component-type have been styled differently and both are selected in Design View, then the styles of both instances are displayed in the Style Definitions pane. In the screenshot above, for example, while one Auto-Calculation has a normal font-weight, the other has a bold font-weight. When the 2-Autocalcs item is selected in the Styles-For pane, both font-weights are displayed.

3. After selecting, in the *Styles-For* column, the component-type to style, styles are defined in the <u>Style</u> <u>Definitions pane</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do this is described in the section <u>Setting Style Values</u> How to do the setting the

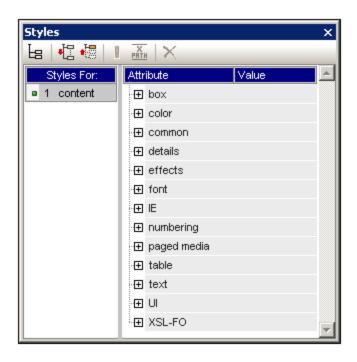

8.4.4 Setting Style Values

For the component-type selected in the *Styles-For* column, style properties are defined in the <u>Style Definitions</u> pane of the <u>Styles sidebar</u> (*screenshot below*). You can select more than one component-type in the *Styles-For* column if you like—by selecting additional component-types with the **Ctrl**-key pressed, or by selecting a range of component-types in the *Styles-For* column with the **Shift**-key pressed. When multiple component-types are selected, any style value you define in the *Style-Definitions* pane is applied to all instances of all the selected component-types.

Style property groups

The available style properties in the *Style-Definitions* column are organized into groups as shown in the screenshot below.

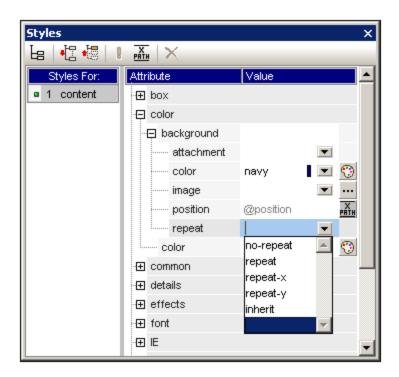

The display of properties can be modified using the <u>List Non-Empty</u> ⁵⁷ <u>Expand All</u> ⁵⁷ <u>and</u> ⁵⁷ <u>Collapse</u> <u>All</u> ⁵⁷ <u>toolbar buttons</u> ⁵⁷. Each group of style properties can be expanded to access style properties or subgroups of style properties (*see screenshot below*).

Entering style values

Style property values (style values for short) can be entered in the following ways, all of which are show in the screenshot below:

- Entered directly in the Value column. To do this, select a property, double-click in its Value column, enter the value using the keyboard, and press **Enter** or click anywhere in the GUI.
- By selecting a value from the dropdown list of the combo box for that property. Click the down arrow of the combo box to drop down the list of style-value options. In the screenshot below, the options for the (background-) repeat property are displayed. Select the required value from the dropdown list.
- By using the icon on the right-hand side of the Value column for that style property. Two types of icon are available, and these are available only for properties to which they are relevant: (i) a color palette for selecting colors (in the screenshot below, see the (background-)color property), and (ii) a dialog for browsing for files (in the screenshot below, see the (background-)image property).

Values for styles can also be assigned via an XPath expression 476.

Modifying or deleting a style value

If a style value is entered incorrectly or is invalid, it is displayed in red. To modify the value, use any of the applicable methods described in the previous section, Entering Property Values (475).

To delete a style value (or, in other words, to reset a style value), click the Reset button in the toolbar of the Styles sidebar. Alternatively, you can double-click in the Value column of the property, and delete the value using the **Delete** and/or **Backspace** key, and then pressing **Enter**.

8.4.5 Style Properties Via XPath

Styles can be assigned to design components via XPath expressions. This enables style property values to be taken from XML data or from the XPath expression itself. Also, by using the doc() function of XPath 2.0/3.0, nodes in any accessible XML document can be addressed. Not only can style definitions be pulled from XML data; this feature also enables style choices to be made that are conditional upon the structure or content of the XML data. For example, using the if...else statement of XPath 2.0/3.0, two different background colors can be selected depending on the position of an element in a sequence. Thus, when these elements are presented as rows in a table, the odd-numbered rows can be presented with one background color while the even-numbered rows are presented with another (see below for example). Also, depending on the content of a node, the presentation can be varied.

Style properties for which XPath expressions are enabled

XPath expressions can be entered for the following style properties:

All properties available in the Styles sidebar

• The Common, Event, and HTML groups of properties in the Properties sidebar

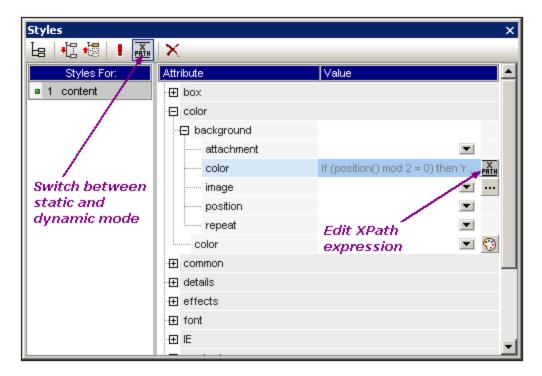

Static mode and dynamic (XPath) mode for property values

For those properties where XPath expressions are enabled 476, two mode are available:

- Static mode, where the value of the property is entered directly in the Value column of the sidebar. For example, for the background-color of a design component, the value red can be entered directly in the sidebar.
- Dynamic, or XPath mode, where an XPath expression is entered. The expression is evaluated at runtime, and the result is entered as the value of the property. For example, for the background color of a design component, the following XPath expression can be entered: /root/colors/color1. At runtime, the content of the node /root/colors/color1 will be retrieved and entered as the value of the background-color property.

Switching between static and dynamic (XPath) modes

For each property for which XPath expressions are enabled, static mode is selected by default. To switch a property to dynamic (XPath) mode, select that property and click the XPath icon in the toolbar of the sidebar (screenshot below).

If a static value was present for that property, it is now cleared and the mode is switched to dynamic. The <u>Edit</u> <u>XPath Expression dialog</u> appears. It is in this dialog that you enter the XPath expression for the property. Click **OK** when finished.

After you enter an XPath expression for the property, an **Edit XPath** expression button appears in the Value column for that property (*screenshot above*). Click this button to subsequently edit the XPath expression. If you wish to switch back to static mode, click the XPath icon in the toolbar. This will clear the XPath expression and switch the property to static mode.

Note: There are two important points to note. First, only one mode (static or dynamic), and the value/expression for that mode, is active at any time. Any value/expression that previously existed for the other mode is cleared; so switching to the other mode will present that mode with an empty entry field. (In order to go back to a previous value/expression, use the <u>Undo command</u>) Second, if you reselect a property after further editing the SPS, then that property will be opened in the mode it was in previously.

Creating and editing the XPath definition

The XPath definition is created and edited in the Edit XPath Expression dialog ⁹¹⁷. This dialog is accessed in two ways:

- Each time you switch to the dynamic mode of a property from static mode (by clicking the XPath icon in the toolbar of the sidebar), the <u>Edit XPath Expression dialog</u> appears. You can now create the XPath expression. (Note that clicking the toolbar icon when already in dynamic mode switches the mode to static mode; it does not pop up the Edit XPath Expression dialog.)
- The <u>Edit XPath Expression dialog</u> also pops up when you click the **Edit XPath Expression** button in the Value field of a property that already has an XPath expression defined for it. The dialog will contain the already defined XPath expression for that property, which you can now edit.

After you enter or edit the XPath expression in the entry field, click **OK** to finish.

Values returned by XPath expressions

The most important benefits of using XPath expressions to set a property value are that: (i) the property value can be taken from an XML file (instead of being directly entered); and/or (ii) an XPath expression can test some condition relating to the content or structure of the XML document being processed, and accordingly select a value. XPath expressions return values in the following two categories:

XML node content

The XPath expression can address nodes in: (i) the XML document being processed by the SPS, or (ii) any accessible XML document. For example the expression Format/@color would access the color attribute of the Format child of the context node. The value of the color attribute will be set as the value of the property for which the XPath expression was defined. A node in some other XML document can be accessed using the doc() function of XPath 2.0. For example, the expression doc('Styles.xml')//colors/color-3 would retrieve the value of the element color-3 in the XML document Styles.xml and set this value as the value of the property for which the XPath expression was defined.

• XPath expression

The value of the property can come from the XPath expression itself, not from the XML document. For example, the background color of an element that is being output as a row can be made to alternate depending on whether the position of the row is odd-numbered or even-numbered. This could be achieved using the XPath 2.0/3.0 expression: if $(position() \mod 2 = 0)$ then 'red' else 'green'. Note that the return value of this expression is either the string red or the string green, and it will be set as the value of the property for which the XPath expression was defined. In the example just cited, the property values were entered as string literals. Alternatively, they could come from an XML document, for example: if $(position() \mod 2 = 0)$ then doc('Styles.xml')//colors/color-1 else doc('Styles.xml')//colors/color-2. Conversely, the XPath expression could be a straightforward string, for example: 'green'. However, this is the same as entering the static value green for the property.

Limitations

The Style Properties Via XPath feature has the following limitations:

- 1. For RTF output, **colors** are entered by StyleVision in a table in the RTF document. This table is created at the time the XSLT-for-RTF is generated (including for RTF Preview) and contains, by default, the 140 standard colors supported by most web browsers. If values for color properties are obtained from the XML data or XPath expression, and are not one of the 140 standard colors, the next best standard color will be used. For example, #FF0001 is not one of the 140 standard colors; so the value #FF0000 (red) will be used.
- 2. For RTF, PDF, and Word 2007+ output, values obtained for the class property from the XML data or a literal in the XPath expression will be applied to the following design components: Auto-Calculations 131, the (contents) placeholder 131, paragraph (block) components 133, and table cells 149.

8.4.6 Composite Styles

A Composite Style is a group of CSS text-styling properties that have been associated with an attribute of an XML instance document node. Additionally, any group of CSS text-styling properties stored in the stylesheet is also considered to be a Composite Style. Composite Styles can then be specified on the following design components:

- Auto-Calculations 371
- The (contents) placeholder (131)
- Paragraph (block) design elements
- Table cells 149

Advantages of Composite Styles

Composite Styles offer the following advantages:

- Styling properties are in the XML data and can therefore be edited by the user. In Authentic View, the RichEdit feature enables a toolbar-based, graphical editing of Composite Styles. See the section, Composite Styles in Authentic (483), for more information about setting up RichEdit for Composite Styles.
- The styling properties of the design components listed above can be a combination of properties stored in the XML data and properties assigned in the SPS.
- In the SPS design phase, the SPS designer can quickly switch between the multiple Composite Styles associated with an element.

Entering the Composite Style in the XML attribute

A Composite Style (composed of multiple styling properties) is entered as the attribute-value of an element in the source XML document. For example, the <code>desc-style</code> attribute in the XML source document listing below contains a default Composite Style:

```
<Desc desc-style="font-family:Verdana; font-size:12pt; color:blue">
```

You can also set more than one Composite Style on an element. In this case, each Composite Style must be entered in a separate attribute:

```
<Desc styleBlue="font-family:Verdana; font-size:12pt; color:blue"
    styleRed ="font-family:Verdana; font-size:12pt; color:red">
```

When multiple Composite Styles are available on an element, you can switch among Composite Styles when setting a value for the *Composite Style* property of a design component (see below).

Note: The attributes that will be used to access the Composite Styles must be defined in the source schema in order for the XML document to be valid.

Supported CSS text-styling properties

The following CSS styles can be used in Composite Styles:

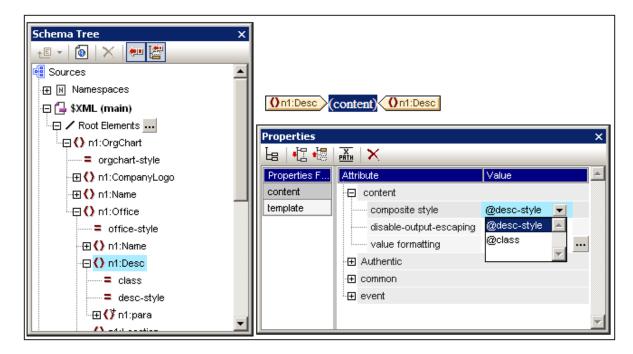

font-family	font-size	font-weight	font-style
color	background-color	text-align	text-decoration

Setting an attribute as the Composite Style value

If you set the Composite Style of a design component to be an attribute, then the Authentic View user can edit this Composite Style. The Authentic View user can place the cursor anywhere within the text output of the design component and use the RichEdit toolbar of Authentic View to edit the Composite Style of that design component.

To set an attribute as the Composite Style of a design component, do the following:

1. In Design View, select the design component to which you wish to assign an attribute as Composite Style. In the screenshot below, the (contents) placeholder of the Desc element has been selected.

2. In the combo box of the Composite Style property of the Content component (see Properties sidebar at bottom right of screenshot above), the attributes of the context element are displayed. Select the attribute you wish to set as the Composite Style of the design component. (Note that there is also an empty entry in the combo box should you wish to apply no Composite Style. In this case, the RichEdit feature of Authentic View will not be enabled in the output of this design component.)

In Authentic View the user can now use the RichEdit toolbar to modify the Composite Style of this design component.

Setting an XPath expression as the Composite Style value

You can also enter an XPath expression as the value of the *Composite Style* property. In this case, however, since the Composite Style is stored in the SPS (not in the XML source document), the Authentic View will not be able to edit the Composite Style.

To set an XPath expression as the value of the *Composite Style* property, click the **XPath** icon in the toolbar of the Properties sidebar, and then enter the XPath expression in the XPath dialog that pops up. The XPath expression will be evaluated as an attribute value template; the returned value will be the value of an HTML style attribute (and its equivalent in non-HTML output formats).

For example, consider the following XPath expression created on the (contents) placeholder of the n1:Person element.

```
if (number(n1:Shares) gt 1000) then 'color:red' else 'color:green'
```

What this expression will do is this: If the n1:Person element has a child element n1:Shares with a number value greater than 1000, then the contents of the n1:Person element is output in red; otherwise, all n1:Person elements are output in green. The value returned by the XPath expression is passed to the output document as the value of an HTML style attribute (or its equivalent in non-HTML output formats).

In the XSLT stylesheet generated from the SPS, this XPath expression will be evaluated as an attribute value template, something like this:

```
<span style="{if (number(n1:Shares) gt 1000) then &apos;color:red&apos; else
&apos;color:green&apos;}">
```

In the HTML output, one of the following lines would be generated depending on how the condition is evaluated:

```
<span style="color:red">
or
     <span style="color:green">
```

Note: Attribute value templates are XSLT constructs that allow the value of an attribute to be read as an XPath expression. They are delimited by curly braces and allow the value of the attribute to be assigned dynamically.

8.5 Text-Styling Flexibility in Authentic

An SPS can be set up so that Authentic View users can also style text. They do this by selecting a text fragment in Authentic View and setting styling properties for the selected text. These styling properties can be pre-defined by you (the SPS designer) or they can be defined by the Authentic View user. In either case, the Authentic View user can be given the option of styling text in Authentic View.

The following text-styling options are available:

- Composite Styles (483): A set of CSS style properties (the Composite Style) is defined on the attribute of an element in the source XML document. By setting this attribute as the Composite Style property-value of a design component, the Composite Style becomes editable with the RichEdit (485) feature of Authentic View. See the section Composite Styles (483) for a description of how this mechanism works.
- RichEdit 485: If an element is created in the SPS design as a RichEdit component, then the Authentic View user can select text fragments within that element and style it using the RichEdit styling properties of Authentic View. RichEdit enables the Authentic View user to specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of text. See the section RichEdit 485 for details.
- Text State Icons (the SPS designer) can create an Authentic View toolbar button and associate this button with an element name. We call such a toolbar button a Text State Icon. When the Authentic View user selects a text fragment in Authentic View and clicks a Text State Icon, the element associated with the Text State Icon is created around the highlighted text (a Text State Icon is enabled only if the schema allows it around the selected text). Consequently, the text formatting defined for this element (in a global template for this element) will be applied to the selected text fragment.

You can use a combination of all three text-styling options in your SPS.

You should note the following points:

- All three text-styling options depend on and require styling-related elements and/or attributes to be
 present in the XML document. Consequently, the schema on which the SPS is based must allow the
 required elements and/or attributes at the hierarchical levels on which they are required.
- Text styling applied by the Authentic View user will appear in both Authentic View as well as the output formats.

Note: The styling options listed above are derived from styling properties stored in the XML file and are additional to styling properties assigned in the SPS.

8.5.1 Composite Styles

The Composite Styles feature gives Authentic View users the ability to style the entire output of the following design components:

- Auto-Calculations 371
- The (contents) placeholder 131
- Paragraph (block) design elements (133)
- <u>Table cells</u> 149

The mechanism for doing this is explained below.

Note: For a further more general description of Composite Styles, see the section <u>Composite Styles</u> ⁴⁷⁹. The description in this section describes how Composite Styles can be set up so that the Authentic View user can edit them.

Entering the Composite Style in the XML attribute

A default Composite Style (composed of multiple styling properties) is entered as the attribute-value of an element in the source XML document. For example, the <code>desc-style</code> attribute in the XML source document listing below contains a default Composite Style:

```
<Desc desc-style="font-family:Verdana; font-size:12pt; color:blue">
```

You, the SPS designer, can now allow the Authentic View user to edit these styling properties. This gives the Authentic View user control over the styling of the design component's text output. You enable user-editing of a Composite Style by setting the Composite Style of the design component to be the attribute containing the default Composite Style (see below).

Note: The attributes that will be used to access the Composite Styles must be defined in the source schema in order for the XML document to be valid.

Supported CSS text-styling properties

The following CSS styles can be used in Composite Styles:

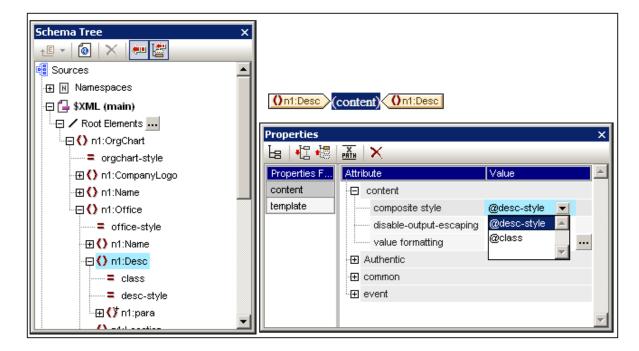

font-family	font-size	font-weight	font-style
color	background-color	text-align	text-decoration

Setting the attribute as the Composite Style of a design component

If you set the Composite Style of a design component to be an attribute, then the Authentic View user can edit this Composite Style. The Authentic View user can place the cursor anywhere within the text output of the design component and use the RichEdit toolbar of Authentic View to edit the Composite Style of that design component.

To set an attribute as the Composite Style of a design component, do the following:

1. In Design View, select the design component to which you wish to assign an attribute as Composite Style. In the screenshot below, the (contents) placeholder of the Desc element has been selected.

2. In the combo box of the Composite Style property of the Content component (see Properties sidebar at bottom right of screenshot above), the attributes of the context element are displayed. Select the attribute you wish to set as the Composite Style of the design component. (Note that there is also an empty entry in the combo box should you wish to apply no Composite Style. In this case, the RichEdit feature of Authentic View will not be enabled in the output of this design component.)

In Authentic View the user can now use the RichEdit toolbar to modify the Composite Style of this design component.

8.5.2 RichEdit

If an element is created in the SPS design as a RichEdit component, then the Authentic View user can mark text fragments within that element and style it using the RichEdit styling properties of Authentic View, as well as set paragraph-level formatting, such as text aliognment.

RichEdit enables the Authentic View user to specify the following:

- Character styles: font, font-weight, font-style, font-decoration, font-size, color, background color.
- Paragraph styles: text alignment.

This description of the RichEdit feature given below is organized as follows:

- The RichEdit mechanism 486
- Creating an element in the SPS design as a RichEdit component
- <u>Using RichEdit in Authentic View</u>

The RichEdit mechanism

When an Authentic View user selects a text fragment in Authentic View and applies RichEdit styling to it, the RichEdit styling element and the attribute that holds the styling information is created around the selected text fragment. The RichEdit style properties that the Authentic View user selects are inserted as the value of this styling attribute.

So, if there is a text fragment in the source XML document like this:

```
 ... Altova StyleVision 2012 features a unique graphical design interface ...
```

and a part of this text fragment is given a RichEdit style property of bold, then the text fragment in the source XML will look like this:

```
... <span style="font-weight: bold">Altova StyleVision 2012</span> features a unique graphical design interface ...
```

The RichEdit styling element in the example above is span and its attribute that is to contain the RichEdit styling properties is style. They could be called anything. For example, instead of calling the styling element span, you could call it Style, and instead of calling the styling attribute style, you could call it css. In this case, the text fragment would then be marked up like this:

```
... <Style css="font-weight: bold">Altova StyleVision 2012</Style> features a unique graphical design interface ...
```

The important thing is that whatever name you choose for the styling element and attribute, **this styling element and attribute must be defined in the schema** and must be allowed within every element containing the text that is to be styled.

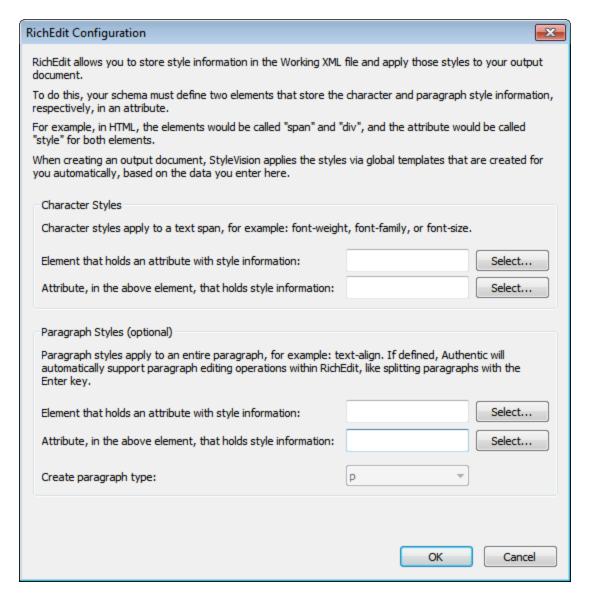

When the text is processed with an XSLT stylesheet, the style properties are passed to the output as markup appropriate to the output format.

RichEdit also enables Authentic View users to apply block-level formatting (such as text-alignment). You can select the element and attribute that will contain the block-level formatting, similarly to how this is done for text fragments as described above. Certain block-level formatting properties, such as block-level text alignment, will then become available to the Authentic View user when the user edits an element that contains the element that has been defined for paragraph styles in the RichEdit Configuration dialog. As with character styles, the schema must be defined to allow the RichEdit paragraph-styling element inside any element in which you wish to make this paragraph styling available.

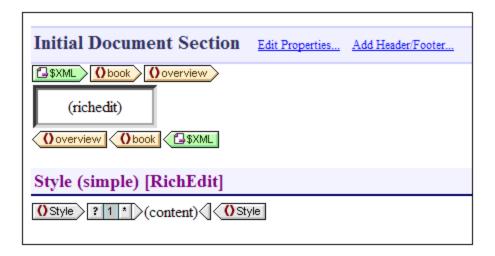

Creating an element as a RichEdit component

To create an element as a RichEdit component, do the following:

- 1. Drag the element from the Schema Tree and drop it at the desired location in the design.
- From the menu that pops up, select Create RichEdit. The RichEdit Configuration dialog (screenshot below) pops up. (If a RichEdit character style has already been created for the document, you must right-click a RichEdit component in the design and select Configure RichEdit Elements/Attributes to pop up the RichEdit Configuration dialog.)

- 3. In the RichEdit Configuration dialog, and in the *Character Styles* pane, enter the name of the styling element and its attribute that is to contain the RichEdit styling properties for text fragments. You can also select the required element and attribute from the schema tree. Click the respective **Select** buttons to open the schema tree.
- 4. To enable block-level formatting (text alignment), do the following. In the *Paragraph Styles* pane, select the element and attribute that will contain the block-level formatting. In the *Create Paragraph Type* combo box, you can select the predefined format of the paragraph; this predefined format will be passed to the output.
- 5. When done, click **OK**. The element is created as a RichEdit component (see screenshot below), and an **uneditable** RichEdit global template for character styles that has the name of the styling element (Style in the screenshot below) is created in the design. If paragraph styles have also been specified, then an uneditable RichEdit global template for paragraph styles is also created.

Note the following:

- The uneditable RichEdit global template is created when the first RichEdit component is created in the SPS. No additional RichEdit global templates are created subsequently.
- When elements are created as RichEdit components subsequent to the creation of the first RichEdit component, the RichEdit Configuration dialog does not appear. All RichEdit components are indicated by having within them a RichEdit text box (see the overview element in the screenshot above). This RichEdit text box appears instead of the usual contents placeholder.
- The RichEdit global template can be reconfigured in that the styling element and attribute for character styles and paragraph styles can be changed. Do this by right-clicking a RichEdit component, selecting Configure RichEdit Element/Attribute, and entering the desired element and attribute names. The new element names (for character styles and paragraph styles) will appear in the title bar of the RichEdit global templates.

All schema elements that have been created as RichEdit components can now be styled with RichEdit properties in Authentic View.

Using RichEdit in Authentic View

In Authentic View, when the cursor is placed inside an element that has been created as a RichEdit component, the buttons and controls in the RichEdit toolbar (*screenshot below*) become enabled. Otherwise they are grayed out.

To apply character styles, select the text to be styled. To apply paragraph styles, place the cursor within the paragraph to be styled. Then specify the required styling via the buttons and controls of the RichEdit toolbar. If the selected text is not already enclosed within the tags of the styling element, it will be enclosed now.

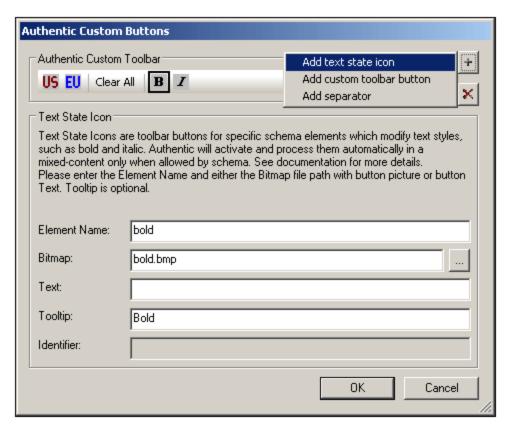

8.5.3 Text State Icons

A Text State Icon is an Authentic View toolbar button that is associated with an element name. In Authentic View, when a Text State Icon is clicked, the selected text fragment is enclosed by the element associated with the Text State Icon. The text formatting defined for this element (in the element's global template) will therefore be applied to the selected text fragment. In this way, the Authentic View user can apply text styles using Text State Icons.

As the SPS designer, you will create the Text State Icons and define the styles of the elements associated with the Text State Icons.

Creating a Text State Icon

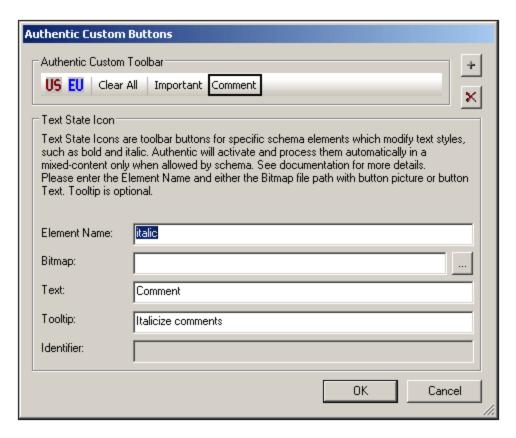

To create a Text State Icon for the Authentic toolbar, first select the command **Authentic | Custom Toolbar Buttons**, then click the **Add** button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select **Add Text State Icon**.

Text State Icons take the following parameters:

- *Element Name:* This is the element that will enclose the selected text fragment when the Text State Icon is clicked in Authentic View.
- Bitmap: The location of an image for the Text State Icon. The file path is relative to the SPS.
- *Text:* If no bitmap is available, the text entered in this field will be used as the button text of the Text State Icon.
- Tooltip: This is an optional guide for the Authentic View user on mouseover.

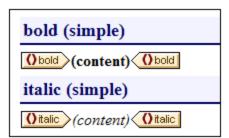

In the example above, we have used familiar bitmaps as the Text State Icons to mark up text with the bold and italic elements. If you wish, you could use any bitmap or button text that you think might be easier for the Authentic View user to relate to. For example, important text fragments could be associated with the bold element, while comments could be associated with the italic element. The Text State Icons could then be created as shown in the screenshot below.

In the above screenshot, note that the **Comment** Text State Icon is associated with the <code>italic</code> element. So, when text is selected in Authentic View and then the **Comment** Text State Icon is clicked, that text fragment will be enclosed by the <code>italic</code> element and will be processed in the way defined for the <code>italic</code> element (described in the next section).

Defining a style rule for the element associated with a Text State Icon

The style properties of an element associated with a Text State Icon can be defined in a global template (see screenshot below).

This screenshot shows the global templates of two elements (bold and italic), each of which has been associated with a Text State Icon. The styling has been done by selecting the (contents) component and defining the desired font style in the Styles sidebar.

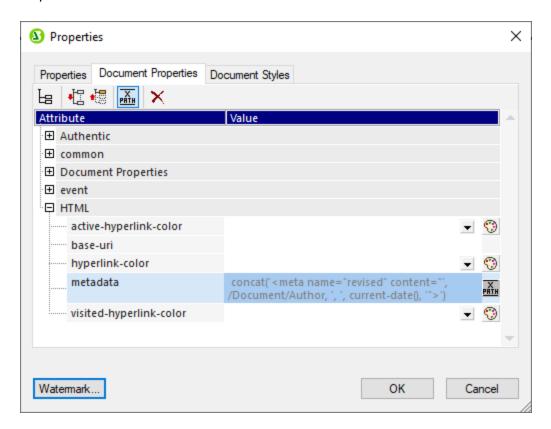

Consequently, whenever the Authentic View user creates these elements around text fragments, the respective global template (with its text styles) is applied to that text fragment.

8.6 HTML Document Properties

Properties of the output HTML document can be specified either in the *Document Properties* tab in the Properties dialog of the <u>Initial Document Section</u> or in Properties View when the <u>Main Template in the Design Tree window</u> is selected.

Via properties of the Initial Document Section

Click the *Edit Properties* hyperlink in the <u>Initial Document Section</u> 493 title bar and then select the *Document Properties* tab.

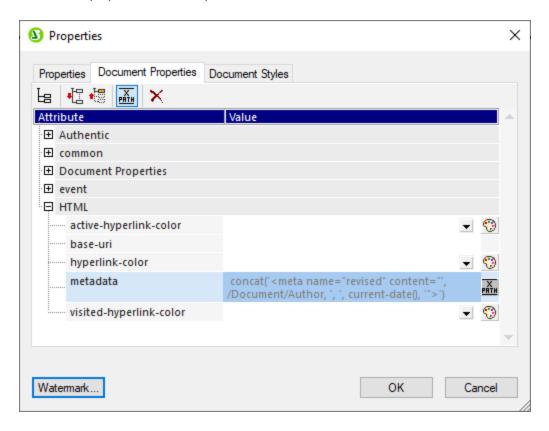

Here you can set various properties of the HTML output document that will be generated. Note the following points:

- These are HTML properties that will be applied at the document level, for example, the class and id properties of the *Common* properties section.
- The *Document Properties* and *HTML* sections contain generic properties that relate to the HTML document as a whole, such as link colors, and information that goes into the meta tags of the HTML document.
- The metadata property of the HTML section enables you to enter any text that you want to go into the HEAD element of the HTML document (see screenshots above and below). The text you enter could, for example, be a script or meta element, or several such elements. You can enter these HTML elements directly as text (without quotes) or, as in the screenshots, as an XPath expression. In the screenshot example, the XPath expression sets a meta tag for the revision date of a document.

Via the properties of the Main Template

In the <u>Design Tree</u> sidebar, select the Main Template. In the Properties sidebar (*screenshot below*), you can now set the properties of the output HTML document.

The properties in this dialog are exactly the same as those in the Document Properties tab described above.

8.7 Designing Print Output

Properties for paged media output (PDF, RTF, and Word 2007+ in the *Enterprise Edition*; and RTF in the *Professional Edition*) can be defined in the *Page Layout* group of properties in the <u>Properties sidebar</u> 53. The following can be designed for print media:

- The document can be divided into sections, each of which can have separate page definitions. The properties that can be defined are listed below.
- Page dimensions (height and width) and and a page orientation (portrait or landscape) can be defined.
- The margins for the body of the page and the available vertical space for headers and footers can be defined. Also, multiple pages can be defined to be facing (that is, with mirror margins) or to have the same let and right margins repeating for each page.
- Headers and footers can be defined for each section.
- Numbering styles and numbering starts can be defined for each section separately, or page numbering can run on from one section to the next.
- For each section, the number and width of columns on a page can be specified.

Note: When a large document is processed by FOP (Apache's FO processor), data in memory is discarded each time a new document section is processed. If you wish to reduce memory use, therefore, it is best to structure your document into multiple document sections.

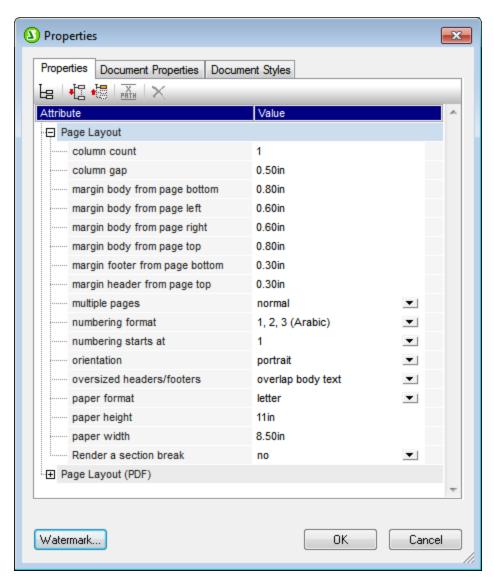

Note: Since page layouts cannot be applied to plain text output, the features for designing print output that are described in this section will not be applied to Text output.

Properties sidebar

Page properties can be defined individually for each section of the document in the *Page Layout* group of properties in the Properties sidebar (*see screenshot below*). These properties for a given section are accessed via the Edit Properties link of the Initial Section and Document Section items in the design (*screenshot below*).

Document Section Edit Properties... Add Header/Footer... Hide Headers/Footers

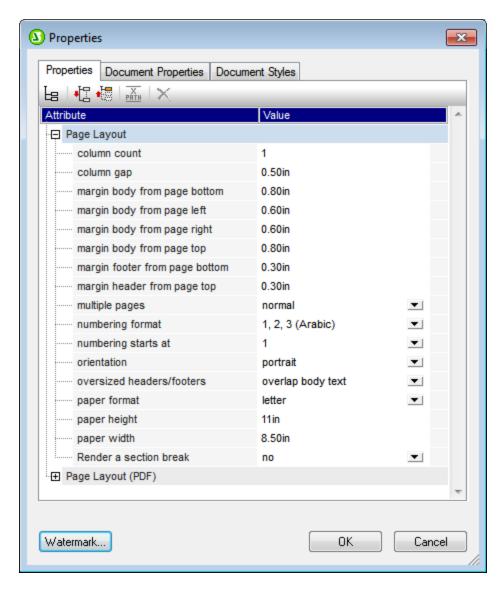

Clicking the Edit Properties link pops up the Properties window, with the Page Layout properties active within it (screenshot below).

How to set the values of these properties is discussed in the section, <u>Page Properties</u> 500.

8.7.1 Document Sections

An SPS can be designed to have multiple document sections, with each document section having its own page definition settings. For example, a report which contains tables of data and text that summarizes this data can be divided into two document sections: one document section can contain the descriptive text and have portrait orientation, while the other document section with the tables of data can have landscape orientation. For each document section, the whole range of <u>page properties</u> (see screenshot below) can be defined. Additionally, each document section can also have different headers and footers.

When an SPS is created, it is created with one document section, called the Initial Document Section. This document section is the first document section of the document (whether a single-sectioned or multiple-sectioned document) and cannot be deleted. Initial Document Section properties include properties and styles for the entire document; these are described in the subsection, Initial Document Section (493).

Note: When a large document is processed by FOP (Apache's FO processor), data in memory is discarded each time a new document section is processed. If you wish to reduce memory use, therefore, it is best to structure your document into multiple document sections.

Inserting document sections

To add a new document section, do the following:

- 1. Place the cursor at the location in the document where you want the new document section to start.
- 2. In the context menu (right-click), select Insert Page / Column / Document Section | New Document Section. Alternatively, select this command from the Insert menu. A new document section will be inserted in the design and is indicated by a document section title bar (see screenshot

below; the Hide/Show Headers/Footers hyperlink shown in the screenshot below appears after a Header or Footer has been added to a document section). In the output, a new document section will start on a new page.

Document Section

Edit Properties... Add Header/Footer... Hide Headers/Footers

- 3. The new document section will have the page layout properties that were assigned to the Initial Document Section at the time the new document section was created. These page layout properties for the document section can be edited via the Edit Properties hyperlink of the Document Section. If required, separate headers and footers can be added for the document section (via the Add Header/Footer hyperlink). How to define page layout properties and headers and footers are described in the respective subsections of this section. When a header or footer is added, it is shown in the design within that document section. The display of headers and footers in the design can be toggled on and off with the Hide/Show Headers/Footers hyperlink; this hyperlink appears after a Header or Footer has been added to a document section.
- 4. If you wish to create a new page for the section immediately after the Initial Document Section, go to the page layout definitions of the Initial Document Section and give the Render a Section Break property a value of Yes. This starts the first non Initial Document Section on a new page. Note the converse effect also, that is, when the property has a value of No. In this case, the first non Initial Document Section starts directly after the Initial Document Section, without rendering a page break. This is useful if the Initial Document Setting is blank—for example, if it contains only design processing templates that produce no output. A property value of No ensures that the first page of the print output document will not be blank (which would have been the case if a blank page with a break after it were to be rendered for the Initial Document Section).

Notes

Note the following points:

- In the PDF and RTF output generated by XSLT 1.0 SPSs, only document sections that are immediate children of the Main Template are allowed. Document sections created inside conditional templates, other templates, or at any level other than that of child of the Main Template, will create only a page break in the PDF output. This restriction does not apply to PDF and RTF output generated by XSLT 2.0 or XSLT 3.0 SPSs.
- In the output document, every document section starts on a new page.
- Page margin properties are also applied to the HTML page.
- When multiple document sections are present in a design, values of the mirror margins property and
 the associated margin-left and margin-right properties are taken from the initial document section. The
 values of these properties in subsequent document sections are ignored.

Deleting a document section

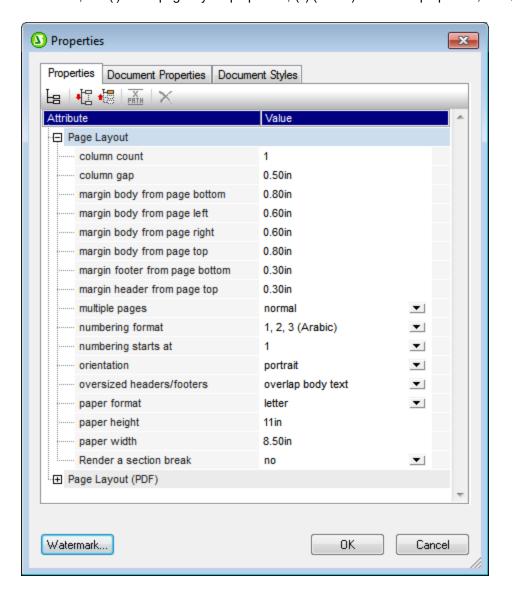

To delete a document section, in the title bar of the document section, right-click the words *Document Section*, and in the menu that pops up select the command **Edit | Delete**. The document section will be deleted, and this will be indicated by the deletion of the title bar. By deleting the document section you will be deleting the page layout properties and headers and footers created for the document section. The content of the document section, however, will not be deleted.

8.7.1.1 Initial Document Section

Whether the document has one document section or more, properties for the document as a whole are defined in those of the Initial Document Section (the first document section of the document, *screenshot of title bar below*). Cover pages are also created in Initial Document Sections.

Initial Document Section Edit Properties... Add Header/Footer...

To edit the properties of the document, click the *Edit Properties* hyperlink in the Initial Document Section title bar. This pops up the Properties dialog of the Initial Document Section (*screenshot below*). This dialog has three tabs, for: (i) basic page layout properties, (ii) (HTML) document properties, and (iii) document styles.

Page layout properties

Page layout properties for the initial document section apply to the first document section of the document; in single-section documents, they apply to the entire document. When a new document section is created, it is created with the page layout properties of the Initial Document Section at that time. The properties of the new document section can be edited subsequently. If a property of the Initial Document Section is changed, this change will not be passed to other document sections that already exist. New document sections will be created with the latest values of the Initial Document Section. The various page layout properties are described in the section Page Layout Properties The **Watermarks** button brings up the Watermarks dialog in which you can define a watermark for the section's pages. A different watermark can be defined for each section.

Document properties

Properties of the output HTML document are specified in the <u>Document Properties tab</u> 492.

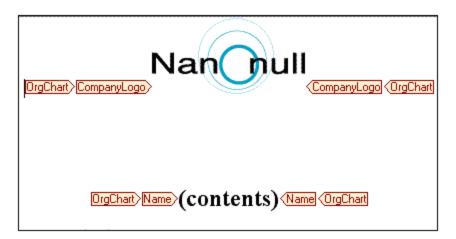

Document styles

The styles that are defined in the Document Styles tab apply to the entire document. If a document has more than one document section, design elements within each document section inherit style properties from the Initial Document Section. To over-ride inherited styles on a given design element, specify the required style values on the individual design elements. To do this click the design element, and, in the Styles sidebar, specify the desired styles.

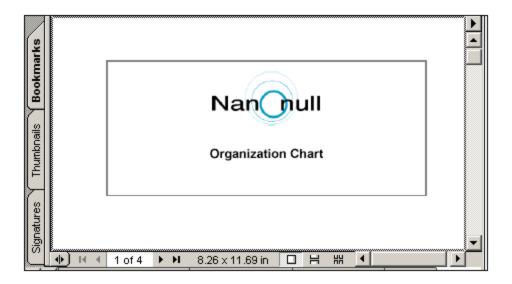

Cover pages

If a cover page is required, it should be designed at the beginning of the Initial Document Section. To ensure that the rest of the document starts on a new page, insert a page break (Insert | Insert Page / Column / Document Section | New Page) below the cover page template. If the page layout properties of the cover page are to be different than those of the following pages, then the entire Initial Document Section should be used for the cover page. The following pages should then start with a new document section.

An example is shown below.

Click the Preview RTF, Preview PDF, or Preview Word 2007+ tab to see the result in the preview window.

8.7.1.2 Page Layout Properties

Page properties are assigned individually for each document section of a document design, in the Page Layout group of properties of that document section. If a design has only one document section, then the page properties of that document section are the page properties of the entire document.

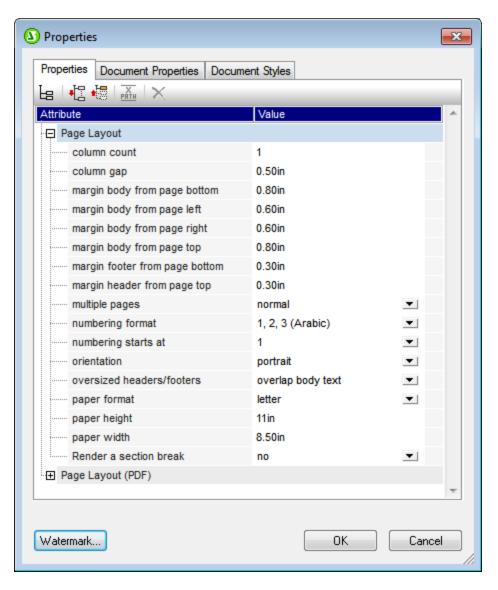

Note: Due to a limitation of FOP, Page Layout properties are available only for the Initial Document Section when FOP is used to generate output.

Accessing the page properties of a document section

To access the page properties of a document section, click the *Edit Properties* link of the <u>Initial Document Section or Document Section item</u> in the design (see *screenshot below*).

This pops up the Properties window, with the Page Layout properties active within it (screenshot below).

Alternatively, clicking the Document Section title bar makes the *Page Layout* group of properties of that document section active in the Properties window.

Page size

Three properties determine the size of pages of a document section: (i) page height, (ii) page width, and (iii) size. Page size can be set in one of two ways:

- You can select a predefined page size from the combo box in the *Paper Format* property field. In this case, values for the *Page height* and *Page width* fields are automatically filled in depending on what value has been selected in the combo box.
- You can specify your own values for the *Page height* and *Page width* properties. In this case, the *Paper Format* field will contain the value custom size.

Valid length dimensions (for the *Page height* and *Page width* properties) are inches (in), centimeters (cm), millimeters (mm), picas (pc), points (pt), pixels (px) (px) (mm). Note that (i) a unit is mandatory; (ii)

there must be no space between the number and the unit; (iii) there is no default unit. Entering an invalid unit or no unit causes the property value to be displayed in red.

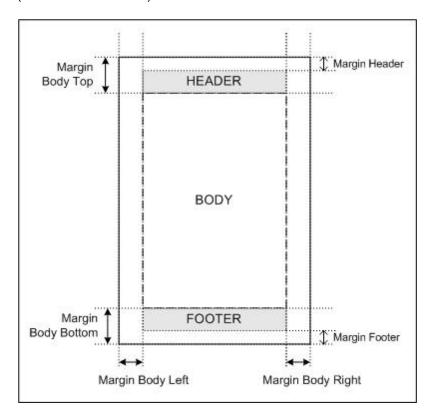

Page margins

The top, bottom, left and right margins of a page can be defined with the four margin properties, *Margin body from page top, Margin body from page bottom, Margin body from page left*, and *Margin body from page right*, respectively. To specify a margin, enter the required number in the relevant margin property field followed by any of the valid length units: inches (in), centimeters (cm), millimeters (mm), picas (pc), points (pt), pixels (px) and ems (em). Note that (i) a unit is mandatory; (ii) there must not be a space between the number and the unit; (iii) there is no default unit. Entering an invalid unit or no unit causes the property value to be displayed in red.

The body area is defined by the page margins you set (see screenshot below).

Header and footer margins

The Margin header from page top and Margin footer from page bottom properties specify the distance from the top of the page to the top of the header and from the bottom of the page to the bottom of the footer, respectively (see screenshot below).

The vertical extents of headers and footers are determined by the actual content of the headers and footers. You should ensure that the vertical extent of a header plus the header margin does not exceed the *Margin body from page top*. Otherwise, the header will be too large to be contained in the space defined for it. Similarly, ensure that the sum of the vertical extent of the footer and footer margin does not exceed the value of the *Margin body from page bottom*.

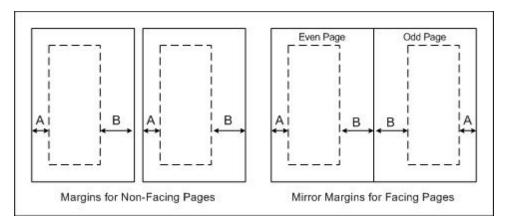

If the actual header or footer is too large for the space assigned for it, then the value of the *Oversized Headers/Footers* property comes into play and can modify the treatment of headers and footers in RTF and Word 2007+ output. If the *Oversized Headers/Footers* property has been set to <code>Overlap Body Text</code>, then the oversized header or footer will superimpose, or be superimposed by, body text. If the option <code>Reduce Body Height</code> has been set, then the vertical extent of the body text is reduced so as to accommodate the oversized header or footer. In the case of PDF output, the option to reduce body height is not available and oversized headers or footers will always either superimpose, or be superimposed by, body text.

Note: In the PDF output, you can also specify separate *Margin body from page top* and *Margin body from page bottom* values for the first and last page of each document section. These settings are available in the *Page Layout (PDF)* group of properties in the Properties window of the document section design element.

The Multiple Pages setting

The Multiple Pages setting has two options:

- If you set *Multiple Pages* to Normal, then all pages in the output will have the same value for all left margins and the same value for all right margins (see screenshot below).
- If, on the other hand, you set *Multiple Pages* to Mirror Margins, then the document pages are treated as facing pages (see screenshot below). This means that for even-numbered pages (left-hand-side pages), the left margin (*Margin body left* property) is the outer margin while the right margin (*Margin body right* property) is the inner margin. For odd-numbered pages (right-hand-side pages), the left margin (*Margin body left* property) is the inner margin while the right margin (*Margin body right* property) is the outer margin.

The settings made for the *Margin body left* and *Margin body right* properties are applied by StyleVision to the odd-numbered pages; these margins will be reversed for even-numbered pages; the inner-margin value of odd-numbered pages becomes the outer-margin value of the even-numbered pages.

Note: If an SPS design has multiple document sections, then the value of the mirror margins setting is taken from the initial document section. The left and right margin values are also taken from the initial document section. The values of these properties in subsequent document sections will be ignored.

Page orientation

Page orientation can be set to portrait or landscape.

Columns

Columns and their widths are specified with two properties: *Column count* and *Column gap*, which specify, respectively, the number of columns and the space between two columns. The width of a column is thus the width of the page body minus the sum of the column gaps, divided by the number of columns.

Text will fill the columns on a page one by one. Only after all the columns have been filled will a new page be started. A column break can be forced by inserting a new column at the desired point in the design. To do this, right-click at the location where the column break is required and select the context menu command Insert Page / Column/ Document Section | New Column.

Page numbering

There are two relevant properties: Numbering format and Numbering starts at. These work as follows:

- The required page number format is set by selecting one of the pre-defined options from the drop-down menu for *Numbering format*. (The *Numbering format* selection also applies to the <u>page total</u> (2020), if this is inserted.)
- The page numbering for a document section can be set to start with any positive integer. This integer is specified in the *Numbering starts at* property. If the numbering is to continue from the previous document section, then this field should be left blank or set to auto.

Note: Page numbers can be inserted in a document by inserting a page number placeholder (with the command **Insert Page / Column / Document Section | Page Number**). The total number of pages in the output document is inserted with the command **Insert Page / Column / Document Section | Page Total**.

Note: MS Word does not always update page numbers automatically. To manually update page numbers in MS Word, press **Ctrl+A** and **F9**.

Page numbering in the RTF output

In order to display page numbering in the RTF output in MS Word, you must select, in MS Word, the entire contents of the document (with **Edit | Select All** or **Ctrl+A**), and then press **F9**. This will cause the page numbering to be displayed—if you have inserted page numbering.

Page totals

To output the total number of pages at various locations in your document, use the page total feature.

Page starts for document sections

For each document section that is not the Initial Document Section, the *Section Starts On* property specifies whether the document section should start on the next page (irrespective of whether it is odd-numbered or even-numbered), or whether it should specifically start on an odd-numbered or even-numbered page. For example, if the previous document section ends on an odd-numbered page and the current document section is specified to start on an odd-numbered page, then the even.numbered page that occurs directly after the end of the previous document section will be left blank. Note that it is the underlying document page-numbering that determines whether a page is odd-numbered or even-numbered. The page numbering that the user specifies is irrelevant for determining the document section start-page.

Page break after the Initial Document Section

If you wish to start the section immediately after the Initial Document Section on a new page, give the *Render a Section Break* property (of the Initial Document Section's page layout properties) a value of *Yes*. This starts the second document section (that is the first section after the Initial Document Section) on a new page. Note that this property is available only for the Initial Document Section, not for any other section.

Note the converse effect also, that is, when the property has a value of *No*. In this case, the first non-Initial-Document-Section starts directly after the Initial Document Section—without rendering a page break. This is useful if the Initial Document Setting is blank—for example, if it contains a set of templates that produces no output. A property value of *No* (for *Render a Section Break*) ensures that the first page of the print output document will not be blank (which would have been the case if a page break were to be rendered after an Initial Document Section that produced no output).

Page layout properties for PDF

For PDF output, you can specify different page margins for the first page of the section. These properties work in the same way as for other pages in the section and are as described in the section, Page Margins 502.

8.7.1.3 Headers and Footers: Part 1

Headers and footers can be added **for each document section** of the document, including the Initial Document Section.

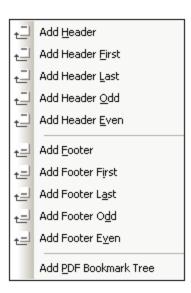

Adding a header or footer for a document section

To add a header or footer for a document section, click the *Add Header/Footer* link of the <u>Initial Document Section or the Document Section title bar (see screenshot below).</u>

Document Section

Edit Properties... Add Header/Footer... Hide Headers/Footers

From the menu that pops up (*screenshot below*), select the required item. A header or footer can be added separately for odd or even pages, or a single header or footer can be added for all pages. Additionally, a separate header/footer template can be created for the first page (**Add Header First**, **Add Footer First**) and/or for the last page of a document section (**Add Header Last**, **Add Footer Last**, *PDF output only*). This is useful if the first and/or last page of a document section must have a different header/footer: for example, when the first page is a cover page (an empty header/footer template could be created in this case).

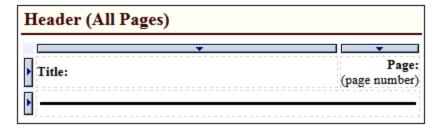

On clicking the required header or footer, a template for the header or footer is created within that document section in Design View The Design View display of header/s and footer/s in a document section can be toggled on and off by clicking the *Hide Headers/Footers* link in the <a href="Initial Document Section or Document Section item" (see screenshot above)." In the Initial Document Section or Document Section item" (see screenshot above).

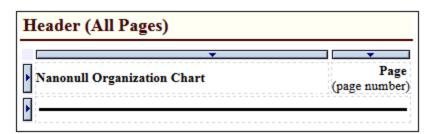

Note: Headers and footers for the last page are supported for PDF output only.

Designing the header/footer in Design View

The header/footer template is designed just like any other template. Components can be dragged from the schema tree or entered statically, and then styled. An example is shown below. When a header is added, the template will look something like this:

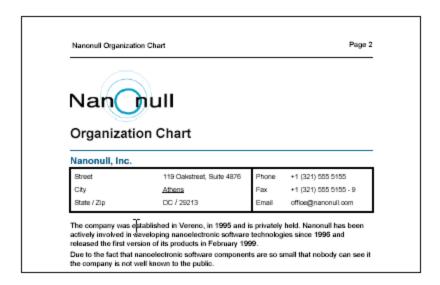

Change the header as required. Note that you can use both static and dynamic content, and even images.

Click the Preview RTF, Preview PDF, or Preview Word 2007+ tab to see the results in the Preview windows. The illustration below shows Page 2 of the Organization Chart document in the PDF Preview window, with the

header as defined above. To display page numbering in the RTF output, you must select Edit | Select All (or Ctrl+A) in MS Word, and then press F9. Also see displaying page-numbering in RTF output 504.

The following points should be noted:

- The vertical extent of the header and footer should not exceed the respective margin body (top or bottom) less the extent of the margin header or margin footer, respectively (see Page Layout Properties 202 for details). The vertical extent of the header or footer, consequently, is determined by the top/bottom body margins and margin header/footer.
- You can define a header/footer either (i) for all pages in the document section, or for (ii) for even and odd pages in the document section separately. Additionally, separate first page and last page headers/footers can be inserted. (See <u>Headers and Footers: Part 2</u> for more information.)
- Page numbering in a document section starts with the number you specify in the Page Layout Properties 502

Deleting a header or footer

To delete a header or footer, right-click the header/footer title bar and, from the menu that pops up, click Edit | Remove.

8.7.1.4 Headers and Footers: Part 2

In this section, we describe how to create the following types of headers and footers:

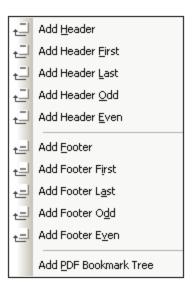

- <u>Different headers/footers for odd-numbered and even-numbered pages</u> 508
- Different headers/footers for different document sections 508
- Simulating headers/footers inside a page 509
- Headers/footers with subtotals 509

Note: In the PDF output, you can also specify separate <u>Margin body from page top</u> and <u>Margin body from page bottom</u> values for the first and last page of each document section. These settings are available in the Page Layout (PDF) group of properties in the Properties window of the document section design element.

Different headers/footers for odd-numbered and even-numbered pages

For each document section, odd-numbered and even-numbered pages can be assigned different headers/footers.

To create different headers for odd-numbered and even-numbered pages, click the *Add Header/Footer* link in the title bar of the respective document section, and select **Add Header Odd** and **Add Header Even** from the menu that pops up (*screenshot below*). This creates two header templates, one for odd-numbered pages, the other for even-numbered pages. Enter the content of the two headers in the templates.

Separate footers for odd-numbered and even-numbered pages can be created in a similar way to that described above for headers.

Different headers/footers for different document sections

Different headers/footers can be created for each document section of the document. To do this, click the *Add Header/Footer* link of the <u>Initial Document Section or the Document Section title bar</u> 499. This pops up the Add Header/Footer menu shown in the screenshot above. Note the following points:

- Headers/footers for odd-numbered and even-numbered pages can be added separately, or a common header/footer can be added for all pages in the document section.
- An additional first-page and/or last page header/footer can be added. These headers/footers will be
 used on the first and/or last page of the document section instead of other headers/footers that might
 be defined for that document section.
- Page numbering for the document section can either <u>run on from the previous document section or</u> <u>start at a designated number</u> 504.
- The Page Total 604 is the page count of the entire document not that of the current document section.

Simulating headers/footers inside a page

Headers and footers can be designed manually inside a <u>layout container</u>. The approach would be to design a single page as a layout container. The header and footer are created within <u>static tables</u> located, respectively, at the top and bottom of the page. If more than one page is to be designed, then multiple layout containers can be used, each separated from the next by a <u>page break</u> (Insert | Page / Column / Document Section | New Page).

Headers/footers with subtotals and running totals

When a document contains a list of numerical items that must be totalled and the list extends over multiple pages, subtotals of each page and/or running totals might be required to appear in the headers and/or footers of each page. The Subtotals.sps example, which is in the (My) Documents folder (33), C:\Documents and Settings\<username>\My

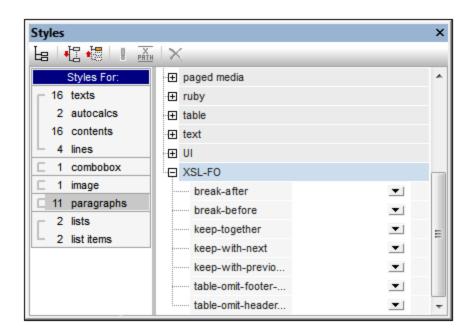

Documents\Altova\StyleVision2025\StyleVisionExamples\Tutorial\Subtotals\, demonstrates how running totals can be created and included in headers and footers.

The following strategy was used to design this SPS:

- Because the listing is in a table and because a table cannot be made to auto-fit a printed page, the number of rows that must be accommodated on a page must be specified. These numbers are given in two variables that have been defined on the top level template, that for the \$XML template; they are named RowsOnFirstPage and RowsPerPage.
- The page count is derived by dividing the total number of list items by the number of rows per page (adjusted to take account of the different number of rows on the first page). The page count is stored in a variable called CountOfPages (defined on the \$XML template).
- A user-defined template is created for the sequence 1 to \$CountOfPages, and a static table is created within this template. Defined on this template are two variables that calculate the which row is to be the first row (\$RowFrom) and the last row (\$RowTill) on each page. The rows in the table are generated by a user-defined template, which selects the items in the XML file (file elements) on the basis of their position with respect to the \$RowFrom and \$RowTill values. If the position of the file element is an integer value that lies in the range delimited by values of the \$RowFrom and \$RowTill variables of the current page, then a row will be generated for the current file element.
- The running totals are generated with Auto-Calculations and inserted into rows at the top and bottom of the tables. Note that the XPath expressions to generate running totals at the top and bottom of pages are different from each other.
- Headers and footers are created in tables, respectively, above and below the main table on the page. The Auto-Calculations to generate the running totals are inserted in the header and footer templates.
- A page break is inserted at the end of each page.

8.7.2 Keeps and Breaks

In PDF documents (*Enterprise edition only*), keeps and breaks for pages and columns can be set in the *XSL-FO* group of styles (Styles sidebar, *screenshot below*). This group of styles enables you to specify whether the current design document block (the block within which the cursor is currently placed) should have a page/column break placed before or after it, or whether it should be kept with adjacent blocks. Whether table headers and footers are omitted (or repeated) at page breaks can also be set using the table-omit properties. For more information about these properties, see the XSL-FO specification.

For the printed version of HTML pages, settings for page breaks and widows/orphans (leading/trailing lines on a page) can be made via the relevant properties in the *Paged Media* group of styles (see screenshot above).

8.7.3 Footnotes

You can insert footnotes in a document by adding the Footnote component (Insert | Insert Footnote) at the location where you want the footnote number to be. Footnotes are available in paged media output (PDF, RTF, and Word 2007+ in the *Enterprise Edition*; and RTF in the *Professional Edition*).

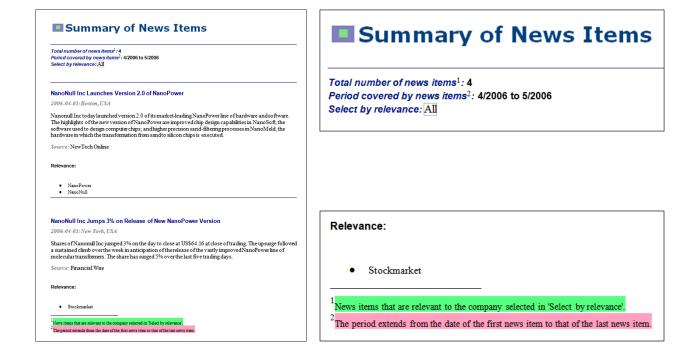

Note the following points:

- The text of the footnote must be placed within the tags of the footnote component, and the footnote text can be formatted.
- In the output, the footnote number appears at the location where the footnote was added. The footnote text appears at the bottom of the page, together with the corresponding footnote number.
- In the output, footnote text will be formatted according to the formatting of the text within the footnote component in the design.
- In the output, footnotes are numbered automatically through to the end of the document.
- In the case of multiple output documents, numbering is re-started for each output document.

In the screenshot below, two footnote components (**Insert | Insert Footnote**) have been inserted. The footnote text has been placed within the tags of the component, and the text has been formatted.

The screenshots below show the output. The screenshot at left shows the complete page, while the screenshots at right show closeups of the footnote numbers (*top*) and footnote texts (*bottom*).

Note: Formatting of footnote numbers is not supported.

8.7.4 PDF Fonts

How the formatter and PDF Viewer use fonts

The formatter (for example, FOP) creates the PDF and the PDF Viewer (typically Adobe's PDF Reader) reads it.

In order to lay out the PDF, the formatter needs to know details about the fonts used in the document, particularly the widths of all the glyphs used. It needs this information to calculate line lengths, hyphenation, justification, etc. This information is known as the metrics of the font, and it is stored with each font. Some

formatters can read the metrics directly from the system's font folder. Others (such as earlier versions of FOP) need the metrics in a special format it can understand. When the metrics of a font are available to the formatter, the formatter can successfully lay out the PDF. You must ensure that the font metrics files of all the fonts you use in your document are available to the formatter you are using.

The formatter can either reference a font or embed it in the PDF file. If the font is referenced, then the PDF Viewer (for example, Adobe Reader) typically will look for that font in its own font resource folder (which contains the Base 14 fonts) first, and then in the system's font folder. If the font is available, it will be used when the PDF is displayed. Otherwise the Viewer will use an alternative from its resource folder or generate an error. An alternative font may have different metrics and could therefore generate display errors.

If the formatter embeds a font in the PDF file, then the PDF Viewer uses the embedded font. The formatter may embed the entire character set of a font or only a subset that contains the glyphs used in the document. This factor affects the size of the PDF file and, possibly, copyright issues surrounding font use (see note below). You might be able to influence the choice between these two options when you set the options for your formatter.

Using fonts in StyleVision

- The default document font used in the PDF output is Helvetica (Acrobat PDF Reader versions prior to 4.0) or Arial MT (Acrobat PDF Reader version 4.0 or later). So, if no font is specified for any text in the design document, Helvetica/ArialMT (a Base 14 font) will be used.
- If you specify Helvetica or Times in the SPS, and if the Acrobat PDF Reader used to view the PDF output is version 4 or higher, then the PDF Reader will use Arial MT and Times New Roman PS MT, respectively, from its own font resources folder. Acrobat PDF Reader does this even if Helvetica and Times are active on the system.
- In StyleVision, you can change the default font for the entire document by first selecting all the text in the document. Then, in the Styles sidebar, select the texts item in the Styles For column, and with the Font group selected, assign the desired font to the font-family attribute. This font is assigned to each text node in the document. An alternative font can then be set for individual text nodes as required.
- If in the XSL Options tab of the Options dialog (<u>Tools | Options</u>) you select FOP 0.93/1.0/2.0 compliant, then only the font-family values Helvetica, Times, Courier, and Symbol (exactly as spelled here) will be passed through to the XSLT-for-FO. Entering any other font-family value on a node will remove the font-family attribute from that node in the resulting FO document—leading to the default Helvetica/ArialMT being output for that node.
- If in the XSL Options tab of the Options dialog (<u>Tools | Options</u>) you select Full usage of XSL-FO standard, then any font-family you enter in the Text Style window will be passed to the XSLT-for-FO document. If the selected font is not available to the formatter, an error may result. In order to avoid such errors, add alternative fonts and a generic fallback. For example:

```
font-family="Bodoni, Garamond, serif"
```

In this example, Garamond is a second choice, and the generic serif is the fallback font. If neither Bodoni nor Garamond is available, then the generic serif font is used. The three generic fonts are: serif (Times or Times New Roman PS MT, depending on the Acrobat Reader version), sans-serif (Helvetica or ArialMT), and monospace (Courier).

Note for HTML use: CSS2 allows alternative choices, as well as a generic font as a fallback (serif, sans-serif, monospace, cursive, and fantasy).

Making fonts available to the formatter

Most formatters already have available to them the Base 14 fonts. It is important to know the names by which the formatter recognizes these Base 14 fonts so that you correctly indicate them to the formatter. This is the basic font support provided by formatters. You can, however, increase the number of fonts available to the formatter by carrying out a few straightforward steps specific to the formatter you are using. The steps for FOP are given below.

Font support in FOP

There are two steps involved in setting up custom fonts:

- 1. Informing FOP how to find the font files.
- 2. Informing FOP how to use the fonts.

How to find the required font files

More recent versions of FOP can automatically detect system fonts or can scan user-specified directories for fonts and register these with FOP. See the <u>Fonts page at the FOP website</u>

If you are using an earlier version of FOP, you will need to first generate a font metrics file (an XML file) for each required font from the font's PostScript or TrueType font files. FOP provides PFM Reader and TTF Reader utilities to convert PostScript and TrueType fonts, respectively, to XML font metrics file. For details of how to do this, see the FOP Fonts page. Next, in the FOP configuration file, the required metrics file for each font must be specified in the metrics-url attribute of the respective font element.

```
<font metrics-url="arial.xml" kerning="yes" embed-url="arial.ttf">
    <font-triplet name="Arial" style="normal" weight="normal"/>
    <font-triplet name="ArialMT" style="normal" weight="normal"/>
</font>
```

Telling FOP how to use the fonts

The <u>FOP configuration file</u>—an XML file called <u>fop.xconf</u> and located in the <u>conf</u> folder in the FOP installation folder—must be edited so that FOP knows how to use the fonts correctly. For each font that you wish to have FOP render, add a <u>font</u> element at the location indicated by the <u>font</u>-element placeholder in the document:

In the example above,

metrics-url	URL of the metrics file. If not absolute, relative to the path in the font-base element of the configuration file. Optional.
embed-url	URL of the font file (usually located in <code>%WINDIR%\Fonts</code>). Required if the Viewer does not have the file on its local system.
name	Maps this font name to the font defined with metrics-url and/or embed-url.

style	Maps this font style to the font defined with metrics-url and/or embed-url.
weight	Maps this font weight to the font defined with metrics-url and/or embed-url.

For more details, see Registering Fonts with FOP at the FOP website.

Editing the batch file (fop.bat) to read the configuration file

After the configuration file has been edited as described above, the FOP executable (fop.bat), which is in the FOP installation folder, must be edited so that FOP reads the configuration file. Do this by changing the last line of fop.bat from:

```
"%JAVACMD%" [...] org.apache.fop.cli.Main %FOP_CMD_LINE_ARGS%
```

to include the location of the configuration file:

```
"%JAVACMD%" [...] org.apache.fop.cli.Main %FOP CMD LINE ARGS% -c conf\fop.xconf
```

See Starting FOP at the FOP website.

Note on font copyrights

Font usage is subject to copyright laws, and the conditions for use vary. Before embedding a font—especially if you are embedding the entire font—make sure that you are allowed to do so under the license you have purchased for that font.

Character sets

Note that the character sets of fonts differ from each other. The Base 14 fonts cover the ISO-8859-1 characters plus the glyphs in the Symbol and Zapf Dingbats fonts. If your document contains a character that is not covered by the Base 14 fonts, then you will have to use a font that contains this character in its character set. Some fonts, such as Arial Unicode, offer the characters covered by Unicode.

Note: When entering font sizes, do not use an intervening space between the point size and its unit. For example, 12pt is correct, 12 pt is incorrect.

8.7.5 Pixel Resolution

If you use pixels as a unit of length in your SPS, you should be aware that pixel-defined lengths are a function of screen resolution. The corresponding absolute lengths in print could be very different from what you see on screen. In this section, we do the following:

- 1. Discuss why pixel-defined sizes have two forms: (i) an abstract form, defined in pixels; (ii) an actual size, obtained by resolving the abstract form in terms of a specific screen resolution.
- 2. Explain StyleVision functionality to deal with this issue.

From pixels to points

A few key points are essential to understanding the factors that affect the abstract and actual dimensions of pixel-defined lengths:

- The pixel is a relative unit: its size depends on screen resolution. The higher the resolution, the smaller the pixel. Screen resolution is given with dpi (dots per inch). A dot in the case of screens is a pixel. So, if screen resolution is 72 dpi, then there are 72 pixels (dots) in one inch of a line of pixels. If screen resolution is 96 dpi, then there are 96 pixels in an inch. How many pixels there are in an inch of screen length depends on the screen resolution. The most commonly available screen resolutions today are 72 dpi, 96 dpi, and 120 dpi. The higher the dpi, the smaller will be the pixels.
- The length unit known as the point is an absolute unit of length, used most commonly in the printing industry: 72 points make up an inch.
- From the above it can be seen that only when screen resolution is 72 dpi will one pixel be equal to one point. For other screen resolutions, the absolute length can be calculated. The table below lists the absolute length (in points) of 100px at various screen resolutions.

Resolution	Pixels	Points	Factor
72 dpi	100	100	1.00
96 dpi	100	75	0.75
120 dpi	100	60	0.60

To convert pixels to points for each screen resolution, we can use a factor given by the ratio of points in one inch (72) to pixels in one inch (dpi), that is, 72 divided by dpi. The conversion factors for various resolutions are given in the table above. For example: 72 div 96 = 0.75 and 72 div 120 = 0.60. Multiplying the length in pixels by the appropriate conversion factor gives the absolute length in points. So 100px on a 96 dpi screen is 75pt.

Since 72 points make an inch, you can obtain the length in inches by dividing the length in points by 72. For example, 100 points is equal to 100 div 72 inches = 1.389in.

Screen resolution and absolute length

In the previous section we have seen that only when the screen resolution is 72 dpi will the absolute length in points be the same as the number of pixels used to define that length. Screen resolutions on Windows systems, however, are typically not 72 dpi but 96 dpi. This means that the number of points of a pixel-defined length on such a screen will be 75% the number of pixels. For example, in the StyleVision Design View screenshot below, the two characters measure 100px and 75pt, respectively.

The reason they are the same height is that the screen resolution in which they appear is 96 dpi. At this resolution 100px is equal to 75pt in absolute terms.

The point to note is that when specifying pixels as a unit of length, be aware of your monitor's screen resolution (normally 96 dpi on Windows systems); it determines the absolute length of the pixel-defined length that you see on screen.

Print output resolution

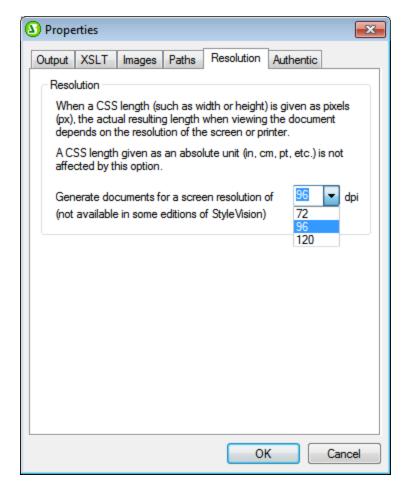

When an SPS is transformed into a print format, such as PDF, RTF, or Word 2007+, non-absolute pixel lengths must be converted to absolute lengths, such as points or inches (because lengths on paper cannot be defined in terms of pixels). The question is: What factor (or screen resolution) should be used to convert from pixels to points?

In StyleVision, you can select the output dpi for each SPS individually. So, for example, if you select 96 dpi, then a 100px character will be rendered in print output as a 75pt character (see the table above). If you select 72 dpi, then the same character will be rendered in print output as a 100pt character. This system applies to all lengths defined in pixels.

Note: Conversion to an absolute measure is not carried out for HTML output. For HTML, the original pixel units are passed to the HTML file unchanged.

Setting print output resolution of an SPS

To set the print output resolution of an SPS, click **File | Properties**. In the Properties dialog that pops up, click the Resolution tab (*screenshot below*).

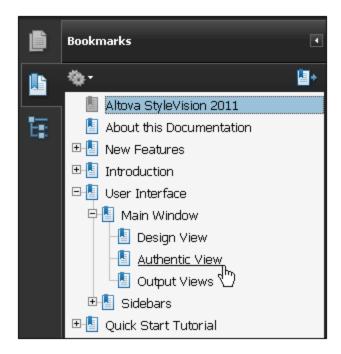

In the Resolution tab, select the required print resolution. The conversion factor for each listed dpi option is given in the conversion table above (in the section, *From Pixels to Points*). Multiplying the pixel count by the

conversion factor gives the absolute length in points. Note that the conversion to absolute units is applied only to print output formats. The HTML output format will retain the original pixel definitions. Note also that this setting does not change the screen resolution of your monitor.

8.7.6 PDF Bookmarks

PDF Bookmarks are navigational links that are displayed in a pane in PDF reader applications (*screenshot below*). They usually reflect the structure of the PDF document and allow the user to navigate to different parts of the document.

StyleVision gives you the flexibility to set up the structure of a document's PDF Bookmarks exactly as you want. By default, all the Tables of Contents (TOCs) defined in the document will be displayed as PDF Bookmarks. Depending on your FOP processor, items that are common to the various TOCs in your document may or may not be merged. If you wish to set up PDF Bookmarks that are different from the TOC structure, you can use the PDF Bookmarks feature to customize PDF Bookmarks. If you create PDF Bookmarks, then these override input from the TOC settings and are the settings adopted for the document's PDF Bookmarks.

TOCs and PDF Bookmarks

What bookmarks are created in the PDF output depends on the TOCs in the document and whether a PDF Bookmark Tree has been created. The following options are available:

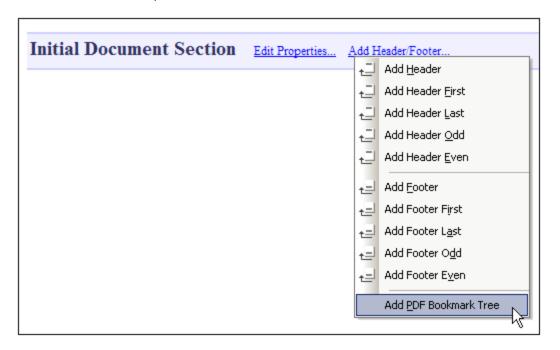

- One TOC in the design: Bookmarks in the PDF will be automatically generated using the TOC structure.
- *Multiple TOCs in the design:* Bookmarks in the PDF will be automatically generated for each TOC, with each TOC being appended to the previous TOC. Note that some FOP processors, such as FOP 0.93, merge items that are common to TOCs.
- A PDF Bookmark Tree is created in the design: If a PDF Bookmark Tree is created in the design, this tree is used for the bookmarks in the PDF; any TOC/s in the design are overridden. If a PDF Bookmark

Tree is created in the design but is empty, then no bookmarks will be generated in the PDF—even if TOCs are present; the PDF Bookmark pane will be empty

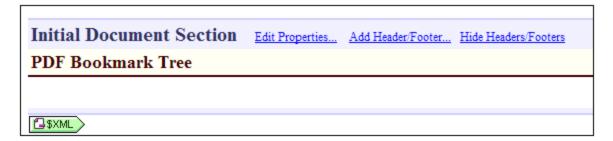

Creating the PDF Bookmark Tree

This section describes how bookmarks can be created in the PDF output using the PDF Bookmark Tree. (If no PDF Bookmark Tree is present in the document, then bookmarks are generated automatically from the TOCs in the design. For information about creating TOCs, see the section <u>Table of Contents</u>, <u>Referencing</u>. <u>Bookmarks</u>

A PDF Bookmark Tree (template) is a template that is defined on a document's Initial Document Section. If the design has multiple document outputs, then PDF Bookmark Trees can be specified for each of the multiple documents, on their respective Initial Document Sections.

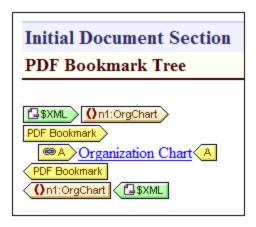

Add the PDF Bookmark Tree template by clicking the *Add Header / Footer* link in the title bar of the Initial Document Section, and then selecting the **Add PDF Bookmark Tree** command (*see screenshot above*). The PDF Bookmark Tree template will be added (*see screenshot below*).

You can now drag nodes from the Schema Tree sidebar into the PDF Bookmark Tree to create a customized PDF Bookmarks structure.

For every node that you drop into the PDF Bookmark Tree, you will be prompted as to whether you wish to create a PDF Bookmark or a template. If you select PDF Bookmark, you will be prompted to enter a target for the bookmark. These targets must be bookmarks (anchors) that already exist in the design. How to create such bookmarks (anchors) is described in the section, <u>Inserting Bookmarks</u>. After you have entered the target bookmark, a PDF Bookmark component is added to the tree (*see screenshot below*).

Each PDF Bookmark component contains a hyperlink component (see screenshot above) that has two key attributes:

- Content which defines the text of the PDF Bookmark. You can delete the default content placeholder and insert any text or suitable component instead.
- A URL property, which specifies the target of the bookmark. If the target bookmark is within the same document, then the URL must be a fragment identifier (and must therefore start with #). For more information, see Defining Hyperlinks 442

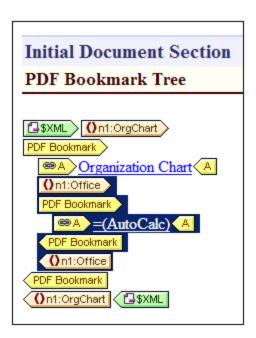

PDF Bookmark targets

The URL property of a PDF Bookmark's hyperlink component is the target bookmark you assigned when the PDF Bookmark was created. This target can be edited by right-clicking the hyperlink component and selecting **Edit URL** from the context menu that pops up.

We recommend that the targets are unique (that is, no PDF Bookmark should point to the same design bookmark). Otherwise the output might be dependent on the FOP version. (For example, FOP 0.95 ignores nested PDF Bookmarks if they have the same destination. Also FOP 0.95 ignores PDF Bookmarks which point to undefined document locations. FOP 1.0, however, does display such bookmarks in the generated Bookmark Tree.) PDF Bookmarks which point to external locations (e.g. http or file urls) are not supported by Apache FOP 0.95 and 1.0.

PDF Bookmark Tree structure

Ideally PDF Bookmarks in the PDF are structured to display the hierarchy of the document. This structure can be specified in the PDF Bookmark Tree by nesting PDF Bookmarks. For example, in the screenshot below, the n1:Office element (highlighted in blue) has been dropped into the PDF Bookmark Tree after the hyperlink component of the Organization Chart bookmark but inside the bookmark itself. The Office PDF Bookmark is therefore nested inside the Organization Chart PDF Bookmark.

Note the following points about the example shown in the screenshot above:

- The XML document contains one n1:orgChart element and two n1:Office elements.
- The n1:orgChart element has a static bookmark. A fragment identifier in the PDF Bookmark's hyperlink component targets this static bookmark.
- The name of the Organization Chart PDF Bookmark is a static text string.
- The bookmarks for the two n1:Office elements are dynamically created using XPath expressions that select the names of the two offices from a child node, n1:Name. The URL of the Office PDF Bookmark component is a dynamically generated fragment identifier, also obtained with the help of the child node, n1:Name.
- The name of each Office PDF Bookmark is generated with an Auto-Calculation that uses the respective child node, n1:Name, of each n1:Office element.

The PDF Bookmarks generated by this PDF Bookmark Tree are as in the screenshot below.

Note: If either the target bookmarks or the PDF Bookmark URLs are incorrect, errors or incorrect PDF Bookmarks are possible, depending upon the FO processor being used (see PDF Bookmark Targets above).

Deleting the PDF Bookmark Tree

Delete the PDF Bookmark Tree either by selecting the tree and clicking the **Delete** key, or by right-clicking the tree and selecting the command **Edit | Delete**.

8.7.7 **PDF Attachments**

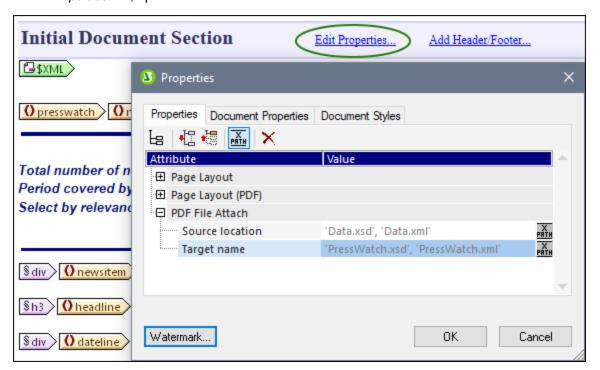

In a PDF file, it is possible to attach other files. The attached file will be available in the PDF. To view a PDF attachment, open the PDF file in PDF Reader and click on the paperclip icon. This opens the Attachments pane, in which attached files—if any are present—are displayed.

When designing an SPS, you can specify: (i) the location of PDF files to attach, and (ii) the names of the attached files. When the PDF is generated, this attachment information is processed and the attachments are created. PDF attachments are created when PDF output is generated via: (i) the File menu command Save Generated PDF (ii) the generate command of StyleVision Server. In both cases, make sure that the files to attach are located at the location/s specified in the SPS design.

Specifying the attached files

To select and attach files, do the following:

- 1. In the Initial Document Section, click Edit Properties (see screenshot below).
- 2. In the *Properties* tab, open the PDF File Attach section.

- 3. For the Source Location property, enter the location of the file you want to attach. Relative paths are evaluated relative to the SPS. If you want to attach more than one file, then you must enter these file locations in an XPath expression, as string items of a sequence. For example: 'Data.xsd', 'Data.xml'.
- 4. For the Target Name property, enter the names of the files as you want them to appear in the Attachment Pane of the PDF. If you want to specify more than one name in this field, use an XPath expression. If there is no entry in this field, then the names of the source files are used as the target names. Each target name will correspond to the source file in the same index position. If there are

more source files than targets, then original names are retained where no target name exists. If there are more target names, then extra target names are ignored.

5. Click **OK** when done.

The files are attached in the order in which they were specified. The PDF Attachment viewer might sort them in a different order.

8.7.8 Watermarks

A watermark is an image or text that is displayed on the background of each page of a document section.

The following options are available:

- Watermarks must be defined separately for each document section. Each section can therefore have a
 different watermark.
- For each document section, you must define (with XPath) some condition to be fulfilled in order for that section's watermarks to be enabled. For example, the condition could be, say, that the drafts attribute of some element must have the value true. If the condition is not fulfilled, or if the condition evaluates to false(), that watermark is disabled.
- A watermark can be a text that you customize in StyleVision or it can be an image you select.
- In the design, you can specify the location and appearance of watermarks on the page.

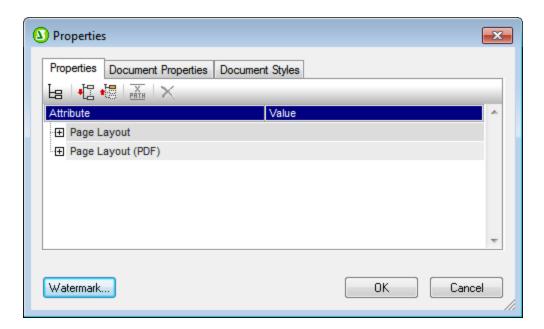

Note: Watermarks are available only for print-output media, not for HTML or Authentic View.

Creating a watermark

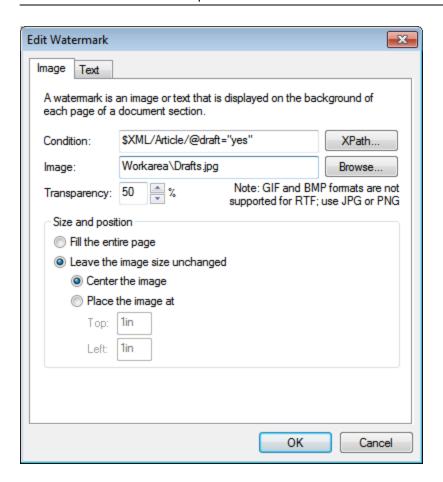

A watermark can be created separately for each document section. To create (or to edit) a watermark, click the *Edit Properties* link of the Initial Section or Document Section items in the design (*screenshot below*).

Document Section Edit Properties... Add Header/Footer... Hide Headers/Footers

In the Properties dialog that pops up (*screenshot below*), click the **Watermark** button at the bottom of the dialog.

This pops up the Edit Watermark dialog (*screenshots below*), in which you specify the properties of the watermark/s of that document section. According to whether you wish to use an image or text as the watermark, select either the *Image* or *Text* tab. (If you wish to define both an image as well as a text as the watermarks of that section, enter the details of each type in their respective tabs. In this case, both types of watermark will be created in the output.)

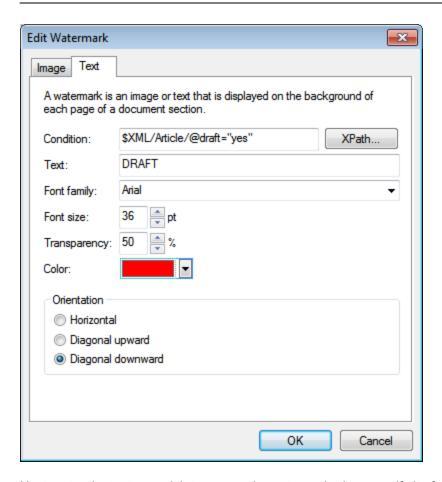

Parameters for image watermarks

The *Image* tab (see screenshot above) contains the parameters for defining an image watermark for that section. An XPath expression specifies the condition for enabling the image watermark. If you do not wish to specify any condition, then enter true() in the *Condition* text box. This causes the condition to evaluate to true(). If the condition evaluates to false(), or if no condition is specified, then the image watermark is not enabled. Next, browse for the image, so that the filepath to the image is entered in the *Image* text box.

You can then set the transparency of the image and its size and position on the page. The *Fill the entire page* option expands the image till one dimension (height or width) is filled. Click **OK** when done.

Parameters for text watermarks

The *Text* tab (see *screenshot below*) contains the parameters for defining a text watermark for that section. An XPath expression specifies the condition for enabling the text watermark. If you do not wish to specify any condition, then enter true() in the *Condition* text box. This causes the condition to evaluate to true(). If the condition evaluates to false(), or if no condition is specified, then the text watermark is not enabled.

Next, enter the text you wish to use as the watermark, then specify its formatting (font family, font size, transparency, and color) and orientation. Note that the text will be stretched to extend across the page in all orientations. Click **OK** when done.

Removing or disabling a watermark

To remove or disable a watermark, in the Edit Watermark dialog (see screenshots above), either delete the condition or set the XPath expression of the condition to false(). Note that the *Image* tab and *Text* tab each have a separate condition, for their respective watermarks.

8.8 Fillable PDF Forms

Fillable PDF forms are editable forms within a PDF document. In this way, a user can add data to a PDF document. The data can be saved with the PDF document but also extracted in FDF and XML formats. In StyleVision, you can create a design for a PDF output document that contains PDF form controls for accepting data input and carrying out user actions. In the PDF document shown below, for example, data can be entered in form fields in one of the following ways: by typing in the data selecting a radio button selecting a check box selecting a chec

First name:	John	
Last name:	Doe	
Email:	mail01@altova.com	
Gender:	female male	
Newsletter:	_	
First Empty	Previous Next Reset Submit	Last Print

This section is organized as follows:

- Creating a Fillable PDF Form 628 describes the parts of a PDF form and how one is created
- Form Controls describes the available form controls (for both data input and carrying out specific user actions)
- Form Data sign describes the mechanisms that an SPS makes available for submitting and extracting form data from a user-edited PDF document

Note: If the fillable parts of a fillable PDF are missing when the PDF is opened on a macOS system, one likely cause is that Java 6 is not installed on the machine. If this is the case, you can install Java 6 from https://support.apple.com/kb/dl1572?locale=en_US. If a version newer than Java 6 has already been installed on your system, then the installation of the older Java 6 version will not affect the working of the newer version, which will be the default version of the system.

Altova website: Fillable PDF forms

8.8.1 Creating a Fillable PDF Form

A fillable PDF form is **created in a layout container**. In the design in the screenshot below left, the layout container is indicated by a dashed line.

Initial Docume	ent Section	a	Edit Properties	Add Header/Footer
\$XML () persons	() person

- Add the layout container by clicking the Insert Layout Container toolbar icon and then clicking the
 location in the design where you wish to insert the layout container. (Alternatively, place the cursor at
 the location where you wish to insert the layout container and select the menu command Insert |
 Insert Layout Container.)
- When you insert the layout container, you are asked whether the layout container should auto-fit the page size. If you select Yes, the layout container will exactly fit the page; otherwise, the layout container can be resized by dragging its right and bottom borders to create the size you want. The auto-fit-page option is available subsequently as a context menu command. In the design screenshot (above left), the layout container has been created to fit the page size. The corresponding PDF preview (in the screenshot above right) shows the layout container (which contains the fillable PDF form) exactly fitting the page.
- If the PDF form is required to repeat for multiple instances of an XML schema element, then the layout container must be placed within the tags of that element. For example, in the design screenshot (above left), the layout container has been created within the person element. This has the effect of creating a layout container for each person element.

See the section <u>Layout Containers</u> 278 for more information.

Adding PDF form components

The fillable PDF form is designed by placing components in the layout container. These components are of two basic types:

- Form controls 532: These controls enable form data input and provide interactive form actions. How to add them are described in the section Form controls 532. When you add a form control, it is automatically added within a layout box 281. You can resize a layout box 281 by dragging its borders.
- Dynamic and static components: These are the regular <u>SPS design components</u>. Dynamic components, which are associated typically with schema nodes, are added within <u>layout boxes</u>. To add static content such as text to the PDF form design, you must first add a <u>layout box</u> and then add the static content to the box. In the screenshot above left, for example, the static text *First name* has been created within a manually added <u>layout box</u>.

You can move <u>layout boxes</u> as follows: (i) Place the cursor over the left or top border till the cursor turns into a crossed double-headed arrow, (ii) Click and drag the layout box to the location where you want it to be. You can resize a layout box by dragging its borders. Resizing is typically needed to properly fit the box contents within the layout box.

See the section <u>Layout Boxes</u> ²⁸¹ for more information.

8.8.2 Form Controls

There are two types of controls for fillable PDF forms:

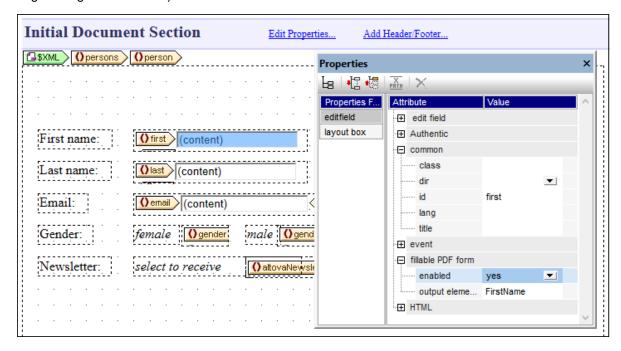

- Data-input controls: (i) input fields 533, (ii) multiline input fields 533, (iii) check boxes 534, and (iv) radio buttons 534. These controls take user input as form data.
- <u>Action controls</u> 536: buttons that perform various actions, which range from the navigation of the form, through data resets, to submission of data to remote servers.

8.8.2.1 Input Fields

If input fields or multiline input fields are enabled for fillable PDF forms, the user can enter data into the input fields of a PDF, and subsequently edit this data. The PDF document can then be saved, and the data in the PDF form can be submitted and/or extracted.

To create an editable input field in a PDF form, carry out the following steps. (Multiline input fields are added in the same way as input fields).

- Select the Insert Input Field (or Insert Multiline Input Field) toolbar icon. Alternatively, select the menu command Insert Form Controls | Input Field (or Insert Form Controls | Insert Multiline Input Field).
- 2. In the form's layout container, click the location where you wish to insert the input field (or multiline input field).
- 3. You will be prompted to select the schema node with which the field is to be associated. This is the node in which user-entered data will be stored. Select the node and click **OK**. The node and input field will be created inside a layout box. In the screenshot below, input fields have been created for the first, last, and email elements. (The end tag is not displayed if the width of the layout box is not large enough to contain it.)

- 4. Select the input field in the design, and then set the enabled property of its Fillable PDF Form group of properties to yes (see screenshot above). Alternatively, you can set the property value to an XPath expression that evaluates to the string yes. This is useful, for example, if you wish to specify via a global user-declared parameter that a control is fillable. In this case, first define a global user-declared parameter with a value of yes, then set the enabled property to an XPath expression that calls the parameter, for example: \$MyFillablePDFParam. Since the parameter's value is yes, the control's fillable property will then be enabled.
- 5. The values of the *output element* and *id* properties provide the name of the data field when the form data is saved or extracted. If you do not set at least one of these properties, then data field names are generated automatically, and cannot be known beforehand. If you wish to process field data, it is easier

to use the data field name that you set here than a generated name. See the section <u>Form Data</u> sepecially <u>Extracting as FDF/XML</u> for more information.

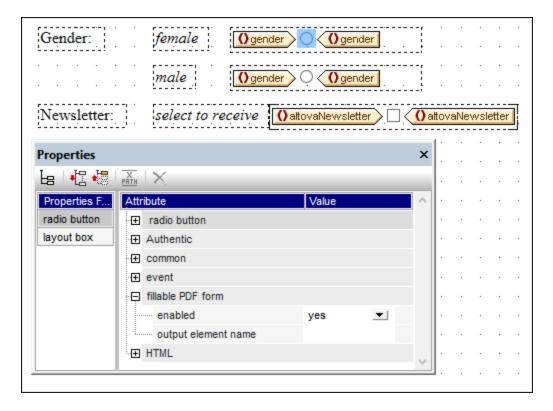

Note the following points:

- Default values of data fields are taken from the corresponding nodes in the Working XML File. If no Working XML File has been assigned, then there are no default values.
- In the displayed PDF form, the default values are shown in the input field when the PDF form is opened.

8.8.2.2 Check Boxes and Radio Buttons

While input fields enable users to enter data without restriction, check boxes and radio buttons enable the entry of data that is restricted to specific values.

- Check box: A checked value and an unchecked value can be defined. If the user checks the box in the PDF form, then the checked value is entered for that data field; otherwise the unchecked value is entered. In the screenshot below, the altovaNewsletter element has been set to take the value of a check box. If the user checks the box in the PDF form, then a value of yes will be entered in the altovaNewsletter element.
- Radio buttons: Multiple radio buttons, each representing a different value, are mapped to a single data field. The value of the radio button that the user selects in the PDF form is entered as the value of that data field. For example, in the screenshot below, a radio button with a value of female and a radio button with a value of male are both mapped to the element gender. Because both radio buttons are mapped to a single element, they automatically become mutually exclusive. This means that only one of them can be selected at a time; the other will be deselected automatically if selected previously. The value of the button that the user selects in the PDF form will be entered in the gender element (that is, either female or male).

Note the following points:

- Default values of data fields are taken from the corresponding nodes in the Working XML File. If no Working XML File has been assigned, then there are no default values.
- Radio buttons are displayed as check boxes in the PDF form.

Inserting check boxes and radio buttons

Insert a check box or radio buttons as follows:

- 1. Select the Insert Check Box or Insert Radio Button toolbar icon. Alternatively, select the menu command Insert Form Controls | Insert Check Box or Insert Form Controls | Insert Radio Button.
- 2. In the form's layout container, click the location where you wish to insert the control.
- 3. You will be prompted to select the schema node with which the control is to be associated. This is the node in which user-entered data will be stored. Select the node and click **OK**. The node and control will be created inside a layout box. In the screenshot above, a check box has been created for the altovaNewsletter element, and radio buttons have been created for the gender element.
- 4. Select the control in the design, and then set the *enabled* property of its *Fillable PDF Form* group of properties to yes (see screenshot above). Alternatively, you can set the property value to an XPath expression that evaluates to the string yes. This is useful, for example, if you wish to specify via a global <u>user-declared parameter</u> that a control is fillable. In this case, first define a global <u>user-declared parameter</u> with a value of yes, then set the *enabled* property to an XPath expression that calls the parameter, for example: \$MyFillablePDFParam. Since the parameter's value is yes, the control's fillable property will then be enabled.
- 5. The values of the *output element* and *id* properties provide the name of the data field when the form data is saved or extracted. If you do not set at least one of these properties, then data field names are generated automatically, and cannot be known beforehand. If you wish to process field data, it is easier

to use the data field name that you set here than a generated name. See the section Form Data sepecially Extracting as FDF/XML seems for more information.

8.8.2.3 Buttons

The button controls enable you to provide the user with actions related to document navigation, data field resets, and form printing. In addition, the **Submit** button enables you to specify the URL of a server to which users can upload form data (in FDF or PDF format) when they have finished filling out the form.

Inserting a button

Insert a button in the fillable PDF form as follows:

- 1. Select Insert | Insert Form Controls | Button.
- 2. Click the location in the <u>layout container</u> where you wish to insert the button.
- 3. If you need to move the button for more precise placement, hover over the top or left edge of the button's <u>layout box</u> till the cursor turns into a crossed double-sided arrow. Then click and drag the layout box to the desired location.
- 4. Select the button by placing the cursor anywhere within the button text.
- 5. In the <u>Properties sidebar</u> 53, go to the button properties. Open the property group *Fillable PDF Form*, and set the *Enabled* property to yes. The button is now enabled to perform a fillable-PDF-form button action. Alternatively, you can set the property value to an XPath expression that evaluates to the string yes. This is useful, for example, if you wish to specify via a global <u>user-declared parameter</u> 403 that a control is fillable. In this case, first define a global <u>user-declared parameter</u> 403 with a value of yes, then set the *enabled* property to an XPath expression that calls the parameter, for example:

 \$MyFillablePDFParam. Since the parameter's value is yes, the control's fillable property will then be enabled
- 6. In the *Fillable PDF Form* property group, you can also set the button's border style. Other properties related to the button's appearance can be set in the *Styles* sidebar.

Button types

After a button has been placed in the design and defined as a fillable-PDF-form button (see previous section above), you can define what kind of action the button will perform. Do this as follows. In the Fillable PDF Form property group (of the Properties sidebar sidebar), select a button action from the combo box of the Form type property.

The following button actions are available.

■ Navigation buttons

There are four navigation buttons: *First page*; *Previous page*; *Next page*; and *Last page*. These buttons enable the end user to navigate through the pages of the PDF document.

■ Data field delete/reset buttons

There are two buttons that enable users to delete/reset data in fields:

- *Empty:* Deletes the content of all fields in the document: not only <u>input fields</u> 533, but also data associated with <u>check box and radio button controls</u> 534.
- Reset: Resets the content of all fields in the document to the values contained in the Working XML File 107. Data associated with check box and radio button controls will also be reset. If no default value exists for a field, then the field is reset to empty.

■ Print button

The **Print** button enables the user to print the PDF form. Which pages to print can be specified in the Print dialog that appears before the print job is sent to the printer. Note that the <u>check box and radio button</u> controls are not selected till the user explicitly clicks in them; default values from the <u>Working XML</u> File are not represented in the PDF form, and are not printed.

■ Submit button

The **Submit** button enables users to submit the PDF form data they have filled to a server. In the <u>Properties sidebar</u> two additional button properties must be specified for the **Submit** button.

- Submit type: Available values are fdf file and pdf file. The selected value determines the format of the document that is submitted to the URL at Submit URL.
- Submit URL: The URL of the server location to which the document is submitted.

For more information about the Submit procedure, see <u>Saving and Submitting</u> 537.

8.8.3 Form Data

A PDF document that contains interactive forms can be thought of as having a form data layer superimposed on the primitive graphics layer. While a PDF file contains both layers, a Forms Data Format (FDF) file contains only the data layer. An FDF file is smaller and simpler than a PDF file, and can be imported into a PDF file that has a form structure that corresponds to the form in the FDF file.

After a user has edited a form in a PDF file that has been created from an SPS, they can do the following:

- Save the edited PDF file 537
- Submit the edited form data 537 to a server as an FDF file, or submit the entire PDF file 537 containing the edited form data to a server
- Extract form data from the edited PDF file to an FDF file 538
- Extract form data from the edited PDF file to an XML file 533

These actions, and also how to design fillable PDF forms so that the user can submit form data to a server, are described in the sub-sections of this section.

8.8.3.1 Saving and Submitting

After a user has entered or edited fillable PDF form data, they can:

- Save the PDF to file
- Submit form data in Forms Data Format (FDF) or the entire PDF file (in PDF format) to a server for further action

Form data can also be extracted to an FDF file or an XML file. How to do this is described in the next section, Extracting form data as FDF/XML 333.

Saving the form to a PDF file

The user can save the filled-in form as a PDF file. This PDF file can be re-opened and edited, transmitted electronically, sent for further processing, or archived.

Note: Default values of data fields associated with <u>check box and radio button controls</u> will not be represented in the PDF file. The user will need to explicitly fill in values for these data fields.

Submitting the form as FDF or PDF

Data in the filled-in form can be submitted to a server in FDF or PDF format.

- The FDF format contains only the form's data. It can be processed to produce files that can be stored, transmitted electronically, and imported back into the corresponding PDF form. The server location to which the FDF file is submitted will typically contain a script with instructions about how to handle the received FDF data.
- The PDF format contains both form data as well as the page's graphics objects (which are used to render the PDF page). The submitted PDF file can be stored for records or be processed further.

StyleVision provides a **Submit** button for fillable PDF forms that has properties to specify (i) the server URL to which the form data is to be submitted, and (ii) the format in which the data is to be submitted (FDF or PDF). When the user clicks this button, the form data is submitted. to the specified server in the specified format.

For more information about the FDF format, see the PDF Reference.

8.8.3.2 Extracting as FDF/XML

After a user has entered fillable PDF form data, they can extract the form data to an FDF file or XML file from an input PDF file. This is done by invoking Altova StyleVision Server's pdfdata command, as follows:

```
stylevisionserver pdfdata [options] InputPDF
```

The options specify the output file formats and locations:

```
--outfdf Specifies the absolute path to the generated FDF file. Form: --outfdf=FILE Specifies the absolute path to the generated XML file. Form: --outxml=FILE
```

Examples of the pdfdata command:

```
stylevisionserver pdfdata --outfdf=C:\test\forms\FDFData.fdf C:\test\forms\TestForm.pdf stylevisionserver pdfdata --outxml=C:\test\forms\XMLData.xml C:\test\forms\TestForm.pdf
```

FDF file

The generated FDF file contains the data of the PDF file's form data fields. The FDF file can be opened in a Adobe Reader, Adobe Acrobat, and any text editor.

- If you open the FDF file in Adobe Reader or Adobe Acrobat, then the application will attempt to open the PDF file that is associated with the FDF file. If it cannot locate the PDF file, then it will prompt you to browse for the PDF file. If the PDF file is located, then the PDF file will be opened and you will be asked, in the yellow ribbon at the top of the document, whether you wish to trust the FDF document. If you trust the FDF document, then the data in the FDF file will be loaded into the PDF file.
- If you open the FDF file in a text editor, you can edit the form data in it and save the FDF file. This FDF file can then be used with a corresponding PDF file.

XML file

The XML file is generated with a root element named pdf-form-data (see listing below) The root element has child page elements, each of which corresponds to a page in the PDF document. Each page element contains child elements that correspond to the form data fields on that page. (We will call the elements at this level form-field elements.) For example: If there are five fields on a page, then there will be five corresponding form-field XML elements in the generated XML file. Note that radio buttons assigned to one XML node in the design will be generated as one form-field XML element in the XML file.

Names of form-field elements

Note the following points:

- If, in the design, a form control has a valid XML element-name value as the string value of its Fillable
 PDF Form property Output element name, then this name is used as the name of the corresponding
 form-field element. If the value of the Output element name property is an invalid XML element name,
 then an XML element name is generated; the replacement is noted as a comment (see the last formfield element in the listing above).
- If, in the design, a form control has no *Output element name* property value (see previous point), but has a valid XML element-name value for its *id* property (under the *Common* group of properties), then the value of the *id* property is used as the name of the corresponding form-field element. If the value of

- the *id* property is an invalid XML element name, then an XML element name is generated; the replacement is noted as a comment.
- If no value is specified for either *Output element name* property or the *id* property, then an XML element name is auto-generated. See, for example, the second form-field element in the listing above.

Additional Functionality 541

9 Additional Functionality

Additional to the <u>content editing</u> ⁽³⁰⁾, <u>structure</u> ⁽²⁹¹⁾, <u>advanced</u> ⁽³⁷⁰⁾, and <u>presentation</u> ⁽⁴⁵⁰⁾ procedures described in this documentation, StyleVision provides a range of miscellaneous additional features. These are listed below and described in detail in the sub-sections of this section.

- Global Resources Global resources provide flexibility in selecting resources. For example, multiple resources (such as files and databases), can be assigned to an alias. When an alias is used as a source (XML, XSD, etc) of an SPS, the resource can be switched among the multiple resources assigned to the alias.
- <u>Authentic Node Properties</u> 559. Individual nodes in the XML document have Authentic View-specific properties. Nodes can be defined to be non-editable, to be displayed with markup tags, to display user information on mouseover, etc.
- Replace Parent Node OnClick With [55]. The value of the parent node of a button or hyperlink can be selected by the Authentic View user. The SPS can be designed to modify presentation based on what the Authentic View user selects.
- Additional Validation 664. A node can be tested using an XPath expression to return a Boolean value that determines whether user input for that node is valid. This test is in addition to document validation against a schema.
- Working with Dates 537. In Authentic View, a graphical date-picker ensures that dates are entered in the correct XML Schema format. Furthermore, dates can be manipulated and formatted as required.
- <u>Unparsed Entity URIs</u> . URIs can be stored in unparsed entities in the DTD on which an XML document is based. The Unparsed Entity URI feature enables images and hyperlinks to use these URIs as target URIs.
- <u>Using Scripts</u> StyleVision contains a JavaScript Editor in which JavaScript functions can be defined. These functions are then available for use as event handlers anywhere within the SPS, and will take effect in the output HTML document.
- HTML Import 538. An HTML file can be imported into StyleVision and an XML, XSD, and SPS files can be created from it.
- New from XSLT 653. An SPS can be created from an XSLT-for-HTML or an XSLT-for-FO. Template structure and styling in the XSLT will be created in the SPS. You can then modify the SPS components and add content and formatting to the SPS.

9.1 Altova Global Resources

542

Altova Global Resources is a collection of aliases for file, folder, and database resources. Each alias can have multiple configurations, and each configuration maps to a single resource (see screenshot below). Therefore, when a global resource is used as an input, the global resource can be switched among its configurations. This is done easily via controls in the GUI that let you select the active configuration. For example, if an XSLT stylesheet for transforming an XML document is assigned via a global resource (an alias), then we can set up multiple configurations for the global resource, each of which points to a different XSLT file. After setting up the global resource in this way, switching the configuration would switch the XSLT file used for the transformation.

A global resource can not only be used to switch resources within an Altova application, but also to generate and use resources from other Altova applications. So, files can be generated on-the-fly in one Altova application for use in another Altova application. All of this tremendously eases and speeds up development and testing. For example, an XML file can be generated by an Altova MapForce mapping and used in StyleVision as an XML Working File in an SPS.

Using Altova Global Resources involves two processes:

- <u>Defining Global Resources</u> Resources are defined and the definitions are stored in an XML file. These resources can be shared across multiple Altova applications.
- <u>Using Global Resources</u> Within StyleVision, files can be located via a global resource instead of via a file path. The advantage is that the resource can be switched by changing the active configuration in StyleVision.

Global resources in other Altova products

Currently, global resources can be defined and used in the following individual Altova products: XMLSpy, StyleVision, MapForce, Authentic Desktop, MobileTogether Designer, and DatabaseSpy.

9.1.1 Defining Global Resources

Altova Global Resources are defined in the Manage Global Resources dialog, which can be accessed in two ways:

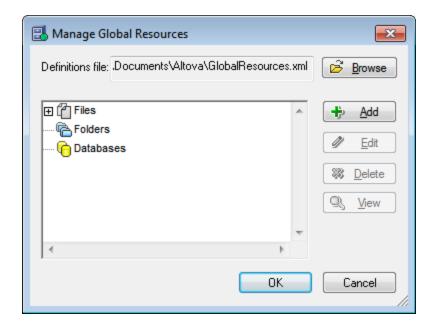

- Click the menu command Tools | Global Resources.
- Click the Manage Global Resources icon in the Global Resources toolbar (screenshot below).

Additional Functionality Altova Global Resources 543

The Global Resources Definitions file

Information about global resources is stored in an XML file called the Global Resources Definitions file. This file is created when the first global resource is defined in the Manage Global Resources dialog (*screenshot below*) and saved.

When you open the Manage Global Resources dialog for the first time, the default location and name of the Global Resources Definitions file is specified in the *Definitions File* text box (*see screenshot above*):

C:\Users\<username>\My Documents\Altova\GlobalResources.xml

This file is set as the default Global Resources Definitions file for all Altova applications. So a global resource can be saved from any Altova application to this file and will be immediately available to all other Altova applications as a global resource. To define and save a global resource to the Global Resources Definitions file, add the global resource in the Manage Global Resources dialog and click **OK** to save.

To select an already existing Global Resources Definitions file to be the active definitions file of a particular Altova application, browse for it via the **Browse** button of the *Definitions File* text box (*see screenshot above*).

Note: You can name the Global Resources Definitions file anything you like and save it to any location accessible to your Altova applications. All you need to do in each application, is specify this file as the Global Resources Definitions file for that application (in the *Definitions File* text box). The resources become global across Altova products when you use a single definitions file across all Altova products.

Note: You can also create multiple Global Resources Definitions files. However, only one of these can be active at any time in a given Altova application, and only the definitions contained in this file will be available to the application. The availability of resources can therefore be restricted or made to overlap across products as required.

Managing global resources: adding, editing, deleting, saving

544

In the Manage Global Resources dialog (*screenshot above*), you can add a global resource to the selected Global Resources Definitions file, or edit or delete a selected global resource. The Global Resources Definitions file organizes the global resources you add into groups: of files, folders, and databases (*see screenshot above*).

To *add a global resource*, click the *Add* button and define the global resource in the appropriate Global Resource dialog that pops up (*see the descriptions of files* 645), *folders* 650, *and databases* 642 *in the subsections of this section*). After you define a global resource and save it (by clicking **OK** in the Manage Global Resources dialog), the global resource is added to the library of global definitions in the selected Global Resources Definitions file. The global resource will be identified by an alias.

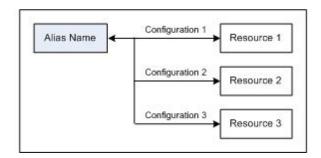

To **edit a global resource**, select it and click **Edit**. This pops up the relevant Global Resource dialog, in which you can make the necessary changes (see the descriptions of <u>files</u> 545, <u>folders</u> 550, and <u>databases</u> in the sub-sections of this section).

To delete a global resource, select it and click Delete.

After you finish adding, editing, or deleting, make sure to click **OK** in the Manage Global Resources dialog to **save your modifications** to the Global Resources Definitions file.

Relating global resources to alias names via configurations

Defining a global resource involves mapping an alias name to a resource (file, folder, or database). A single alias name can be mapped to multiple resources. Each mapping is called a configuration. A single alias name can therefore be associated with several resources via different configurations (*screenshot below*).

In an Altova application, you can then assign aliases instead of files. For each alias you can switch between the resources mapped to that alias simply by changing the application's active Global Resource configuration (active configuration). For example, in Altova's XMLSpy application, if you wish to run an XSLT transformation on the XML document MyXML.xml, you can assign the alias MyXSLT to it as the global resource to be used for XSLT transformations. In XMLSpy you can then change the active configuration to use different XSLT files. If Configuration-1 maps First.xslt to MyXSLT and Configuration-1 is selected as the active configuration, then First.xslt will be used for the transformation. In this way multiple configurations can be used to access multiple resources via a single alias. This mechanism can be useful when testing and comparing resources. Furthermore, since global resources can be used across Altova products, resources can be tested and compared across multiple Altova products as well.

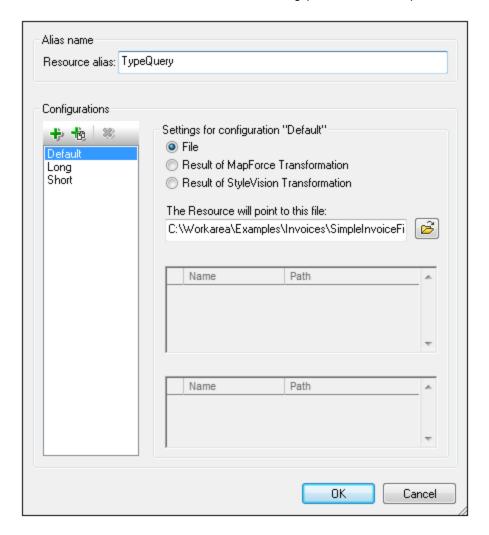

9.1.1.1 Files

The Global Resource dialog for Files (*screenshot below*) is accessed via the **Add | File** command in the <u>Manage Global Resources dialog</u> ⁵⁴². In this dialog, you can define configurations of the alias that is named in the *Resource Alias* text box. After specifying the properties of the configurations as explained below, save the alias definition by clicking **OK**.

After saving an alias definition, you can add another alias by repeating the steps given above (starting with the **Add | File** command in the Manage Global Resources dialog ⁵⁴²).

Global Resource dialog

An alias is defined in the Global Resource dialog (screenshot below).

Global Resource dialog icons

Add Configuration: Pops up the Add Configuration dialog in which you enter the name of the configuration to be added.

Add Configuration as Copy: Pops up the Add Configuration dialog in which you can enter the name of the configuration to be created as a copy of the selected configuration.

Delete: Deletes the selected configuration.

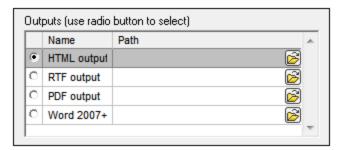

Open: Browse for the file to be created as the global resource.

Defining the alias

Define the alias (its name and configurations) as follows:

- 1. Give the alias a name: Enter the alias name in the Resource Alias text box.
- 2. Add configurations: The Configurations pane will have, by default, a configuration named <code>Default</code> (see screenshot above), which cannot be deleted or renamed. You can add as many additional configurations as you like by: (i) clicking the Add Configuration or Add Configuration as Copy icons, and (ii) giving the configuration a name in the dialog that pops up. Each added configuration will be shown in the Configurations list. In the screenshot above, two additional configurations, named <code>Long</code> and <code>Short</code>, have been added to the Configurations list. The Add Configuration as Copy command enables you to copy the selected configuration and then modify it.
- 3. Select a resource type for each configuration: Select a configuration from the Configurations list, and, in the Settings for Configuration pane, specify a resource for the configuration: (i) File, (ii) Output of an Altova MapForce transformation, or (iii) Output of an Altova StyleVision transformation. Select the appropriate radio button. If a MapForce or StyleVision transformation option is selected, then a transformation is carried out by MapForce or StyleVision using, respectively, the .mfd or .sps file and the respective input file. The result of the transformation will be the resource.
- 4. Select a file for the resource type: If the resource is a directly selected file, browse for the file in the Resource File Selection text box. If the resource is the result of a transformation, in the File Selection text box, browse for the .mfd file (for MapForce transformations) or the .sps file (for StyleVision transformations). Where multiple inputs or outputs for the transformation are possible, a selection of the options will be presented. For example, the output options of a StyleVision transformation are displayed according to what edition of StyleVision is installed (the screenshot below shows the outputs for Enterprise Edition).

Select the radio button of the desired option (in the screenshot above, 'HTML output' is selected). If the resource is the result of a transformation, then the output can be saved as a file or itself as a global resource. Click the icon and select, respectively, Global Resource (for saving the output as a global resource) or Browse (for saving the output as a file). If neither of these two saving options is selected, the transformation result will be loaded as a temporary file when the global resource is invoked.

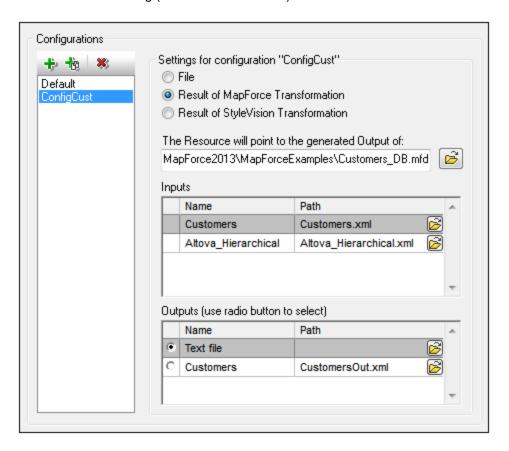

5. Define multiple configurations if required: You can add more configurations and specify a resource for each. Do this by repeating Steps 3 and 4 above for each configuration. You can add a new configuration to the alias definition at any time.

6. Save the alias definition: Click **OK** to save the alias and all its configurations as a global resource. The global resource will be listed under Files in the Manage Global Resources dialog ⁵⁴².

Result of MapForce transformation

Altova MapForce maps one or more (existing) input document schemas to one or more (new) output document schemas. This mapping, which is created by a MapForce user, is known as a MapForce Design (MFD). XML files, text files, databases, etc, that correspond to the input schema/s can be used as data sources. MapForce generates output data files that correspond to the output document schema. This output document is the Result of MapForce Transformation file that will become a global resource.

If you wish to set a MapForce-generated data file as a global resource, the following must be specified in the Global Resource dialog (see screenshot below):

- A .mfd (MapForce Design) file. You must specify this file in the Resource will point to generated output of text box (see screenshot above).
- One or more input data files. After the MFD file has been specified, it is analyzed and, based on the input schema information in it, default data file/s are entered in the *Inputs* pane (see screenshot above). You can modify the default file selection for each input schema by specifying another file.
- An output file. If the MFD document has multiple output schemas, all these are listed in the Outputs pane (see screenshot above) and you must select one of them. If the output file location of an

547

individual output schema is specified in the MFD document, then this file location is entered for that output schema in the <code>Outputs</code> pane. From the screenshot above we can see that the MFD document specifies that the <code>Customers</code> output schema has a default XML data file (<code>CustomersOut.xml</code>), while the <code>Text file</code> output schema does not have a file association in the MFD file. You can use the default file location in the Outputs pane or specify one yourself. The result of the MapForce transformation will be saved to the file location of the selected output schema. This is the file that will be used as the global resource

Note: The advantage of this option (Result of MapForce transformation) is that the transformation is carried out at the time the global resource is invoked. This means that the global resource will contain the most up-to-date data (from the input file/s).

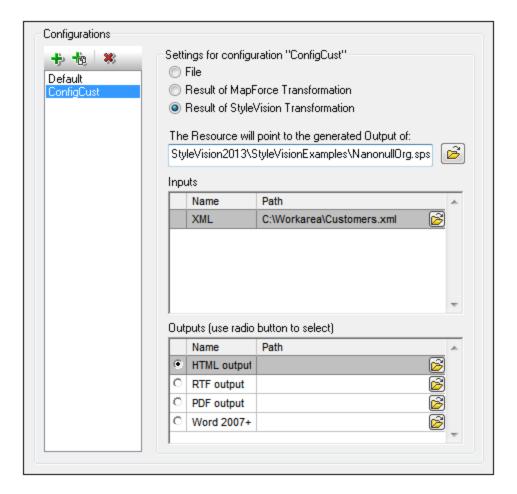

Note: Since MapForce is used to run the transformation, you must have Altova MapForce installed for this functionality to work.

Result of StyleVision transformation

548

Altova StyleVision is used to create StyleVision Power Stylesheet (SPS) files. These SPS files generate XSLT stylesheets that are used to transform XML documents into output documents in various formats (HTML, PDF, RTF, Word 2007+, etc). If you select the option *Result of StyleVision Transformation*, the output document created by StyleVision will be the global resource associated with the selected configuration.

For the StyleVision Transformation option in the Global Resource dialog (see screenshot below), the following files must be specified.

- A .sps (SPS) file. You must specify this file in the Resource will point to generated output of text box (see screenshot above).
- *Input file/s.* The input file might already be specified in the SPS file. If it is, it will appear automatically in the *Inputs* pane once the SPS file is selected. You can change this entry. If there is no entry, you must add one.
- Output file/s. Select the output format in the Outputs pane, and specify an output file location for that format.

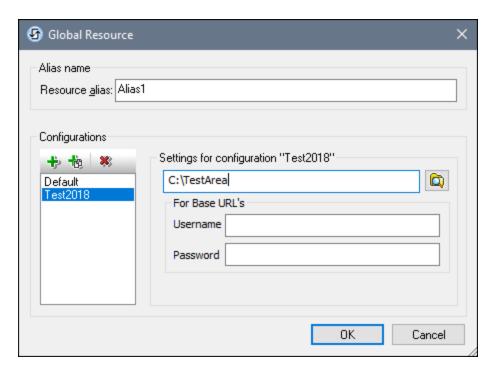

Note: The advantage of this option (Result of StyleVision transformation) is that the transformation is carried out when the global resource is invoked. This means that the global resource will contain the most up-to-date data (from the input file/s).

Note: Since StyleVision is used to run the transformation, you must have Altova StyleVision installed for this functionality to work.

9.1.1.2 Folders

550

In the Global Resource dialog for Folders (screenshot below), add a folder resource as described below.

Global Resource dialog icons

- Add Configuration: Pops up the Add Configuration dialog in which you enter the name of the configuration to be added.
- Add Configuration as Copy: Pops up the Add Configuration dialog in which you can enter the name of the configuration to be created as a copy of the selected configuration.
- Delete: Deletes the selected configuration.
- Open: Browse for the folder to be created as the global resource.

Defining the alias

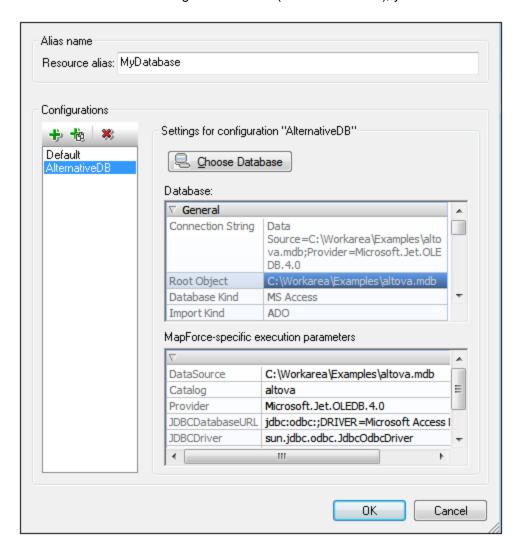

Define the alias (its name and configurations) as follows:

- 1. Give the alias a name: Enter the alias name in the Resource Alias text box.
- 2. Add configurations: The Configurations pane will have a configuration named Default (see screenshot above). This Default configuration cannot be deleted nor have its name changed. You can enter as many additional configurations for the selected alias as you like. Add a configuration by clicking the Add Configuration or Add Configuration as Copy icons. In the dialog which pops up, enter the

- configuration name. Click **OK**. The new configuration will be listed in the Configurations pane. Repeat for as many configurations as you want.
- 3. Select a folder as the resource of a configuration: Select one of the configurations in the Configurations pane and browse for the folder you wish to create as a global resource. If security credentials are required to access a folder, then specify these in the *Username* and *Password* fields.
- 4. Define multiple configurations if required: Specify a folder resource for each configuration you have created (that is, repeat Step 3 above for the various configurations you have created). You can add a new configuration to the alias definition at any time.
- 5. Save the alias definition: Click **OK** in the Global Resource dialog to save the alias and all its configurations as a global resource. The global resource will be listed under Folders in the Manage Global Resources dialog ⁶⁴².

9 1 1 3 Databases

In the Global Resource dialog for Databases (screenshot below), you can add a database resource as follows:

Global Resource dialog icons

552

Add Configuration: Pops up the Add Configuration dialog in which you enter the name of the configuration to be added.

Add Configuration as Copy: Pops up the Add Configuration dialog in which you can enter the name of the configuration to be created as a copy of the selected configuration.

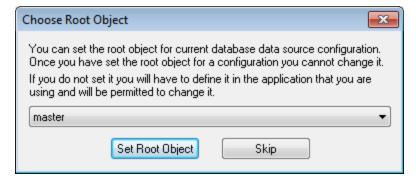

Delete: Deletes the selected configuration.

Defining the alias

Define the alias (its name and configurations) as follows:

- 1. Give the alias a name: Enter the alias name in the Resource Alias text box.
- 2. Add configurations: The Configurations pane will have a configuration named Default (see screenshot above). This Default configuration cannot be deleted nor have its name changed. You can enter as many additional configurations for the selected alias as you like. Add a configuration by clicking the Add Configuration or Add Configuration as Copy icons. In the dialog which pops up, enter the configuration name. Click OK. The new configuration will be listed in the Configurations pane. Repeat for as many configurations as you want.
- 3. Start selection of a database as the resource of a configuration: Select one of the configurations in the Configurations pane and click the **Choose Database** icon. This pops up the Create Global Resources Connection dialog.
- 4. Connect to the database: Select whether you wish to create a connection to the database using the Connection Wizard, an existing connection, an ADO Connection, an ODBC Connection, or JDBC Connection. Complete the definition of the connection method as described in the section Connecting to a Database (63). If a connection has already been made to a database from StyleVision, you can click the Existing Connections icon and select the DB from the list of connections that is displayed.
- 5. Select the root object: If you connect to a database server where a root object can be selected, you will be prompted, in the Choose Root Object dialog (screenshot below), to select a root object on the server. Select the root object and click Set Root Object. The root object you select will be the root object that is loaded when this configuration is used.

If you choose not to select a root object (by clicking the **Skip** button), then you can select the root object at the time the global resource is loaded.

6. Define multiple configurations if required: Specify a database resource for any other configuration you have created (that is, repeat Steps 3 to 5 above for the various configurations you have created). You can add a new configuration to the alias definition at any time.

7. Save the alias definition: Click **OK** in the Global Resource dialog to save the alias and all its configurations as a global resource. The global resource will be listed under databases in the Manage Global Resources dialog.

9.1.2 Using Global Resources

There are several types of global resources (file-type, folder-type, and database-type). Particular scenarios in StyleVision allow the use of particular types of global resources. For example, you can use file-type or folder-type global resources for a Working XML File or a CSS file. Or you can use a database-type resource to create a new DB-based SPS. Some scenarios in which you can use global resources in StyleVision are listed here:

Files and Folders 533 and Databases 556.

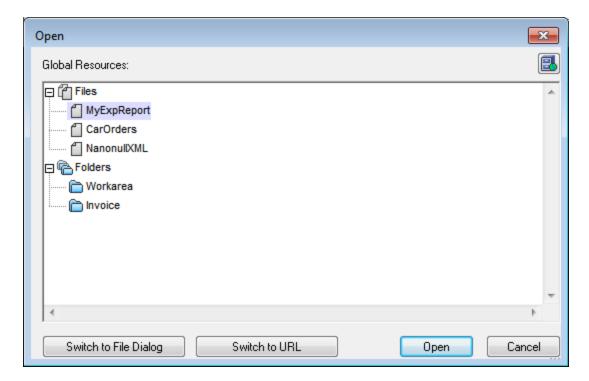

Selections that determine which resource is used

There are two application-wide selections that determine what global resources can be used and which global resources are actually used at any given time:

- The active Global Resources XML File is selected in the Global Resource dialog that are present in the active Global Resources XML File are available to all files that are open in the application. Only the definitions in the active Global Resources XML File are available. The active Global Resources XML File can be changed at any time, and the global-resource definitions in the new active file will immediately replace those of the previously active file. The active Global Resources XML File therefore determines: (i) what global resources can be assigned, and (ii) what global resources are available for look-up (for example, if a global resource in one Global Resource XML File is assigned but there is no global resource of that name in the currently active Global Resources XML File, then the assigned global resource (alias) cannot be looked up).
- The active configuration is selected via the menu item Tools | Active Configuration or via the Global Resources toolbar . Clicking this command (or drop-down list in the toolbar) pops up a list of configurations across all aliases. Selecting a configuration makes that configuration active application-wide. This means that wherever a global resource (or alias) is used, the resource corresponding to the active configuration of each used alias will be loaded. The active configuration is applied to all used aliases. If an alias does not have a configuration with the name of the active configuration, then the default configuration of that alias will be used. The active configuration is not relevant when assigning resources; it is significant only when the resources are actually used.

9.1.2.1 Assigning Files and Folders

File-type and folder-type global resources are assigned differently. In any one of the <u>usage scenarios</u> below, clicking the **Switch to Global Resources** button displays the Open Global Resource dialog (*screenshot below*).

554

Manage Global Resources: Displays the Manage Global Resources dialog.

Selecting a *file-type global resource* assigns the file. Selecting a *folder-type global resource* causes an Open dialog to open, in which you can browse for the required file. The path to the selected file is entered relative to the folder resource. So if a folder-type global resource were to have two configurations, each pointing to different folders, files having the same name but in different folders could be targeted via the two configurations. This could be useful for testing purposes.

You can switch to the file dialog or the URL dialog by clicking the respective button at the bottom of the dialog. The **Manage Global Resources** icon in the top right-hand corner pops up the <u>Manage Global Resources</u> dialog.

Usage scenarios

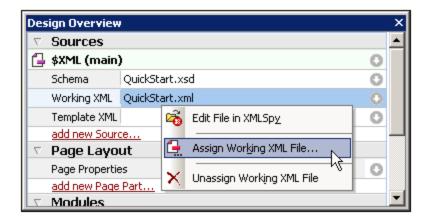

File-type and folder-type global resources can be used in the following scenarios:

- Adding and modifying schema sources and Working XML Files 553 and Template XML Files 553
- Saving as Global Resource 555
- Adding modules and CSS files
- Adding global resources to a project 556

Schema, Working XML File, Template XML File

In the Design Overview sidebar (*screenshot below*), the context menus for the Schema, Working XML File, Template XML File contains an entry that pops up the Open dialog in which you can assign the <u>schema</u> or <u>Working XML File</u> via a global resource. Clicking the **Switch to Global Resources** button pops up a dialog with a list of all file-type global resources that are defined in the Global Resources XML File currently active in

StyleVision. (How to set the currently active Global Resources XML File is described in the section <u>Defining Global Resources</u> (542).)

If a global resource has been selected as the file source, it is displayed in the relevant entry in the Design Overview sidebar (*screenshot below*).

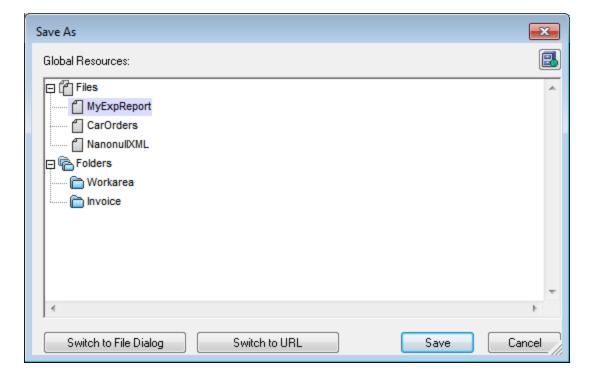

Adding modules and CSS files from a global resource

In the <u>Design Overview sidebar</u> 45, the **Add New Module** and **Add New CSS File** commands pop up the Open dialog, in which you can click Switch to Global Resources to select a Global Resource to be used. Modules and CSS files can then be changed by changing the configuration.

Saving as global resource

A newly created file can be saved as a global resource. Also, an already existing file can be opened and then saved as a global resource. When you click the **File | Save** or **File | Save As** commands, the Save dialog appears. Click the **Switch to Global Resource** button to access the available global resources (*screenshot below*), which are the aliases defined in the current Global Resources XML File.

555

Select an alias and then click **Save**. If the alias is a <u>file alias</u> ⁶⁴⁵, the file will be saved directly. If the alias is a <u>folder alias</u> ⁶⁵⁰, a dialog will appear that prompts for the name of the file under which the file is to be saved. In either case the file will be saved to the location that was defined for the <u>currently active configuration</u> ⁶⁵⁷.

Note: Each configuration points to a specific file location, which is specified in the definition of that configuration. If the file you are saving as a global resource does not have the same filetype extension as the file at the current file location of the configuration, then there might be editing and validation errors when this global resource is opened in StyleVision. This is because StyleVision will open the file assuming the filetype specified in the definition of the configuration.

Global Resources in projects

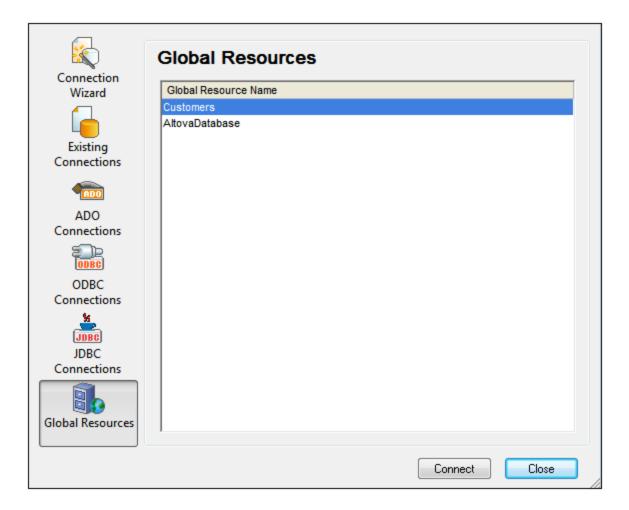

556

Global resources can also be added to the currently active project via the **Project | Add Global Resource to Project** command. This pops up a dialog listing the file-type global resources in the currently active <u>Global Resources XML File</u> Select a global resource and click **OK** to add it to the project. The global resource appears in the Project sidebar and can be used like any other file.

9.1.2.2 Assigning Databases

When an SPS is created from a database (DB) with the **File | New from DB** command, you can select the option to use a global resource (*screenshot below*). Other commands where a database-type global resource can be used are database-related commands in the menu.

Additional Functionality Altova Global Resources 557

In the Connection dialog (*screenshot above*), all the database-type global resources that have been defined in the currently active <u>Global Resources XML File</u> are displayed. Select the required global resource and click **Connect**. If the selected global resource has more than one configuration, then the database resource for the currently active configuration is used (check **Tools | Active Configuration** or the Global Resources toolbar), and the connection is made.

9.1.2.3 Changing the Active Configuration

One configuration of a global resource can be active at any time. This configuration is called the active configuration, and it is active application-wide. This means that the active configuration is active for all global resources aliases in all currently open files and data source connections. If an alias does not have a configuration with the name of the active configuration, then the default configuration of that alias will be used. As an example of how to change configurations, consider the case in which a file has been assigned via a global resource with multiple configurations. Each configuration maps to a different file. So, which file is selected depends on which configuration is selected as the application's active configuration.

Switching the active configuration can be done in the following ways:

- Via the menu command **Tools | Active Configuration**. Select the configuration from the command's submenu.
- In the combo box of the Global Resources toolbar (*screenshot below*), select the required configuration.

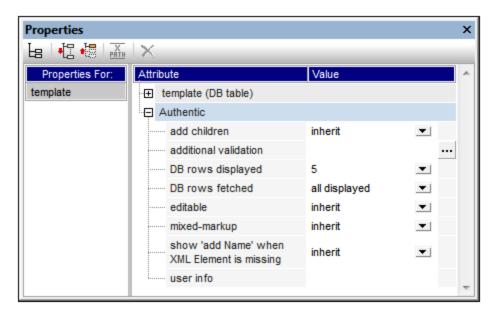

In this way, by changing the active configuration, you can change source files that are assigned via a global resource.

9.2 Authentic Node Properties

Authentic node properties are properties you set for the display of a node **in Authentic View**. For example, a node can be displayed with XML markup tags, be defined to be non-editable, and/or to have user information displayed when the cursor is placed over the node. Authentic node properties can be set on various SPS components. What properties are available for a component depends upon the type of component it is.

To assign Authentic node properties, select the required component in the design. Then, in the *Authentic* group of properties in the Properties sidebar (*screenshot below*), specify the required Authentic node settings. Alternatively, you can right-click the node-template and select **Edit Authentic Properties**.

Defining Authentic Properties

The following node settings can be made to control the behavior of individual nodes in the Authentic View display.

Add children

This setting is available when the selected node is an element. It allows you to define what child elements of the selected element are inserted when the selected element is added. The options are: all child elements, mandatory child elements, and no child element.

Additional validation

In addition to validation of the XML document against a schema, additional validation can be specified for individual nodes and Auto-Calculations. You can set an XPath expression to define the validity range of the XML content of the node or Auto-Calculation. If the XML value of the node is invalid, this is made known to the Authentic View user by means of an error message when the XML document is validated (F8). See Additional Validation for details.

DB rows displayed and fetched

The *DB Rows Displayed* and *DB Rows Fetched* properties define, respectively, how many DB rows will be displayed in Authentic View and how many DB records are originally loaded. The *DB Records Fetched* property thus enables you to speed up the loading and display time.

Content is editable

Defines whether the node is editable or not. By default the node is editable. This setting is available when the selected node is an element, attribute, or contents. Auto-Calculation results cannot be edited because the value is computed with the XPath expression you enter for the Auto-Calculation; this option is therefore not available for Auto-Calculations.

Mixed mark up

This setting is available when the selected node is an element or attribute, and enables you to specify how individual nodes will be marked up in the mixed markup mode of Authentic View. The following options exist: large markup (tags with node names); small markup (tags without node names); and no markup.

Show "add Name" when XML Element is missing

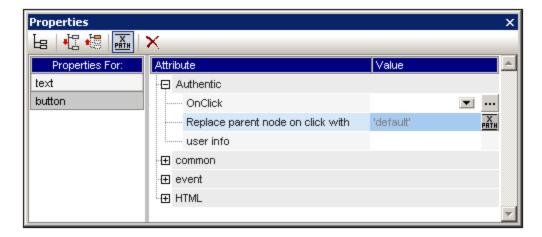

Determines whether a prompt ("Add [element/attribute name]") will appear in Authentic View when the selected element or attribute is missing. By default, the prompt will be displayed. This setting is available when the selected node is an element or an attribute.

User info

Text entered in this text box appears as a tooltip when the mouse pointer is placed over the node. It is available when the selected node is an element, attribute, contents, or an Auto-Calculation. If both the element/attribute node as well as the contents node has User Info, then the User Info for the contents node is displayed as the tooltip when the mouse is placed over the node.

9.3 Replace Parent Node OnClick With

With the Replace Parent Node OnClick With property (in the Authentic group of properties, assignable in the Properties sidebar, see screenshot below), you can specify text content of the parent node of a button or hyperlink 442.

When the Authentic View user clicks the design component (a button or hyperlink), the text you, the SPS designer, have specified will be inserted as the XML content of the design component's parent node. This enables you to allow the Authentic View user to make certain selections (by clicking a button or hyperlink) that will alter the presentation of the XML document in Authentic View.

Usage mechanism

This feature can be used as follows:

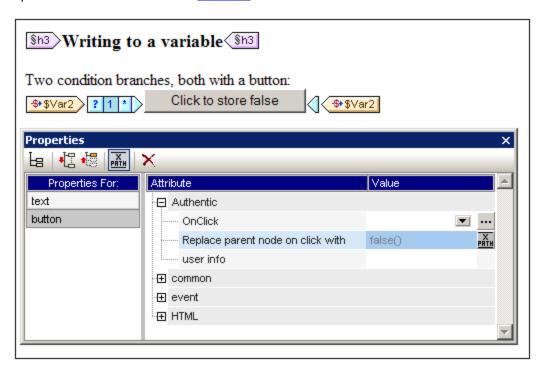

- 1. In the design, insert the design component (button or hyperlink) within the node for which you wish to insert text content.
- 2. Select the design component in the design, and, in the Properties sidebar, select that design component (in the *Properties For* column), and enter a value for the *Replace Parent Node OnClick With* property (which is in the Authentic group of properties; see screenshot above). This value can be entered as a text value directly or via an XPath expression. (Click the XPath icon in the toolbar of the Properties sidebar to enter the value as an XPath expression). In the screenshot above, the value is an XPath string expression 'default'. Now, if the Authentic View user clicks the design component in Authentic View, the text default will be entered as the text content of the parent node of the design component. This result can also be obtained if you enter a text value (not an XPath expression) of default directly as the value of the *Replace Parent Node OnClick With* property.
- 3. Now that you know what content the parent node will have when the Authentic View user clicks the design component, you can set up processing based on the text content of the parent node. For example, using a condition you can specify that when the content of the parent node is default, then some default formatting is applied; or, when the content is hide, the text of a node is hidden. In this way you can use this feature to achieve powerful effects that might otherwise have required the deployment of scripts set.

Note: For this feature to work correctly, in the schema, the parent node must be defined to allow text content.

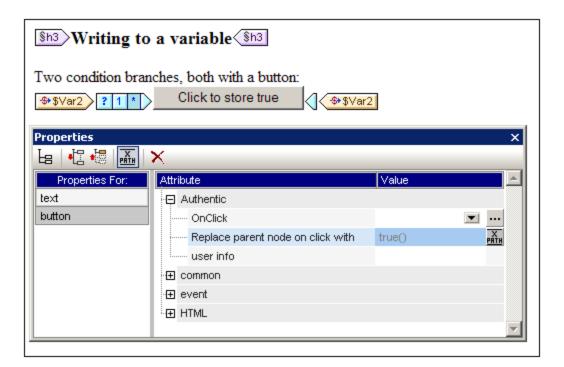

Usage with variables

The parent node can also be a <u>variable</u> that has been defined on an ancestor node. The value of the variable can then be set up by the SPS designer using the *Replace Parent Node OnClick With* property. When the Authentic View user clicks the design component (<u>button</u> or <u>hyperlink</u> (422)), the value defined for the *Replace Parent Node OnClick With* property of the design component is assigned to the variable. You can now set up alternative processing options based on the value of the variable.

A simple example is shown below. When the value of the variable Var2 is set to Boolean true(), a button enabling the value to be changed to Boolean false() is displayed (see screenshot below). This processing is specified in the first branch of a condition (33).

The Otherwise branch of the condition specifies processing that displays a button enabling the value of the variable to be changed to Boolean true() (screenshot below). You can define additional processing according to the value of the variable Var2 (true() or false()).

In this way you, the SPS designer, can allow Authentic View users to select from a range of options that then produce specific and corresponding processing of the document.

564 Additional Functionality Additional Validation

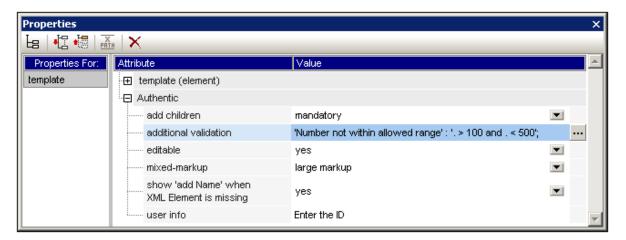

9.4 Additional Validation

The Additional Validation setting is available when the selected component is an element or attribute node, contents (contents placeholder), a data-entry device, or an Auto-Calculation. You can set an XPath expression to define the validity range of the XML content of the node or Auto-Calculation. An XML value that falls outside this defined range is invalid. If the XML value of the node is invalid, this is made known to the Authentic View user by means of an error message when the XML document is validated (F8). The error message that is displayed is the text you enter into the Error message field of the Additional Validation setting.

Setting Additional Validation

To set additional validation, do the following:

- 1. Select the component for which additional validation is required.
- 2. In the Properties sidebar, select the *Authentic* group of properties, and click the Edit button of the Additional Validation property (*screenshot below*). This pops up the Additional Validation dialog.

3. In the Additional Validation dialog (*screenshot below*), add a row for an Additional Validation entry by clicking the **Add** button near the top left of the pane.

4. In the XPath expression column, enter an XPath expression to define the validity range of the XML data in that component.

- 5. Enter an error message to display when the data is invalid.
- 6. Click **OK** to finish.

Additional Functionality Unparsed Entity URIs

9.5 Unparsed Entity URIs

566

If you are using a DTD and have declared an unparsed entity in it, you can use the URI associated with that entity for image and hyperlink targets in the SPS. This is useful if you wish to use the same URI multiple times in the SPS. This feature makes use of the XSLT function unparsed-entity-uri to pass the URI of the unparsed entity from the DTD to the output, and is therefore only available in the outputs (HTML, RTF, PDF, Word 2007+); not in Authentic View. Note that unparsed entity URIs are not processed for Text output.

Using this feature requires that the DTD, XML document, and SPS documents be appropriately edited, as follows:

- 1. In the DTD, the <u>unparsed entities must be declared</u> 566, with (i) the URI, and (ii) the notation (which indicates to StyleVision the resource type of the entity).
- 2. In the XML document, the unparsed entity must be <u>referenced</u> 560. This is done by giving the names of the required unparsed entities.
- 3. In the SPS, unparsed entities can be used to target <u>images</u> and <u>hyperlinks</u> by <u>correctly</u> accessing the relevant dynamic node values as unparsed entities 566.

Declaring and referencing unparsed entities

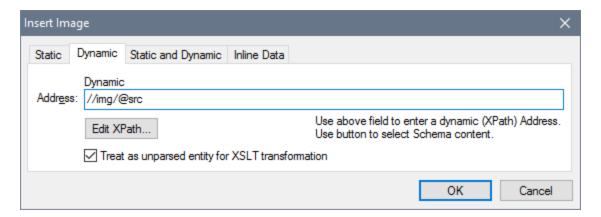

Given below is a cut-down listing of an XML document. It has an internal DTD subset which declares two unparsed entities, one with a GIF notation (indicating a GIF image) and the other with an LNK notation (indicating a hyperlink). The img/@src and link/@href nodes in the XML code reference the unparsed entities by giving their names.

SPS images and hyperlinks that use unparsed entities

Images and hyperlinks in the SPS that reference unparsed entity URIs are used as follows:

- 1. Insert the image or hyperlink via the **Insert** menu.
- 2. In the object's Edit dialog, select the Dynamic tab properties (*screenshot below*), and enter an XPath expression that selects the node containing the name of the unparsed entity. In the XML document example given above, these nodes would be, respectively, the //img/@src and //link/@href nodes.

Additional Functionality Unparsed Entity URIs 567

Then check the Treat as Unparsed Entity check box at the bottom of the dialog. This causes the
content of the selected node to be read as an unparsed entity. If an unparsed entity of that name is
declared, the URI associated with that unparsed entity is used to locate the resource (image or
hyperlink).

When the stylesheet is processed, the URI associated with the entity name is substituted for the entity name.

Note: If the URI is a relative URI, then the XSLT processor expands it to an absolute URI applying the base URI of the DTD. For example, if the unparsed entity is associated with the relative URI "nanonull.gif", then this URI will be expanded to file:///c:/someFolder/nanonull.gif, where the DTD is in the folder someFolder.

9.6 New from XSLT, XSL-FO or FO File

An SPS design can be based on existing XSLT files that were designed for HTML output or XSLT files with XSLFO commands for output in PDF or FO files. This means that SPS files do not have to be designed from scratch, but can take an already existing XSLT file as a starting point.

Steps for creating an SPS from XSLT

The steps for creating an SPS file from an XSLT, XSLT-for-FO, or FO file are as follows.

- 1. Select the command File | New | New from XSLT, XSL-FO or FO File.
- 2. In the Open dialog that appears, browse for the file you want.
- 3. In the next dialog you will be prompted to select a schema on which the SPS is to be based. Select the schema you want.
- 4. An SPS based on the structure and formatting in the XSLT or FO file will be created and displayed in Design View 36.
- 5. You can now modify the SPS in the usual way. For example, you could drag in nodes from the Schema Tree 48, modify the styling and presentation or add additional styling, and use StyleVision functionality such as Auto-Calculations 371 and Conditional Templates 381.
- 6. You can save the SPS and use a <u>Working XML File</u> to preview <u>various output formats</u> Subsequently you can <u>generate stylesheets and output files</u> using the <u>Save Generated Files</u> command.

Example

The example discussed below is located in the (My) Documents folder (My), C:\Documents and Settings\<username>\My

Documents\Altova\StyleVision2025\StyleVisionExamples/Tutorial/NewFromXSLT. This folder contains the files: SimpleExample.xslt, SimpleExample.xsd, and SimpleEample.xml.

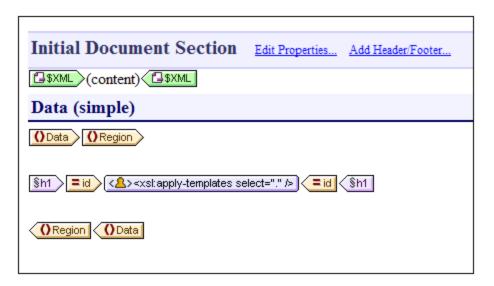

The XML file is shown below.

```
■ XML file used in charts example: YearlySales.xml
   <?xml version="1.0" encoding="UTF-8"?>
   <Data xm]ns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
         xsi:noNamespaceSchemaLocation="YearlySales.xsd">
          <ChartType>Pie Chart 2D</ChartType>
          <Region id="Americas">
                 <Year id="2005">30000</year>
                 <Year id="2006">90000</year>
                 <Year id="2007">120000
                 <Year id="2008">180000</year>
                 <Year id="2009">140000</year>
                 <Year id="2010">100000
          </Region>
          <Region id="Europe">
                 <Year id="2005">50000</year>
                 <Year id="2006">60000</year>
                 <Year id="2007">80000</year>
                 <Year id="2008">100000
                 <Year id="2009">95000</year>
```

The XSLT file is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"</pre>
xmlns:xs="http://www.w3.org/2001/xMLSchema" xmlns:fn="
http://www.w3.org/2005/xpath-functions">
   <xsl:output method="xml" version="1.0" encoding="UTF-8" indent="yes"/>
   <xsl:template match="/">
      <html>
         <head>
            <title>Simple Example for New From XSLT</title>
         </head>
            <xsl:apply-templates/>
         </body>
      </html>
   </xsl:template>
   <xsl:template match="Data">
      <xsl:for-each select="Region">
         <h1 style="color:red">
            <xsl:apply-templates select="@id"/>
         </h1>
      </xsl:for-each>
   </xsl:template>
</xsl:stylesheet>
```

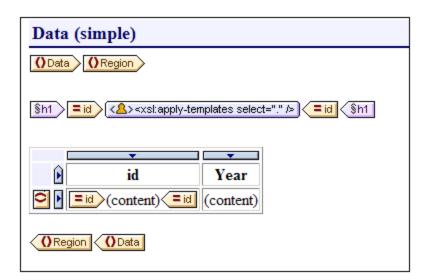

Follow the steps 1 to 4 listed above to obtain the SPS in Design View. The SPS will look something like this:

Notice that the two templates in the XSLT have been created in the SPS. Now switch to the HTML Preview (screenshot below), and notice that the h1 element's styling (color:red) has been also passed to the SPS.

In Design View select the h1 element and change its color to black (in the Styles sidebar, in the *Color* group of properties). Then, from the Schema Tree, drag the Year element and create it as a table at the location shown in the screenshot below. Reverse the contents of the two columns so that the Year ID is in the first column.

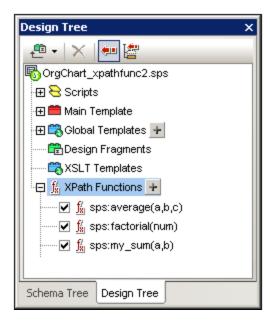

You can make additional changes in the content, structure, and presentation properties of the document, then preview the output and save files using the **Save Generated Files** command.

9.7 User-Defined XPath Functions

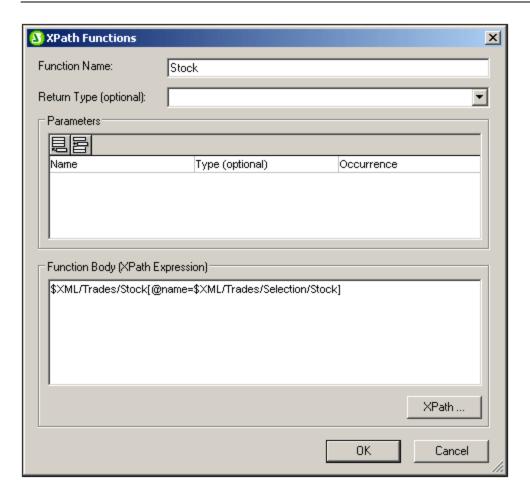

The SPS designer can define customized **XPath 2.0/3.0** functions. A user-defined XPath function can be reused in any design component that accepts an XPath expression, for example, in Auto-Calculations, conditions, and combo boxes.

Defining and editing user-defined XPath functions

User-defined XPath functions are created (and subsequently accessed for editing) in either the Schema Tree sidebar or the Design Tree sidebar (see screenshot below). All the user-defined XPath functions in an SPS are listed under the XPath Functions item in both the Schema Tree and Design Tree sidebars and can be accessed via either sidebar.

To create a user-defined XPath function, click the icon of the XPath Functions item. This pops up the XPath Functions dialog (*screenshot below*). If you wish to edit a function that has already been created, double-click its entry in the list of XPath functions. The XPath Functions dialog (*screenshot below*) will appear and the function definition can be edited.

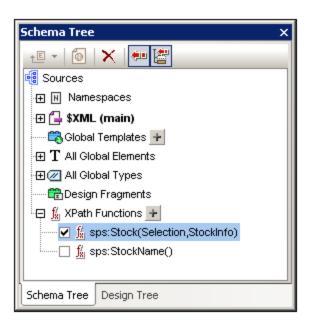

After a user-defined XPath function is created, it is available for use anywhere in the design.

Namespace of user-defined XPath functions

User-defined XPath functions are created in the namespace: http://www.altova.com/StyleVision/user-xpath-functions. This namespace is bound to the prefix sps:, so user-defined XPath functions must be called using this namespace prefix. For example, sps:MyFunction().

Enabling and disabling user-defined XPath functions

Each user-defined XPath function can be enabled or disabled by, respectively, checking or unchecking the check box to the left of the function's entry in the list of user-defined XPath functions (see screenshot below).

This feature is useful if two functions have the same name. Such a situation could arise, for example, when an imported SPS module contains a function having the same name.

Calling a user-defined XPath function

A user-defined XPath function can be called in an XPath expression at any location in the design. For example, the user-defined XPath function <code>sps:MyFunction</code> defined above can be called, for example, with the following XPath expression in an Auto-Calculation:

sps:MyFunction()/@name.

This XPath expression would be evaluated as follows:

- 1. The sps:MyFunction() function is evaluated. Let's say the function is defined as follows: \$XML/Trades/Stock[@name=\$XML/Trades/Selection/Stock]. When the function is evaluated it returns the /Trades/Stock element that has a name attribute with a value that matches the content of the /Trades/Selection/Stock element.
- 2. The result of Step 1 is returned to the XPath expression in the function call. Now the value of the name attribute of this /Trades/Stock element is returned as the value of the Auto-Calculation.

Deleting a function

To delete a function, select it in the XPath Functions list in the Schema Tree or Design Tree sidebar and then click the **Remove Item** icon in the toolbar of the sidebar. Alternatively, you can right-click the XPath function and select **Remove Item** from the context menu.

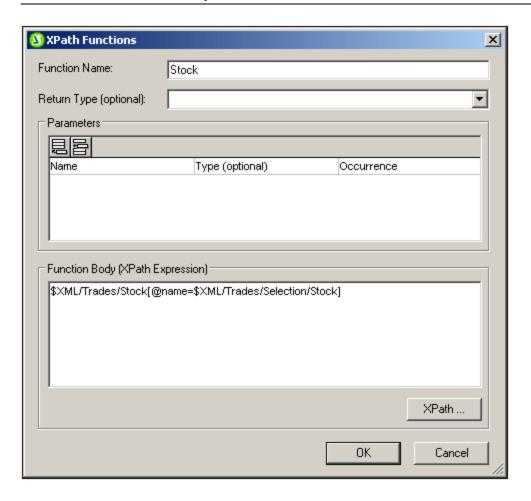

9.7.1 Defining an XPath Function

A user-defined XPath function requires: (i) a name (a text string), and (ii) a definition (an XPath expression).

Additionally, you can specify one or more **parameters** for the function. A user-defined XPath function can also have an optional **return type** (specified by selecting a type from the dropdown list of the *Return Type* combo box). A return type is useful if you wish to check that the datatype of the returned value conforms to the selected datatype. Note that the return value is not converted to the selected datatype. If there is a type mismatch, an error is returned. If no return type is specified, no datatype check is carried out.

After a user-defined XPath function is created, it is available for use anywhere in the design. In the XSLT stylesheet, it is created as an Xsl:function element that is a child of the xsl:stylesheet element, as shown in the listing below.

The sps:Stock function shown in the screenshot below and listed above returns the /Trades/Stock element that has a name attribute with a value that matches the content of the /Trades/Selection/Stock element. The sps:Average function listed above returns the average of three input parameter-values. The function definition uses the avg() function of XPath 2.0/3.0. The return datatype is specified to be of the xs:decimal type, which is the datatype returned by the avg() function when evaluating input values of datatype xs:integer. If the return type is specified, then the datatype of the return value is checked to see if it conforms with the specified type. If it doesn't, an error is returned.

Defining the function

To define a function, click the icon of the XPath Functions item in the Schema Tree or Design Tree. This pops up the XPath Functions dialog (*screenshot above*). If you wish to edit a function that has already been created, double-click its entry in the list of XPath functions. Then enter a name for the function and a definition in the Function Body pane. Parameter definitions can be entered if required (see the next two sections, Parameters and Sequences and Parameters and Nodes 533, for details). A return type for the function can also be specified (*see above*).

The most important point to bear in mind when writing the XPath expression that defines XPath function is that there is **no context node** for the XPath expression. If the XPath expression must locate a node then the context node for the expression can be provided in one of the following ways:

- 1. The XPath expression starts with the document root. The document root is specified in the first location step of the XPath expression as \$XML. For example, the XPath expression \$XML/Trades/Stock[1] locates the first Stock child element of the /Trades element. The variable \$XML (which locates the document root of the main schema) is defined globally by StyleVision in all SPS designs.
- 2. The context node can be passed as a parameter. See the section <u>Parameters and Nodes</u> below for an explanation.

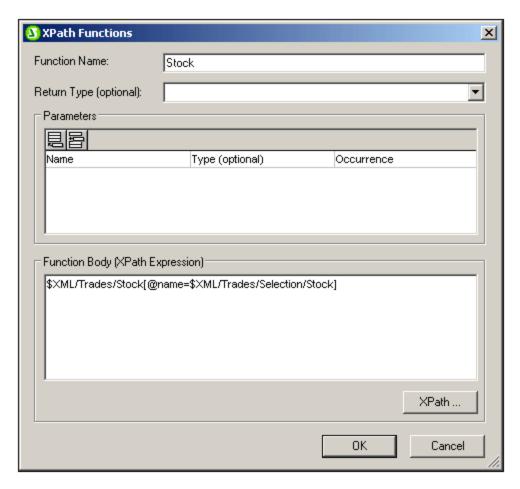

In the following cases, errors are returned:

If a parameter is defined but is not used in the body of the definition.

- If the datatype of the value returned by the function does not match the return type defined for the function.
- If any function in the SPS contains an error, an XSLT error is generated for the whole design, even if the function containing the error is not called. Note, however, that a function can be disabled by unchecking its check box in the list of user-defined XPath functions. When disabled in the design, the function is not included in the XSLT document generated from the design. In this way, an XPath expression containing an error can be excluded from the XSLT and no XSLT error will be generated.

9.7.2 Reusing Functions to Locate Nodes

In the previous section we saw how an XPath function can be built to locate a node. The <code>sps:Stock</code> function which is defined as shown in the screenshot below returns the <code>/Trades/Stock</code> element that has a <code>name</code> attribute with a value that matches the content of the <code>/Trades/Selection/Stock</code> element.

We could modularize the location steps of the XPath expression

XML/Trades/Stock[@name=\$XML/Trades/Selection/Stock] into separate XPath functions. For example as follows:

- The function sps:Stocks(), with the definition: \$XML/Trades/Stock
- The function sps:SelectedStock(), with the definition: \$XML/Trades/Selection/Stock

The whole XPath expression can then be written in another XPath expression as:

```
sps:Stocks()[@name=sps:SelectedStock()]
```

When XPath functions are created in this way to locate a node or nodeset, these functions can be re-used in other XPath expressions across the SPS design, thus considerably simplifying the writing of complex XPath expressions.

9.7.3 Parameters in XPath Functions

A user-defined XPath function can be assigned any number of parameters. The function's parameters are defined in the *Parameters* pane of the XPath Functions dialog (see screenshot below). These parameters can then be used in the definition of the user-defined XPath function (in the *Function Body* pane).

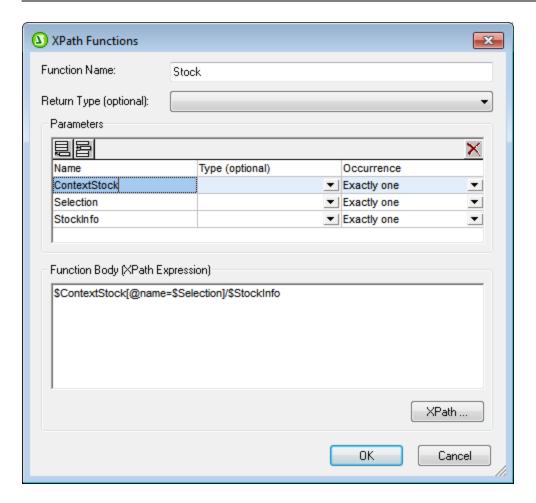

User-defined XPath function mechanism

The steps below explain how an XPath function works.

- 1. In a function call (for example, in an Auto-Calculation), the number of arguments in the function call must match the number of parameters defined for the user-defined function (as defined in the *Parameters* pane of the user-defined function; see screenshot below). Additionally, the number of items submitted by each argument (in the function call) must match the *Occurrence* definition of the corresponding parameter. If a datatype restriction has been specified for a parameter (in the Type column of the *Parameters* pane), the value/s submitted by the argument must match this datatype.
- 2. The arguments passed to the function's parameters are then used in the XPath function (as defined in the Function Body pane; see screenshot below). The result obtained by evaluating the XPath expression is then checked against the optional Return Type definition (see screenshot below). If the datatype is as expected, the result is used in the XPath expression from which the function was called.

Order of parameters

The order of the user-defined function's parameters is important because, when the function is called, the arguments submitted in the function call will be assigned to the parameters according to the order in which they are defined in the *Parameters* pane (see screenshot below).

So if the sps:Stock user-defined XPath function is defined as in the screenshot above and if it is called with the following XPath expression:

```
sps:Stock($XML, Node1, Node2)
```

then these three arguments—\$XML, Node1, Node2—will be assigned, in that order, respectively, to the parameters \$ContextStock, \$Selection, and \$StockInfo.

Note that each argument in the function call is separated from the next by a comma. So, each argument, as delimited by the commas in the function call, will be passed to the corresponding parameter (as ordered in the *Parameters* pane; see *screenshot above*).

The order of parameters in the *Parameters* pane can be controlled with the **Append**, **Insert**, and **Delete** icons of the *Parameters* pane.

Datatype of parameters

Optionally, the datatypes of parameters of the user-defined function can be defined. If a datatype is specified, then the datatype of the incoming argument will be checked against the parameter's datatype, and an error will be returned if the types do not match. This feature enables the input data (from the function call's arguments) to be checked.

Occurrence

Each parameter of the user-defined XPath function can be considered to be a sequence. The *Occurrence* property of a parameter specifies how many items must be submitted for that parameter by the corresponding argument of the function-call.

In both function definitions and in function calls, commas are used to separate one parameter or argument from another as well as to separate items within a sequence. It is important, therefore, to note the context in which a comma is used: to separate parameters/arguments or to separate sequence items.

- In parameters/arguments, if required, parentheses are used to delimit sequences—in the function definition (parameters) or in the function call (arguments).
- In sequences, parentheses are ignored.

In this context, the following examples and points should be noted:

- Parentheses in parameters/arguments: Several XPath functions take a single sequence as an argument, for example, the <code>avg()</code> and <code>count()</code> functions. If this sequence is enumerated using comma separators or range operators, the sequence must be enclosed in parentheses to unambiguously show that it is a single sequence—and not multiple comma-separated sequences. For example, in the function <code>avg((count(\$a), \$b, \$c))</code>, the XPath 2.0 <code>avg()</code> function takes the single sequence (<code>count(\$a), \$b, \$c)</code> as its argument. Since the items of the sequence are enumerated, making up a sequence of three items, the sequence must be enclosed in parentheses and submitted as a single argument to the <code>avg()</code> function: <code>avg((count(\$a), \$b, \$c))</code>. Without the inner pair of parentheses, the definition of the <code>avg()</code> function would have three parameters, and that would be an error (since the <code>avg()</code> function expects one argument consisting of a single sequence).
- **No parentheses in parameters/arguments:** Similarly, the <code>count()</code> function also takes a single sequence as its one-parameter argument. However, since in our example <code>count(\$a)</code> the single sequence is not a comma-separated enumerated list, but is fetched instead by the variable/parameter \$a, the argument does not need to be enclosed by an inner set of parentheses: So the expression <code>count(\$a)</code> is correct.
- Parentheses and commas in function calls: In a function call, parentheses must be correctly used so that each argument corresponds to a parameter (as defined in the Parameters pane of the XPath Functions dialog). For example, if a user-defined XPath function named MyAverage() is defined with the XPath 2.0 expression: avg((count(\$a),\$b,\$c)), then the following function call would be valid: MyAverage((1,2,3),4,5). The values corresponding to the three parameters \$a, \$b, and \$c would be, respectively, the sequence (1,2,3), the singleton-sequence 4, and the singleton sequence 5. Singleton-sequences can, optionally, be enclosed in parentheses. The value returned by MyAverage() in this case would be 4.

9.7.3.1 Parameters and Sequences

It is important to note the relationship between parameters and sequences, and how parameters and sequences are used in XPath expressions. We use the following definitions to make these relationships clearer:

A sequence consists of items that are either atomic values or nodes. A comma can be used to
construct a sequence, by placing it between the items of a sequence and so allowing the sequence to
be built.

- An XPath function can be defined to take *parameters*. For example, in the XPath 2.0 expression count (\$a), the part within the function's parentheses is the parameter of the function and it must be a sequence of items.
- An *argument* consists of one or more items in a function call. For example, the function count (//Person) has one argument: //Person. This argument is valid because it returns one sequence of nodes, which corresponds to the signature of the count () function. (The signature of a function specifies the number of parameters and the expected datatype of each parameter. It also specifies what the function will return and the datatype of the returned object)
- The function <code>substring('StyleVisionExamples', 6, 6)</code>—which returns the string <code>Vision</code>—has three arguments. This is valid according to the <code>signature</code> of the <code>substring()</code> function, and is specified by it. When a function call has multiple arguments, these are separated by commas.

Parentheses as sequence delimiters

A key point to note when constructing XPath expressions is this: *Parentheses are used to delimit sequences* that use the comma separator or range operator to enumerate sequences. As a result, each parentheses-delimited sequence is read as one parameter (in function definitions) or one argument (in function calls).

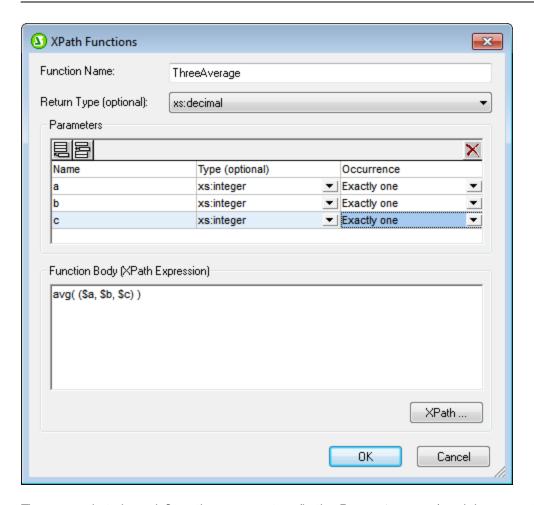

Parentheses are not necessary around a path (or locator) expression (example of a path expression: //Person/@salary), because a path expression can be read unambiguously as one parameter or one argument. It is in fact a one-sequence parameter/argument.

Here are some examples to illustrate the points made above:

- avg ((10, 20, 30)) The avg function of XPath 2.0 takes one sequence of items as its single argument. Since this sequence is a comma-separated enumeration, the inner pair of parentheses are necessary in order to delimit the mandatory single sequence. Without the inner parentheses, the argument would have three arguments and therefore be invalid. (The outer pair of parentheses are the parentheses of the function.)
- avg (//Person/@salary) This path expression selects the salary attribute nodes of all Person elements and returns their attribute-values as the sequence to be evaluated (that is, to be averaged). No parentheses are required because the sequence is not enumerated before the argument is read. The argument is the single path (or locator) expression. The path expression is evaluated and the returned values are submitted to the function as the items of a sequence.
- count ((10 to 34)) This is an enumeration via the range operator. The range operator 'to' generates a sequence of comma-separated items (the integers from 10 to 34) before the argument is read. As a result, the count() function has within its argument a comma-separated sequence of 25 items. To read this as one single-sequence argument, delimiting parentheses are required. Without such parentheses, the function call would have 25 arguments instead of one—thus invalidating the function call, since the count() function must, according to its signature, have only one argument.
- count ((10 to 34, 37)) The inner parentheses indicate that everything within them is the one argument of the function call—a single sequence consisting of 26 items.
- count (//Person) No sequence-delimiter parentheses are required around the single argument. The arguent is a path expression that collects the //Person nodes in the XML document and returns these nodes as the items of the sequence to be counted.

Using XPath parameters in XPath functions

When parameters are used in the definition of a user-defined XPath function, ensure (i) that the number of arguments in a function call to this user-defined XPath function is correct, and (ii) that the arguments evaluate correctly to the expected type and occurrence.

The screenshot above defines three parameters (in the *Parameters* pane) and then uses these parameters (in the *Function Body* pane) to define an XPath function.

Each parameter that is defined in the *Parameters* can be considered to be a single sequence. The number of items allowed within the single sequence is specified with the *Occurrence* property. In the definition above, each parameter is defined (in its *Occurrence* property) as a singleton-sequence (that is, a sequence of exactly one item). Each argument of the function call must therefore be a sequence of one item. The *Type* property specifies the datatype of the items of the sequence.

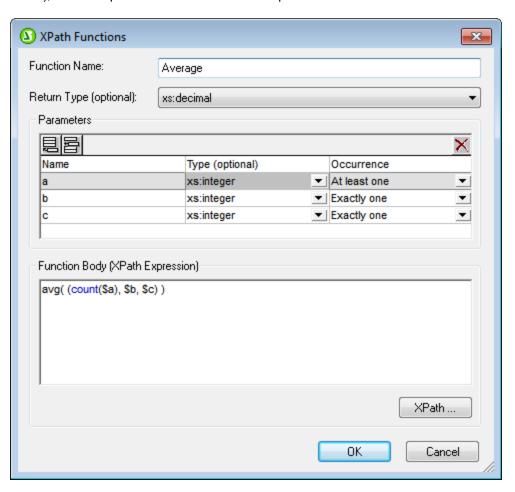

In the definition of our example XPath function (in the *Function Body* pane), each parameter provides one item of the sequence that is to be averaged. Since the XPath parameters together constitute a sequence, the sequence must be enclosed in parentheses to ensure that the entire sequence is read as the one parameter of the avg() function. If, at runtime, any of the arguments in the function call (corresponding to the three parameters) is not a singleton-sequence, an error is returned.

Given below are examples of XPath parameter usage in calls to the XPath function <code>ThreeAverage()</code> shown in the screenshot above. In Design View, you can insert an Auto-Calculation and give it the XPath expressions listed below to see the results. The function has been defined to take a sequence of three integers and average them.

• sps:ThreeAverage (10, 20, 30) returns 20. There are three valid arguments in the function call, corresponding to the three XPath parameters.

- sps:ThreeAverage ((10), (20), (30)) returns 20. There are three valid input arguments, corresponding to the three XPath parameters. Each input argument has been enclosed with parentheses (which are redundant, since each sequence is a singleton-sequence; however, this redundancy is not an error).
- sps:ThreeAverage ((10), 20, 30) returns 20. There are three valid input arguments, corresponding to the three XPath parameters. The first argument has been enclosed with parentheses (redundant, but not an error).
- sps:ThreeAverage((10,20), (30), (40)) returns an error because the first argument is not valid. It is not a singleton-sequence, as required by the property definition of the first \$a parameter ('Exactly one').
- sps:ThreeAverage((10,20,30)) returns an error because only one input argument is submitted, inside the parentheses. Additionally, the argument is invalid because the sequence is not a singleton-sequence.

If the Occurrence property of a parameter is set to At-least-one (as in the definition shown in the screenshot below), then that parameter is defined as a sequence of one-or-more items.

In the definition above, the first parameter has been defined as a sequence of one or more items, the next two parameters as singleton-sequences. The function has been defined to count the number of items submitted by the first parameter, add the result to the sum of the two integers submitted by the other two parameters, and then divide the result by three to obtain the average. Notice the following:

- The sequence that is the parameter of the <code>avg()</code> function is enclosed in parentheses. This is to specify that the <code>avg()</code> function takes a single sequence consisting of three items as its parameter. The single sequence consists of three integers: the first submitted by the <code>count()</code> function; the second and third are the two parameters <code>b</code> and <code>c</code>.
- The argument of the <code>count()</code> function is not enclosed in sequence-delimiter parentheses because the argument is unambiguously a single sequence.

Here are examples of parameter usage in calls to the XPath function <code>Average()</code> shown in the screenshot above.

- sps:Average((1,2),3,4) returns 3. There are three valid input arguments, corresponding to the three parameters. The first argument is enclosed in parentheses to delimit it. When the count() function operates on it, the function will return the value 2, which will be the first item of the sequence submitted to the avg() function.
- sps:Average (4,4,4) returns 3. There are three valid input arguments. The first argument is allowed to be a sequence of one item (see the *Occurrence* property of its corresponding parameter). No parentheses are required to indicate separate arguments.

Additional points of interest

The following additional points should be noted:

- If an parameter is defined as having At-least-one occurrence, then a function such as MyAverage() could be defined with an XPath expression such as avg((\$a)). This function would accept an argument that is a single sequence of one-or-more items. The function could be called as follows: sps:MyAverage((2,3,4)), and it would return the value 3. The input argument must be enclosed in parentheses to ensure that the input is being read as a single sequence rather than as three singleton-sequences (which would be the case if there were no enclosing parentheses).
- If an XPath parameter \$a\$ is defined as having None-or-one occurrence, then a function such as MyAverage() could be defined with an XPath expression such as avg((\$a, \$b, \$c)). This function would accept as its argument three sequences, with the possibility of the first sequence being empty. If the first sequence is to be empty, then an empty sequence must be explicitly submitted as the first input argument. Otherwise an error is reported. If the function were called as follows: sps:MyAverage(30,20,10), it would return the value 20. The function could also be called with: sps:MyAverage((),20,10), returning 15 (note that the empty sequence does count: as an input value of empty; for a return value of 10, the first item would have to be 0). The following, however, would generate an error: sps:MyAverage(20,10), because no first empty sequence is supplied and, as a consequence, the third input argument is considered to be absent.

Complex examples

Besides providing the benefit of being able to re-use an XPath expression, user-defined XPath functions also enable the construction of complex customized XPath functions that are not available in the XPath 2.0 function set. For example, a factorial function could easily be constructed with an XPath expression that takes a singleton-sequence as its single parameter. If the parameter \$num\$ is the number to be factorialized, then the XPath expression to create the function would be:

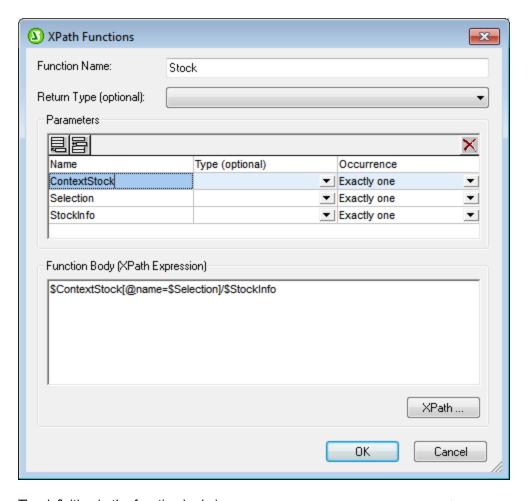

```
if ($num < 2) then 1 else $num * sps:Factorial($num - 1)
```

If this function were called Factorial(), then the factorial of, say 6, could be obtained by calling the function with: sps:Factorial(6).

9.7.3.2 Parameters and Nodes

When using parameters in XPath functions that locate nodes, it is important to bear in mind that the function has no context node, no matter from where in the design it is called. The context node can be supplied either in the XPath expression that is used to define the function (that is, in the *Function Body* pane) or in the XPath expression that is used to call the XPath function. In the latter case, the context can be supplied via arguments in the function call.

Consider the user-defined XPath function Stock(), which is defined with three parameters as shown in the screenshot below.

The definition in the function body is <code>\$ContextStock[@name=\$Selection]/\$StockInfo</code>, which uses the three parameters but contains no context node information. The context node information can be supplied in the XPath expression that calls the function, for example in this way:

```
sps:Stock( $XML/Trades/Stock, $XML/Trades/Selection/Stock, @name )
```

The function call has three arguments, the value of each of which supplies either context or node-locator information. Alternatively, the following XPath expressions can be used as the function-call and give the same results:

```
sps:Stock( /Trades/Stock, /Trades/Selection/Stock, @name )
```

```
sps:Stock( /Trades/Stock, //Selection/Stock, @name )
```

The \$XML variable, which returns the document root, can be left out in function calls from design components because in the XPath expressions of design components the context node is known.

Notice that in the function-call listed above there are three input arguments corresponding respectively to the three parameters defined for the user-defined XPath function:

- \$ContextStock = \$XML/Trades/Stock (the /Trades/Stock element)
- \$Selection = \$XML/Trades/Selection/Stock (the /Trades/Selection/Stock element)
- \$StockInfo = @name

The XPath expression in the function definition is:

```
$ContextStock[@name=$Selection]/$StockInfo
```

When the input arguments are substituted, the XPath expression in the function definition becomes:

```
$XML/Trades/Stock[@name=$XML/Trades/Selection/Stock]/@name
```

It is important to note that it is the nodesets that are passed to the function, not the text strings.

It is in this way that the context node and location steps are passed to the function via parameters. The function can then be evaluated to locate and return the required nodes.

9.8 Working with Dates

If the source document contains nodes that take date values, using the xs:date or xs:dateTime datatypes in the underlying XML Schema makes available the powerful date and time manipulation features of XPath 2.0/3.0 (see examples below 587). StyleVision supports the xs:date or xs:dateTime datatypes by providing:

- 1. A graphical <u>date picker</u> to help Authentic View users enter dates in the correct lexical format of the datatype for that node. The date picker, since it is intended for data input, is available only in Authentic View.
- 2. A wide range of date formatting 589 possibilities via the Input Formatting 455 feature.

These StyleVision features are described in the sub-sections of this section: <u>Using the Date-Picker</u> and <u>Formatting Dates</u>. In the rest of the introduction to this section, we show how XPath 2.0 can be used to make calculations that involve dates.

Note: Date and time data cannot be manipulated with XPath 1.0. However, with XPath 1.0 you can still use the <u>Date Picker</u> to maintain data integrity and use Input Formatting to provide <u>date formatting</u>.

Date calculations with XPath 2.0

Data involving dates can be manipulated with XPath 2.0 expressions in <u>Auto-Calculations</u> (Given below are a few examples of what can be achieved with XPath 2.0 expressions.

- The XPath 2.0 functions <code>current-date()</code> and <code>current-dateTime()</code> can be used to obtain the current date and date-time, respectively.
- Dates can be subtracted. For example: current-date() DueDate would return an xdt:dayTimeDuration value; for example, something like P24D, which indicates a positive difference of 24 days.
- Time units can be extracted from durations using XPath 2.0 functions. For example: days-from-duration(xdt:dayTimeDuration('P24D')) would return the integer 24.

Here is an XPath 2.0 expression in an Auto-Calculation. It calculates a 4% annual interest on an overdue amount on a per-day basis and returns the sum of the principal amount and the accumulated interest:

Such a calculation would be possible with XPath 2.0 only if the <code>DueDate</code> element were defined to be of a date type such as <code>xs:date</code> and the content of the element is entered in its lexically correct form, that is, <code>YYYY-MM-DD[±HH:MM]</code>, where the timezone component (prefixed by \pm) is optional. Using the Date Picker ensures that the date is entered in the correct lexical form.

9.8.1 Using the Date-Picker

The Date Picker (screenshot below) is a graphical calendar in Authentic View for entering dates in the correct lexical format for nodes of xs:date and xs:dateTime datatype.

The lexical format is entered appropriately according to the datatype.

- For xs:date, the format of the entry is YYYY-MM-DD[±HH:MM], where the timezone component (prefixed by ±) is optional according to the XML Schema specification. A value for the timezone component can be selected in the Date Picker.
- For xs:dateTime, the format of the entry is YYYY-MM-DDTHH:MM:SS[±HH:MM]. The timezone component (prefixed by ±) is optional according to the XML Schema specification. A value for the timezone component can be selected by the user.

Inserting and deleting a Date Picker in the design

A Date Picker can be inserted in the SPS design: (i) for any node that is of datatype xs:date or xs:dateTime, and (ii) when that node is created either as contents or as an input field. A Date Picker can be inserted in one of two ways:

- By default when a node of datatype xs:date or xs:dateTime is created in the SPS. To set this default, toggle the Auto-Add Date Picker feature ON. Do this by selecting/de-selecting the command Authentic | Auto-add Date Picker. When the Auto-Addition of the Date Picker is switched on, the Date Picker is inserted when any element of datatype xs:date or xs:dateTime is created as either contents or an input field, or changed to either of these two components.
- By clicking the menu command Insert | Date Picker when the cursor is at the desired location within the xs:date or xs:dateTime node in the SPS. This command can be accessed via the Insert menu, or via the context menu when the cursor is within the xs:date or xs:dateTime node.

When the Date Picker is inserted, the Date Picker icon appears at that location. To delete a Date Picker, use the **Delete** or **Backspace** buttons.

Using the Date Picker in Authentic View

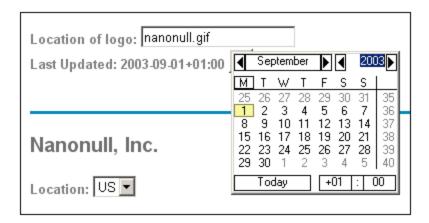

In Authentic View, the Date Picker appears as an icon (screenshot below).

To modify the date, click the icon. This pops up the Date Picker (*screenshot below*). To enter a new date, select the required date in the Date Picker. The date will be entered in the correct lexical format according to that node's datatype.

To enter a timezone, click the Timezone button, which is set to a default of No Timezone. The timezone will be entered in the lexical format appropriate to the node's datatype (*screenshot below*).

9.8.2 Formatting Dates

A date in an XML document is saved in the format specific to the datatype of its node. For example, the value of an xs:date node will have the format YYYY-MM-DD[±HH:MM], while the value of an xs:dateTime node will

have the format YYYY-MM-DDTHH: MM: SS [±HH: MM]. These formats are said to be the lexical representations of that data. By default, it is the lexical representation of the data that is displayed in Authentic View and the output. However, in the SPS, the Value Formatting feature can be used to display dates in alternative formats in Authentic View and, in some cases, optionally in the output.

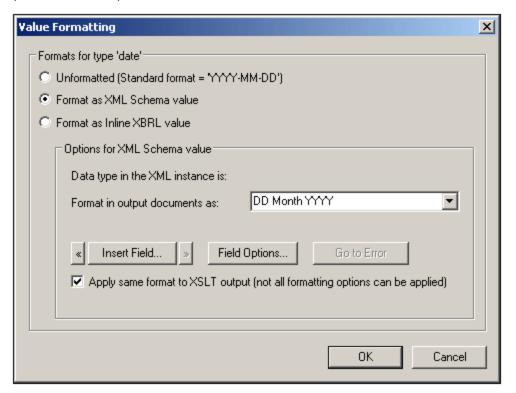

Value Formatting for dates can be used to define custom formats for nodes and Auto-Calculations of the following datatypes:

- xs:date
- xs:dateTime
- xs:duration
- xs:gYear
- xs:gYearMonth
- xs:qMonth
- xs:gMonthDay
- xs:gDay

Using Value Formatting to format date nodes

To format dates alternatively to the lexical format of the date node, do the following:

- 1. Select the contents placeholder or input field of the node. Note that value formatting can only be applied to nodes created as contents or an input field.
- 2. In the Properties sidebar, select the autocalc item, and then the *AutioCalc* group of properties. Now click the Edit button of the *Value Formatting* property. This displays the Value Formatting dialog (screenshot below).

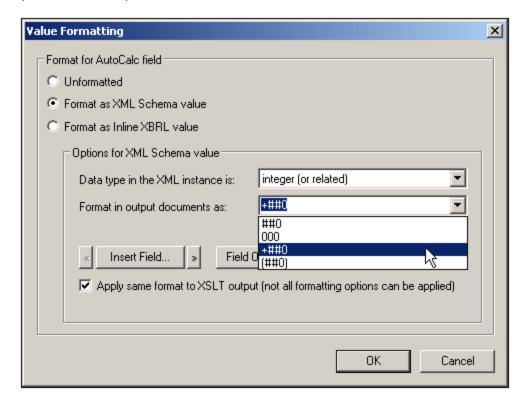

By default, the *Unformatted* radio button (the standard lexical format for the node's datatype) is selected.

- 3. To define an alternative format, select the *Format* radio button.
- 4. You can now select a predefined date format from the drop-down list of the combo box (*screenshot below*), or define your own format in the input field of the combo box. See <u>Value Formatting Syntax</u> for details about the syntax to use when defining your own format.

Using Value Formatting to format Auto-Calculations

When Auto-Calculations evaluate to a value that is a lexical date format, Value Formatting can be used to format the display of the result. Do this as follows:

- 1. Select the Auto-Calculation in the design.
- 2. In the Properties sidebar, select the content item, and then the *AutoCalc* group of properties. Now click the Edit button of the *Value Formatting* property. This pops up the Value Formatting dialog (screenshot below).

By default, the *Unformatted* radio button is selected.

- 3. To define an alternative format, select the *Format* radio button.
- 4. In the Options for XML Schema value pane, in the *Datatype* combo box, select the date datatype to which the Auto-Calculation will evaluate. In the *Format* combo box, you can then select a predefined date format from the drop-down list (available options depend on the selected datatype), or define your own format in the input field of the combo box. See <u>Value Formatting Syntax</u> for details about the syntax to use when defining your own format.

Applying Value Formatting to the output

The Value Formatting that you define applies to Authentic View. Additionally, some Value Formatting definitions—not all—can also be applied to HTML, Text, RTF, PDF, and Word 2007+ output. To do this, check the Apply Same Format to XSLT Output check box. If this option is not checked or if it is not available, then only Authentic View will display the Value Formatting; the output will display the value in its lexical format (for nodes) or, in the case of Auto-Calculations, in the format to which the Auto-Calculation evaluates.

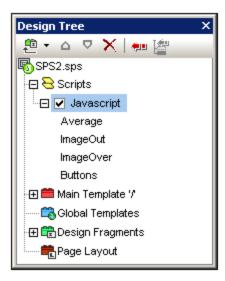

9.9 Using Scripts

In StyleVision, you can define JavaScript functions for each SPS in a JavaScript editor (available as a tab in the Design View). The function definitions created in this way are stored in the header of the HTML document and can be called from within the body of the HTML document. Such functions are useful when:

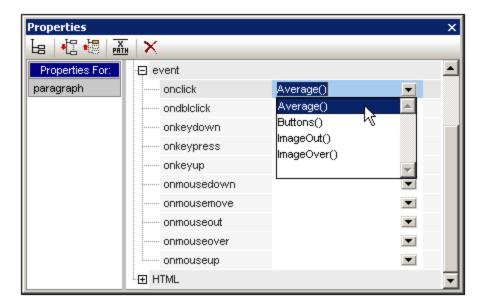

- You wish to achieve a complex result using multiple script statements. In this case it is convenient to
 write all the required scripts, as separate functions, in one location (the header) and refer to the
 functions subsequently in the design document.
- You wish to use a particular script at multiple locations in the design document.

How to define functions in the JavaScript Editor is described in the sub-section <u>Defining JavaScript</u> Functions ⁵⁹¹.

In the GUI, all JavaScript functions which are defined for a given SPS in the JavaScript Editor are listed in the Design Tree window under the Scripts entry (*screenshot below*). The screenshot below indicates that four JavaScript functions, Average, ImageOut, ImageOver, and Buttons, are currently defined in the active SPS.

The functions defined in the JavaScript Editor are available as event handler calls within the GUI. When a component in the design document is selected, any of the defined functions can be assigned to an event handler property in the Event property group in the Properties sidebar (*screenshot below*). How to assign a JavaScript function to an event handler is described in the section Assigning Function to Event Handlers.

Note: Scripts are applicable in the HTML output only. They are not applicable in Authentic View.

Scripts in modular SPSs

When an <u>SPS module is added to another SPS module</u> (330), the scripts in the added module are available within the referring SPS, and can be used as event handlers via the Properties sidebar for components in the referring SPS. For more information about using modular SPSs, see the section <u>Modular SPSs</u> (330).

9.9.1 Defining JavaScript Functions

To define JavaScript functions, do the following:

1. In Design View, switch to the JavaScript Editor by clicking the Design View tab and selecting JavaScript (*screenshot below*).

2. In the JavaScript Editor, type in the function definitions (see screenshot below).

```
function DisplayTime()
 2
 3
         now = new Date();
 4
         hours = now.getHours();
 5
         mins = now.getMinutes();
 6
         secs = now.getSeconds();
 7
         result = hours + ":" + mins + ":" + secs;
 8
         alert(result);
 9
10
11 🔵
         function ClearStatus()
12
13
       window.status="";
14
```

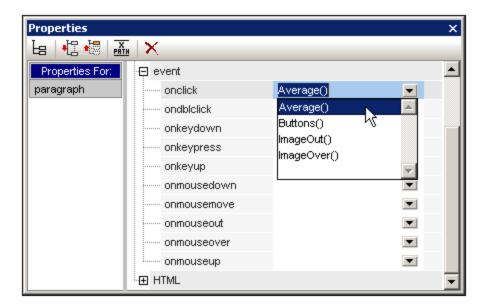

The screenshot above shows the definitions of two JavaScript functions: DisplayTime and ClearStatus. These have been described for the active SPS. They will be entered in the header of the HTML file as follows:

```
<script language="javascript">
<!-- function DisplayTime()
{
  now = new Date();
  hours = now.getHours();
  mins = now.getMinutes();
  secs = now.getSeconds();
  result = hours + "." + mins + "." + secs;
  alert(result)
}
function ClearStatus()
{
  window.status="";
}
-->
</script>
```

These functions can now be called from anywhere in the HTML document. In StyleVision, all the defined functions are available as options that can be assigned to an event handler property in the *Event* property group in the Properties sidebar. See <u>Assigning Function to Event Handlers</u> for details.

9.9.2 Assigning Functions as Event Handlers

In the StyleVision GUI, you can assign JavaScript functions as event handlers for events that occur on the HTML renditions of SPS components. These event handlers will be used in the HTML output. The event handler for an available event—such as <code>onclick</code>—is set by assigning a global function as the event handler. In the Properties sidebar, global functions defined in the JavaScript Editor are available as event handlers in the dropdown boxes of each event in the *Events* property group for the selected component (*screenshot below*).

To assign a function to an event handler, do the following:

- 1. Select the component in the SPS for which the event handler is to be defined. The component can be a node or content of any kind, dynamic or static.
- 2. In the Properties sidebar select the *Event* group. This results in the available events being displayed in the Attribute column (*screenshot above*).
- 3. In the Value column of the required event, click the down arrow of the combo box. This drops down a list of all the functions defined in the JavaScript Editor.
- 4. From the dropdown list, select the required function as the event handler for that event.

In the HTML output, when that event is triggered on the component for which the event handler is defined, the JavaScript function is executed.

9.9.3 External JavaScript Files

An SPS can access external JavaScript files in two ways:

- 1. By creating a User-Defined Element or User-Defined XML Block. These design objects can contain a SCRIPT element that accesses the external JavaScript file. Note that location of the User-Defined Element or User-Defined XML Block is within the BODY element of the design (and therefore within the BODY element of the HTML output, not within the HEAD element).
- 2. By adding a script in the Javascript Editor that accesses the external file. A script that is added in this way will be located in the HEAD element of the HTML output.

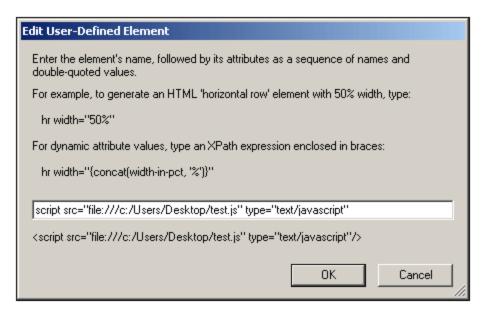

User-Defined Elements and User-Defined XML Blocks

External JavaScript files can be accessed by means of <u>User-Defined Elements</u> and <u>User-Defined XML Blocks</u>. Using these mechanisms, a SCRIPT element that accesses the external JavaScript file can be inserted at any location within the BODY element of the output HTML document.

A User-Defined Element 46 could be inserted as follows:

1. Place the cursor at the location in the design where the SCRIPT element that accesses the JavaScript file is to be inserted.

2. From the **Insert** menu or context menu, select the command for inserting a <u>User-Defined Element</u> 146.

- 3. In the dialog that pops up (see screenshot above), enter the SCRIPT element as shown above, giving the URL of the JavaScript file as the value of the src attribute of the SCRIPT element: for example, script type="text/javascript" src="file:///c:/Users/mam/Desktop/test.js"
- 4. Click **OK** to finish.

You can also use a <u>User-Defined XML Block</u> to achieve the same result. To do this use the same procedure as described above for User-Defined Elements, with the only differences being (i) that a <u>User-Defined XML Block</u> is inserted instead of a <u>User-Defined Element</u> and (ii) that the <u>SCRIPT</u> element is inserted as a complete XML block, that is, with start and end tags.

JavaScript Editor

The <u>JavaScript Editor</u> enables you to insert an external script in the HEAD element of the HTML output. Do this by entering, in the JavaScript Editor, the following script fragment, outside any other function definitions that you create.

```
var script = document.createElement('script');
script.type = 'text/javascript';
    script.src = 'file:///c:/Users/Desktop/test.js';
var head = document.getElementsByTagName('head')[0];
head.appendChild(script)
```

The external JavaScript file that is located by the URL in script.src is accessed from within the HEAD element of the output HTML document.

9.10 HTML Import

In StyleVision you can import an HTML file and create the following documents based on it:

- An SPS document based on the design and structure of the imported HTML file.
- An XML Schema, in which HTML document components are created as schema elements or attributes. Optionally, additional elements and attributes that are not related to the HTML document can be created in the user-defined schema.
- An XML document with: (i) a structure based on the XML Schema you have created, and (ii) content from the HTML file.
- XSLT stylesheets based on the design in Design View.

HTML-to-XML: step-by-step

The HTML Import mechanism, which enables the creation of XML files based on the imported HTML file, consists of the following steps:

- 1. Creating New SPS via HTML Import [599]. When an HTML file is imported into StyleVision, a new SPS document is created. The HTML document is displayed in Design View with HTML markup tags. A user-defined XML Schema with a document element called UserRoot is created in the Schema Tree window. This is the schema on which the SPS is based. The HTML document content and markup that is displayed in Design View at this point is included in the SPS as static content.
- 2. Creating the Schema and SPS Design Components from the HTML document to the required location in the schema tree (in the Schema Tree window); and, optionally, (ii) adding your own nodes to the schema tree. In the Design Window, HTML content that has been used to build nodes in the schema tree will now be displayed with schema node tags around the content. HTML content that has no corresponding schema node will continue to be displayed without schema node tags.
- 3. In the Design Document, assign formatting to nodes, refine processing rules, or add static content as required. These modifications will have an effect only on the SPS and the generated XSLT. It will not have an effect on either the generated schema or XML file.
- 4. After you have completed the schema tree and the design of the SPS, you can generate and save the following:
 - an XML Schema corresponding to the schema tree you have created;
 - an XML data file with a structure based on the schema and content for schema nodes that are created with the (content) placeholder in the SPS design;
 - a SPS (.sps file) and/or XSLT stylesheet based on your design.

9.10.1 Creating New SPS via HTML Import

To create a new SPS file from an HTML document, do the following:

- 1. Select the menu command File | New | New from HTML File.
- 2. In the Open dialog that pops up, browse for the HTML file you wish to import. Select it and click **Open**.
- 3. You will be asked whether relative paths should be converted to absolute paths. Make your choice by clicking either **Yes** or **No**.

A new SPS document is created. The document is displayed in Design View and is marked up with the predefined HTML formats available in StyleVision (*screenshot below*).

■A Sample Article ■

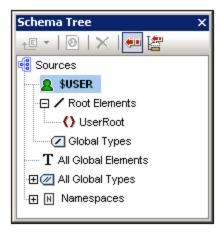

This is a simple article, marked up in HTML. It is the example HTML document used to demonstrate how STYLEVISION can generate schema files, XML files, and stylesheets from an HTML document. It contains headlines, paragraphs, two lists, a table, an image, a hyperlink, horizontal rules, and inline italics. A number of these elements have attributes.

p It is important to note that the HTML-to-XML conversion involves two parallel processes: p

- · Creation of a schema tree
- Design of a STYLEVISION Power Stylesheet (SPS)

Note that the HTML document is displayed within the main template. There is no global template.

In the Schema Tree sidebar, a user-defined schema is created (*screenshot below*) with a root element (document element) called UserRoot.

Note that there is no global element in the All Global Elements list.

SPS structure and design

The SPS contains a single template—the main template—which is applied to the document node of a temporary internal XML document. This XML document has the structure of the user-defined schema which was created in the Schema Tree window. In Design View, **at this point**, the HTML document components within the main template are included in the SPS as static components. The representation of these HTML components

in Authentic View will be as non-editable, non-XML content. The XSLT stylesheets will contain these HTML components as literal result elements. The schema, at this point, has only the document element Root; consequently, the temporary internal XML document contains only the document element Root with no child node.

When you create HTML selections as elements and attributes in the user-defined schema, you can do this in either of two ways:

- 1. By converting the selection to an element or attribute. In the design, the node tags are inserted with a (content) placeholder within the tag. In the schema, an element or attribute is created. In the XML document, the selection is converted to the text content of the schema node which is created in the XML document. The contents of the node created in the XML document will be inserted dynamically into the output obtained via the SPS.
- 2. By **surrounding** the selection with an element or attribute. In the design, the selection is surrounded by the node tags; no (content) placeholder is inserted. This means that the selection is present in the SPS design as static content. In the schema, an element or attribute is created. In the XML document, the node is created, but is empty. The static text which is within the schema node tags in the design will be output; no dynamic content will be output for this node unless a (content) placeholder for this node is explicitly inserted in the design.

The significance of the (content) placeholder is that it indicates locations in the design where data from the XML document will be displayed (in the output) and can be edited (in Authentic View).

9.10.2 Creating the Schema and SPS Design

The schema is created by dragging selections from Design View into the user-defined schema. You do this one selection at a time. The selection is dropped on a node in the schema tree (relative to which the new node will be created, either as a child or sibling). You select the type of the node to be created (element or attribute) and whether the selection is to be converted to the new node or surrounded by it.

The selection

The selection in Design View can be any of the following:

- A node in the HTML document.
- A text string within a node.
- Adjacent text strings across nodes.
- An image.
- A link.
- A table.
- A list.
- A combination of any of the above.

In this section we explain the process in general for any selection. The special cases of tables and lists are discussed in more detail in the section <u>Creating Tables and Lists as Elements/Attributes</u> (602).

To make a selection, click an HTML document component or highlight the required text string. If multiple components are to be selected, click and drag over the desired components to highlight the selection. Note that StyleVision extends the selection at the beginning and end of the selection to select higher-level elements till the first and last selected elements belong to the same parent.

The location in the schema tree

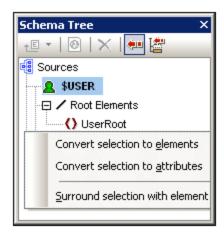

On dragging the selection over the desired schema tree node, the mouse pointer will be changed to one of the following symbols.

- Dropping the node when the Create as Child symbol appears, creates the selection as a child node of the node on which the selection is dropped.

You should select the node on which the selection is to be dropped according to whether the selection is to be created as a sibling or child of that node.

Selecting how the node is created

When you drop the selection (see previous section), a context menu pops up (screenshot below) in which you make two choices: (i) whether the node is to be created as an element or attribute; (ii) whether the selection is to be converted to the node or whether the node is to simply surround the selection.

The following points should be noted:

- When a selection is converted to a node (element or attribute), the node tags, together with a
 contained (content) placeholder, replace the selection in the design. In the design and the output the
 text content of the selection is removed from the static content. In the output, the text of the selection
 appears as dynamic content of the node in the XML document.
- If an HTML node is converted to an XML node, the XML node tags are inserted within the HTML node tags.
- When a selection (including HTML node selections) is surrounded by an XML node, the XML node tags
 are inserted before and after the selection. In the design and the output, the text content of the
 selection is retained as static text.
- The inserted node tags are inserted with the necessary path (that is, with ancestor node tags that establish a path relative to the containing node). The path will be absolute or relative depending on the context of the node in the design.
- How to create nodes from table and list selections are described in <u>Creating Tables and Lists as Elements/Attributes</u> 602.

Adding and deleting nodes in the schema

You can add additional nodes (which are not based on an HTML selection) to the user-defined schema. Do this by right-clicking on a node and selecting the required command from the context menu. Alternatively, you can use the toolbar icons of the Schema Tree sidebar.

To delete a node, select the node and then use either the context menu or the toolbar icon. Note, however, that when a node is deleted, some paths in the design could be invalidated.

Modifying the design

You can modify the structure of the design by dragging components around and by inserting static and dynamic components. Styles can also be modified using the various styling capabilities of StyleVision.

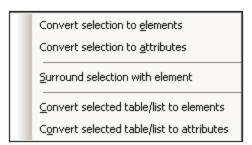

9.10.3 Creating Tables and Lists as Elements/Attributes

Tables and lists in the HTML document can be converted to element or attribute nodes in the XML Schema so that they retain the table or list structure in the schema.

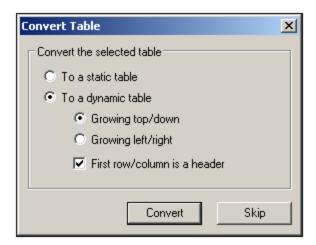

Converting a table to elements/attributes

To convert a table to schema nodes, do the following:

- 1. Select the HTML table by highlighting some text in it.
- 2. Drag it to the node in the schema tree as a sibling or child of which you want to create it.
- 4. In the context menu that now pops up (*screenshot below*), select the command **Convert selected table/list to elements** or **Convert selected table/list to attributes** according to whether you wish to create the contents of table cells as elements or attributes, respectively.

5. In the Convert Table dialog that pops up (*screenshot below*), select whether the table created in the SPS should be a static table or dynamic table.

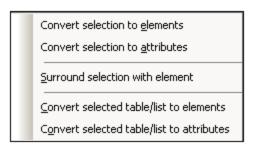

If the **static table** option is selected, then for each cell in the table, a schema node is created. In the design, each node is inserted with the (content) placeholder. The data in the table cells is copied to the temporary internal XML document (and to the generated XML document). The **dynamic table** option is available when the structure of all rows in the table are identical. When created in the SPS, the rows of the dynamic table are represented by a single row in the design (because each row has the same structure). The table data will be copied to the XML file. The dynamic table can grow top/down (rows are arranged vertically relative to each other) or left/right (rows become columns and extend from left to right). If you indicate that the first row/column is a header, then (i) a header row containing the column headers as static text is included in the design; and (ii) the schema element/attribute nodes take the header texts as their names. If the first row/column is not indicated as a header, then no header row is included in the design.

6. After you have selected the required option/s, click **Convert** to finish.

Converting a list to elements/attributes

To convert a list to schema nodes, do the following:

- 1. Select the HTML list by highlighting some text in it.
- 2. Drag it to the node in the schema tree as a sibling or child of which you want to create it.
- 4. In the context menu that now pops up (*screenshot below*), select the command **Convert selected table/list to elements** or **Convert selected table/list to attributes** according to whether you wish to create the contents of table cells as elements or attributes, respectively.

5. In the Convert List dialog that pops up (*screenshot below*), select whether the list created in the SPS should be a static list or dynamic list.

If the **static list** option is selected, then for each list item, a schema node is created. In the design, each node is inserted with the text of the HTML list item included as static content of the list item. If the **dynamic list** option is selected, then each list item is represented by a single list item node in the design. In the design, the list item element is inserted with the (content) placeholder.

6. After you have selected the required option, click **Convert** to finish.

9.10.4 Generating Output

After completing the SPS, you can generate the following output using the **File | Save Generated Files** command:

- Generated user-defined schema, which is the schema you have created in the Schema Tree sidebar.
- Generated user-defined XML data, which is an XML document based on the schema you have created and containing data imported from the HTML file.
- XSLT stylesheets for HTML, Text, RTF, PDF, and Word 2007+ output.
- HTML, Text, RTF, FO, PDF, and Word 2007+ output.

9.11 XML Signatures

An SPS can be designed with an XML signature configured for Authentic View. When XML signatures are enabled, the Authentic View user can digitally sign the Authentic XML file with the enabled signature. After the document has been signed, any modification to it will cause the verification of the signature to fail. Whenever a signed Authentic XML document is opened in the Authentic View of any Altova product, the verification process will be run on the document and the result of the verification will be displayed in a window.

Note: XML signatures can be enabled in the Enterprise edition of StyleVision. If an SPS with an enabled signature is opened in StyleVision Professional or StyleVision Basic, a message indicating that the feature is not supported in these versions is displayed.

Note: XML signatures can be used, and will be verified, in the Authentic View of the Enterprise edition of the following Altova products: Authentic Desktop, Authentic Browser, XMLSpy, and StyleVision.

Working with XML signatures in StyleVision and Authentic View

This section provides an overview of how XML signatures are enabled in an SPS, how Authentic XML documents are signed with XML signatures, and how the signatures are verified.

1. **Enabling and configuring the XML signature:** In StyleVision, the <u>Design Overview sidebar</u> provides access to the Configure XML Signature dialog (*screenshot below*), in which you must enable the signature.

In this dialog you also specify whether the Authentic View user can choose an own certificate/password and whether the Authentic XML document is signed automatically when it is saved. A certificate or password can be specified in the SPS by the SPS designer in the XML Signature Settings dialog (603), which is accessed via the XML Signature Settings button. The specified certificate/password is used as the default. It can be overridden by the Authentic View user's

certificate/password if this has been allowed. When the Authentic View user signs the XML document, the certificate or password is used together with the XML data to generate the signature.

- 2. In the XML Signature Settings dialog (see screenshot above), the following settings are specified: (i) The certificate or password to use. If a certificate is specified, the certificate's key information can be saved with the signature by checking the Append Keyinfo checkbox (at the bottom of the XML Signature Settings dialog); this obviates the need for the Authentic View user to specify a certificate during verification. If a password is specified, the password information can be saved in the SPS file. This enables the Authentic View user to verify the Authentic XML document without needing to enter the password to run the verification process.
 - (ii) The placement of the signature: The XML signature can be included in the Authentic XML file, or be saved in a separate (detached) file. If the signature is in a separate file, it will have to be delivered together with the Authentic XML file and saved to the correct location relative to the Authentic XML file. Note also that if you place the XML signature within the Authentic XML file, the schema will need to be modified to accommodate the Signature element. This issue is discussed in the section, XML document validity.
 - (iii) *The transformation method:* This specifies how the XML will be transformed before being processed to generate the XML signature. The options are described in the section describing the XML Signature Settings dialog 603.
- 3. Authentic View user actions: The following Authentic View user actions are possible:

 (i) Choosing the certificate/password: Signatures are authenticated with either a certificate or a password. The authentication object (certificate or password) is required when the signature is created and again when it is verified. If an Authentic XML document has a signature-enabled SPS assigned to it, the SPS might specify a default certificate or password for the signature. Whether a default certificate or password has been specified or not, the signature can be configured to allow the Authentic View user to select an own certificate/password. The Authentic View user can do this at any time in the XML Signature dialog (screenshot below). Selecting an own certificate/password overrides the default certificate/password. The own certificate/password is stored in memory and is used for the current session. If, after an own certificate/password has been selected, the Authentic View user closes the file or the application, the SPS reverts to its default setting for the certificate/password.

(ii) Signing the document: The Authentic XML document can be signed either automatically or manually. Automatic signing is specified in the signature configuration and causes the document to be signed automatically when it is saved. If the automatic-signing option has not been activated, the

document can be signed manually. This is done by clicking the XML Signature toolbar icon Authentic | XML Signature command, and, in the XML Signature dialog that then pops up (screenshot above), clicking the Sign Document button. Note that signing the document with an embedded signature would require the schema to allow the Signature element as the last child element of the root (document) element. Otherwise the document will be invalid against the schema. This issue is discussed in the section, XML document validity

(iii) Verifying the Authentic XML document: If an SPS has XML Signatures enabled, the verification process will be run on the signature each time the Authentic View XML document is loaded. If the password or certificate key information is not saved with the SPS and signature, respectively, the Authentic View user will be prompted to enter the password or select a certificate for verification. Note that if an embedded signature is generated, it will be saved with the XML file when the XML file is saved. The generated signature must be explicitly removed (via the **Remove Signature** button of the XML Signature dialog; see screenshot above) if you do not wish to save it with the XML file. Similarly, if a detached signature is generated, it too must be explicitly removed if it is not required.

The sub-sections of this section describe in detail each of the processes discussed above:

- XML Signature Configuration 607
- XML Signature Settings 608
- Signing the Authentic XML Document 611
- Signature Verification in Authentic 612
- XML Document Validity 614
- Working with Certificates 615

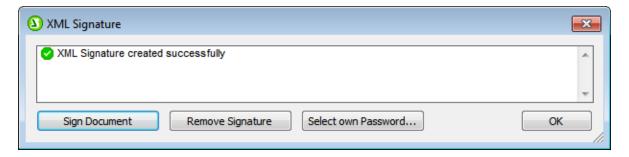

9.11.1 XML Signature Configuration

In the Configure XML Signatures dialog (screenshot below), the options listed below may be configured.

• Enabling XML signatures: Checking this option enables XML signature support in Authentic. As a result Authentic View users can sign the Authentic XML document they have edited. Also, when a document is loaded in Authentic View, the signature-verification process is executed. If XML signature support is disabled, then signing in Authentic is not possible and the XML document, when loaded in Authentic View, will not run the signature-verification process.

Own certificate/password for Authentic users: With this option the SPS designer can specify whether
the Authentic View user may select an own certificate/password. (If this option is checked, the
Authentic View user can select an own certificate/password via a button in the XML Signature dialog
(see screenshot below), and that selection will replace the default certificate/password specified by the
SPS designer.) If the SPS designer unchecks this option, a prompt appears asking for a
certificate/password to be specified for the signature.

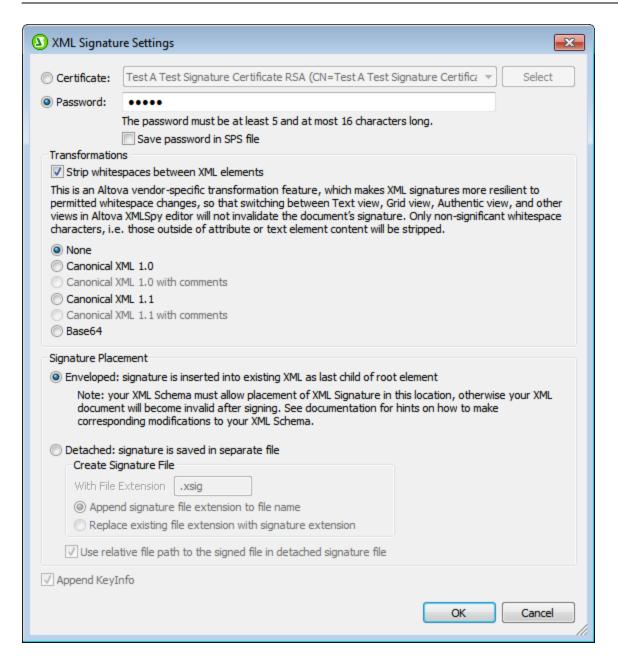

- Show messages on load: Select the individual options for messages. A message will be displayed each time the document is loaded and the selected condition is true.
- Sign automatically on save: If this option is checked, the Authentic XML document will be signed automatically when the document is saved. The certificate/password used will be that currently saved: either the certificate/password specified by the SPS designer, or the certificate/password specified by the Authentic View user—if this option has been allowed.

Clicking the **Edit XML Signature Settings** button opens the XML Signature Settings dialog, in which you can specify: the default certificate/password to be used; where the signature will be placed; transformation options; etc.

9.11.2 XML Signature Settings

In the XML Signature Settings dialog (*screenshot below*), you can specify the default certificate/password to be used for the signature, where the signature will be placed, transformation options, whether certificate key information is saved with the XML file, etc. The individual settings are described below.

Authentication method: certificate or password

The signature can be based on a certificate or a password. Select the radio button of the method you wish to use.

• Certificate: Click the Select button and browse for the certificate you want. The certificate you select must have a private key. The signature is generated using the private key of the certificate. For the signature to be verified subsequently, access to the certificate (or to a public-key version of it) is required. The public key of the certificate is used to verify the signature. For more details about certificates, see the section Working with Certificates 1. Alternatively, the certificate's key information can be saved with the signature by checking the Append Keyinfo check box at the bottom of the dialog. In this case, no certificate will be referenced for verifying the signature; the key information

- saved with the signature will be used. **Note:** StyleVision's XML Signature feature supports only certificates of type RSA-SHA1 and DSA-SHA1.
- Password: Enter a password with a length of five to 16 characters. This password will subsequently be required to verify the signature. Alternatively, the password can be saved with the SPS file. In this case, verification will be carried out directly, without Authentic Viewprompting for a password.

The certificate/password you specify will be the default for the signature.

Transformations

The XML data is transformed and the result of the transformation is used for the creation of the signature. You can specify the canonicalization algorithm to be applied to the file's XML data (the <code>SignedInfo</code> content) prior to performing signature calculations. Significant points of difference between the algorithms are noted below:

- Canonical XML with or without comments: If comments are included for signature calculation, then any
 change to comments in the XML data will result in verification failure. Otherwise, comments may be
 modified or be added to the XML document after the document has been signed, and the signature will
 still be verified as authentic. The Comments option is available for detached signatures and is disabled
 for enveloped signatures.
- Base64: The root (or document) element of the XML document is considered to be Base64 encoded, and is read in its binary form. If the root element is not Base64, an error is returned or the element is read as empty.
- None: No transformation is carried out and the XML data from the binary file saved on disk is passed directly for signature creation. Any subsequent change in the data will result in a failed verification of the signature. However, if the Strip Whitespace check box option is selected, then all whitespace is stripped and changes in whitespace will be ignored. A major difference between the None option and a Canonicalization option is that canonicalization produces an XML data stream, in which some differences, such as attribute order, are normalized. Consequently, a canonicalization transformation will normalize any changes such as that of attribute order (so verification will succeed), while notransformation will reflect such a change (verification will fail). Note, however, that a default canonicalization is performed if the signature is embedded (enveloped). So the XML data will be used as is (i.e. with no transformation), when the signature is detached, None is selected, and the Strip Whitespaces checkbox is unchecked.

Signature placement

The signature can be placed within the XML file or be created as a separate file. The following options are available:

- Enveloped: The signature element is created as the last child element of the root (document) element.
- Detached: The XML signature is created as a separate file. In this case, you can specify the file extension of the signature file and whether the file name is created with: (i) the extension appended to the name of the XML file (for example, test.xml.xsig), or (ii) the extension replacing the XML extension of the XML file (for example, test.xsig). You can also specify whether, in the signature file, the reference to the XML file is a relative or an absolute path.

Append key information

The *Append Keyinfo* option is available when the signature is certificate-based. It is unavailable if the signature is password-based.

If the option is selected, public-key information is placed inside the signature, otherwise key information is not included in the signature. The advantage of including key information is that the certificate itself (specifically the

public-key information in it) will not be required for the verification process (since the key information is present in the signature).

9.11.3 Signing the Authentic XML Document

The Authentic XML document can be signed in two ways:

- Automatically when the Authentic XML document is saved. For this method to be used, the SPS
 designer must activate the Sign Automatically on Save option in the Configure XML Signature dialog (607)
- Manually via the Sign Document button in the XML Signature dialog (see screenshot below). This
 dialog is accessed by clicking the XML Signature toolbar icon or the Authentic | XML Signature
 menu command. This way of (manually) signing the XML document is described below.

Manually signing the Authentic XML document

In addition to automatic signing on save—a feature which the SPS designer enables via the SPS—the Authentic View user can sign the document manually.

The signature will be generated in accordance with the signature settings that are current at the time of signing. All of the signature settings except the certificate/password must be specified by the SPS designer in the Configure XML Signature and XML Signature Settings dialogs. The certificate/password can be specified by the SPS designer or by the Authentic View user. The following possibilities are available:

- The SPS designer specifies the certificate/password. The own certificate option is not available to the Authentic View user. See SPS only 611 below for details.
- The SPS designer specifies the certificate/password. The own certificate option is available to the Authentic View user. See SPS + Authentic View user 612 below for details.

SPS only

The SPS designer specifies the certificate/password. The Authentic View user is not given the option of selecting an own certificate/password (done by deactivating this option in the <u>Configure XML Signature</u> dialog). The Authentic View user signs the document using the SPS-specified certificate/password. There are two possibilities:

• If a certificate has been specified (as opposed to a password), then the Authentic View user must have access to the private-public-key certificate that has been specified. The private key of the certificate will be used to generate the signature.

• If a password has been specified in the signature settings, this password is used directly when signing. The Authentic View will not be asked for it when signing.

Note: Either the certificate or the password option must be set as the Authentication method in the ML Signature Settings dialog. However, no value needs to be set for the selected method. For example, the Password option can be selected but no password need be set. In this case, the Authentic View user must set a password when signing the document. Similarly, if the certificate method were selected but no certificate were specified, then the Authentic View user would need to specify a certificate for generating the signature.

SPS + Authentic View user

The SPS designer specifies the certificate/password. The Authentic View user may select an own certificate/password (this option is enabled in the Configure XML Signature dialog). The Authentic View user can now choose whether to use the certificate/password specified in the SPS file (the default certificate/password) or to use an own certificate/password. The own certificate/password is saved in memory and will be used for the current session only. When the SPS file or XML file is closed, the signature setting reverts to the default certificate/password.

To use an own certificate/password, the Authentic View user must do the following:

1. Click the XML Signature toolbar icon or the **Authentic | XML Signature** menu command to pop up the XML Signature dialog (*screenshot below*).

- 2. Click the **Select Own Certificate** or **Select Own Password** button. (Which of these buttons appears depends on which of the two options (certificate or password) was selected in the <u>XML Signature</u> <u>Settings</u> dialog.)
- 3. Either browse for the certificate file or enter the password you want.
- 4. The Authentic View user can either sign the document right away (by clicking **Sign Document**) and/or click **OK** to finish.

On clicking **OK**, the user-defined certificate/password setting is saved to memory and will be used for the current session.

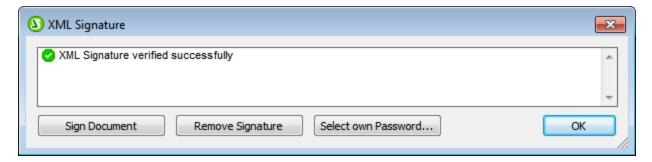

9.11.4 Signature Verification in Authentic

Signature verification occurs each time the Authentic XML document is refreshed or reloaded. If the signature certificate's key information has been appended to the signature or if a signature's password is available in the SPS, then the verification is carried out directly using this authentication information. If the authentication information is not available, then a message to that effect is displayed. In this case, the signature will have to be verified manually.

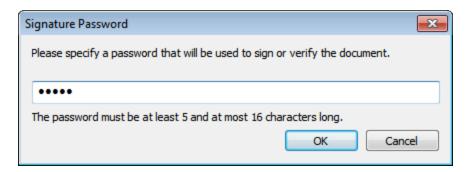

Manual signature verification

To verify the signature of a **signed** document manually, the Authentic View user must click the XML Signature toolbar icon or the menu command **Authentic | XML Signature**.

If the authentication information has been saved with the signature (certificate's key information) or with the SPS (password), then the verification is carried out directly and the verification result is displayed, as in the screenshot below.

If no authentication information is available, the Authentic View user will be prompted for a certificate or password. For example, in the screenshot below, the user is prompted to enter the password for signature verification.

Note that the XML Signature toolbar icon (or **Authentic | XML Signature** menu command) runs the verification process only if the document has already been signed. Otherwise, the command will display a Verification Failed message.

In this case, the option to sign the document is available.

9.11.5 XML Document Validity

If an XML signature is embedded in the XML document, a <code>Signature</code> element in the namespace <code>http://www.w3.org/2000/09/xmldsig#</code> is added to the XML document. In order for the document to remain valid according to a schema, the schema must contain the appropriate element declarations. StyleVision embeds signatures within the document. The signature is said to be <code>Enveloped</code>. The <code>Signature</code> element is created as the last child element of the root (or document) element.

If you do not wish to modify the schema of the XML document, the XML signature can be created in an external file. For more details, see the description of the placement options in the section, XML Signature Settings (603).

Given below are excerpts from XML Schemas that show how the Signature element of an enveloped signature can be allowed. You can use these examples as guides to modify your own schemas.

In the first of the two listings below, the XML Signature Schema is imported into the user's schema. The XML Signature Schema is located at the web address: <a href="http://www.w3.org/TR/xmldsig-core/

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"</pre>
           xmlns:xsig="http://www.w3.org/2000/09/xmldsig#"
           elementFormDefault="qualified"
           attributeFormDefault="unqualified">
  <xs:import namespace="http://www.w3.org/2000/09/xmldsig#"</pre>
              schemaLocation="http://www.w3.org/TR/xmldsig-core/xmldsig-core-schema.xsd"/>
   <xs:element name="Root">
      <xs:complexType>
         <xs:sequence>
            <xs:element ref="FirstChildOfRoot"/>
            <xs:element ref="SecondChildOfRoot" minOccurs="0"/>
            <xs:element ref="ThirdChildOfRoot" minOccurs="0"/>
            <xs:element ref="xsiq:Signature" minOccurs="0"/>
         </xs:sequence>
      </xs:complexType>
   </xs:element>
</xs:schema>
```

A second option (*listing below*) is to add a generic wildcard element which matches any element from other namespaces. Setting the processContents attribute to lax causes the validator to skip over this element—because no matching element declaration is found. Consequently, the user does not need to reference the XML Signatures Schema. The drawback of this option, however, is that any element (not just the signature element) can be added at the specified location in the XML document without invalidating the XML document.

W3C Specification

For more details about XML signatures, see the W3C specification for XML signatures at http://www.w3.org/TR/xmldsig-core/.

9.11.6 Working with Certificates

Authorization certificates are commonly used to create and verify XML signatures. This section contains information about obtaining, importing, and exporting certificates. It is organized into the following sub-sections:

- Obtaining a certificate with a private-public-key pair 615
- Importing a private-public-key certificate 615
- The certificate stores on a Windows machine 616
- Exporting a public-key certificate 617

Obtaining a certificate with a private-public-key pair

A certificate can be obtained in the following ways:

- From a certificate authority. The certificate authority verifies the identity of the certificate's owner. Certificates obtained in this way are in contrast to self-signed certificates, which can be created by anyone with a certificate creation tool.
- By creating a self-signed certificate. Such certificates are not verified by any authority, but often provide adequate security. A number of certificate creation tools, such as Microsoft's Visual Studio, are available.

For use with XML signatures you will need a certificate with a private-public-key pair.

Note: StyleVision's XML Signature feature supports only certificates of type RSA-SHA1 and DSA-SHA1.

Importing a private-public-key certificate

After a private-public-key certificate has been obtained, you will need to import it to your Windows certificate store. Do this as follows:

 Double-click the certificate file to open the Certificate Import Wizard (screenshot below), and click Next.

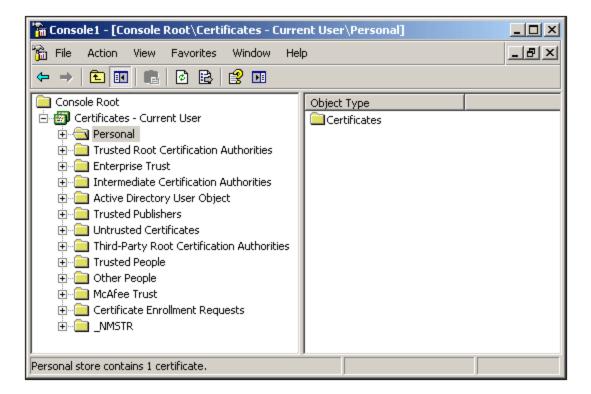

- 2. In the File to Import window, ensure that the certificate file is selected, then click Next.
- 3. Type in the password for the private key. You must know the password if you intend to use the private key to create an XML signature. The password for the private key will be supplied to you when you obtain the certificate. After typing in the password, click **Next**.
- 4. You can allow the wizard to automatically select the store in which to place the certificate—according to the certificate type—or you can select the store yourself. (It might be better to select the store yourself, so you know the location of the certificate.) Click **Next** when done.
- 5. Click **Finish** to complete the process.

Certificate stores on a Windows machine

The certificate store on a Windows XP machine can be accessed as follows:

- 1. In the Start menu, select Run.
- 2. Type in mmc and click **OK**. A Console window pops up (screenshot below).

- 3. In the Console window, select the command File | Add/Remove Snap-in.
- 4. In the Standalone tab of the Add/Remove Snap-in dialog that pops up, click Add.
- 5. In the Add Standalone Snap-in dialog that pops up, select Certificates and click Add.
- 6. Close the Add Standalone Snap-in dialog.
- 7. In the Add/Remove Snap-in dialog, click **OK**.
- 8. The Console Root in the Console window will now contain a Certificates item (*see screenshot above*). This Certificates item contains the certificate stores of your machine.
- 9. Save the Console as a Microsoft Management Console File (.msc file) via the **File | Save** command of the Console window. You can subsequently use this MSC file (via the **File | Open** command of a Console window) to access the certificate stores on your machine.

Exporting a public-key certificate

If you have a certificate with a private-public key, you might wish to export this certificate with only a public key. This public-key certificate can then be sent to receivers for use in verifying signatures created with the private key of the certificate.

A public-key certificate can be exported from an existing private-public-key certificate as follows:

- 1. Open the certificate stores in a Console window. Do this as follows: (i) Enter mmc on the **Start** menu's **Run** command line; (ii) In the Console window that pops up, select **File | Open**, and select the MSC file in which the certificate stores were saved (see section immediately above this section).
- 2. Browse for the certificate that you wish to export as a public-key certificate and right-click it.
- 3. In the context menu that pops up, select **All Tasks | Export**. This pops up the Certificate Export Wizard (*screenshot below*).

- 4. Select Next.
- 5. In the Export Private Key window, select No, do not export the private key, and click Next.
- 6. In the Export File Format window, select the required format (leave the default DER format unchanged if you are not sure), and click **Next**.
- 7. In the File to Export window, browse for the location where you wish to save the file and provide a name for the file (without a file extension, which will be automatically appended). Click **Next** when done.
- 8. Click **Finish** to complete the export.

A public-key certificate will be created at the location you specified. This public-key certificate can be sent to receivers of XML files signed with the corresponding private key. The receiver can then import this public-key certificate to a certificate store on his or her machine and use the public key of this certificate for verification.

9.12 ASPX Interface for Web Applications

If an HTML report of DB or XML data for the Internet is to be created with an SPS, then the usual procedure for creating the report with StyleVision would be as follows:

- 1. If the source data is in a DB, then, with the finished SPS active in StyleVision, generate an XML file from the DB. (If the source data is in an XML file, then this step is not required.)
- 2. Also from the SPS, generate the XSLT-for-HTML file.
- 3. Transform the XML file using the generated XSLT-for-HTML file.
- 4. Place the resulting HTML file on the server.

For a web application, the HTML file could become outdated if the source (DB or XML) data is modified. Updating the HTML file on the Web server with the new data would require: (i) for DB-based data, the regeneration of the XML file, (ii) transforming the new XML file using the XSLT-for-HTML, and (iii) placing the result HTML file on the server.

StyleVision provides a solution to quickly update HTML web pages. This is a feature for automatically generating an ASPX application. All the required ASPX application files (the <code>.aspx</code> file, XSLT file, and the code files) are generated by StyleVision. These files can then be placed on the server together with the source DB file or XML file and the XSLT-for-HTML file. Each time the <code>.aspx</code> file—which is the web interface file—is refreshed, the following happens: (i) for DB-based data, a new XML file is generated from the DB; for XML-based data, this step is not required; (ii) the XML file is transformed using the XSLT-for-HTML file that is on the server; and (iii) the output of the transformation is displayed in the web interface page. In this way, the web interface page will quickly display the latest and up-to-date DB or XML data.

Generating files for an ASPX solution

After creating the DB-based SPS or XML-based SPS, do the following to create an ASPX solution:

- 1. With the SPS active in StyleVision, generate the ASPX files by clicking the command, File | Web Design | Generate ASPX Web Application. The ASPX application files will be created in the folder location you specify. The folder in which you generate the ASPX application will contain the following files among others:
 - Readme.doc
 - SPSFilename.aspx
 - SPSFilename.xslt
 - SPSFilename.cs
- 2. Place the DB file or XML file on the server, in the same folder as the ASPX application. The <code>.aspx</code> file is the entry point of the application. Refreshing this file will cause the DB or XML data that is displayed in it to be updated.

Note: You will need to have <u>Altova's RaptorXML application</u> installed in order for the XSLT transformation to run correctly. If you have problems with the transformation, see the ReadMe.doc file for details about setting up RaptorXML.

How it works

The folder in which you generate the ASPX application will contain the following files among others:

- Readme.doc
- SPSFilename.aspx
- SPSFilename.xslt
- SPSFilename.cs

SPSFilename.aspx is the URL of the output document. SPSFilename.aspx executes C# code stored in the file SPSFilename.cs. This C# code reads the XML content (from files or a database as required) and passes it to RaptorXML, together with the SPSFilename.xslt file. (RaptorXML contains Altova's XSLT transformation engine. It can be downloaded from the Altova website.) RaptorXML performs a transformation of the XML content, using the provided XSLT file. The result is an HTML document, which the web application then displays in the browser. When the XML content changes, for example because of changes made to the database, browsing to SPSFilename.aspx (or refreshing the page in the browser) will automatically fetch the most recent data from the database or XML file and render an updated document.

9.12.1 Example: Localhost on Windows 7

The procedure outlined below sets up your local host to serve an ASPX application. For more information, see the file Readme.doc in the ASPX application folder. This folder and file are generated when you select the command File | Web Design | Generate ASPX Web Application with an SPS file active.

Install RaptorXML

Make sure that the latest version of RaptorXML is installed. RaptorXML contains Altova's transformation engine. It will be used to transform the (DB-generated) XML file.

Activate Internet Information Services (Microsoft's web server)

If Internet Information Services (IIS) is not activated, carry out the steps below to activate it. Step 5 shows how to test whether IIS has been activated.

- 1. Go to Control Panel | Programs and Features | Turn Windows features on or off.
- 2. Set the Internet Information Services checkbox. The tri-state checkbox will change to Partly checked.
- 3. Additionally, set the *Internet Information Services* | *World Wide Web Services* | *Application Development Features* | *ASP.NET* checkbox.
- 4. Click **OK**. When the process is complete, you will have a folder named C:/inetpub/wwwroot. This is the web server's root folder.
- 5. As a test, go to localhost in a browser. This will display the IIS welcome screen

In StyleVision, generate the ASPX application

Generate the ASPX application as follows:

- 1. It is recommended that the database and the SPS file be in the same folder.
- 2. After the SPS file has been completed, issue the command *Files* | *Web Design* | *Generate ASPX Web Application*.
- 3. In the dialog that opens, create a folder below C:/inetpub/wwwroot and select that folder, for example: C:/inetpub/wwwroot/Test1.

4. On confirming your folder selection, StyleVision will generate the following files in it: <FileName>.aspx, <FileName>_AltovaDataBaseExtractor.cs, Web.config, and a folder App_Code containing the various files.

Note: In order to save files to C:/inetpub/wwwroot you will need to run StyleVision as an administrator. Do this by restarting StyleVision. Right-click the StyleVision executable file or a shortcut to it and select **Run as Administrator**.

Make ASPX aware of the generated application

Carry out the following steps to make ASPX aware of the application you have generated with StyleVision:

- 1. Go to Control Panel | Administrative Tools | Internet Information Services (IIS) Manager.
- 2. In the *Connections* panel, expand the tree to display the folder (for example, Test1). The folder's icon will be a standard yellow folder at this point.
- 3. In the folder's context menu, issue the command *Convert to Application*, then click **OK** in the dialog. The folder's icon will now be a globe.
- 4. In the Connections panel, expand the tree to display Application Pool and select this.
- 5. In the context menu for *DefaultAppPool* (available in the main pane when you select the *Application Pools* item in the Connections pane), select the command **Advanced Settings**.
- 6. For the *Identity* property, select *Custom account* and enter your Windows user name and password.
- 7. For the *Enable 32-Bit Applications* property, enter True. (This is so the database drivers have access). This step applies only to 64-bit versions of Windows 7.

Run the application

In the browser, go to <code>localhost/Test1/<FileName>.aspx</code> (assuming <code>Test1</code> is the name of the folder in which the ASPX application has been saved). The transformed HTML will be displayed in the browser. Refreshing this ASPX page will cause the latest data from the database or XML file to be displayed.

Note: If the browser hangs at this point, make sure that the RaptorXML is correctly licensed.

9.13 PXF File: Container for SPS and Related Files

An SPS design that uses XSLT 2.0 or 3.0 can be saved as a Portable XML Form (PXF) file. The PXF file format has been specially developed by Altova to package the SPS design with related files (such as the schema file, source XML file, image files used in the design, and XSLT files for transformation of the source XML to an output format). The benefit of the PXF file format is that all the files required for Authentic View editing and for the generation of output from Authentic View can be conveniently distributed in a single file.

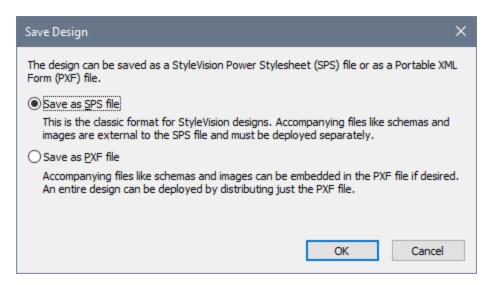

This section describing the use of PXF files is organized in two parts:

- Creating a PXF file 622
- Editing a PXF File 625
- Deploying a PXF file 626

Note: PXF files can be created only from SPSs designed with XSLT 2.0 or 3.0.

9.13.1 Creating a PXF File

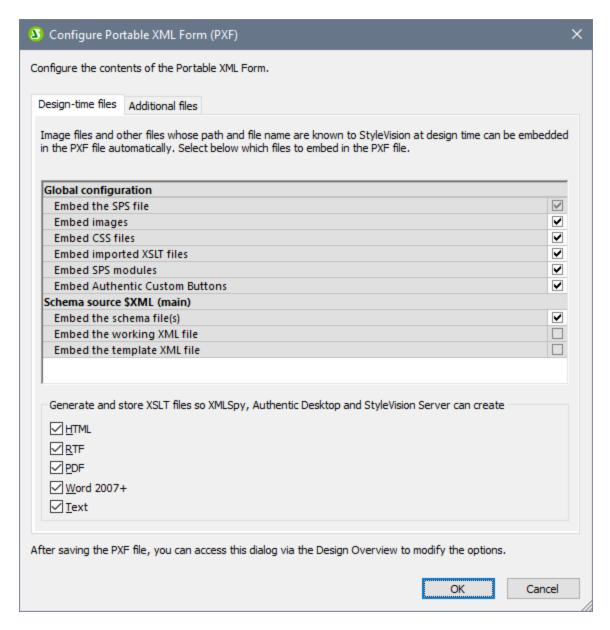

To create a PXF file that will contain an SPS design plus related files, open the SPS design in StyleVision and select the command **File | Save As**. This pops up the Save Design dialog (*screenshot below*).

The **SPS format** is the standard Altova format for StyleVision designs. In this section we are concerned with the PXF format and so will not consider the SPS format here. Saving a file as an SPS is described in detail in the <u>User Reference section</u> (932).

Save as PXF

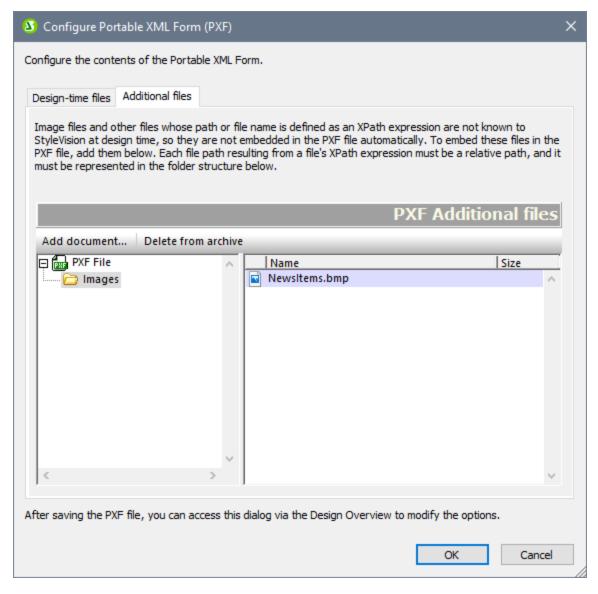

Selecting the PXF option causes the familiar Save As dialog of Windows systems to pop up. Saving works exactly as described for the <u>Save Design solution</u>—with the additional step of selecting the files you wish to include in the PXF file. After you specify the PXF filename, the Configure PXF dialog (*screenshot below*) will appear, in which you can select/deselect the files you wish to embed.

In the Global Configuration pane of the *Design-time Files* tab, you can select/deselect the design-related source files to be embedded/omitted. You can additionally choose to embed XSLT files generated from the design. In the XSLT files pane, select the output formats for which you wish to generate and embed XSLT files. If an XSLT file is included in the PXF file and the PXF file is opened in the Authentic View of an Altova product, then the toolbar button to generate and view that output format is enabled in Authentic View (*screenshot below*).

In the Additional Files tab (screenshot below), you can specify any additional files you wish to include that are not design-time files. These could be, for example, image files referenced in the design by a URL generated with an XPath expression. In the screenshot below, the image file <code>NewsItems.bmp</code> located in the <code>Images</code> folder is selected for inclusion in the PXF file.

To include an additional file in the PXF file, click the **Add Document** button and then browse for the file you want. The Open dialog (in which you browse for the required file) opens the folder in which the SPS is located. Files from this folder or any descendant folder may be selected. After an additional file has been added to the PXF file, it and the folder structure leading to it are displayed. The screenshot above indicates that the additional file <code>NewsItems.bmp</code> is in a folder named <code>Images</code>, which is itself contained in the folder in which the SPS file is located.

If a file is selected from a folder located in any level above the folder containing the SPS file, an error is reported.

In the SPS design, any reference to an additional file must be made with a relative path and must use the folder structure shown in the *Additional Files* pane. For example, <code>NewsItems.bmp</code> in the screenshot above must be referenced with the relative path: <code>Images/NewsItems.bmp</code>.

Note: In order to save PXF files, the option Embed Images for RTF and Word 2007+ (File | Properties |

Images) must be selected.

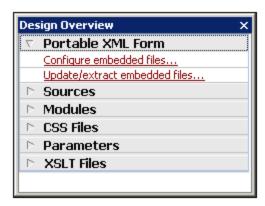

9.13.2 Editing a PXF File

A PXF file can be opened in StyleVision via the <u>File | Open</u> good command and edited. These edits can be of two types:

- The configuration of the PXF file can be edited
- The content of individual component files such as the SPS and Authentic XML can be edited in StyleVision, while other component files (such as image and CSS files) can be edited in external applications. All component files must however be explicitly updated in StyleVision.

Entry point for PXF editing

The entry point for editing the PXF configuration and for updating the PXF file is the PXF item in the Design Overview sidebar (*screenshot below*).

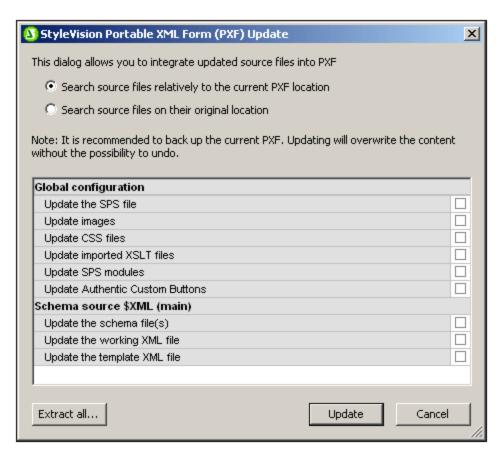

Configure embedded files

Clicking the *Configure Embedded Files* link in Design Overview (*see screenshot above*) opens the Configure Portable XML Form (PXF) dialog. The configuration options are exactly the same as described in the section, Creating a PXF File 622.

Updating embedded files

Clicking the *Update Embedded Files* link in Design Overview (see screenshot above) opens the Portable XML Form (PXF) Update dialog (screenshot below).

First, select whether the source files should be retrieved relative to their current PXF locations or from their original locations. Then check the files you wish to update and click **Update**. A new PXF file will be created and will overwrite the existing PXF file. Therefore, before you update, it is highly recommended that you back up the original PXF file.

9.13.3 Deploying a PXF File

After a PXF file has been created, it can be transported, downloaded, copied, and saved like any other data file. Since the PXF file can contain all the files required to edit an XML file in Authentic View and to generate output reports, it is the only file an Authentic user needs in order to get started and to generate output.

A PXF file can be opened in the <u>Authentic View of Altova products</u>. To give you an idea of how a PXF file may be used, here is a list of some usage scenarios in XMLSpy:

- The PXF file is opened via the **File | Open** command. The embedded XML file will be displayed in Authentic View using the embedded SPS, and can be edited in Authentic View. The **File | Save** command saves changes to the PXF (the embedded XML is modified).
- The PXF file contains no embedded XML file and is opened via the **File | Open** command. If no XML file is included, then a Template XML file based on the SPS design is opened in Authentic View. The **File | Save** command will save this XML file as an embedded file in the PXF file.

- In the Altova product XMLSpy, an XML file can be associated with a PXF file so that the embedded SPS of the PXF file is used for Authentic View editing. The association is done via the menu command **Authentic | Assign a StyleVision Stylesheet**. When changes are saved, they will be saved to the XML file; the PXF file will be unchanged.
- If an XSLT stylesheet for one of the output formats has been embedded in the PXF file, then the Authentic View user will be able to generate output in that format. This is done with the appropriate output-generation toolbar button (*screenshot below*). In Authentic View, individual output-generation toolbar buttons will be enabled only if the PXF file was configured to contain the XSLT stylesheet for that output. For example, if the PXF file was configured to contain the XSLT stylesheets for HTML and PDF, then only the toolbar buttons for HTML and PDF output will be enabled while those for RTF and DocX (Word 2007+) output will be disabled.

Note: If a PXF file is located on a web server and will be used with the Authentic Browser Plug-in, you must ensure that the server does not block the file. You can do this by adding (via the IIS administration panel, for example) the following MIME type for PXF (.pxf) file extensions: application/x-zip-compressed.

10 Databases

When a DB is used as the basis of an SPS—that is, as the main schema of an SPS—the SPS can be used in the following ways:

- To edit the DB in <u>Authentic View</u> 26.
- To generate an XML Schema having a structure based on the DB (if the DB does not contain a schema; only XML DBs, such as IBM DB2 version 9 upwards, contain schemas).
- To generate an XML file with data from the DB (if the required DB data is not already in XML format).
- To design and generate XSLT stylesheets for HTML, Text, RTF, PDF, and Word 2007+ output.
- To generate DB reports (based on the SPS design) in HTML, Text, RTF, PDF, and Word 2007+ format. These reports can be previewed in StyleVision

When a DB is the source of a subsidiary schema in an SPS, then data from the DB can be included in the design document, but the DB itself cannot be edited in Authentic View. It is the XML document or DB associated with the main schema that can be edited.

General procedure

This section describes the procedure for working with DBs in StyleVision. After an introductory sub-section which provides an overview of how DBs work in StyleVision the sub-sections of this section describe the various steps in the work procedure. Note that we distinguish between two broad types of DBs: non-XML DBs and XML DBs. The term DB is used in two senses: generically, it refers to all DBs; specifically, to non-XML DBs. XML DBs are always referred to as XML DBs. The distinction should be borne in mind because the method of selecting the DB data that provides the schema and XML data for the SPS is different for these two types of DB.

- Connecting to a DB (633): Describes how to connect to non-XML DBs, including IBM DB2 versions below 9...
- DB Data Selection Describes how the schema and XML data for the SPS is selected from the DB's table structure, for non-XML and XML DBs separately.
- The DB Schema and DB XML file (1007): When DB tables (from non-XML DBs) are loaded, StyleVision generates and works with temporary XML Schema and XML data files based, respectively, on the DB structure and data. For XML DBs, the schema and XML files are not generated by StyleVision but referenced directly from the DB or, in the case of schemas, from another file location.
- <u>DB Filters: Filtering DB Data</u> 100: DB data that is loaded into the temporary XML file can be filtered.
- <u>SPS Design Features for DB</u> 715: In the SPS, special DB functionality, such as DB controls and DB Queries, are available.
- Generating Output Files ⁷¹⁹: A wide range of DB report-related files can be generated by StyleVision.

Supported databases

The table below lists all the supported databases. If your Altova application is a 64-bit version, ensure that you have access to the 64-bit database drivers needed for the specific database you are connecting to.

Database	Notes
Firebird 2.x, 3.x, 4.x	
IBM DB2 8.x,	

Databases 629

Database	Notes
9.x, 10.x, 11.x, 12.x	
IBM Db2 for i 6.x, 7.4, 7.5	Logical files are supported and shown as views.
IBM Informix 11.70 and later	
MariaDB 10 and later	MariaDB supports native connections. No separate drivers are required.
Microsoft Access 2003 and later	You can connect to an Access 2019 database from Altova products (i) only if the corresponding version of Microsoft Access Runtime is installed and (ii) only if the database does not use the "Large Number" data type.
Microsoft Azure SQL Database	SQL Server 2016 codebase
Microsoft SQL Server 2005 and later Microsoft SQL Server on Linux	
MySQL 5 and later	MySQL 5.7 and later supports native connections. No separate drivers are required.
Oracle 9i and later	
PostgreSQL 8 and later	PostgreSQL connections are supported both as native connections and driver-based connections through interfaces (drivers) such as ODBC or JDBC. Native connections do not require any drivers.
Progress OpenEdge 11.6	
SQLite 3.x	SQLite connections are supported as native, direct connections to the SQLite database file. No separate drivers are required. In Authentic view, data coming from a SQLite database is not editable. When you
	attempt to save SQLite data from the Authentic view, a message box will inform you of this known limitation.
Sybase ASE 15, 16	
Teradata 16

Altova website: P Database Reporting

Databases DBs and StyleVision 631

10.1 DBs and StyleVision

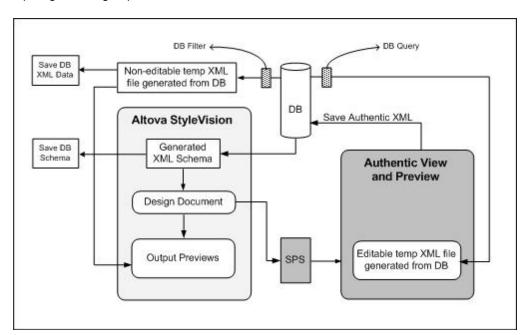

In StyleVision, you can create DB-based SPSs. These stylesheets enable you to do two things:

- Edit DBs in Authentic View, and
- Generate reports from DBs.

After you have created the SPS, you can view reports in StyleVision and generate report files in HTML, RTF, PDF, and Word 2007+ format. You can also save the following DB-related XML files that StyleVision generates:

- XML Schema based on DB structure (not applicable for XML DBs, where a schema is already available)
- XML file having structure defined in the generated schema and content from the DB (not applicable for XML DBs, where the data is already available in XML format)
- SPS that you design, and which is based on the generated schema
- XSLT stylesheet for HTML output (based on design of SPS)
- XSLT stylesheet for Text output (based on design of SPS)
- XSLT stylesheet for RTF output (based on design of SPS)
- XSLT stylesheet for XSL-FO output (based on design of SPS)
- XSLT stylesheet for Word 2007+ output (based on design of SPS)
- HTML output
- Text output
- RTF output
- PDF output
- Word 2007+ output

The saved XML file can then be processed with the required XSLT stylesheet/s. This provides more flexible report-generating capabilities.

Note: The XML Schema and XML files are generated from non-XML DBs by StyleVision, and you cannot alter their structure or content for use in Authentic View. This is because the structure of these files is related to the

632 Databases DBs and StyleVision

structure of the non-XML DB. Editing the DB and creating reports from the DB depend on the unique XML structure generated by StyleVision from the DB.

Broad mechanism for working with DB-based SPSs

Given below are the steps involved in creating and using DB-based SPSs. These steps cover the two uses of DB-based StyleVision Power Stylesheets: editing the DB and creating HTML, Text, RTF, PDF, and Word 2007+ reports from the DB.

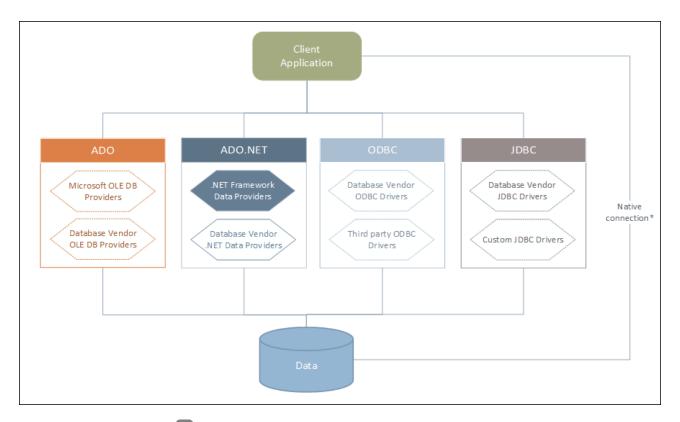

- Connect to the DB should be filtered out from the XML Schema..
- When the connection is made, a <u>temporary XML Schema</u> is generated based on the structure of the DB and that schema is displayed in the Schema Window of StyleVision in tree form. In the case of XML DBs, a pre-existing schema (either in the DB or at a file location) is referenced.
- Temporary StyleVision-internal XML files are also created 100. One is non-editable (see diagram above) and is used for the previews and as the source of the generated XML data file. The other is an editable XML file, which is displayed in Authentic View (see screenshot above). When changes made to this file in Authentic View are saved (with the File | Save Authentic XML Data command), the modifications are written back to the DB. The non-editable XML file is updated if necessary each time an output view is newly accessed or when the XML data is saved.
- In StyleVision, you can define <u>top-level filters</u> to restrict the data imported into the non-editable XML File, i.e. for the output views and the reports.
- A <u>DB Query</u> is used within Authentic View to restrict the list of records displayed in Authentic View. It is used only during editing.
- If editing changes have been saved to the DB, then the next time an output view window is accessed, the non-editable XML file is updated with the modified contents of the DB and the refreshed file is displayed in the preview.
- A DB-based SPS is created in the same way as the standard schema-based SPS: by dragging-and-dropping nodes into the Design Window, inserting static stylesheet components, assigning display properties, etc. These mechanisms are described in this documentation.

10.2 Connect to a Data Source

In the most simple case, a database can be a local file such as a Microsoft Access or SQLite database file. In a more advanced scenario, a database may reside on a remote or network database server which does not necessarily use the same operating system as the application that connects to it and consumes data. For example, while StyleVision runs on a Windows operating system, the database from which you want to access data (for example, MySQL) might run on a Linux machine.

To interact with various database types, both remote and local, StyleVision relies on the data connection interfaces and database drivers that are already available on your operating system or released periodically by the major database vendors. In the constantly evolving landscape of database technologies, this approach caters for better cross-platform flexibility and interoperability.

The diagram below illustrates data connectivity options available between StyleVision (illustrated as a generic client application) and a data store (which may be a database server or database file).

^{* &}lt;u>Direct native connections</u> are supported for SQLite, MySQL, MariaDB, PostgreSQL databases. To connect to such databases, you do not need to install any additional drivers on your system.

As shown in the diagram above, StyleVision can access any of the major database types through the following data access technologies:

- ADO (Microsoft® ActiveX® Data Objects), which, in its turn, uses an underlying OLE DB (Object Linking and Embedding, Database) provider
- ADO.NET (A set of libraries available in the Microsoft .NET Framework that enable interaction with data)

- JDBC (Java Database Connectivity)
- ODBC (Open Database Connectivity)

Note: Some ADO.NET providers are not supported or have limited support. See ADO.NET Support Notes (69).

About data access technologies

The data connection interface you should choose largely depends on your existing software infrastructure. You will typically choose the data access technology and the database driver which integrates tighter with the database system to which you want to connect. For example, to connect to a Microsoft Access 2013 database, you would build an ADO connection string that uses a native provider such as the Microsoft Office Access Database Engine OLE DB Provider. To connect to Oracle, on the other hand, you may want to download and install the latest JDBC, ODBC, or ADO.NET interfaces from the Oracle website.

While drivers for Windows products (such as Microsoft Access or SQL Server) may already be available on your Windows operating system, they may not be available for other database types. Major database vendors routinely release publicly available database client software and drivers which provide cross-platform access to the respective database through any combination of ADO, ADO.NET, ODBC, or JDBC. In addition to this, several third party drivers may be available for any of the above technologies. In most cases, there is more than one way to connect to the required database from your operating system, and, consequently, from StyleVision. The available features, performance parameters, and the known issues will typically vary based on the data access technology or drivers used.

10.2.1 Start Database Connection Wizard

StyleVision provides a Database Copnnection Wizard that guides you through the steps required to set up a connection to a data source. Before you go through the wizard steps, be aware that for some database types it is necessary to install and separately configure several database prerequisites, such as a database driver or database client software. These are normally provided by the respective database vendors, and include documentation tailored to your specific Windows version. For a list of database drivers grouped by database type, see <u>Database Drivers Overview</u> 636.

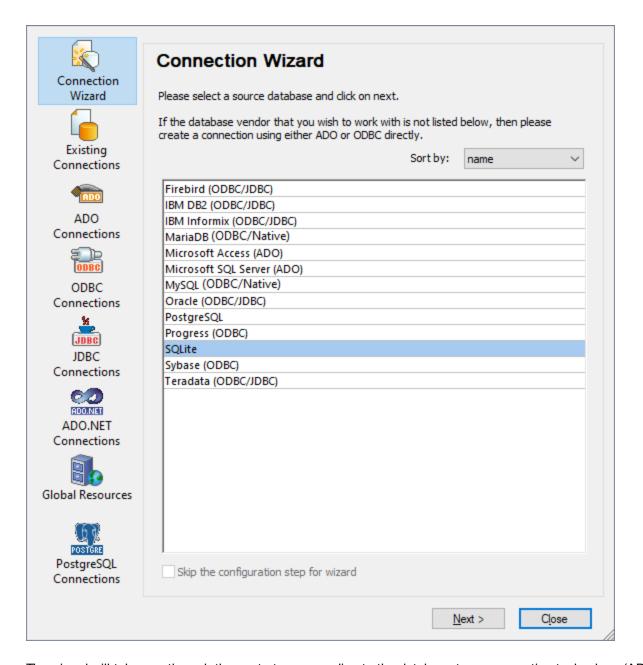

To start the Database Connection Wizard (see screenshot below), do the following:

On the File menu, click New, and then click New From DB.

The Database Connection Wizard (screenshot below) is started. On the left hand side of the window, you can select the most suitable from the following ways to connect to your database:

- Connection Wizard, which prompts you to choose your database type and then guides you through the steps for connecting to a database of that type
- Select a data access technology: ADO, ADO, NET, ODBC, or JDBC
- Use an Altova global resource in which database connection is stored
- A native PostgreSQL connection

In the Connection Wizard pane (see screenshot below) databases can be sorted alphabetically by the name of the database type or by recent usage. Select the option you want in the Sort By combo box. After you have selected the database type to which you want to connect, click Next.

The wizard will take you through the next steps according to the database type, connection technology (ADO, ADO.NET, ODBC, JDBC), and driver that will be used. For examples applicable to each database type, see Database Connection Examples.

Alternatively to using Connection Wizard, you can use one of the following database access technologies:

- Setting up an ADO Connection 640
- Setting up an ADO.NET Connection 645
- Setting up an ODBC Connection 654
- Setting up a JDBC Connection 651

10.2.2 Database Drivers Overview

636

This topic gives an overview of database drivers. Even though a number of database drivers might be already available on your Windows operating system, you may still need to download an alternative driver.

Database vendors may provide drivers either as separate downloadable packages, or bundled with database client software. In the latter case, the database client software normally includes any required database drivers, or provides you with an option during installation to select the drivers and components you wish to install. Database client software typically consists of administration and configuration utilities used to simplify database administration and connectivity, as well as documentation on how to install and configure the database client and any of its components.

Configuring the database client correctly is crucial for establishing a successful connection to the database. Before installing and using the database client software, we recommend that you carefully read the installation and configuration instructions of the database client; these may vary for each database version and for each Windows version.

To understand the capabilities and limitations of each data access technology with respect to each database type, refer to the documentation of that particular database product and also test the connection against your specific environment. To avoid common connectivity issues, note the following:

- Some ADO.NET providers are not supported or have limited support. See <u>ADO.NET Support Notes</u> 650.
- When installing a database driver, it is recommended that it has the same platform as the Altova application (32-bit or 64-bit). For example, if you are using a 32-bit Altova application on a 64-bit operating system, install the 32-bit driver, and set up your database connection using the 32-bit driver, see also Viewing the Available ODBC Drivers 655.
- When setting up an ODBC data source, it is recommended that you create the data source name (DSN) as a System DSN instead of as a User DSN. For more information, see <u>Setting up an ODBC</u> Connection 652.
- When setting up a JDBC data source, ensure that JRE (Java Runtime Environment) or Java Development Kit (JDK) is installed and that the CLASSPATH environment variable of the operating system is configured. For more information, see <u>Setting up a JDBC Connection</u> [65].
- For the installation instructions and support details of any drivers or database client software that you install from a database vendor, check the documentation provided with the installation package.

Available data-access technologies

The table below lists common database drivers you can use to connect to a particular database through a particular data access technology. Note that this list is neither exhaustive nor prescriptive; you can use other native or third party alternatives in addition to the drivers shown below.

Database	Interf ace	Drivers
Firebird	ADO. NET	Firebird ADO.NET Data Provider (https://www.firebirdsql.org/en/additional-downloads/)
	JDBC	Firebird JDBC driver (https://www.firebirdsql.org/en/jdbc-driver/)
	ODBC	Firebird ODBC driver (https://www.firebirdsql.org/en/odbc-driver/)

Database	Interf ace	Drivers
IBM DB2	ADO	IBM OLE DB Provider for DB2
	ADO. NET	IBM Data Server Provider for .NET
	JDBC	IBM Data Server Driver for JDBC and SQLJ
	ODBC	IBM DB2 ODBC Driver
IBM DB2 for i	ADO	IBM DB2 for i5/OS IBMDA400 OLE DB Provider IBM DB2 for i5/OS IBMDARLA OLE DB Provider IBM DB2 for i5/OS IBMDASQL OLE DB Provider
	ADO. NET	.NET Framework Data Provider for IBM i
	JDBC	IBM Toolbox for Java JDBC Driver
	ODBC	iSeries Access ODBC Driver
IBM Informix	ADO	IBM Informix OLE DB Provider
	JDBC	IBM Informix JDBC Driver
	ODBC	IBM Informix ODBC Driver
Microsoft Access	ADO	Microsoft Jet OLE DB Provider Microsoft Access Database Engine OLE DB Provider
	ADO. NET	.NET Framework Data Provider for OLE DB
	ODBC	Microsoft Access Driver
MariaDB	ADO. NET	In the absence of a dedicated .NET connector for MariaDB, use Connector/NET for MySQL (https://dev.mysql.com/downloads/connector/net/).
	JDBC	MariaDB Connector/J (https://downloads.mariadb.org/)

Database	Interf ace	Drivers
	ODBC	MariaDB Connector/ODBC (https://downloads.mariadb.org/)
	Native conne ction	Available. No drivers are required.
Microsoft SQL Server	ADO	Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL) Microsoft OLE DB Provider for SQL Server (SQLOLEDB) SQL Server Native Client (SQLNCLI)
	ADO. NET	 .NET Framework Data Provider for SQL Server .NET Framework Data Provider for OLE DB
	JDBC	Microsoft JDBC Driver for SQL Server (https://docs.microsoft.com/en-us/sql/connect/jdbc/microsoft-jdbc-driver-for-sql-server)
	ODBC	ODBC Driver for Microsoft SQL Server (https://docs.microsoft.com/en-us/SQL/connect/odbc/download-odbc-driver-for-sql-server)
MySQL	ADO. NET	Connector/NET (https://dev.mysql.com/downloads/connector/net/)
	JDBC	Connector/J (https://dev.mysql.com/downloads/connector/j/)
	ODBC	Connector/ODBC (https://dev.mysql.com/downloads/connector/odbc/)
	Native conne ction	Available for MySQL 5.7 and later. No drivers are required.
Oracle	ADO	Oracle Provider for OLE DB Microsoft OLE DB Provider for Oracle
	ADO. NET	Oracle Data Provider for .NET (http://www.oracle.com/technetwork/topics/dotnet/index-085163.html)
	JDBC	JDBC Thin Driver JDBC Oracle Call Interface (OCI) Driver

Database	Interf ace	Drivers
		These drivers are typically installed during the installation of your Oracle database client. Connect through the OCI Driver (not the Thin Driver) if you are using the Oracle XML DB component.
	ODBC	Microsoft ODBC for Oracle Oracle ODBC Driver (typically installed during the installation of your Oracle database client)
PostgreS QL	JDBC	PostgreSQL JDBC Driver (https://jdbc.postgresql.org/download.html)
	ODBC	psqlODBC (https://odbc.postgresql.org/)
	Native conne ction	Available. No drivers are required.
Progress OpenEdg	JDBC	JDBC Connector (https://www.progress.com/jdbc/openedge)
е	ODBC	ODBC Connector (https://www.progress.com/odbc/openedge)
SQLite	Native conne ction	Available. No drivers are required.
Sybase	ADO	Sybase ASE OLE DB Provider
	JDBC	jConnect™ for JDBC
	ODBC	Sybase ASE ODBC Driver
Teradata	ADO. NET	.NET Data Provider for Teradata (https://downloads.teradata.com/download/connectivity/net-data-provider-for-teradata)
	JDBC	Teradata JDBC Driver (https://downloads.teradata.com/download/connectivity/jdbc-driver)
	ODBC	Teradata ODBC Driver for Windows (https://downloads.teradata.com/download/connectivity/odbc-driver/windows)

10.2.3 ADO Connection

Microsoft ActiveX Data Objects (ADO) is a data access technology that enables you to connect to a variety of data sources through OLE DB. OLE DB is an alternative interface to ODBC or JDBC; it provides uniform access to data in a COM (Component Object Model) environment. ADO is a precursor of the newer ADO.NET 645 and is still one of the possible ways to connect to Microsoft native databases such as Microsoft Access or SQL Server, although you can also use it for other data sources.

Importantly, you can choose between multiple ADO providers, and some of them must be downloaded and installed on your workstation before you can use them. For example, for connecting to SQL Server, the following ADO providers are available:

- Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL)
- Microsoft OLE DB *Provider* for SQL Server (SQLOLEDB)
- SQL Server Native Client (SQLNCLI)

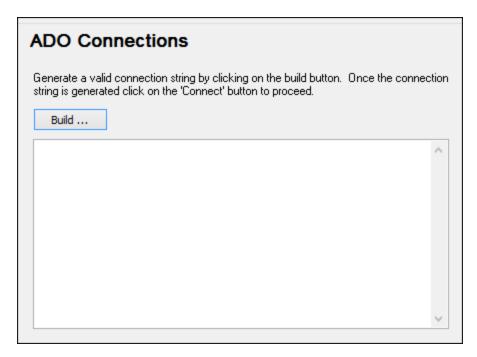

From the providers listed above, the recommended one is MSOLEDBSQL; you can download it from https://docs.microsoft.com/en-us/sql/connect/oledb/download-oledb-driver-for-sql-server?view=sql-server-ver15. Note that it must match the platform of StyleVision (32-bit or 64-bit). The SQLOLEDB and SQLNCLI providers are considered deprecated and thus are not recommended.

Note: The *Microsoft OLE DB Provider for SQL Server (SQLOLEDB)* is known to have issues with parameter binding of complex queries like Common Table Expressions (CTE) and nested SELECT statements.

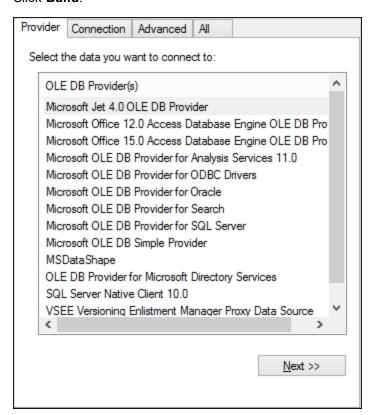

Set up an ADO connection

To set up an ADO connection, do the following:

- 1. Start the database connection wizard 634.
- 2. Click ADO Connections.

3. Click Build.

4. Select the data provider through which you want to connect. The table below lists a few common scenarios.

To connect to this database	Use this provider
Microsoft Access	 Microsoft Office Access Database Engine OLE DB Provider (recommended) Microsoft Jet OLE DB Provider
	If the Microsoft Office Access Database Engine OLE DB Provider is not available in the list, make sure that you have installed either Microsoft Access or the Microsoft Access Database Engine Redistributable (https://www.microsoft.com/en-us/download/details.aspx?id=54920) on your computer.
SQL Server	Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL) - this is the recommended OLE DB provider. In order for this provider to appear in the list, it must be downloaded from https://docs.microsoft.com/en-us/sql/connect/oledb/download-oledb-driver-for-sql-server?view=sql-server-ver15 and installed. Microsoft OLE DB Provider for SQL Server (OLEDBSQL) SQL Server Native Client (SQLNCLI)
Other database	Select the provider applicable to your database. If an OLE DB provider to your database is not available, install the required driver from the database vendor (see <u>Database Drivers</u> <u>Overview</u> Overview Overview Overview Alternatively, set up an ADO.NET, ODBC, or JDBC connection. If the operating system has an ODBC driver to the required database, you could also use the Microsoft OLE DB Provider for ODBC Drivers, or preferably opt for an ODBC connection ODBC connection ODBC Drivers.

5. Having selected the provider of choice, click **Next** and complete the wizard.

The subsequent wizard steps are specific to the provider you chose. For SQL Server, you will need to provide or select the host name of the database server, the authentication method, the database name, as well as the database username and password. For an example, see Connecting to Microsoft SQL Server (ADO) For Microsoft Access, you will be asked to browse for or provide the path to the database file. For an example, see Connecting to Microsoft Access (ADO) For Microsoft Ac

The complete list of initialization properties (connection parameters) is available in the **All** tab of the connection dialog box—these properties vary depending on the chosen provider and may need to be set explicitly in order for the connection to be possible. The following sections provide guidance on configuring the basic initialization properties for Microsoft Access and SQL Server databases:

- Setting up the SQL Server Data Link Properties 643
- Setting up the Microsoft Access Data Link Properties

10.2.3.1 Connect to an Existing MS Access Database

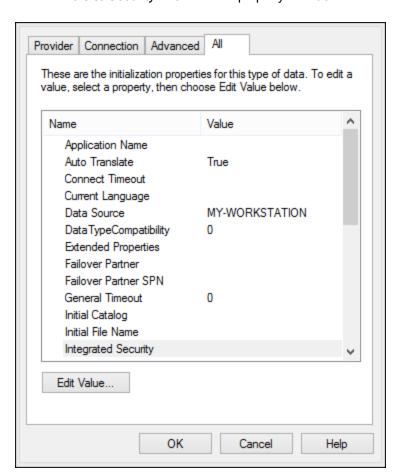

The procedure given below is suitable if you want to connect to a Microsoft Access database that is not password-protected. If the database is password-protected, use the method given in the <u>Connection Example for Microsoft Access (ADO)</u> 674.

- 1. Run the database connection wizard (see Starting the Database Connection Wizard 634).
- 2. Select Microsoft Access (ADO), and then click Next.
- 3. Browse for the database file, or enter the path to it (either relative or absolute).
- 4. Click Connect.

10.2.3.2 Set Up SQL Server Data Link Properties

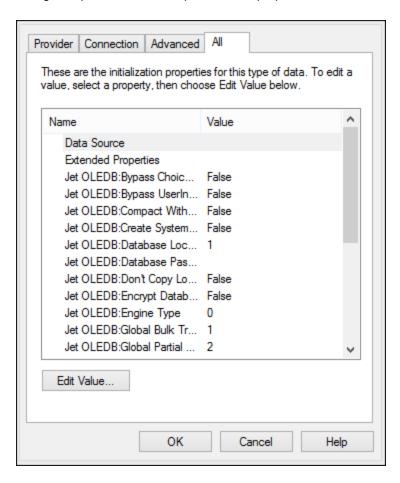

If you connect to a Microsoft SQL Server database through ADO 640, check the following properties in the All tab of the Data Link Properties dialog box (screenshot below).

- Integrated Security: If SQL Server Native Client is the data provider on the Provider tab, set this property to a space character.
- Persist Security Info: Set this property to True.

10.2.3.3 Set Up MS Access Data Link Properties

If you connect to a Microsoft Access database through ADO 640, then in the All tab of the Data Link Properties dialog box (screenshot below), check the properties listed below the screenshot.

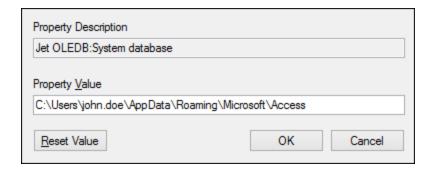

Data Source

This property stores the path to the Microsoft Access database file. We recommend using the UNC (Universal Naming Convention) path format, for example: $\$ \\anyserver\\share\\$\filepath

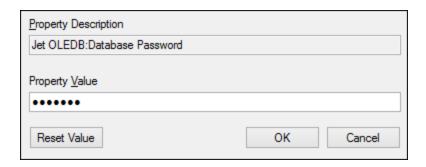

Jet OLEDB: System Database

This property stores the path to the workgroup information file. You may need to explicitly set the value of this property before you can connect to a Microsoft Access database. If you cannot connect due to a "workgroup information file" error, locate the workgroup information file (System.MDW) applicable to your user profile, and set the property value to the path of the System.MDW file.

Jet OLEDB: Database Password

If the database is password-protected, set the value of this property to the database password.

ADO.NET Connection 10.2.4

ADO.NET is a set of Microsoft .NET Framework libraries designed to interact with data, including data from databases. To connect to a database from StyleVision through ADO.NET, Microsoft .NET Framework 4 or later is required. Connect to a database through ADO.NET by selecting a .NET provider and supplying a connection string.

A .NET data provider is a collection of classes that enables connecting to a particular type of data source (for example, a SQL Server, or an Oracle database), executing commands against it, and fetching data from it. So, when you use ADO.NET, StyleVision interacts with a database through a data provider—one that is optimized to work with the specific type of data source that it is designed for.

There are two types of .NET providers:

- Supplied by default with Microsoft .NET Framework.
- Supplied by major database vendors, as an extension to the .NET Framework. Such ADO.NET providers must be installed separately and can typically be downloaded from the website of the respective database vendor.

Note: Certain ADO.NET providers are not supported or have limited support. See ADO.NET Support Notes 650.

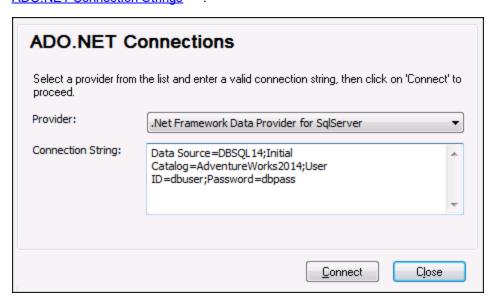

Set up the connection as follows.

- 1. Start the database connection wizard 634.
- 2. Click ADO.NET Connections.
- 3. Select a .NET data provider from the list. The list of providers available by default with the .NET Framework appears in the "Provider" list. Vendor-specific .NET data providers are available in the list only if they are already installed on your system. To become available, vendor-specific .NET providers must be installed into the GAC (Global Assembly Cache) by running the .msi or .exe file supplied by the database vendor.
- 4. Enter a database connection string. A connection string defines the database connection information as semicolon-delimited key/value pairs of connection parameters. For example, a connection string such as Data Source=DBSQLSERV; Initial Catalog=ProductsDB; User

 ID=dbuser; Password=dbpass connects to the SQL Server database ProductsDB on server

 DBSQLSERV, with the user name dbuser and password dbpass. You can create a connection string by typing the key/value pairs directly into the "Connection String" dialog box. Another option is to create it with Visual Studio (see Creating a Connection String in Visual Studio (36)). The syntax of the connection string depends on the provider selected from the "Provider" list. For examples, see Sample ADO.NET Connection Strings

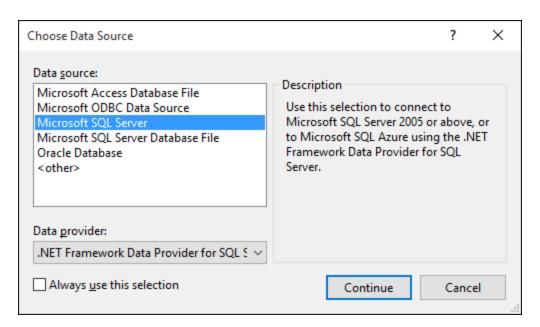

5. Click Connect.

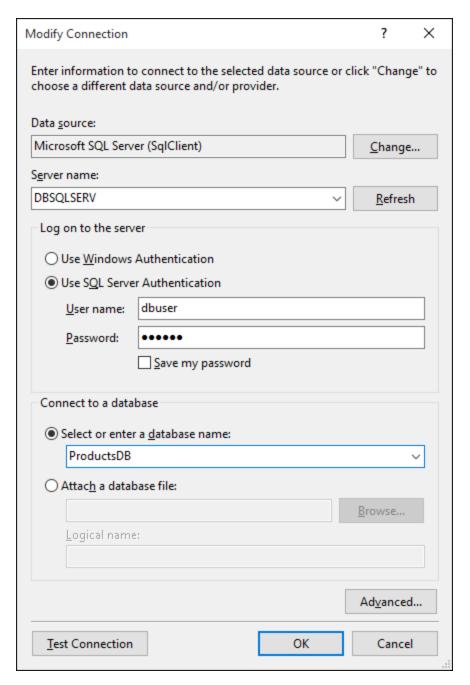

10.2.4.1 Creating a Connection String in Visual Studio

In order to connect to a data source using ADO.NET, a valid database connection string is required. The following instructions show you how to create a connection string from Visual Studio.

- 1. On the Tools menu, click Connect to Database.
- 2. Select a data source from the list (in this example, Microsoft SQL Server). The Data Provider is filled automatically based on your choice.

3. Click Continue.

- 4. Enter the server host name and the user name and password to the database. In this example, we are connecting to the database ProductsDB on server DBSQLSERV, using SQL Server authentication.
- 5. Click OK.

If the database connection is successful, it appears in the Server Explorer window. You can display the Server Explorer window using the menu command **View | Server Explorer**. To obtain the database connection string, right-click the connection in the Server Explorer window, and select **Properties**. The connection string is now displayed in the Properties window of Visual Studio. Note that, before pasting the string into the "Connection String" box of StyleVision, you will need to replace the asterisk (*) characters with the actual password.

10.2.4.2 Sample ADO.NET Connection Strings

To set up an ADO.NET connection, you need to select an ADO.NET provider from the database connection dialog box and enter a connection string (see also <u>Setting up an ADO.NET Connection</u> GAS). Sample ADO.NET connection strings for various databases are listed below under the .NET provider where they apply.

.NET Data Provider for Teradata

This provider can be downloaded from Teradata website

(https://downloads.teradata.com/download/connectivity/net-data-provider-for-teradata). A sample connection string looks as follows:

Data Source=ServerAddress; User Id=user; Password=password;

.NET Framework Data Provider for IBM i

This provider is installed as part of *IBM i Access Client Solutions - Windows Application Package*. A sample connection string looks as follows:

DataSource=ServerAddress; UserID=user; Password=password; DataCompression=True;

For more information, see the ".NET Provider Technical Reference" help file included in the installation package above.

.NET Framework Data Provider for MySQL

This provider can be downloaded from MySQL website (https://dev.mysql.com/downloads/connector/net/). A sample connection string looks as follows:

Server=127.0.0.1; Uid=root; Pwd=12345; Database=test;

See also: $\frac{https://dev.mysql.com/doc/connector-net/en/connector-net-programming-connecting-connection-string.html}{}$

.NET Framework Data Provider for SQL Server

A sample connection string looks as follows:

```
Data Source=DBSQLSERV; Initial Catalog=ProductsDB; User ID=dbuser; Password=dbpass
```

See also: https://msdn.microsoft.com/en-us/library/ms254500(v=vs.110).aspx

IBM DB2 Data Provider 10.1.2 for .NET Framework 4.0

A sample connection string looks as follows:

```
Database=PRODUCTS; UID=user; Password=password; Server=localhost:50000;
```

Note: This provider is typically installed with the IBM DB2 Data Server Client package. If the provider is missing from the list of ADO.NET providers after installing IBM DB2 Data Server Client package, refer to the following technical note: https://www-01.ibm.com/support/docview.wss?uid=swg21429586. See also: https://www.ibm.com/support/knowledgecenter/en/SSEPGG_10.1.0/com.ibm.swg.im.dbclient.adonet.ref.doc/doc/DB2ConnectionClassConnectionStringProperty.html

Oracle Data Provider for .NET (ODP.NET)

The installation package which includes the ODP.NET provider can be downloaded from the Oracle website (see http://www.oracle.com/technetwork/topics/dotnet/downloads/index.html). A sample connection string looks as follows:

Data Source=DSORCL; User Id=user; Password=password;

where DSORCL is the name of the data source which points to an Oracle service name defined in the tnsnames.ora file, as described in Connecting to Oracle (ODBC) 685.

To connect without configuring a service name in the tnsnames.ora file, use a string such as:

```
Data Source=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP) (HOST=host) (PORT=port)))
(CONNECT_DATA=(SERVER=DEDICATED) (SERVICE_NAME=MyOracleSID)));User
Id=user;Password=password;
```

See also: https://docs.oracle.com/cd/B28359_01/win.111/b28375/featConnecting.htm.

10.2.4.3 ADO.NET Support Notes

The following table lists known ADO.NET database drivers that are currently not supported or have limited support in StyleVision.

Database	Driver	Support notes
All databases	.Net Framework Data Provider for ODBC	Limited support. Known issues exist with Microsoft Access connections. It is recommended to use ODBC direct connections instead.
	.Net Framework Data Provider for OleDb	Limited support. Known issues exist with Microsoft Access connections. It is recommended to use ADO direct connections instead.
Firebird	Firebird ADO.NET Data Provider	Limited support. It is recommended to use ODBC or JDBC instead.
Informix	IBM Informix Data Provider for .NET Framework 4.0	Not supported. Use DB2 Data Server Provider instead.
IBM DB2 for i (iSeries)	.Net Framework Data Provider for i5/OS	Not supported. Use .Net Framework Data Provider for IBM i instead, installed as part of the IBM i Access Client Solutions - Windows Application Package.
Oracle	.Net Framework Data Provider for Oracle	Limited support. Although this driver is provided with the .NET Framework, its usage is discouraged by Microsoft, because it is deprecated.
PostgreSQL	_	No ADO.NET drivers for this vendor are supported. Use a native connection instead.

Database	Driver	Support notes
Sybase	_	No ADO.NET drivers for this vendor are supported.

10.2.5 JDBC Connection

JDBC (Java Database Connectivity) is a database access interface which is part of the Java software platform from Oracle. JDBC connections are generally more resource-intensive than ODBC connections but may provide features not available through ODBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; ; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC drivers from the database vendor must be installed. These may be JDBC drivers installed as part of a database client installation, or supported JDBC libraries (.jar files) that are downloaded separately. See also <u>Database Connection Examples</u>.
- The CLASSPATH environment variable must include the path to the JDBC driver (one or several .jar files) on your Windows operating system. When you install some database clients, the installer may configure this variable automatically. See also Configuring the CLASSPATH 653.

Connect to SQL Server via JDBC with Windows credentials.

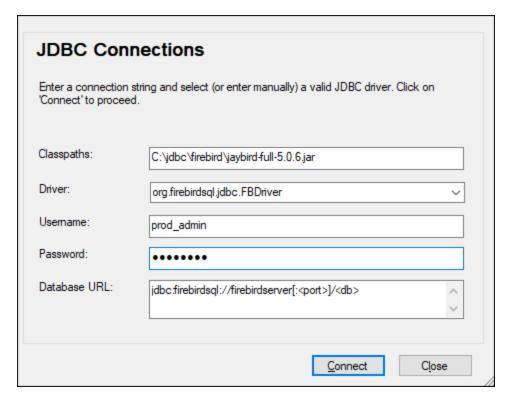

If you connect to SQL Server through JDBC with Windows credentials (integrated security), note the following:

- The sqljdbc_auth.dll file included in the JDBC driver package must be copied to a directory that is on the system PATH environment variable. There are two such files, one for the x86 and one for x64 platform. Make sure that you add to the PATH the one that corresponds to your JDK platform.
- The JDBC connection string must include the property integratedSecurity=true.

For further information, refer to *Microsoft JDBC driver for SQL Server* documentation, https://docs.microsoft.com/en-us/sql/connect/jdbc/building-the-connection-url.

Set up a JDBC connection

- 1. Start the database connection wizard 634 and click JDBC Connections.
- 2. If required, enter a semicolon-separated list of .jar file paths in the *Classpaths* field. The .jar libraries entered here will be loaded into the environment in addition to those already defined in the CLASSPATH environment variable. JDBC drivers found in the source .jar libraries referenced via the Classpaths field and the system's CLASSPATH are listed in the Driver dropdown list (see next step).

3. In the *Driver* field, select a JDBC driver from the list or enter a Java class name. The list will contain the JDBC drivers configured through in the *Classpaths* field (see above) and the <u>CLASSPATH</u> environment variable.

The JDBC driver paths defined in the CLASSPATH variable, as well as any .jar file paths entered directly in the database connection dialog box are all supplied to the Java Virtual Machine (JVM). The JVM then decides which drivers to use in order to establish a connection. It is recommended that you keep track of Java classes loaded into the JVM so as not to create potential JDBC driver conflicts and avoid unexpected results when connecting to the database.

- 4. Enter the username and password of the database in the corresponding fields.
- 5. In the *Database URL* field, enter the JDBC connection URL (JDBC connection string) in the format specific to your database type. The following table describes the syntax of JDBC connection strings for common database types.

Database	JDBC Connection URL
Firebird	<pre>jdbc:firebirdsql://<host>[:<port>]/<database alias="" or="" path=""></database></port></host></pre>
IBM DB2	jdbc:db2://hostName:port/databaseName
IBM DB2 for i	jdbc:as400://[host]
IBM Informix	jdbc:informix- sqli://hostName:port/databaseName:INFORMIXSERVER=myserver

Database	JDBC Connection URL
MariaDB	jdbc:mariadb://hostName:port/databaseName
Microsoft SQL Server	jdbc:sqlserver://hostName:port;databaseName=name
MySQL	jdbc:mysql://hostName:port/databaseName
Oracle	<pre>jdbc:oracle:thin:@hostName:port:SID jdbc:oracle:thin:@//hostName:port/service</pre>
Oracle XML DB	jdbc:oracle:oci:@//hostName:port:service
PostgreSQL	jdbc:postgresql://hostName:port/databaseName
Progress OpenEdge	jdbc:datadirect:openedge://host:port;databaseName=db_name
Sybase	jdbc:sybase:Tds:hostName:port/databaseName
Teradata	jdbc:teradata://databaseServerName

Note that syntax variations of the formats listed above are also possible. For example, the database URL may exclude the port or may include the username and password of the database. Check the documentation of the database vendor for further details.

6. Click Connect.

10.2.5.1 Configuring the CLASSPATH

The CLASSPATH environment variable is used by the Java Runtime Environment (JRE) or the Java Development Kit (JDK) to locate Java classes and other resource files on your operating system. When you connect to a database through JDBC, this variable must be configured to include the path to the JDBC driver on your operating system, and, in some cases, the path to additional library files specific to the database type you are using.

The following table lists sample file paths that must be typically included in the CLASSPATH variable. Importantly, you may need to adjust this information based on the location of the JDBC driver on your system, the JDBC driver name, as well as the JRE/JDK version present on your operating system. To avoid connectivity problems, check the installation instructions and any pre-installation or post-installation configuration steps applicable to the JDBC driver installed on your operating system.

Database	Sample CLASSPATH entries
Firebird	C:\Program Files\Firebird\Jaybird-2.2.8-JDK_1.8\jaybird-full-2.2.8.jar
IBM DB2	<pre>C:\Program Files (x86)\IBM\SQLLIB\java\db2jcc.jar;C:\Program Files (x86)\IBM\SQLLIB\java\db2jcc_license_cu.jar;</pre>
IBM DB2 for i	C:\jt400\jt400.jar;
IBM Informix	<pre>C:\Informix_JDBC_Driver\lib\ifxjdbc.jar;</pre>

Database	Sample CLASSPATH entries
Microsoft SQL Server	C:\Program Files\Microsoft JDBC Driver 4.0 for SQL Server\sqljdbc_4.0\enu\sqljdbc.jar
MariaDB	<pre><installation directory="">\mariadb-java-client-2.2.0.jar</installation></pre>
MySQL	<pre><installation directory="">\mysql-connector-java-Version-bin.jar;</installation></pre>
Oracle	<pre>ORACLE_HOME\jdbc\lib\ojdbc6.jar;</pre>
Oracle (with XML DB)	<pre>ORACLE_HOME\jdbc\lib\ojdbc6.jar;ORACLE_HOME\LIB\xmlparserv2.jar; ORACLE_HOME\RDBMS\jlib\xdb.jar;</pre>
PostgreSQL	<pre><installation directory="">\postgresql.jar</installation></pre>
Progress OpenEdge	%DLC%\java\openedge.jar;%DLC%\java\pool.jar;
	Note: Assuming the Progress OpenEdge SDK is installed on the machine, % DLC% is the directory where OpenEdge is installed.
Sybase	C:\sybase\jConnect-7_0\classes\jconn4.jar
Teradata	<pre><installation directory="">\tdgssconfig.jar;<installation directory="">\terajdbc4.jar</installation></installation></pre>

Note the following points:

- The CLASSPATH setting is available in the Environment Variables setting of your Windows system. Include in the CLASSPATH the path where the JDBC driver is located, separating it from other paths by a semi-colon.
- Changing the CLASSPATH variable may affect the behavior of Java applications on your machine. To understand possible implications before you proceed, refer to the Java documentation.
- Environment variables can be user or system. To change system environment variables, you need administrative rights on the operating system.
- After you change the environment variable, restart any running programs for settings to take effect. Alternatively, log off or restart your operating system.

10.2.6 ODBC Connection

ODBC (Open Database Connectivity) is a widely used data access technology that enables you to connect to a database from StyleVision. It can be used either as primary means to connect to a database, or as an alternative to native, OLE DB, or JDBC-driven connections.

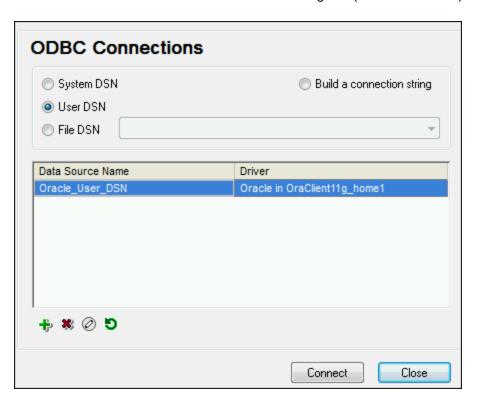

To connect to a database through ODBC, first you need to create an ODBC data source name (DSN) on the operating system. This step is not required if the DSN has already been created, perhaps by another user of the operating system. The DSN represents a uniform way to describe the database connection to any ODBC-aware client application on the operating system, including StyleVision. DSNs can be of the following types:

System DSN

- User DSN
- File DSN

A *System* data source is accessible by all users with privileges on the operating system. A *User* data source is available to the user who created it. Finally, if you create a *File DSN*, the data source will be created as a file with the .dsn extension which you can share with other users, provided that they have installed the drivers used by the data source.

Any DSNs already available on your machine are listed by the database connection dialog box when you click **ODBC connections** on the ODBC connections dialog box (*screenshot below*).

If a DSN to the required database is not available, the StyleVision database connection wizard will assist you to create it; however, you can also create it directly on your Windows operating system. In either case, before you proceed, ensure that the ODBC driver applicable for your database is in the list of ODBC drivers available to the operating system (see <u>Viewing the Available ODBC Drivers</u>).

Connect with a new DSN

To connect with a new DSN, carry out the following steps. Note that, to create a System DSN, you need administrative rights on the operating system and StyleVision must be run as administrator..

- 1. Start the database connection wizard 634.
- 2. On the database connection dialog box, click **ODBC Connections**.
- 3. Select a data source type (User DSN, System DSN, File DSN).
- 4. Click Add *.
- 5. Select a driver, and then click **User DSN** or **System DSN** (depending on the type of the DSN you want to create). If the driver applicable to your database is not listed, download it from the database vendor and install it (see <u>Database Drivers Overview</u>).

6. On the dialog box that pops up, fill in any driver specific connection information to complete the setup.

For the connection to be successful, you will need to provide the host name (or IP address) of the database server, as well as the database username and password. There may be other optional connection parameters—these parameters vary between database providers. For detailed information about the parameters specific to each connection method, consult the documentation of the driver provider. Once created, the DSN becomes available in the list of data source names. This enables you to reuse the database connection details any time you want to connect to the database. Note that User DSNs are added to the list of User DSNs whereas System DSNs are added to the list of System DSNs.

Connect with an existing DSN

To connect with an existing DSN, do the following.

- 1. Start the database connection wizard 634.
- 2. Click ODBC Connections.
- 3. Choose the type of the existing data source (User DSN, System DSN, File DSN).
- 4. Click the existing DSN record, and then click Connect.

Build a connection string based on an existing .dsn file

Do this as follows.

- 1. Start the database connection wizard 634.
- 2. Click ODBC Connections.
- 3. Select Build a connection string and then click Build.
- 4. If you want to build the connection string using a File DSN, click the *File Data Source* tab. Otherwise, click the *Machine Data Source* tab. (System DSNs and User DSNs are known as "Machine" data sources.)
- 5. Select the required .dsn file, and then click **OK**.

Connect by using a prepared connection string

Do this as follows.

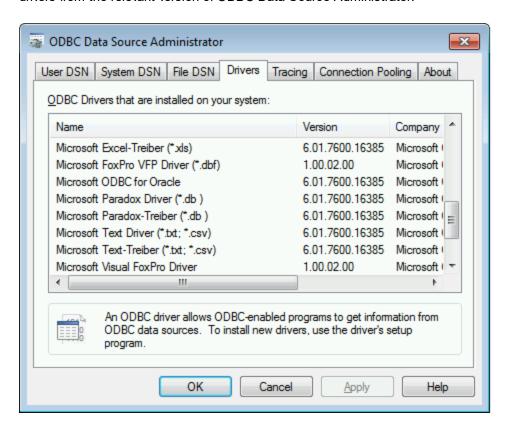

- 1. Start the database connection wizard 634.
- 2. Click ODBC Connections.
- 3. Select Build a connection string.
- 4. Paste the connection string into the provided box, and then click **Connect**.

10.2.6.1 Available ODBC Drivers

You can view the ODBC drivers available on your operating system in the ODBC Data Source Administrator. You can access the ODBC Data Source Administrator (odbcad32.exe) from the Windows Control Panel, under Administrative Tools. On 64-bit operating systems, there are two versions of this executable:

- The 32-bit version of the odbcad32.exe file is located in the c:\windows\Syswow64 directory (assuming that c: is your system drive).
- The 64-bit version of the odbcad32.exe file is located in the C:\Windows\System32 directory.

Any installed 32-bit database drivers are visible in the 32-bit version of ODBC Data Source Administrator (*screenshot below*), while 64-bit drivers—in the 64-bit version. Therefore, ensure that you check the database drivers from the relevant version of ODBC Data Source Administrator.

If the driver to your target database does not exist in the list, or if you want to add an alternative driver, you will need to download it from the database vendor (see <u>Database Drivers Overview</u> 636). Once the ODBC driver is available on your system, you are ready to create ODBC connections with it (see <u>Setting up an ODBC</u> Connection 654).

10.2.7 SQLite Connection

<u>SQLite</u> is a file-based, self-contained database type, which makes it ideal in scenarios where portability and ease of configuration is important. Since SQLite databases are natively supported by StyleVision, you do not need to install any drivers to connect to them.

SQLite database support notes

- On Linux, statement execution timeout for SQLite databases is not supported.
- Full text search tables are not supported.
- SQLite allows values of different data types in each row of a given table. All processed values must be
 compatible with the declared column type; therefore, unexpected values can be retrieved and run-time
 errors may occur if your SQLite database has row values which are not the same as the declared
 column type.

Important: It is recommended to create tables with the STRICT keyword to ensure more predictable behavior of your data. Otherwise, the data may not be read or written correctly when values of different types are mixed in one column. To find out more about STRICT tables, see the <u>SQLite documentation</u>.

10.2.7.1 Connect to an Existing SQLite Database

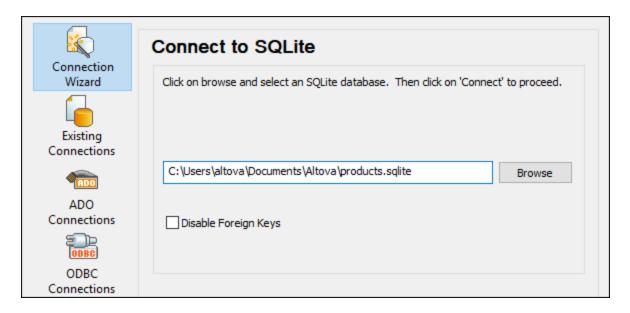

To connect to an existing SQLite database, do the following.

- 1. Run the database connection wizard (see Starting the Database Connection Wizard 634).
- 2. Select **SQLite**, and then click **Next**.
- 3. Browse for the SQLite database file, or enter the path (either relative or absolute) to the database. The **Connect** button becomes enabled once you enter the path to a SQLite database file. Optionally, select the **Disable Foreign Keys** check box, see <u>Foreign Key Constraints</u> 653.
- 4. Click Connect.

10.2.7.2 Foreign Key Constraints

When you connect to an existing SQLite database from StyleVision, foreign key constraints are enabled by default. Foreign key constraints help preserve the integrity of data in your database. For example, when foreign keys are enabled, it is not possible to delete a record from a table if it has dependencies in another table.

In certain cases, you may want to temporarily override this behavior and disable foreign keys, perhaps, in order to update or insert multiple rows of data without getting data validation errors. To explicitly disable foreign keys before connecting to the SQLite database, select the **Disable Foreign Keys** option available on the database connection wizard.

When foreign keys are disabled, you will be able to perform operations on data that would otherwise not be possible due to validation checks. At the same time, however, there is also the risk of introducing incorrect data into the database, or creating "orphaned" rows. (An example of an "orphaned" row would be an address in

the "addresses" table not linked to any person in the "person" table, because the person was deleted but its associated address was not.)

10.2.8 Native Connections

Native connections are direct connections to a database's own network protocols and drivers. Therefore, no additional drivers need to be installed. Native connections provide the most efficient method of interacting with the database and full feature support.

If you intend to deploy files for execution on a Linux or macOS server, you do not need to install drivers on the target server.

You can set up native connections to the following DBs:

- MariaDB
- MvSQL
- SQLite
- PostgreSQL

Connection setup

To set up a native connection, follow the steps below:

- 1. Start the database connection wizard 634.
- 2. Select the DB you want to connect to.
- 3. In the dialog that appears, enter the relevant connection details, for example, the host (e.g., *localhost*), optionally the port (typically 5432), SSL Mode in the case of MySQL, the database name, username, and password in the corresponding boxes.
- 4. Click Connect.

SQLite conections

For detailed information about SQLite connections, see the topic SQLite Connection 657.

Notes for PostrgreSQL

If the PostgreSQL database server is on a different machine, note the following:

- The PostgreSQL database server must be configured to accept connections from clients. Specifically, the pg_hba.conf file must be configured to allow non-local connections. Secondly, the postgresql.conf file must be configured to listen on specified IP address(es) and port. For more information, check the PostgreSQL documentation (https://www.postgresql.org/docs/9.5/static/client-authentication-problems.html).
- The server machine must be configured to accept connections on the designated port (typically, 5432) through the firewall. For example, on a database server running on Windows, a rule may need to be created to allow connections on port 5432 through the firewall, from Control Panel > Windows Firewall > Advanced Settings > Inbound Rules.

10.2.9 Global Resources

After you have created a database as a global resource, its connection details are stored and can be used across all Altova products installed on your machine.

Create a database as a global resource

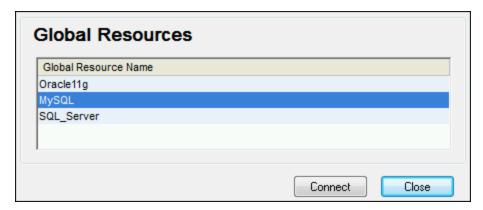

To create a database as a global resource, do the following

- 1. On the Tools menu of StyleVision, click Global Resources.
- 2. Click Add, and then click Database.
- 3. Type in a name for the global resource in the Resource Alias field.
- 4. Click **Choose Database**. The <u>Connection Wizard</u> appears.
- 5. Use the Connection Wizard to add a database connection as described above.

Use a global-resource database

To use a database that has been created as a global resource (see above), do the following:

- 1. Start the Connection Wizard as described above.
- 2. Select Global Resources. All the databases that have been created as global resources will be listed by their names in the Global Resources pane (see screenshot below).

3. Select the global resource that you want. Tip: Move the mouse cursor over a global resource in the list to see information about the database.

10.2.10 Database Connection Examples

This section includes examples for connecting to a database from StyleVision through ADO, ODBC, or JDBC. The ADO.NET connection examples are listed separately, see <u>Sample ADO.NET Connection Strings</u> ⁶⁴⁹. For instructions about establishing a native connection to PostgreSQL and SQLite, see <u>Setting up a PostgreSQL Connection</u> ⁶⁵⁹ and <u>Setting up a SQLite Connection</u> ⁶⁵⁹, respectively.

Note the following points:

• The instructions may differ if your Windows configuration, network environment and the database client or server software are not the same as the ones described in each example.

• For most database types, it is possible to connect using more than one data access technology (ADO, ADO.NET, ODBC, JDBC) or driver. The performance of the database connection, as well as its features and limitations will depend on the selected driver, database client software (if applicable), and any additional connectivity parameters that you may have configured outside StyleVision.

10.2.10.1 Firebird (JDBC)

This example illustrates how to connect to a Firebird database via JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; ; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The Firebird JDBC driver must be available on your operating system (it takes the form of a .jar file which provides connectivity to the database). The driver can be downloaded from the Firebird website (https://www.firebirdsql.org/). This example uses Jaybird 5.0.6.
- You have the following database connection details: host, port, database path, name, or alias, username, and password.

Connection

- 1. <u>Start the database connection wizard</u> and click **JDBC Connections** (see <u>JDBC Connection</u> for a screenshot of the dialog).
- 2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have added the filepath to the CLASSPATH 653 of the system, you can leave this field empty.
- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.
- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the Firebird example

Field	Value
Classpaths	C:\jdbc\firebird\jaybird-full-5.0.6.jar
Driver	org.firebirdsql.jdbc.FBDriver
Database URL	jdbc:firebirdsql:// <host>[:<port>]/<database alias="" or="" path=""></database></port></host>

10.2.10.2 Firebird (ODBC)

This example illustrates how to connect to a Firebird 2.5.4 database running on a Linux server.

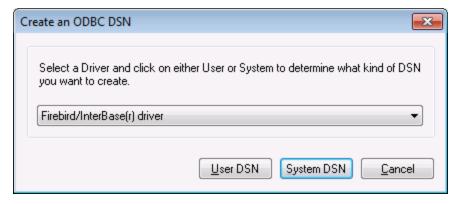

Prerequisites

- The Firebird database server is configured to accept TCP/IP connections from clients.
- The Firebird ODBC driver must be installed on your operating system. This example uses the Firebird ODBC driver version 2.0.3.154 downloaded from the <u>Firebird website</u>.
- The Firebird client must be installed on your operating system. Note that there is no standalone installer available for the Firebird 2.5.4 client; the client is part of the Firebird server installation package. You can download the Firebird server installation package from the Firebird website. Look for Windows executable installer for full Superclassic/Classic or Superserver. To install only the client files, choose Minimum client install no server, no tools when going through the wizard steps.
- You have the following database connection details: server host name or IP address, database path (or alias) on the server, user name, and password.

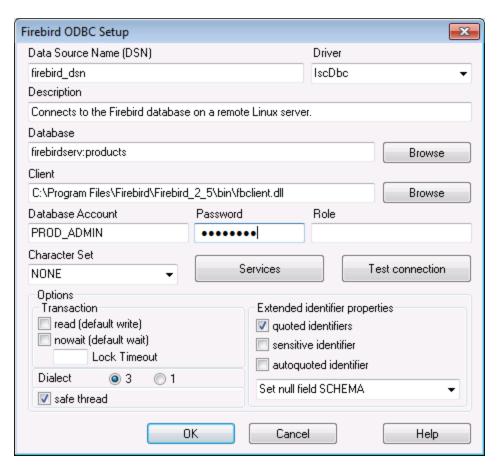

Important: The platform of both the Firebird ODBC driver and client (32-bit or 64-bit) must correspond to that of StyleVision. Additionally, the version of the Firebird client must correspond to the version of Firebird server to which you are connecting.

Connection

- 1. Start the database connection wizard 634 and click ODBC Connections.
- 2. Select *User DSN* (or *System DSN* if you have administrative privileges), and then click **Create a New DSN** .

3. Select the Firebird driver, and then click *User DSN* or *System DSN*, depending on what you selected in the previous step. If the Firebird driver is not available in the list, make sure that it is installed on your operating system (see also <u>Viewing the Available ODBC Drivers</u> 655).

4. Enter the database connection details as follows:

Data Source Name (DSN)	Enter a descriptive name for the data source you are creating.
Database	Enter the server host name or IP address, followed by a colon, followed by the database alias (or path). In this example, the host name is firebirdserv, and the database alias is products, as follows:
	firebirdserv:products
	Using a database alias assumes that, on the server side, the database administrator has configured the alias <i>products</i> to point to the actual Firebird (.fdb) database file on the server (see the Firebird documentation for more details).
	You can also use the server IP address instead of the host name, and a path instead of an alias; therefore, any of the following sample connection strings are valid:
	firebirdserver:/var/Firebird/databases/butterflies.fdb 127.0.0.1:D:\Misc\Lenders.fdb

	If the database is on the local Windows machine, click Browse and select the Firebird (.fdb) database file directly.
Client	Enter the path to the fbclient.dll file. By default, this is the bin subdirectory of the Firebird installation directory.
Database Account	Enter the database user name supplied by the database administrator (in this example, PROD_ADMIN).
Password	Enter the database password supplied by the database administrator.

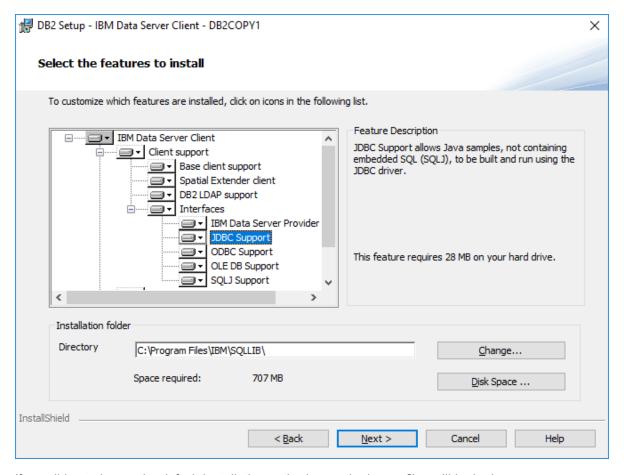

5. Click **OK** to finish.

10.2.10.3 IBM DB2 (JDBC)

This example illustrates how to connect to an IBM DB2 database server via JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; ; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC driver (one or several .jar files that provide connectivity to the database) must be available on your operating system. This example uses the JDBC driver available after installing the IBM Data Server Client version 10.1 (64-bit). For the JDBC drivers to be installed, choose a *Typical* installation, or select this option explicitly on the installation wizard.

If you did not change the default installation path, the required .jar files will be in the C:\Program Files\IBM\SQLLIB\java directory after installation.

• You have the following database connection details: host, port, database path, name, or alias, username, and password.

Connection

- 1. Start the database connection wizard and click JDBC Connections (see <u>JDBC Connection</u> for a screenshot of the dialog).
- 2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have <u>added the filepath to the CLASSPATH</u> of the system, you can leave this field empty.
- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.
- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the IBM DB2 example

Field Va	ue
----------	----

Classpaths	C:\Program Files\IBM\SQLLIB\java\db2jcc.jar
Driver	com.ibm.db2.jcc.DB2Driver
Database URL	jdbc:db2://hostName:port/databaseName

10.2.10.4 IBM DB2 (ODBC)

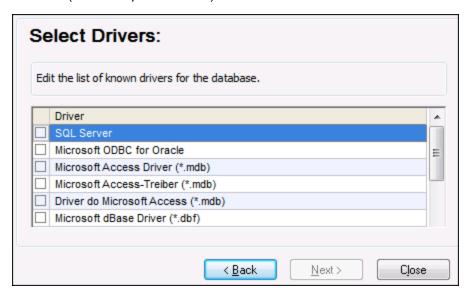

This example illustrates how to connect to an IBM DB2 database via ODBC.

Prerequisites

- IBM Data Server Client must be installed and configured on your operating system (this example uses IBM Data Server Client 9.7). For installation instructions, check the documentation supplied with your IBM DB2 software. After installing the IBM Data Server Client, check if the ODBC drivers are available on your machine (see <u>Viewing the Available ODBC Drivers</u> 655).
- Create a database alias. There are several ways to do this:
 - o From IBM DB2 Configuration Assistant
 - o From IBM DB2 Command Line Processor
 - From the ODBC data source wizard (for this case, the instructions are shown below)
- You have the following database connection details: host, database, port, username, and password.

Connection

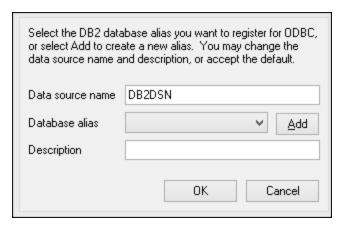

- 1. Start the database connection wizard 634, select Connection Wizard and then IBM DB2 (ODBC/JDBC). Click Next.
- 2. Select ODBC and click Next.
- 3. If prompted to edit the list of known drivers for the database, select the database drivers applicable to IBM DB2 (see *Prerequisites* above) and click **Next**.

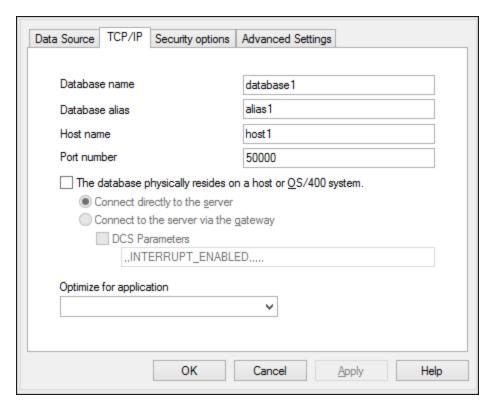

4. Select the IBM DB2 driver you want from the list, and then click **Connect**. (To edit the list of available drivers, click **Edit Drivers**, and then check or uncheck the IBM DB2 drivers you wish to add or remove, respectively.)

5. Enter a data source name (in the screenshot below, DB2DSN), and then click Add.

- 6. On the *Data Source* tab, enter the user name and password for the database.
- 7. On the *TCP/IP* tab, enter the database name, a name for the alias, the host name, and the port number, and then click **OK**.

8. Enter the username and password again, and then click **OK**.

10.2.10.5 IBM DB2 for i (JDBC)

This example illustrates how to connect to an IBM DB2 for i database server via JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; ; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC driver (one or several .jar files that provide connectivity to the database) must be available on your operating system. This example uses the open source Toolbox for Java/JTOpen version 9.8 (http://jt400.sourceforge.net/). After you download the package and unpack to a local directory, the required .jar files will be available in the lib subdirectory.
- You have the following database connection details: host, port, database path, name, or alias, username, and password.

Connection

1. Start the database connection wizard 634 and click JDBC Connections (see <u>JDBC Connection</u> 651 for a screenshot of the dialog).

2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have <u>added the filepath to the CLASSPATH 653</u> of the system, you can leave this field empty.

- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.
- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the IBM DB2 for i example

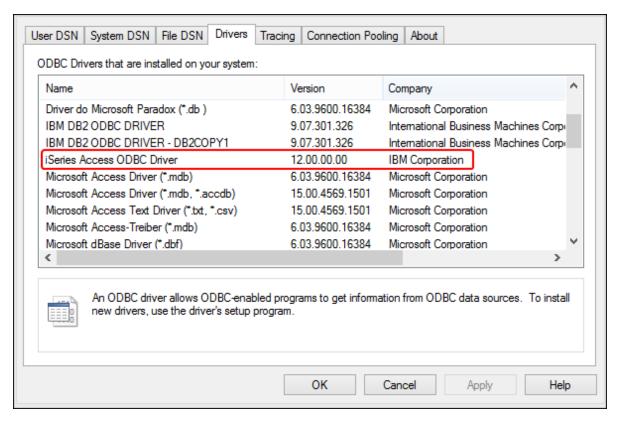

Field	Value
Classpaths	C:\jdbc\jtopen_9_8\jt400.jar
Driver	com.ibm.as400.access.AS400JDBCDriver
Database URL	jdbc:as400://host[: <port>]/<database alias="" or="" path=""></database></port>

10.2.10.6 IBM DB2 for i (ODBC)

This example illustrates how to connect to an *IBM DB2 for i* database via ODBC.

Prerequisites

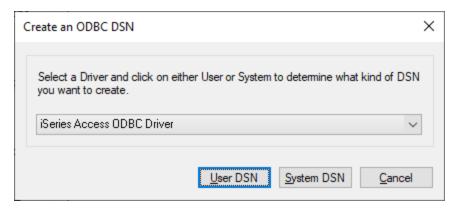

• *IBM System i Access for Windows* must be installed on your operating system. For installation instructions, check the documentation supplied with your *IBM DB2 for i* software. After installation, check if the ODBC driver is available on your machine 655.

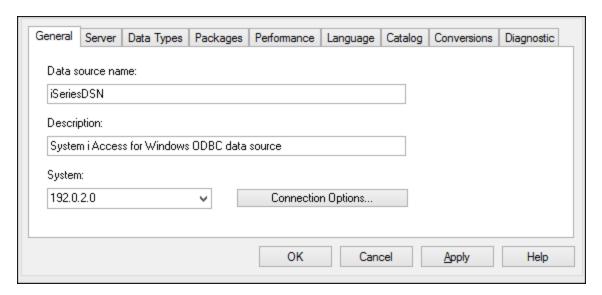

- You have the following database connection details: the IP address of the database server, and the database user name and password.
- Run System i Navigator and follow the wizard to create a new connection. When prompted to specify a system, enter the IP address of the database server. After creating the connection, verify the connection by click it and selecting File | Diagnostics | Verify Connection.

Connection

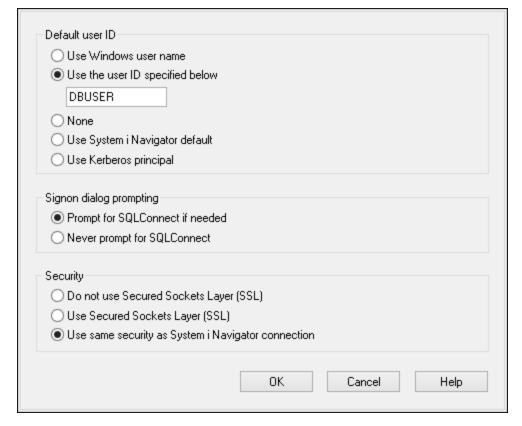

- 1. Start the database connection wizard 634 and click ODBC Connections.
- 2. Click User DSN. and click Create a New DSN **.
- 3. Select iSeries Access ODBC Driver from the list, and click User DSN (or System DSN if applicable).

4. Enter a data source name and select the connection from the System combo box. In this example, the data source name is iSeriesDSN and the System is 192.0.2.0.

5. Click **Connection Options**, select *Use the User ID Specified Below* and enter the name of the database user (in this example, *DBUSER*).

- 6. Click **OK**. The new data source becomes available in the list of DSNs.
- 7. Click Connect.
- 8. Enter the user name and password to the database when prompted, and then click **OK**.

10.2.10.7 IBM Informix (JDBC)

This example illustrates how to connect to an IBM Informix database server via JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; ; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC driver (one or several .jar files that provide connectivity to the database) must be available on your operating system. In this example, IBM Informix JDBC driver version 3.70 is used. For the driver's installation instructions, see the documentation accompanying the driver or the "IBM Informix JDBC Driver Programmer's Guide").
- You have the following database connection details: host, name of the Informix server, database, port, username, and password.

Connection

- 1. Start the database connection wizard and click JDBC Connections (see <u>JDBC Connection</u> for a screenshot of the dialog).
- 2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have added the filepath to the CLASSPATH of the system, you can leave this field empty.
- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.
- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the IBM Informix example

Field	Value
Classpaths	C:\Informix_JDBC_Driver\lib\ifxjdbc.jar
Driver	com.informix.jdbc.IfxDriver
Database URL	<pre>jdbc:informix- sqli://hostName:port/databaseName:INFORMIXSERVER=myserver;</pre>

10.2.10.8 MariaDB (ODBC)

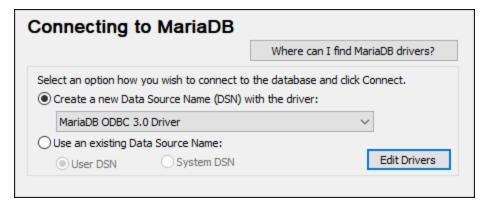

This example illustrates how to connect to a MariaDB database server via ODBC.

Prerequisites

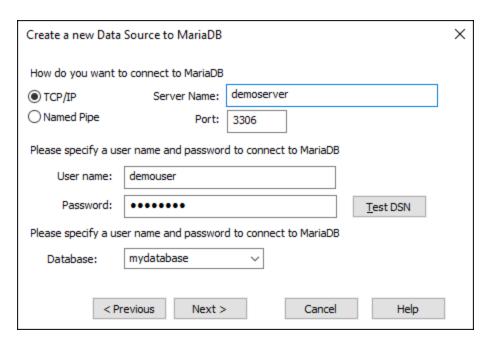

- The MariaDB ODBC Connector must be installed.
- You have the following database connection details: host, database, port, username, and password.

Connection

- 1. <u>Start the database connection wizard</u> 634, select **Connection Wizard** and then *MariaDB* (ODBC/Native). Click **Next**.
- Select Create a new Data Source Name (DSN) with the driver, and choose MariaDB ODBC 3.0 Driver. (If no such driver is available in the list, click Edit Drivers, and select any available MariaDB driver from the the list of ODBC drivers installed on your system.) Click Connect. to start the New Data Source Wizard.

- 3. In the first screen of the wizard, enter a name for the data source, optionally, a description to help you identify this ODBC data source in the future, and click **OK**.
- 4. In the next screen (screenshot below), fill in the database connection credentials (TCP/IP Server, User Name, and Password), select a database, and click **Test DSN**.

 Upon successful connection, a message to that effect is displayed. Click **Next** and complete the wizard. Other parameters may be required, for example, SSL certificates if you are connecting to MariaDB via a secure connection.

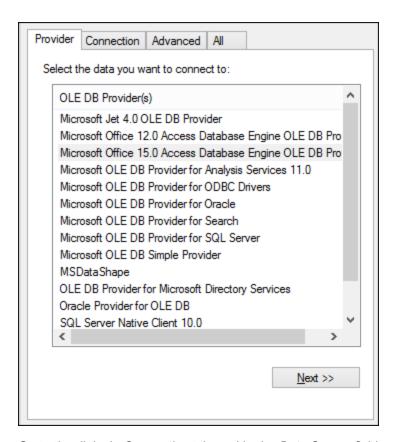

Note: If the database server is remote, it must be configured by the server administrator to accept remote connections from your machine's IP address.

10.2.10.9 Microsoft Access (ADO)

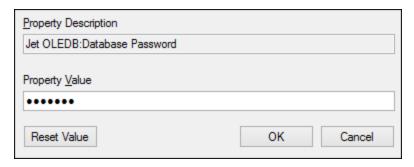

A simple way to connect to a Microsoft Access database is to follow the wizard and browse for the database file, as shown in <u>Connecting to an Existing Microsoft Access Database</u>. An alternative approach is to set up an ADO connection explicitly, as shown in this topic. This approach is useful if your database is password-protected. (It is also possible to connect to Microsoft Access through an ODBC connection, but it has limitations, so it is best to avoid it.)

Connection

- 1. Start the database connection wizard 634.
- 2. Click ADO Connections, then click Build.
- 3. In the dialog that appears (*screenshot below*), go to the *Provider* tab, select *Microsoft Office 15.0*Access Database Engine OLE DB Provider, and then click **Next**.

- 4. Go to the dialog's *Connection* tab, and in the *Data Source* field, enter the path to the Microsoft Access file in UNC format, for example, \myserver\mynetworkshare\Reports\Revenue.accdb, where myserver is the name of the server and mynetworkshare is the name of the network share.
- 5. On the All tab, double click the Jet OLEDB:Database Password property and enter the database password as property value (see screenshot below)

If you are still unable to connect, locate the workgroup information file (System.MDW) applicable to your user profile, and set the value of the Jet OLEDB: System database property to the path of the System.MDW file.

10.2.10.10 Microsoft Azure SQL (ODBC)

In order to connect properly to an Azure SQL database, you must install the latest SQL Server Native Client.

For information about connecting to an Azure SQL database in the cloud, see this Altova blog entry.

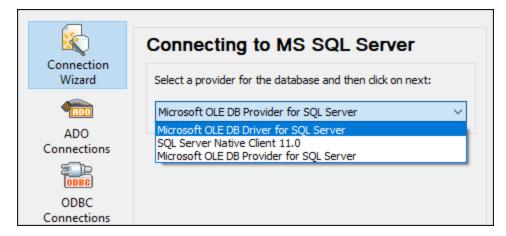

10.2.10.11 Microsoft SQL Server (ADO)

This example illustrates how to connect to a SQL Server database through ADO. These instructions work with the recommended <u>Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL)</u> that matches your StyleVision platform (32-bit or 64-bit). For other ADO providers, the instructions would be similar but you may need to set additional connection properties as described in <u>Setting up the SQL Server Data Link Properties</u> [643].

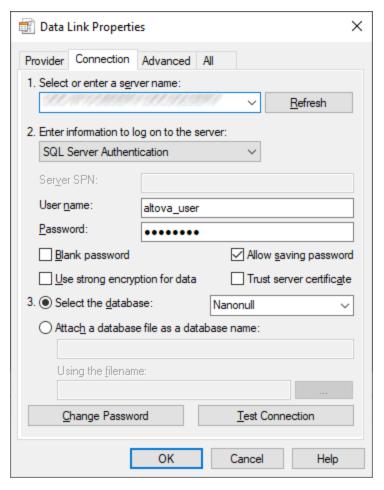

Note: The *Microsoft OLE DB Provider for SQL Server (SQLOLEDB)* is known to have issues with parameter binding of complex queries like Common Table Expressions (CTE) and nested SELECT statements.

Connection

- 1. <u>Start the database connection wizard</u> 634, select **Connection Wizard** and then *Microsoft SQL Server* (ADO). Click **Next**.
- 2. A list of available ADO providers is displayed (*screenshot below*). In this example, we use *Microsoft OLE DB Driver for SQL Server*. If it's not in the list, make sure that it is installed on your computer.

3. Click **Next**. The Data Link Properties dialog appears (*screenshot below*).

- 4. In the *Connection* tab, select or enter the name of the database server, for example, *SQLSERV01*. If you are connecting to a named SQL Server instance, the server name will be something like *SQLSERV01\SOMEINSTANCE*.
- 5. If the database server was configured to allow connections from users authenticated on the Windows domain, select Windows Authentication. Otherwise, select SQL Server Authentication, clear the Blank password check box, and enter the database credentials in the relevant boxes.
- 6. Select the *Allow saving password* check box and the database to which you are connecting (in this example, *Nanonull*).
- 7. You can test the connection by clicking **Test Connection**.
- 8. Click **OK** when done.

10.2.10.12 Microsoft SQL Server (ODBC)

This example illustrates how to connect to a SQL Server database via ODBC.

Prerequisites

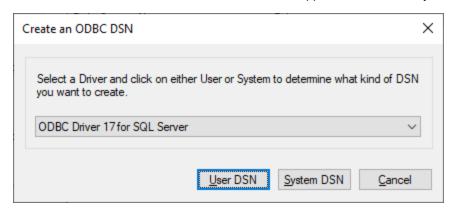

Download and install the Microsoft ODBC Driver for SQL Server from the Microsoft website. This example uses Microsoft ODBC Driver 17 for SQL Server to connect to a SQL Server 2016 database. You might need a

677

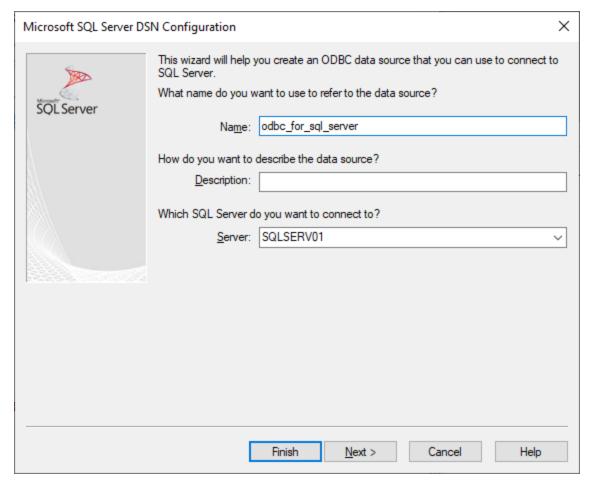

different ODBC driver version, depending on your SQL Server version. For information about compatibility, see the driver's system requirements.

Connection

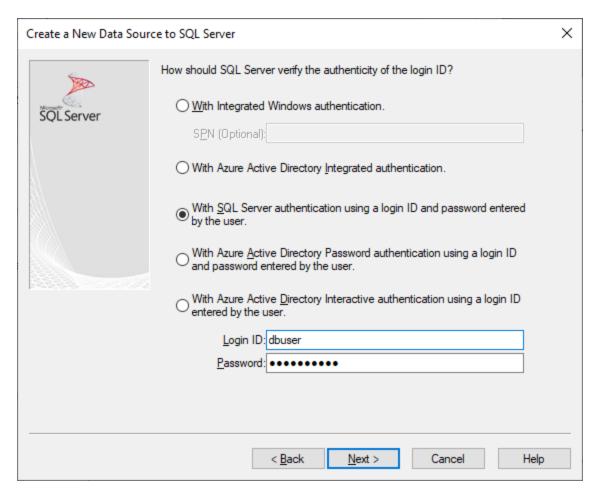

- 1. Start the database connection wizard 634 and click ODBC Connections.
- 2. Select *User DSN* (or *System DSN* if you have administrative privileges), and then click **Create a New DSN** .
- 3. Select the driver from the list. Note that the driver appears in the list only after it has been installed.

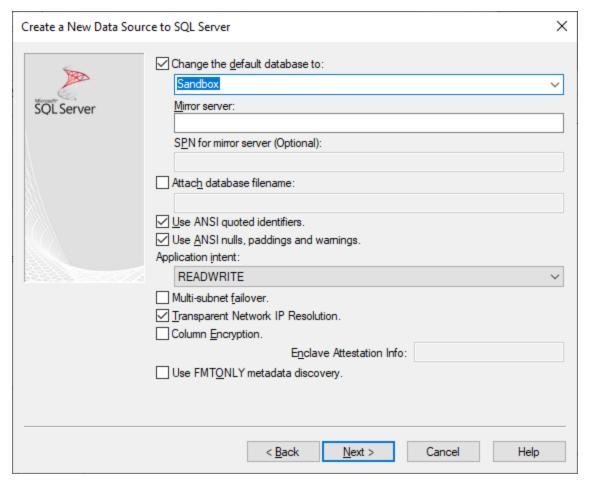

- 4. Click *User DSN* (or *System DSN* if you are creating a System DSN). Creating a System DSN requires that StyleVision be run as an administrator. Therefore, in order to create a System DSN, cancel the wizard, make sure that you run StyleVision as an administrator, and perform the steps above again.
- 5. Enter a name for the data source, enter, optionally, a description to identify this connection, and select from the list the SQL Server to which you are connecting. Click **Next** to go to the next screen.

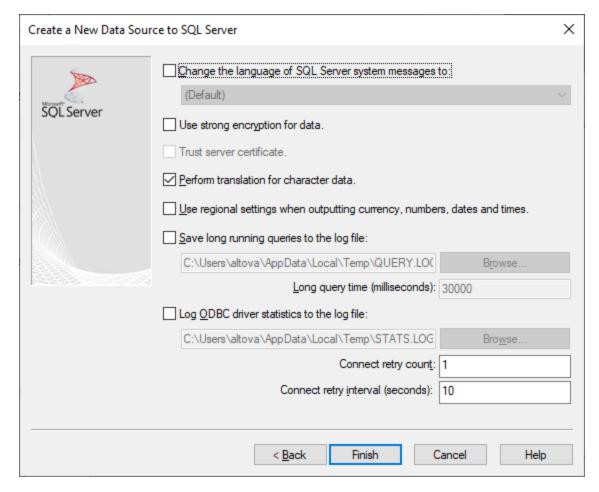

6. In the next screen, select the authentication method to use. If the database server was configured to allow connections from users authenticated on the Windows domain, select With Integrated Windows authentication. Otherwise, select one of the other options, as applicable. This example uses With SQL Server Authentication, which requires that the user name and password be entered in the relevant boxes. Click Next when done.

7. In the next screen of our example (*screenshot below*), we have selected *Change the default database* and entered *Sandbox* (the name of the database to which to connect). Click **Next** after you have entered the settings you want.

8. Click **Next** and, optionally, configure additional parameters for this connection. Click **Finish** when done.

- 9. A confirmation dialog box listing the connection details opens. Click **OK**.
- 10. The data source now appears in the list of *User* or *System* data sources.

10.2.10.13 MySQL (ODBC)

This example illustrates how to connect to a MySQL database server from a Windows machine via the MySQL ODBC, which driver must be downloaded and installed separately. This example uses MySQL Connector/ODBC 8.0.

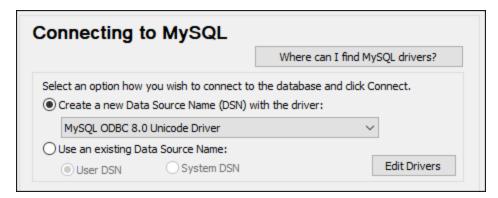

Prerequisites

- MySQL ODBC driver must be installed on your operating system. Check the <u>MySQL documentation</u> for the driver version recommended for your database server version.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the MySQL ODBC driver.
- You have the following database connection details: host, database, port, username, and password.

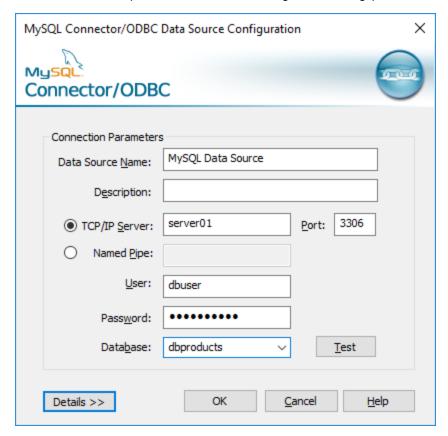

Connection

Start the database connection wizard 634, select Connection Wizard and then MySQL (ODBC/Native). Click Next.

2. Select *Create a new Data Source Name (DSN) with the driver*, and select a MySQL driver. (If no such driver is available in the list, click **Edit Drivers**, and select any available MySQL driver from the the list of ODBC drivers installed on your system. See also <u>Viewing the Available ODBC Drivers</u> (55).)

3. Click Connect. to open the Data Source Configuration dialog (screenshot below).

- 4. In the Data Source Name box, enter a descriptive name that will help you identify this ODBC data source in future. Optionally enter a description.
- 5. Fill in the database connection credentials (TCP/IP Server, User, Password), select a database, and then click **OK**.

Note: If the database server is remote, it must be configured by the server administrator to accept remote connections from your machine's IP address. Also, if you click **Details >>**, there are several additional parameters available for configuration. Check the driver's documentation before changing the default values.

10.2.10.14 Oracle (JDBC)

This example shows how to connect to an Oracle database server using the JDBC interface. The connection is created as a pure Java connection, using the Oracle Instant Client Package (Basic) available from the Oracle website. The advantage of this connection type is that it requires only the Java environment and the .jar libraries supplied by the Oracle Instant Client Package.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The Oracle Instant Client Package (Basic) must be available on your operating system. The package can be downloaded from the official Oracle website. This example uses Oracle Instant Client Package version 12.1.0.2.0, for Windows 32-bit and, consequently, Oracle JDK 32-bit.
- You have the following database connection details: host, port, service name, username, and password.

Connection

- 1. Start the database connection wizard and click JDBC Connections (see <u>JDBC Connection</u> for a screenshot of the dialog).
- 2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have <u>added the filepath to the CLASSPATH 653</u> of the system, you can leave this field empty.
- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.
- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the Oracle example

Field	Value
Classpaths	C:\jdbc\instantclient_12_1\ojdbc7.jar
Driver	oracle.jdbc.OracleDriver or oracle.jdbcdriver.OracleDriver
Database URL	jdbc:oracle:thin:@//host:port:service

10.2.10.15 Oracle (ODBC)

This example shows how to connect from StyleVision to an Oracle database server on a network machine, via an Oracle database client installed on the local operating system.

The example includes instructions for setting up an ODBC data source (DSN) using the database connection wizard in StyleVision. If you have already created a DSN, or if you prefer to create it directly from the *ODBC Data Source Administrator* in Windows, you can do so, and then select it when prompted by the wizard. For more information about ODBC data sources, see Setting up an ODBC Connection [65].

Prerequisites

- The Oracle database client (which includes the ODBC Oracle driver) must be installed and configured on your system. For instructions, see the Oracle documentation.
- The tnsnames.ora file located in Oracle home directory contains an entry that describes the database connection parameters, in a format similar to this:

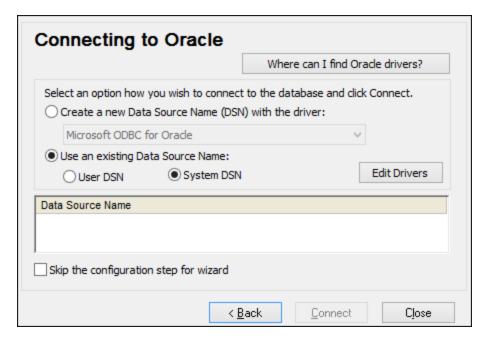

For Oracle database client 11.2.0, the default Oracle home directory path could be as follows:

```
C:\app\username\product\11.2.0\client 1\network\admin\tnsnames.ora
```

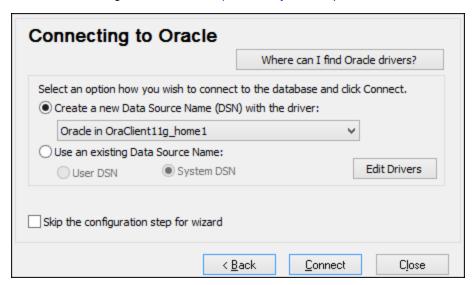

You can add new entries to tnsnames.ora, either by pasting the connection details and saving the file, or by running the Oracle Net Configuration Assistant, if available. If you want these values to appear in dropdown lists during the configuration process, then you may need to add the path to the admin folder as a tns admin environment variable.

Connection

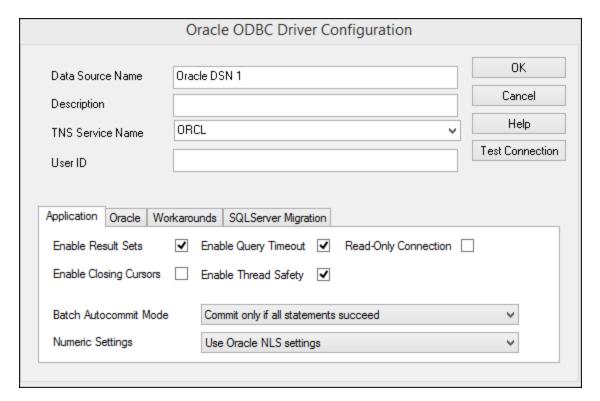

- 1. <u>Start the database connection wizard</u> select **Connection Wizard** and then *Oracle (ODBC/JDBC)*. Click **Next**.
- 2. Select ODBC and click Next.
- 3. In the dialog that appears (screenshot below), click Edit Drivers.

- 4. From the list of Oracle drivers available on your system, select the Oracle driver you wish to use and click **Back**.
- 5. Select *Create a new data source name (DSN) with the driver*, and then select the Oracle driver chosen in step 4. (Avoid using the Microsoft-supplied driver called Microsoft ODBC for Oracle driver. Microsoft recommends using the <u>ODBC driver provided by Oracle</u>.)

- 6. Click Connect.
- 7. In the dialog that appears fill in the required fields (shown filled in the screenshot below). The connection name must be entered in the TNS Service Name field as it is defined in the tnsnames.ora file (see Prerequisites above). Note: If you wish to have the dropdown list of the combo box automatically filled with the values of the tnsnames.ora file, then you may need to add the path to the admin folder as a TNS ADMIN environment variable.

- 8. Click **OK** when done.
- 9. In the dialog that appears, enter the username and password to the database, and then click **OK**.

10.2.10.16 PostgreSQL (ODBC)

This example shows how to connect to a PostgreSQL database server from a Windows machine via a PostgreSQL ODBC driver installed on the local machine. This example uses the *psqlODBC* driver (version 11.0) downloaded from the official website (see also <u>Database Drivers Overview</u> 639).

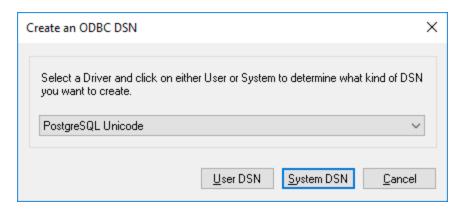

Note: You can also connect to a PostgreSQL database server directly (without the ODBC driver), see <u>Native</u> Connections ⁶⁵⁹.

Prerequisites

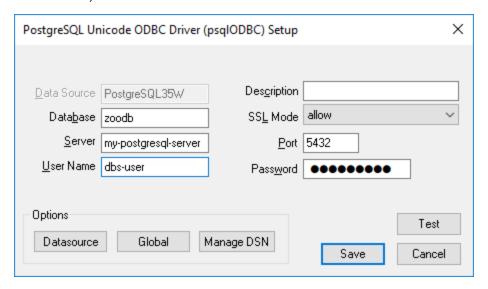

- psqlODBC driver must be installed on your system.
- You have the following database connection details: server, port, database, user name, and password.

Connection

- 1. Start the database connection wizard 634 and click ODBC Connections.
- 2. Select *User DSN* (or *System DSN* if you have administrative privileges), and then click **Create a New**
- 3. Select the driver from the drop-down list (*screenshot below*) and click **User DSN**. (If no PostgreSQL driver is available in the list, make sure that the PostgreSQL ODBC driver is installed on your operating system.)

4. In the dialog that appears (*screenshot below*), fill in the database connection (supplied by the database administrator).

5. Click Save.

The connection will become now available in the list of ODBC connections. To connect to the database, you can either double-click the connection or select it and then click **Connect**.

10.2.10.17 Progress OpenEdge (JDBC)

This example illustrates how to connect to a Progress OpenEdge 11.6 database server via JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either
 Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to
 the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you
 may have set in application **Options**;; (ii) the JVM path found in the Windows registry; (iii) the
 JAVA_HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.

• The operating system's PATH environment variable must include the path to the bin directory of the JRE or JDK installation directory, for example C:\Program Files (x86)\Java\jre1.8.0 51\bin.

- The Progress OpenEdge JDBC driver must be available on your operating system. In this example, JDBC connectivity is provided by the openedge.jar and pool.jar driver component files available in C: \Progress\OpenEdge\java as part of the OpenEdge SDK installation.
- You have the following database connection details: host, port, database path, name, or alias, username, and password.

Connection

- 1. Start the database connection wizard and click JDBC Connections (see <u>JDBC Connection</u> for a screenshot of the dialog).
- 2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have added the filepath to the CLASSPATH 653 of the system, you can leave this field empty.
- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.
- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the Progress OpenEdge example

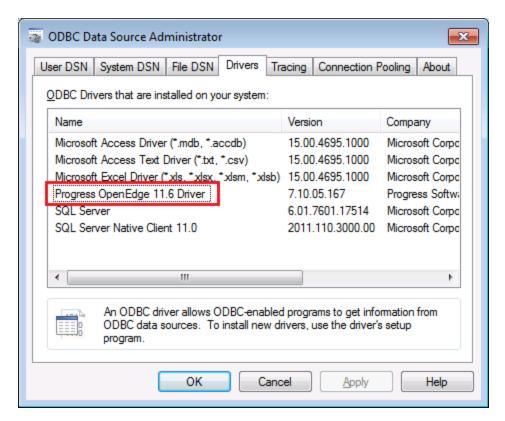

Field	Value	
Classpaths	<pre>C:\Progress\OpenEdge\java\openedge.jar;C: \Progress\OpenEdge\java\pool.jar;</pre>	
Driver	com.ddtek.jdbc.openedge.OpenEdgeDriver	
Database URL	jdbc:datadirect:openedge://host:port;databaseName=db_name	

10.2.10.18 Progress OpenEdge (ODBC)

This example shows how to connect to a Progress OpenEdge database server via the Progress OpenEdge 11.6 ODBC driver.

Prerequisites

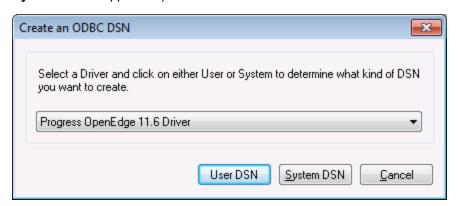

• The ODBC Connector for Progress OpenEdge driver must be installed on your system (see also <u>Database Drivers Overview</u> 630). Download the version that corresponds to your version of StyleVision (32-bit or 64-bit). After installation, <u>check if the ODBC driver is available on your machine</u> 6550.

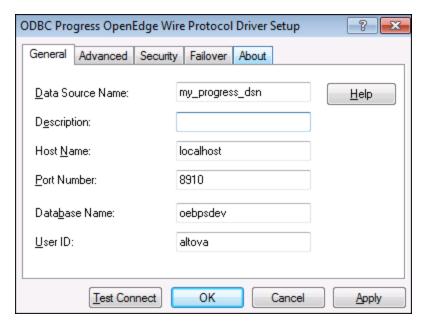

• You have the following database connection details: host name, port number, database name, user ID, and password.

Connection

- 1. Start the database connection wizard 634 and click ODBC Connections.
- 2. Select *User DSN* (or *System DSN* if you have administrative privileges), and then click **Create a New DSN** .
- 3. Select *Progress OpenEdge Driver* from the drop-down list (*screenshot below*) and click **User DSN** (or **System DSN** if applicable).

4. Fill in the database connection details (Database, Server, Port, User Name, Password), and click OK.

- 5. To verify connectivity before saving the entered data, click **Test Connect**. To save, click **OK**.
- 6. The new data source now appears in the list of ODBC data sources. Click **Connect** to start the connection.

10.2.10.19 Sybase (JDBC)

This example illustrates how to connect to a Sybase database server via JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; ; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- Sybase *jConnect* component must be installed on your operating system (in this example, *jConnect 7.0* is used, installed as part of the *Sybase Adaptive Server Enterprise PC Client* installation).
- You have the following database connection details: host, port, database path, name, or alias, username, and password.

Connection

- 1. <u>Start the database connection wizard</u> and click **JDBC Connections** (see <u>JDBC Connection</u> for a screenshot of the dialog).
- 2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have <u>added the filepath to the CLASSPATH of the System</u>, you can leave this field empty.
- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.

- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the Sybase example

Field	Value	
Classpaths	C:\sybase\jConnect-7_0\classes\jconn4.jar	
Driver	com.sybase.jdbc4.jdbc.SybDriver	
Database URL	jdbc:sybase:Tds:hostName:port/databaseName	

10.2.10.20 Teradata (JDBC)

This example illustrates how to connect to a Teradata database server via JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: (i) the custom JVM path you may have set in application **Options**; ; (ii) the JVM path found in the Windows registry; (iii) the JAVA HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC driver (one or more .jar files that provide connectivity to the database) must be available on your operating system. In this example, Teradata JDBC Driver 16.20.00.02 is used. For more information, see https://downloads.teradata.com/download/connectivity/jdbc-driver.
- You have the following database connection details: host, port, database path, name, or alias, username, and password.

Connection

- 1. Start the database connection wizard and click JDBC Connections (see <u>JDBC Connection</u> for a screenshot of the dialog).
- 2. In the *Classpaths* field, enter the path to the .jar file that provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. If you have added the filepath to the CLASSPATH 653 of the system, you can leave this field empty.
- 3. In the *Driver* field, select the appropriate driver. Relevant drivers will be available only if a valid .jar file path is in the *Classpaths* field or in the CLASSPATH environment variable.
- 4. Enter the username and password for the database in the corresponding fields.
- 5. Enter the JDBC connection string in the *Database URL* field according to the pattern in the table below, replacing the highlighted values with the ones applicable to your database server.
- 6. Click Connect.

Connection details of the Teradata example

Field	Value	
Classpaths	C:\jdbc\teradata\	
Driver	com.teradata.jdbc.TeraDriver	
Database URL	jdbc:teradata://databaseServerName	

10.2.10.21 Teradata (ODBC)

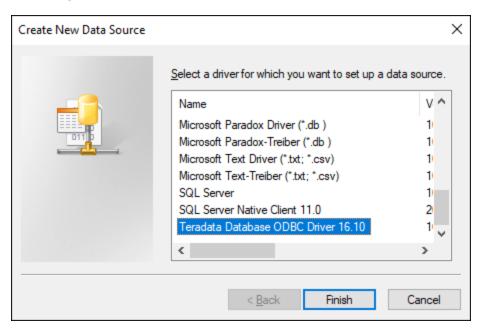

This example illustrates how to connect to a Teradata database server via ODBC.

Prerequisites

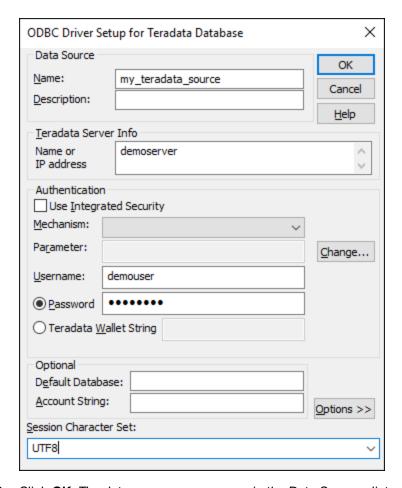

- The Teradata ODBC driver must be installed (downloadable from the Teradata website).
- You have the following database connection details: host, username, and password.

Connection

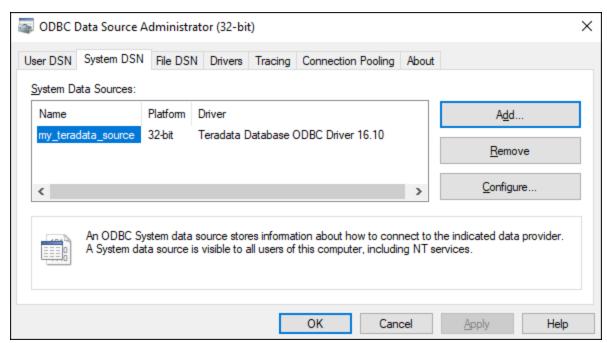

- 1. Press the **Windows** key, start typing ODBC, and select *Set up ODBC data sources (32-bit)* from the list of suggestions. (If appropriate, select the 64-bit option instead.)
- 2. In the ODBC Data Source Administrator dialog that appears, click the *System DSN* tab, and then click **Add**.
- 3. In the Create New Data Source dialog (screenshot below), select *Teradata Database ODBC Driver* and click **Finish**.

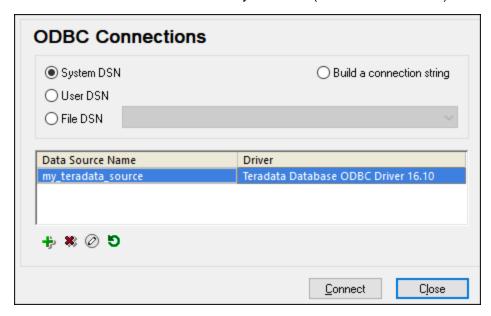

4. Enter the database and authentication details, and click **OK** when done.

5. Click **OK**. The data source now appears in the Data Sources list.

- 6. Run StyleVision and start the database connection wizard 634.
- 7. Click **ODBC Connections** and select *System DSN* (see screenshot below).

8. The data source you just created will be listed. Click **Connect** to start teh connection.

Note: If you get the following error: "The driver returned invalid (or failed to return) SQL_DRIVER_ODBC_VER: 03.80", then make sure that the path to the ODBC client (for example, C:\Program Files\Teradata\Client\16.10\bin) exists in your system's PATH environment variable. If this path is missing, then add it manually.

10.3 DB Data Selection

Selecting the schema and XML data that will be used in the SPS involves selecting one or more tables, or a cell. or a specific schema, depending on whether the database (DB) being used is a non-XML DB (such as MS Access) or an XML DB (IBM DB2 version 9.0, etc). We refer to the selection of the schema and XML data as DB data selection, and it is carried out immediately after connecting to the DB.

How the DB data is selected depends upon the type of DB to which the connection is being made:

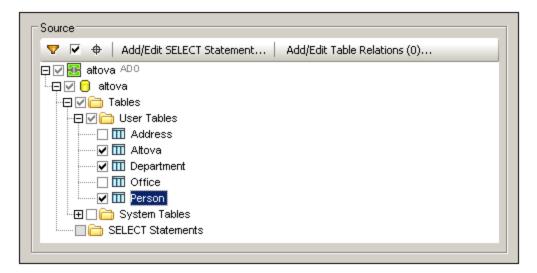

- In the case of <u>non-XML databases</u> , you select the table/s for which the SPS is being created. StyleVision automatically generates: (i) a schema based on the structure of the table/s, and (ii) temporary XML files based on this schema and containing the data in the selected table/s. How to select the tables is described in the section <u>DB Data Selection | Non-XML Databases</u> .
- In the case of XML databases 703, you must do two things. First, select the XML cell 703 of the DB in which the required XML data is stored. This XML data is loaded as the Working XML File 31 of the SPS. Second, select the schema 703 on which the SPS will be based. How to select the XML data and schema is explained in the section, DB Data Selection | XML Databases 703.

10.3.1 Non-XML Databases

After a connection has been made to a non-XML database, the Insert Database Objects dialog appears. This dialog consists of two parts. In the upper Source pane, which contains a graphical representation of the tables in the DB, you select the tables required for the SPS. An XML Schema and XML data files will be generated by StyleVision on the basis of the tables selected. In the lower Preview pane of the Insert Database Objects dialog, you can preview the contents of the selected table.

The Source pane

In the Source pane, the DB tables are displayed graphically (see screenshot below). Select the tables required for the SPS by checking the respective check boxes.

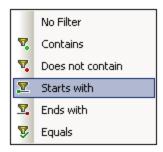

The toolbar of the Source pane (*screenshot below*) contains three icons, respectively, from left to right: **Filter Folder Contents**, **Checked Objects Only**, and **Object Locator**. The **Checked Objects Only** icon toggles the display between all tables and checked tables.

Filtering folder contents

To filter objects in the Source pane, do the following:

- 1. Click the **Filter Folder Contents** icon in the toolbar of the Source pane. The Filter icon appears next to the Tables folder.
- 2. Click the Filter icon next to the Tables folder, and select the filtering option from the popup menu (screenshot below), for example, Starts with.

3. In the entry field that appears, enter the filter string (in the screenshot below, the filter string on the Tables folder is A). The filter is applied as you type.

The object locator

To find a specific database item by its name, you can use the Source pane's Object Locator. This works as follows:

1. In the toolbar of the Source pane, click the Object Locator icon. A combo box appears at the bottom of the Source pane.

2. Enter the search string in the entry field of this list, for example Altova (*screenshot below*). Clicking the drop-down arrow displays all objects that contain the search string.

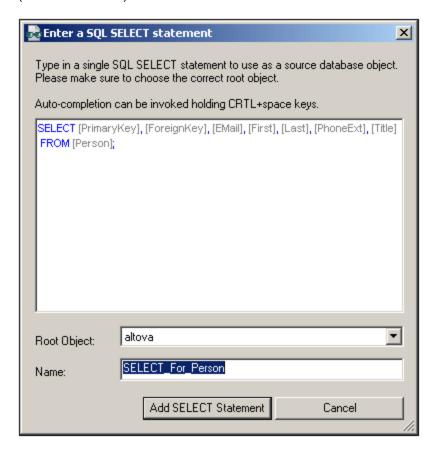

3. Click the object in the list to see it in the Source pane.

Adding and editing SELECT statements for local views

You can create SELECT statements in SQL to create local views. When the schema is generated from a DB connection which has local views (or SELECT statements) defined for it, the schema that is generated for the DB will contain a table for each SELECT statement.

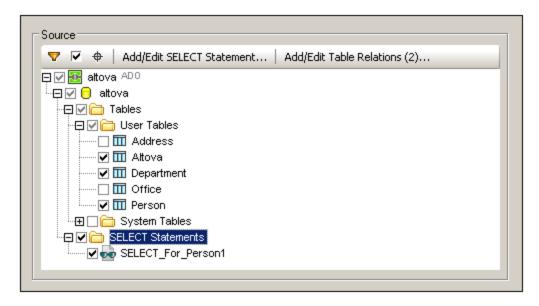

To create a SELECT statement, do the following:

 Click the Add/Edit SELECT Statement tab. This pops up the Enter a SQL Select Statement dialog (screenshot below).

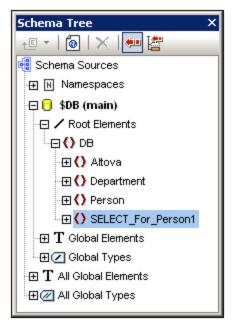

2. Enter the SELECT statement. If you connect to an Oracle or IBM DB2 database using JDBC, then the SELECT statement must have no final semicolon. If you wish to create a SELECT statement for an entire table, right-click the table in the Insert Database Objects dialog and select the context menu command Generate and Add a SELECT Statement.

3. Click **Add Select Statement**. The SELECT statement is added to the list of SELECT statements in the Insert Database Objects dialog (*screenshot below*).

Note: If you connect to an Oracle or IBM DB2 database using JDBC and use a SELECT statement with the Add/Remove Table command to retrieve data, then the SELECT statement must have no final semicolon.

When you click **Finish** in the Insert Database Objects dialog, a table is created for each SELECT statement (screenshot below).

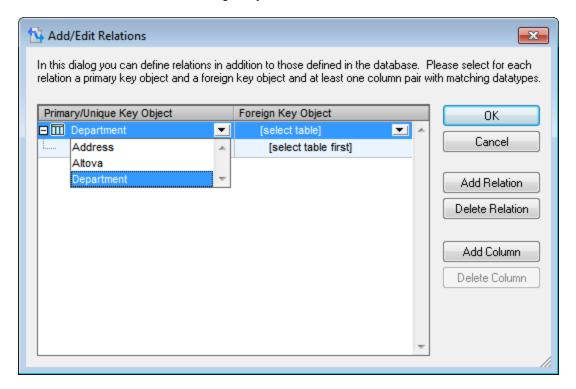

Local relations between tables

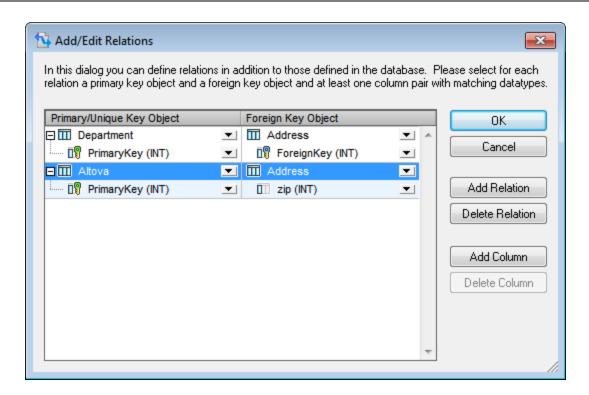

You can create local relations between two tables, similar to the primary-key/foreign-key kind of relationship. The relation is local, in StyleVision, which means that the database itself does not have to be modified. The local relationship will be represented in the generated schema.

To create a local relation, do the following:

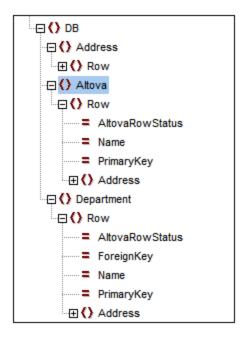

- 1. In the Insert Database Objects dialog, click the **Add/Edit Relations** tab. This pops up the Add/Edit Table Relations dialog (see screenshot below).
- Click the Add Relation button, and in the Primary/Unique Key column, click the dropdown button of the Select Table combo box (screenshot below). Select a table for the Foreign Key column also. The relationship that will be generated eventually will select rows in which the selected Primary/Unique Key column matches the selected Foreign Key column.

- 3. Select the Primary/Unique Key table column that must match the Foreign Key table column, and then select the Foreign Key column. Once again, use the combo boxes in the respective columns (see screenshot below). Notice that if there is a type mismatch, an error sign will be displayed.
- 4. Add more local relations, if required, by repeating steps 2 and 3 above.

5. Click **OK** to complete the relation. When the schema is generated, it will reflect the newly created relations.

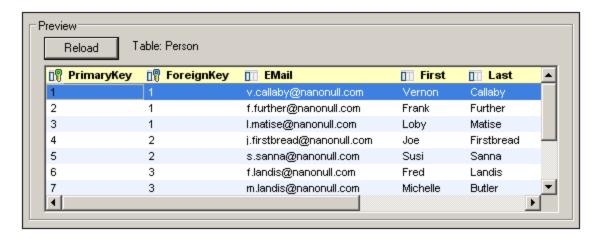

Look at the two screenshots above and see how, in the generated schema, <code>Altova</code> and <code>Department</code> each contain <code>Address</code>. Those <code>Department</code> rows with <code>PrimaryKey</code> values equal to the <code>ForeignKey</code> value of the <code>Address</code> row will be output. And those <code>Altova</code> rows with <code>PrimaryKey</code> values equal to the <code>zip</code> value of the <code>Address</code> row will be output.

Note: Local relations between SQL SELECT statements are not supported.

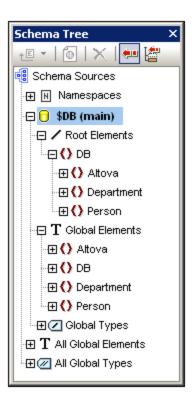

Previews and the Preview pane

To preview the structure and contents of a table, select the table in the Source pane and then click the **Preview** button or **Reload** button—according to which of the two is displayed—in the Preview pane (*screenshot below*). The contents of the table are displayed in a table format in the Preview pane (*screenshot below*).

Generating the XML Schema and Working XML File from the DB

After you have selected the tables for which you wish to use in the SPS, click **Finish** to generate and load the XML Schema. An XML Schema with a structure corresponding to that of the DB with the selected tables is displayed in the Schema Tree Window. A Working XML File having a structure corresponding to that defined in the generated schema and containing data from the selected tables is also generated and is used for the output previews.

Note that all the selected DB tables are created in the XML Schema as children of the DB document element and as items in the Global Elements list. For a complete description of the structure of the generated XML schema, see The DB Schema and DB XML files. Note that the XML Schema generated from the DB will not be altered by any DB Filter that may be built subsequently.

After you have connected to the DB and generated the XML Schema, you can use the full range of StyleVision features to design an SPS for the DB.

10.3.2 XML Databases

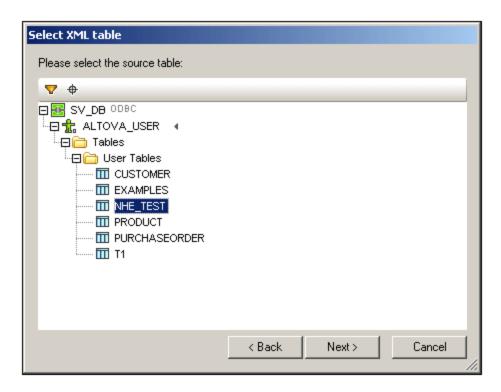

After having made the connection to the XML database (currently only IBM DB2 XML databases are supported) via the Open Database dialog (via the **File | New | New from XML Column in DB Table** command; see previous sections), you will need to do two things:

- Select the cell in the DB that contains the required XML document. The XML document will be loaded automatically as the Working XML File.
- Select the XML Schema for the SPS.

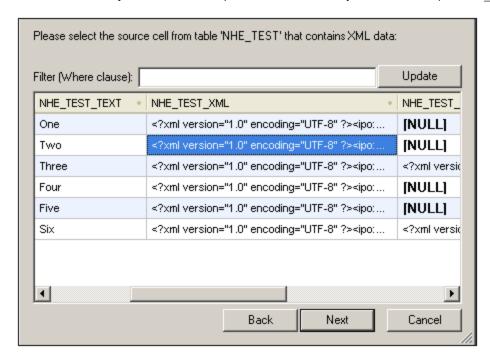

Selecting the XML Cell and Working XML File

After making the connection to the IBM DB2 database, the Select XML Table dialog (*screenshot below*) appears.

1. In the Select XML Table dialog, select the table that contains the XML data you wish to create as the Working XML File. In the screenshot below, the table NHE TEST has been selected.

2. Click **Next**. This pops up the Choose XML Field dialog (*screenshot below*). If you wish to filter the selection displayed in the pane, enter an SQL where clause and click **Update**. Note that the where clause should be just the condition (without the where keyword, for example: NHE TEST TEXT= 'Two')

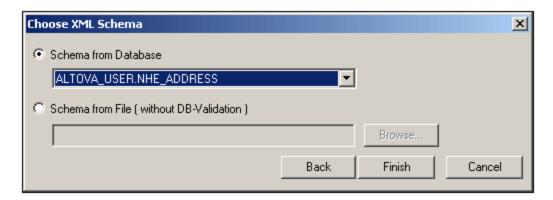

- 3. Select the cell containing the XML data you wish to create as the Working XML File. In the screenshot above, the selected cell is highlighted in blue.
- 4. Click **Next**. This pops up the Choose XML Schema dialog, in which you select the schema to be used for the SPS. *See next section*.

Note: If you connect to an Oracle or IBM DB2 database using JDBC and use a SELECT statement with the Add/Remove Table command to retrieve data, then the SELECT statement must have no final semicolon.

Selecting the XML Schema for the SPS

The schema that will be used for the SPS can be either an XML Schema contained in the DB or a schema at a file location that can be accessed by StyleVision. To select the schema, do the following:

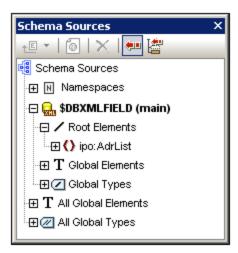

1. In the Choose XML Schema dialog (*screenshot below*), select the appropriate radio button according to whether you wish to select the schema from among those stored in the DB or from a file location. Note that if a non-DB schema is selected—that is, a schema from an external file—then no DB validation will be carried out.

- 2. Select the schema. Schemas stored in the DB are listed in the dropdown list of the Schemas from Database combo box, and can be selected from there. An external schema can be selected by browsing for it.
- 3. Click Finish to complete.

The schema tree

After completing the process to select the XML data and the schema, the selected XML data is created as the Working XML File and the schema is loaded into the SPS. Both are displayed in the Schema Tree window (screenshot below).

The SPS can now be built using the usual StyleVision mechanisms. Note that the data in the Working XML File can be edited in Authentic View and saved to the DB.

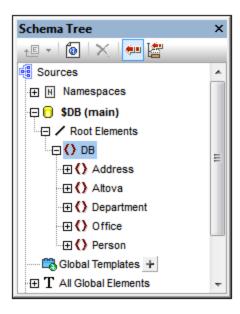

Note: The Working XML File should be valid against the schema selected for the SPS. Also ensure that the schema's <u>root element (document element)</u> corresponds to the root element of the XML document.

10.4 The DB Schema and DB XML files

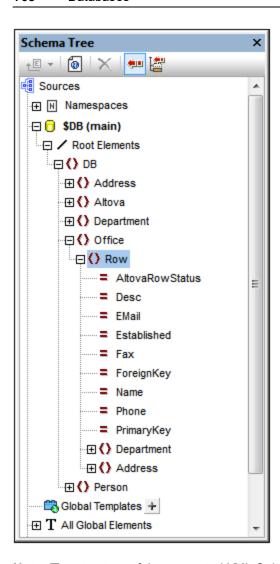

The DB XML Schema

When you load a non-XML database (non-XML DB) into StyleVision, an XML Schema with a structure based on that of the DB is generated by StyleVision and displayed in the Schema Tree window. (In the case of XML DBs, an existing schema (either stored in the DB or at a file location) is specified as the schema to be used in the SPS.) This section on schemas, therefore, refers only to non-XML DBs.

The XML Schema is created with a document element called DB. The DB element contains child elements which correspond to the top-level tables in the DB. These top-level table elements are also created as entries in the Global Elements list in the Schema Tree Window. The top-level elements in the screenshot below are: Address, Altova, Department, Office, and Person; they correspond to tables in the DB.

Each top-level table element may have an unlimited number of rows (see screenshot below). Each row corresponds to a record in the DB. In the schema tree the rows are represented by a single Row element. Each Row element has attributes which correspond to the fields of the table. One of these attributes is generated by StyleVision for every row of every table: AltovaRowStatus, which holds the current status of the row: added, updated, and/or deleted. The remaining attributes are the fields of the respective DB table.

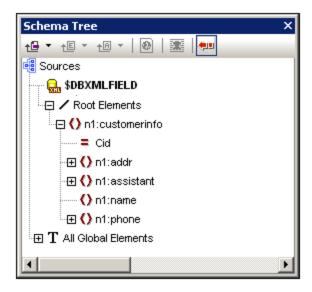

Note: The structure of the generated XML Schema is as outlined above. Whatever tables are selected during the connection step are included in the structure. The construction of a DB Filter does not affect the structure of the XML Schema.

New DB Schema Structure

The structure of the XML Schema generated from DBs starting with the 2005 version of StyleVision is different than the structure generated in previous versions of StyleVision. The new structure enables the editing of databases in the Authentic View of Altova products—a feature which was not available with earlier versions. As a result, any SPS generated with earlier versions of StyleVision will generate an error when opened in versions of StyleVision starting from the 2005 version. To be able to use the DB editing and reporting features of StyleVision, you should recreate the SPS in the current version of StyleVision.

DB XML data files

After a connection to the XML DB has been made, the XML schema and column with XML data selected, the Schema Tree window (*screenshot below*) will list the selected schema and the column that will be used for the Working XML File.

Two **temporary** XML files are generated from the DB (see <u>DBs and StyleVision</u> for an illustration):

- A temporary editable XML file, which can be edited in Authentic View
- A temporary non-editable XML File, which is used as the Working XML File (for previews and output generation)

The temporary **editable XML file** is generated when the DB is loaded into StyleVision. It can be edited in Authentic View after the SPS has been created. The display in Authentic View can be filtered by using the Query mechanism available in Authentic View. Any modification made in Authentic View to the editable data is written to this temporary XML File. Clicking **File | Save Authentic XML Data** saves the information in the temporary editable XML file to the DB.

The temporary **non-editable XML file** is generated when the DB is loaded into StyleVision. It is used as the Working XML File and for generating HTML, RTF, PDF, and Word 2007+ output. The editable XML file must be saved before changes made in Authentic View can be viewed in a preview.

Note:

- In the Authentic View of other <u>Authentic View products</u> only one temporary (editable) XML file is created when a DB-based SPS is opened. Modifications made in Authentic View are written to this file. When the file is saved, the information in the XML file is written to the DB.
- You can filter the data that goes into the non-editable temporary XML File for report-generation. (See Edit DB Filter (1048) for details.)
- You do not have to specifically assign a Working XML File in order to see HTML, Text, RTF, PDF, and Word 2007+ previews. The automatically generated (non-editable) temporary XML file is used for this purpose.

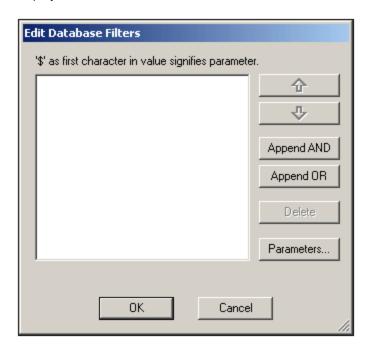

10.5 **DB Filters: Filtering DB Data**

The data that is imported into the temporary non-editable XML file from the database (DB) can be filtered. (Note that the non-editable XML file is used for report generation, and the effect of a DB filter will therefore be seen only in the HTML, Text, RTF, PDF, and Word 2007+ preview; not in Authentic Preview, which displays the temporary editable XML file, and not in Authentic View.) The DB filter (DB Filter) can be created either within the DB itself (if this is supported in your DB application), or it can be created within the SPS (SPS file). In the SPS, one DB Filter can be created for each top-level data table in the XML Schema (i.e. for the data tables that are the children of the DB element). Each time a DB Filter is created or modified, the data from the DB is reloaded into the temporary non-editable XML file that is generated for the DB. In this way, DB Filters help you to keep the XML file down to an optimal size and to thus make processing for report generation more efficient.

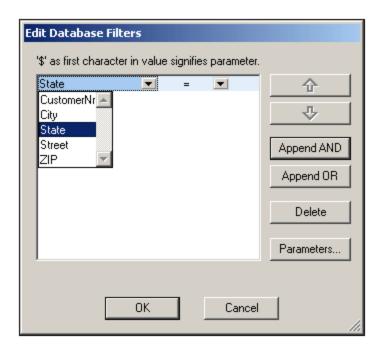

Note: Using a DB Filter modifies the data that is imported into the temporary non-editable XML File. If you save an SPS with a DB Filter and then generate an XML File from the SPS, the generated XML File will be filtered according to the criteria in the DB Filter.

Creating a DB Filter

- 1. In the Design Document or Schema Tree, select the data table element for which you wish to create a DB Filter (either by clicking the start or end tag of the element, or by selecting the element in the schema tree).
- 2. Select <u>Database | Edit DB Filters</u> or click the icon in the toolbar. The following dialog is displayed:

3. Click the **Append AND** or **Append OR** button. This appends an empty criterion for the filter (shown below).

- 4. Enter the expression for the criterion. An expression consists of: (i) a field name (available from the associated combo-box); (ii) an operator (available from the associated combo-box); and (iii) a value (to be entered directly). For details of how to construct expressions see the Expressions in criteria
 section below.
- 5. If you wish to add another criterion, click the **Append AND** or **Append OR** button according to which logical operator (AND or OR) you wish to use to join the two criteria. Then add the new criterion. For details about the logical operators, see the section Re-ordering criteria in DB Filters 13.

Expressions in criteria

Expressions in DB Filter criteria consist of a field name, an operator, and a value. The **available field names** are the columns of the selected top-level data table; the names of these fields are listed in a combo-box (see screenshot above). The **operators** you can use are listed below:

```
Equal to
=
               Not equal to
<>
<
               Less than
<=
               Less than or equal to
               Greater than
>
               Greater than or equal to
>=
LIKE
               Phonetically alike
NOT LIKE
               Phonetically not alike
IS NULL
               Is empty
NOT NULL
               Is not empty
```

If IS NULL or NOT NULL is selected, the Value field is disabled. **Values** must be entered without quotes (or any other delimiter). Values must also have the same formatting as that of the corresponding DB field; otherwise the expression will evaluate to FALSE. For example, if a criterion for a field of the date datatype in an MS

Access DB has an expression StartDate=25/05/2004, the expression will evaluate to FALSE because the date datatype in an MS Access DB has a format of YYYY-MM-DD.

Using parameters with DB Filters

You can also enter the name of a parameter as the value of an expression. This causes the parameter to be called and its value to be used as the value of that expression. The parameter you enter here can be a parameter that has already been declared for the stylesheet, or it can be a parameter that you declare subsequently. Note, however, that when a parameter that has not been declared is typed into the value field, the **OK** button is disabled.

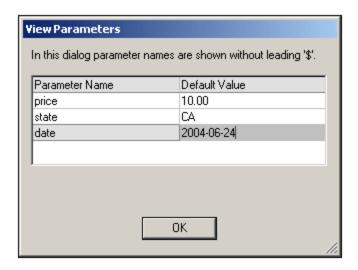

Parameters are useful if you wish to use a single value in multiple expressions, or if you wish to pass a value to a parameter from the command line (see <u>StyleVision Server</u> ⁸⁹⁵ for details).

To enter the name of a parameter as the value of an expression, type \$ into the value input field followed (without any intervening space) by the name of the parameter. If the parameter has already been declared (see Parameters (see Para

Declaring parameters from the Edit DB Filter dialog

To access the Edit Parameters dialog (in order to declare parameters), do the following:

1. Click the **Parameters...** button in the Edit DB Filters dialog. This pops up the Edit Parameters dialog shown below.

2. Type in the name and value of the parameter in the appropriate fields.

Alternatively, you can access the Edit Parameters dialog and declare or edit a DB Parameter by selecting **Edit** | **Stylesheet Parameters**.

Note: The Edit Parameters dialog contains **all** the parameters that have been defined for the stylesheet. While it is an error to use an undeclared parameter in the SPS, it is not an error to declare a parameter and not use it.

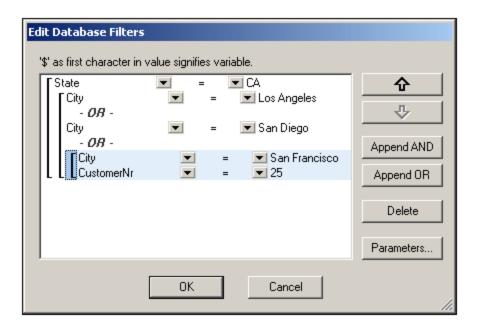

713

After a DB Filter is created for a data table element, that element in the Schema Tree is displayed with the filter symbol, as shown for the Addresses element in the screenshot below.

Re-ordering criteria in DB Filters

The logical structure of the DB Filter and the relationship between any two criteria or sets of criteria is indicated graphically. Each level of the logical structure is indicated by a square bracket. Two adjacent criteria or sets of criteria indicate the AND operator, whereas if two criteria are separated by the word OR then the OR operator is indicated. The criteria are also appropriately indented to provide a clear overview of the logical structure of the DB Filter.

The DB Filter shown in the screenshot above may be represented in text as:

State=CA AND (City=Los Angeles OR City=San Diego OR (City=San Francisco AND CustomerNr=25))

You can re-order the DB Filter by moving a criterion or set of criteria up or down relative to the other criteria in the DB Filter. To move a criterion or set of criteria, do the following:

- 1. Select the criterion by clicking on it, or select an entire level by clicking on the bracket that represents that level.
- 2. Click the Up or Down arrow button in the dialog.

The following points should be noted:

- If the adjacent criterion in the direction of movement is at the same level, the two criteria exchange places.
- A set of criteria (i.e. criteria within a bracket) changes position within the same level; it does not change levels.

714 Databases DB Filters: Filtering DB Data

An individual criterion changes position within the same level. If the adjacent criterion is further
outward/inward (i.e. not on the same level), then the selected criterion will move outward/inward, one
level at a time.

To delete a criterion in a DB Filter, select the criterion and click **Delete**.

Modifying a DB Filter

To modify a DB Filter, select <u>Database | Edit DB Filters</u> 1048. This pops up the Edit DB Filters dialog box. You can now edit the expressions in any of the listed criteria, add new criteria, re-order criteria, or delete criteria in the DB Filter. After you have completed the modifications, click OK. The data from the DB is automatically reloaded into StyleVision so as to reflect the modifications to the DB Filter.

Clearing (deleting) a DB Filter

10.6 SPS Design Features for DB

You can design a DB-based SPS just as you would design any other schema-based SPS, that is by dragging-and-dropping schema nodes from the schema window into the design document; by inserting static content directly in the design document; and by applying suitable formatting to the various design components. The following points, however, are specific to DB-based SPSs.

Creating a dynamic table for a DB table

To create a dynamic table for a DB table, do the following:

- 1. In the schema tree, select the top-level DB table to be created as a dynamic table, drag it into the design.
- 2. When you drop it, create is as contents and delete the contents placeholder. If the Auto-Add DB Controls feature is on, your design will look something like this:

- 3. In the schema tree, select the Row element of the DB table you wish to create as a dynamic table.
- 4. Drag it to a location inside the Addresses element.
- 5. When you release the element, select Create Table from the menu that pops up, and select the DB fields you wish to create as columns of the dynamic table. The DB table is created as a dynamic table.

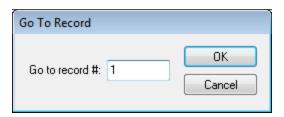

Note: You can also create a DB table in any other format, such as (contents).

Auto-add DB Controls

The **Authentic | Auto-add DB Controls** menu command or the toolbar icon toggles the auto-insertion of navigation controls for DB tables on and off. When the toggle is switched on, this toolbar icon has a black border; when the toggle is off, the toolbar icon has no border. If the Auto-insert toggle is on, DB Controls (see screenshot below) are automatically inserted when a DB table is dropped into the Design document. It is dropped, by default, immediately after the start tag of the table.

These controls enable the Authentic View user to navigate the records of the DB table in Authentic View. The first (leftmost) button navigates to the first record; the second button navigates to the previous record; the third button is the Goto Record button, which pops up the Goto Record dialog (*screenshot below*); it pops up a dialog that prompts you for the number of the record to which you wish to go; the fourth button navigates to the next record; and the fifth button navigates to the last record.

To manually insert the navigation controls in the Design document—which is useful if you wish to insert the controls at some other location than the default location—then do the following:

- 1. Turn the Auto-insert DB Controls toggle off.
- 2. Place the cursor at the location where you wish the navigation controls to appear (but within the DB table element's start and end tags).
- 3. Right-click, and from the popup menu, select **Insert DB Control | Navigation** or **Insert DB Control | Navigation+Goto**. Alternatively, these commands can be accessed via the **Insert** menu.

Inserting a DB Query button for

The DB Query button enables the Authentic View user to submit a DB query. This helps the user to build conditions for the records to be displayed in Authentic View. Query buttons can be inserted for individual DB tables anywhere between:

- The start tag of the DB table element and the start tag of the DB table element's (child) Row element.
- The end tag of the DB table element and the end tag of that table element's (child) Row element.

To insert a DB Query button in your Design document, do the following:

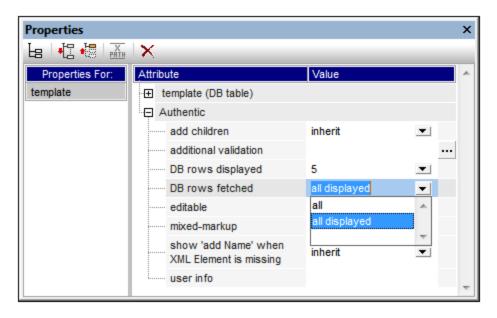

- 1. Place the cursor at the allowed location (see above) where you wish the Query button to appear.
- 2. Right-click, and from the context menu (or **Insert** menu), select **Insert | DB Control | Query Button**. The Query Button is inserted at that point in the Design document.

When it is clicked in Authentic View, the Query button will pop up the Edit Database Query dialog. This dialog is described in the Authentic View documentation [889].

Records displayed and records fetched

You can control the number of records displayed in Authentic View and the number of records fetched when the file is loaded. To make these settings, do the following:

- 1. In Design View, select the Row element that corresponds to the records to be displayed/fetched.
- 2. In the Properties sidebar, select template in the Properties For column, and the Authentic group of properties.

- 3. For the property *DB Rows Displayed*, select all from the dropdown list or enter the number of rows to be displayed.
- 4. For the property *DB Rows Fetched*, select all or all displayed from the dropdown list, or enter the number of rows to be fetched. The value all displayed is the default. This property determines how many rows are fetched when the DB data is loaded. If the value is less than that of the *DB Rows Displayed* property, then the value of *DB Rows Displayed* is used as the value of *DB Rows Fetched*. The *DB Rows Fetched* property enables you to reduce the number of rows initially loaded, thus speeding up the loading and display time. Additional rows (records) are loaded and displayed when the row navigation buttons in Authentic View are used.

Note:

- The number of rows displayed is applied to Authentic View.
- If a large number of tables is open in Authentic View, then the user will get an error message saying that too many tables are open. On the design side, you can reduce the number of tables that are open by reducing the number of rows displayed (because a row can contain tables). On the user side, the user can use queries to reduce the number of tables loaded into Authentic View.

AltovaRowStatus

In the XML Schema that is created from a DB, each table has an AltovaRowStatus attribute. The value of this attribute is automatically determined by StyleVision and consists of three characters, which are initialized to ---. If a row is modified, or a new row is added, the value is changed using the following characters.

А	The row has been added (but not yet saved to the DB).	
U , u	The row has been updated (but not yet saved to the DB).	
D, d, X	The row has been deleted (but not yet saved to the DB).	

These values can be used to provide users with information about rows being edited. The status information exists up to the time when the file is saved. After the file is saved, the status information is initialized (indicated by ---).

Formatting design document components

When records are added, modified, or deleted, StyleVision formats the added/modified/deleted records in a certain way to enable users to distinguish them from other records. Datatype errors are also flagged by being displayed in red. If you wish to maintain this differentiation, make sure that the formatting you assign to rows in a table do not have the same properties as those assigned by StyleVision. The formatting assigned by StyleVision is as follows:

Added	А	Bold, underlined
Modified (Updated)	U, u	Underlined
Deleted	D, d, X	Strikethrough
Datatype error		Red text

10.7 Generating Output Files

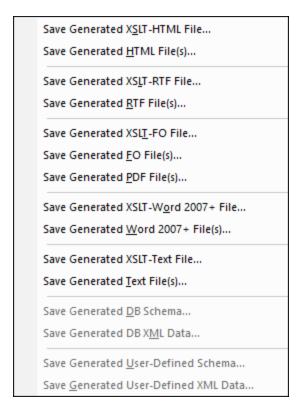

After you have created a DB-based SPS, you can generate files related to it and save them. The following files can be generated and saved:

- The XML Schema based on the DB structure
- The XML file having the structure of the generated XML Schema and content from the DB
- The XSLT file for HTML output
- The HTML output file
- The XSLT file for RTF output
- The RTF output file
- The XSLT file for FO output (XSL-FO)
- The FO output file
- The PDF output file
- The XSLT file for Word 2007+ output
- The Word 2007+ output file

The files can be generated and saved from within the GUI or from the command line.

From within the StyleVision GUI

1. In the File menu, select the Save Generated Files item. This pops up the following submenu.

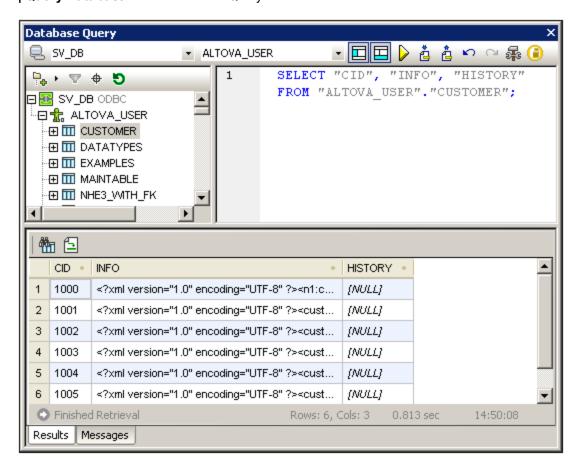

- 2. Select the file you wish to generate. This pops up the Save As dialog.
- 3. Browse for the desired folder, enter the desired filename, and click **OK**.

From the command line

From the command line, you can call StyleVision so that it generates and saves files associated with a DB-based SPS. You can save not only the XML Schema and XSLT files, but also an XML file with data from the DB, and HTML, RTF, PDF, and Word 2007+ output files based on the design in the SPS.

10.8 Query Database

The **Query Database** command in the **Database** menu opens the Database Query window (*screenshot below*). Once the Query Window is open, its display can be toggled on and off by clicking either the **Database** | **Query Database** command or the Query Database toolbar icon .

Overview of the Database Query window

The Database Query window consists of three parts:

- A <u>Browser pane</u> ⁷²⁵ at top left, which displays connection info and database tables.
- A Query pane 229 at top right, in which the query is entered.
- A tabbed Results/Messages pane T32. The Results pane displays the query results in what we call the Result Grid. The Messages pane displays messages about the query execution, including warnings and errors.

The Database Query window has a toolbar at the top. At this point, take note of the two toolbar icons below. The other toolbar icons are described in the section, Query Pane: Description and Features (729).

Toggles the Browser pane on and off.

Toggles the Results/Messages pane on and off.

Overview of the Query Database mechanism

The Query Database mechanism is as follows. (It is described in detail in the sub-sections of this section.)

- 1. A connection to the database is established via the Database Query | Connect to a Data Source window.
- 2. The connected database or parts of it are displayed in the <u>Browser pane</u> which can be configured to suit viewing requirements.
- 3. A <u>query</u> written in a syntax appropriate to the database to be queried is entered in the <u>Query</u> pane ⁷³¹, and the query is executed.
- 4. The <u>results of the query</u> (732) can be viewed through various filters.

10.8.1 Data Sources

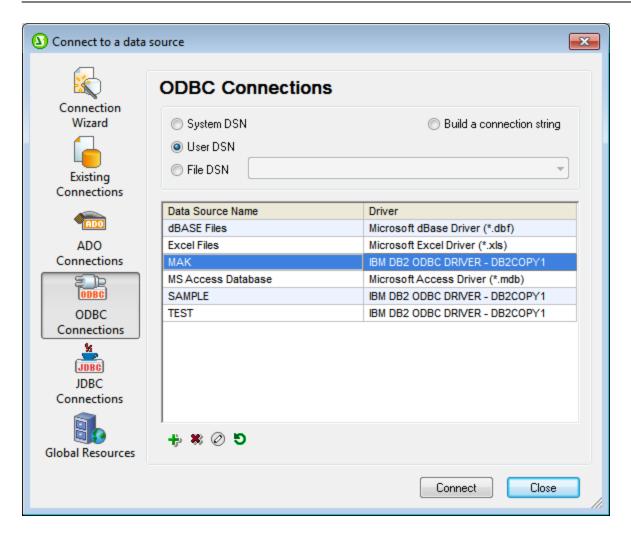

In order to guery a database, you have to first connect to the required database This section describes how to:

- Connect to a database, and
- Select the required data source and root object from among multiple existing connections.

Connecting to a database

among these.

When you click the **Query Database** command in the **Database** menu for the first time in a session (and when no database connection exists), the Connect to a Data Source dialog (*screenshot below*) pops up to enable you to connect to a database. To make connections subsequently, click the Quick Connect icon in the Database Query window. If connections already exist, you can <u>select the required connection</u> from

How to connect to a database via the Connect to a Data Source dialog is described in the section Connecting to a Data Source (633).

Supported databases

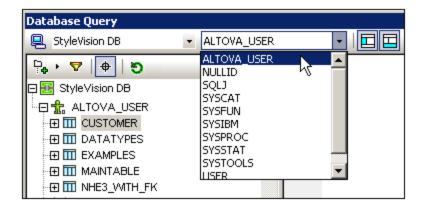

The table below lists all the supported databases. If your Altova application is a 64-bit version, ensure that you have access to the 64-bit database drivers needed for the specific database you are connecting to.

Database	Notes
Firebird 2.x, 3.x, 4.x	
IBM DB2 8.x, 9.x, 10.x, 11.x, 12.x	
IBM Db2 for i 6.x, 7.4, 7.5	Logical files are supported and shown as views.
IBM Informix	

Database	Notes
11.70 and later	
MariaDB 10 and later	MariaDB supports native connections. No separate drivers are required.
Microsoft Access 2003 and later	You can connect to an Access 2019 database from Altova products (i) only if the corresponding version of Microsoft Access Runtime is installed and (ii) only if the database does not use the "Large Number" data type.
Microsoft Azure SQL Database	SQL Server 2016 codebase
Microsoft SQL Server 2005 and later Microsoft SQL Server on Linux	
MySQL 5 and later	MySQL 5.7 and later supports native connections. No separate drivers are required.
Oracle 9i and later	
PostgreSQL 8 and later	PostgreSQL connections are supported both as native connections and driver-based connections through interfaces (drivers) such as ODBC or JDBC. Native connections do not require any drivers.
Progress OpenEdge 11.6	
SQLite 3.x	SQLite connections are supported as native, direct connections to the SQLite database file. No separate drivers are required.
	In Authentic view, data coming from a SQLite database is not editable. When you attempt to save SQLite data from the Authentic view, a message box will inform you of this known limitation.
Sybase ASE 15, 16	
Teradata 16	

Selecting the required data source

All the existing connections and the root objects of each are listed, respectively, in two combo boxes in the toolbar of the Database Query window (*screenshot below*). After selecting the required data source in the left-hand combo box, you can select the required root object from the right-hand combo box.

In the screenshot above, the database with the name <code>StyleVision DB</code> has been selected. Of the available root objects for this database, the root object <code>ALTOVA_USER</code> has been selected. The database and the root object are then displayed in the <code>Browser pane</code> 25.

10.8.2 Browser Pane: Viewing the DB Objects

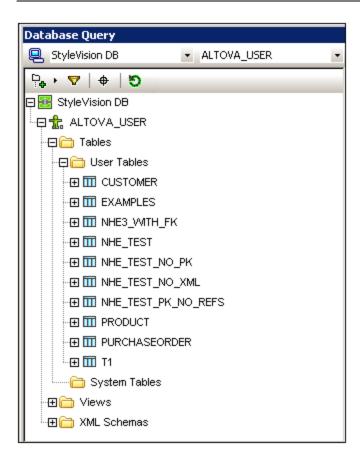

The Browser pane provides an overview of objects in the selected database. This overview includes database constraint information, such as whether a column is a primary or foreign key. In IBM DB2 version 9 databases, the Browser additionally shows registered XML schemas in a separate folder (see screenshot below).

This section describes the following:

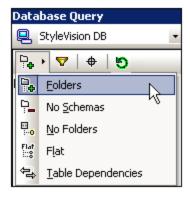

- The <u>layouts</u> 725 available in the Browser pane.
- How to filter 727 database objects.
- How to find
 database objects.
- How to refresh 729 the root object of the active data source.

Browser pane layouts

The default Folders layout displays database objects hierarchically. Depending on the selected object, different context menu options are available when you right-click an item.

To select a layout for the Browser, click the Layout icon in the toolbar of the Browser pane (*screenshot below*) and select the layout from the drop-down list. Note that the icon changes with the selected layout.

The available layouts are:

- Folders: Organizes database objects into folders based on object type in a hierarchical tree, this is the default setting.
- No Schemas: Similar to the Folders layout, except that there are no database schema folders; tables are therefore not categorized by database schema.
- No Folders: Displays database objects in a hierarchy without using folders.
- *Flat:* Divides database objects by type in the first hierarchical level. For example, instead of columns being contained in the corresponding table, all columns are displayed in a separate Columns folder.

• *Table Dependencies:* Categorizes tables according to their relationships with other tables. There are categories for tables with foreign keys, tables referenced by foreign keys and tables that have no relationships to other tables.

To sort tables into User and System tables, switch to Folders, No Schemas or Flat layout, then right-click the Tables folder and select **Sort into User and System Tables**. The tables are sorted alphabetically in the User Tables and System Tables folders.

Filtering database objects

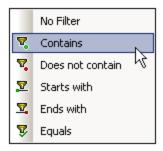

In the Browser pane (in all layouts except No Folders and Table Dependencies), schemas, tables, and views can be filtered by name or part of a name. Objects are filtered as you type in the characters, and filtering is case-insensitive by default.

To filter objects in the Browser, do the following:

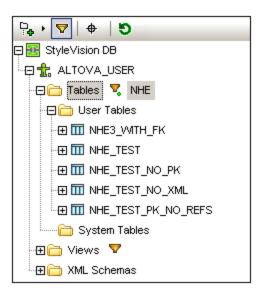

1. Click the Filter Folder Contents icon in the toolbar of the Browser pane. Filter icons appear next to the Tables and Views folders in the currently selected layout (*screenshot below*).

2. Click the filter icon next to the folder you want to filter, and select the filtering option from the popup menu, for example, Contains.

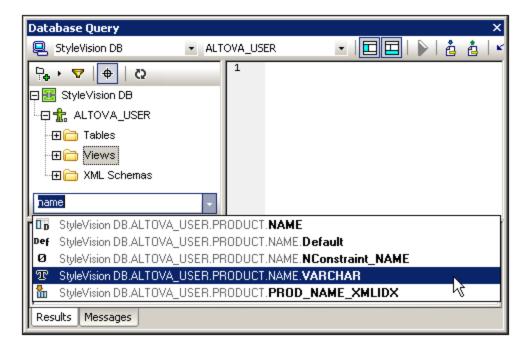

3. In the entry field that appears, enter the filter string (in the screenshot below, the filter string on the Tables folder is NHE). The filter is applied as you type.

Finding database objects

To find a specific database item by its name, you can use the Browser pane's Object Locator. This works as follows:

- 1. In the toolbar of the Browser pane, click the Object Locator icon. A drop-down list appears at the bottom of the Browser pane.
- 2. Enter the search string in the entry field of this list, for example name (*screenshot below*). Clicking the drop-down arrow displays all objects that contain the search string.

3. Click the object in the list to see it in the Browser pane.

Refreshing the root object

The root object of the active data source can be refreshed by clicking the **Refresh** button of the Browser pane's toolbar.

10.8.3 Query Pane: Description and Features

The Query pane is an intelligent SQL editor for entering queries to the selected database. After entering the query, clicking the <u>Execute command</u> of the Database Query window executes the query and displays the result and execution messages in the <u>Results/Messages pane</u>. How to work with queries is dscribed in the next section, <u>Query Pane: Working with Queries</u> 1. In this section, we describe the main features of the Query pane:

- <u>SQL Editor icons</u> in the Database Query toolbar
- SQL Editor options 729
- Auto-completion of SQL statements 730
- Definition of regions in an SQL script (731)
- Insertion of comments in an SQL script (731)
- Use of bookmarks 731

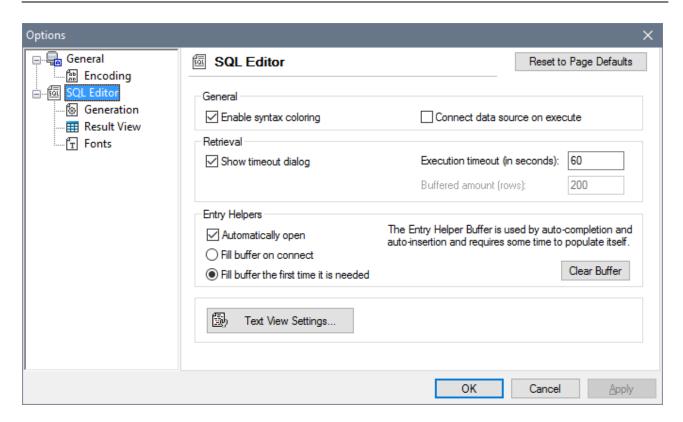

SQL Editor icons in the Database Query toolbar

The following icons in the toolbar of the Database Query window are used when working with the SQL Editor:

	Execute	Executes currently selected SQL statement. If script contains multiple statements and none is selected, then all are executed.
Ė	Import SQL File	Opens an SQL file in the SQL Editor.
Ė	Export SQL File	Saves SQL queries to an SQL file.
2	Undo	Undoes an unlimited number of edits in SQL Editor.
C	Redo	Redoes an unlimited number of edits in SQL Editor.
₽	Options	Open the Options dialog of SQL Editor.
	Open SQL Script in DatabaseSpy	Opens the SQL script in Altova's DatabaseSpy product.

SQL Editor options

Clicking the **Options** icon in the Database Query toolbar pops up the Options dialog (*screenshot below*). A page of settings can be selected in the left-hand pane, and the options on that page can be selected. Click the **Reset to Page Defaults** button to reset the options on that page to their original settings.

The key settings are as follows:

- **General | Encoding:** Options for setting the encoding of new SQL files, of existing SQL files for which the encoding cannot be detected, and for setting the Byte Order Mark (BOM). (If the encoding of existing SQL files can be detected, the files are opened and saved without changing the encoding.)
- **SQL Editor:** Options for toggling syntax coloring and data source connections on execution on/off. A timeout can be set for query execution, and a dialog to change the timeout can also be shown if the specified time is exceeded. Entry helpers refer to the entry helpers that appear as part of the autocompletion feature. When you type in an SQL statement, the editor displays a list of context-sensitive auto-completion suggestions. These suggestions can be set to appear automatically. If the automatic display is switched off, then you can ask for an auto-completion suggestion in SQL Editor at any point in the SQL query by pressing **Ctrl+Spacebar**. The buffer for the entry helper information can be filled either on connection to the data source or the first time it is needed. The Text View settings button opens a dialog in which you can specify settings such as indentation and tab size of text in the SQL Editor.
- SQL Editor | SQL Generation: The application generates SQL statements when you drag objects
 from the Browser pane into the Query pane. Options for SQL statement generation can be set in the
 SQL generation tab. Use the Database list box to select a database kind and set the statement
 generation options individually for the different database kinds you are working with. Activating the
 Apply to all databases check box sets the options that are currently selected for all databases.
 Options include appending semi-colons to statements and surrounding identifiers with escape
 characters.
- SQL Editor | Result View: Options to configure the Result tab.
- **SQL Editor** | **Fonts:** Options for setting the font style of the text in the Text Editor and in the Result View.

Definition of regions in an SQL script

Regions are sections in SQL scripts that are marked and declared to be a unit. Regions can be collapsed and expanded to hide or display parts of the script. It is also possible to nest regions within other regions. Regions are delimited by --region and --endregion comments, respectively, before and after the region. Regions can optionally be given a name, which is entered after the --region delimiter (see screenshot below).

To insert a region, select the statement/s to be made into a region, right-click, and select **Insert Region**. The expandable/collapsible region is created. Add a name if you wish. In the screenshot above, also notice the line-numbering. To remove a region, delete the two --region and --endregion delimiters.

Insertion of comments in an SQL script

Text in an SQL script can be commented out. These portions of the script are skipped when the script is executed.

- To comment out a block, mark the block, right-click, and select Insert/Remove Block Comment. To remove the block comment, mark the comment, right-click and select Insert/Remove Block Comment.
- To comment out a line or part of a line, place the cursor at the point where the line comment should start, right-click, and select Insert/Remove Line Comment. To remove the line comment, mark the comment, right-click and select Insert/Remove Line Comment.

Use of bookmarks

Bookmarks can be inserted at specific lines, and you can then navigate through the bookmarks in the document. To insert a bookmark, place the cursor in the line to be bookmarked, right-click, and select Insert/Remove Bookmark. To go to the next or previous bookmark, right-click, and select Go to Next Bookmark or Go to Previous Bookmark, respectively. To remove a bookmark, place the cursor in the line for which the bookmark is to be removed, right-click, and select Insert/Remove Bookmark. To remove all bookmarks, right-click, and select Remove All Bookmarks.

10.8.4 Query Pane: Working with Queries

After connecting to a database, an SQL script can be entered in the SQL Editor and executed. This section describes:

- How an SQL script is entered in the SQL Editor.
- How the script is executed in the Database Query window.

The following icons are referred to in this section:

Execute Query Executes currently selected SQL statement. If script contains

multiple statements and none is selected, then all are executed.

Import SQL File

Opens an SQL file in the SQL Editor.

Creating SQL statements and scripts in the SQL Editor

The following GUI methods can be used to create SQL statements or scripts:

- *Drag and drop:* Drag an object from the Browser pane into the SQL Editor. An SQL statement is generated to query the database for that object.
- Context menu: Right-click an object in the Browser pane and select Show in SQL Editor | Select.
- Manual entry: Type SQL statements directly in SQL Editor. The Auto-completion feature can help with editing.
- Import an SQL script: Click the Import SQL File icon in the toolbar of the Database Query window.

Executing SQL statements

If the SQL script in the SQL Editor has more than one SQL statement, select the statement to execute and click the **Execute** icon in the toolbar of the Database Query window. If no statement in the SQL script is selected, then all the statements in the script are executed. The database data is retrieved and displayed as a grid in the Results tab (752). Messages about the execution are displayed in the Messages tab (753).

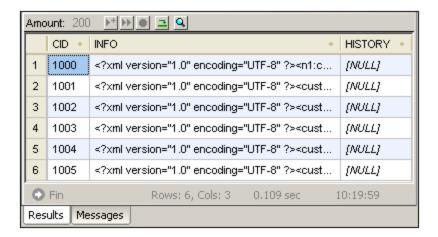

10.8.5 Results and Messages

The Results/Messages pane has two tabs:

- The Results tab shows the data that is retrieved by the query.
- The Messages tab 733 shows messages about the query execution.

Results tab

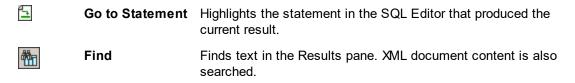

The data retrieved by the query is displayed in the form of a grid in the Results tab(screenshot below).

The following operations can be carried out in the Results tab, via the context menu that pops up when you right-click in the appropriate location in the Results tab:

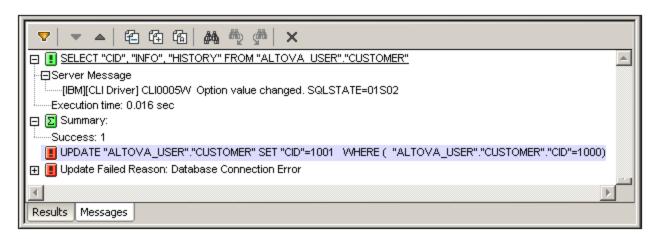

- Sorting on a column: Right-click anywhere in the column on which the records are to be sorted, then select Sorting | Ascending/Descending/Restore Default.
- Copying to the clipboard: This consists of two steps: (i) selecting the data range; and (ii) copying the selection. Data can be selected in several ways: (i) by clicking a column header or row number to select the column or row, respectively; (ii) selecting individual cells (use the Shift and/or Ctrl keys to select multiple cells); (iii) right-clicking a cell, and selecting Selection | Row/Column/All. After making the selection, right-click, and select Copy Selected Cells. This copies the selection to the clipboard, from where it can be pasted into another application. To copy the header together with the cells, use the command Copy Selected Cells with Header.

The Results tab has the following toolbar icons:

Messages tab

The Messages tab provides information on the previously executed SQL statement and reports errors or warning messages.

The toolbar of the Messages tab contains icons that enable you to customize the view, navigate it, and copy messages to the clipboard. The **Filter** icon enables the display of particular types of messages to be toggled on or off. The **Next** and **Previous** icons lets you step through the list, downwards and upwards, respectively. Messages can also be copied with or without their child components to the clipboard, enabling them to be pasted in documents. The **Find** function enables you to specify a search term and then search up or down the listing for this term. Finally, the **Clear** icon clears the contents of the Report pane.

Note: These toolbar icon commands are also available as context menu commands.

XBRL 735

11 XBRL

About XBRL

XBRL is an XML language that is used for business reporting (see Wikipedia and xbrl.org for more information). An XBRL taxonomy is an XML Schema (.xsd document) that defines the structure of a financial report; an XBRL instance document (a .xml document) contains the data to be reported. One of the most commonly used XBRL taxonomies is US-GAAP, which is the basis of financial reports that US companies submit to the US Securities and Exchange Commission (SEC). Internationally, it is the International Financial Reporting Standards (IFRS) that is most commonly used.

One way to generate reports to submit to regulators (such as the SEC) is to transform an XBRL instance document (which contains the business or financial data) with an XSLT stylesheet to a suitable output format (such as HTML or text). In StyleVision, users can create an SPS based on an XBRL taxonomy. From the SPS, an HTML output document can be generated that contains the report to be submitted.

StyleVision's XBRL features

If an SPS is based on an XBRL taxonomy, then the taxonomy is displayed in a tree structure that is derived from the relationships in the presentation linkbase of the taxonomy. Users can then visually design the report to be created in the same way like they would design any other SPS to dragging taxonomy components from the schema tree into the design.

While the manual creation of a design can be painstaking, the XBRL Table Wizard provides a quick and easy way to automatically create a report in table format. The structure and contents of the table can be customized, and the table can subsequently be edited in the design to add new table elements and specify formatting properties. Furthermore, if a taxonomy is extended from the US-GAAP taxonomy, tables can be automatically generated in line with best practices recommended for US-GAAP taxonomies.

About Inline XBRL

Often, regulators, such as the SEC, allow company reports to be submitted as (X)HTML documents that contain XBRL data. XBRL data that is contained in an (X)HTML document is known as Inline XBRL; it is stored in an Inline XBRL element. The advantage for companies is that the (X)HTML document contains both the XBRL data as well as the presentation information. This saves the company the trouble of generating a human-readable report from an XBRL instance document.

In StyleVision, you can include Inline XBRL templates in an SPS so that Inline XBRL elements are generated in output documents.

In this section

This section is organized into the following sub-sections:

- <u>Taxonomy Manager</u> which describes how to use the Taxonomy Manager tool to install, upgrade, and manage taxonomies for use with StyleVision.
- <u>Creating an XBRL SPS File</u> taxonomy as the starting point. <u>Taxonomy Packages</u> are also supported.
- <u>Taxonomy Structure</u> explains the structure of the schema tree, which is the source of the taxonomy components that will be used for the SPS design, and <u>Taxonomy Source Properties</u> documents the various taxonomy property settings.

- <u>Taxonomy Source Properties</u> describes the settings to define properties of the source taxonomy when used in an SPS.
- XBRL Templates describes the various XBRL templates that can be inserted in the design.
- Open, Closed, and Classic Modes 776 describes these "modes", which determine whether the data is constrained, and the templates that can use these modes.
- The XBRL Table Wizard shows how to use the XBRL Table Wizard.

 US-GAAP Table Wizard to generating tables from the entries of a US-GAAP taxonomy's Presentation linkbase.
- The XBRL Chart Wizard explains how chart representations of data in the XBRL file can be created.
- Properties and Formatting (832) explains how CSS styles are used for formatting XBRL tables and how you can use these styles.
- Inline XBRL 834 shows how content from the XBRL file can be output to an (X)HTML file as an Inline XBRL element.
- Altova XBRL Extension Functions 838 lists the XPath extension functions developed by Altova for use with XBRL in an SPS.

Useful inks

The XBRL International website is a good reference point for XBRL. The XBRL recommendations can also be accessed via the XBRL International website.

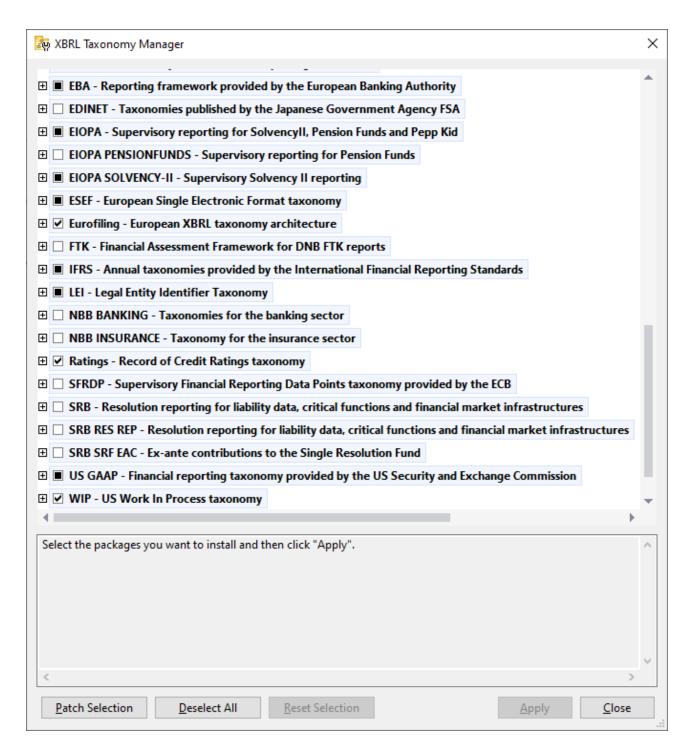

Altova website: & XBRL Rendering

11.1 Taxonomy Manager

XBRL Taxonomy Manager is an Altova tool that provides a centralized way to install and manage XBRL taxonomies for use across all Altova's XBRL-enabled applications, including StyleVision.

 On Windows, Taxonomy Manager has a graphical user interface (screenshot below) and is also available at the command line. (Altova's desktop applications are available on Windows only; see list below.)

• On Linux and macOS, Taxonomy Manager is available at the command line only. (Altova's server applications are available on Windows, Linux, and macOS; see list below.)

Altova's XBRL-enabled applications

Desktop applications (Windows only)	Server applications (Windows, Linux, macOS)
Altova XBRL Add-ins for Excel (EBA, ESEF, EIOPA, WIP)	MapForce Server (Standard and Advanced Editions)

MapForce Enterprise Edition	RaptorXML+XBRL Server
StyleVision Enterprise Edition	StyleVision Server
XMLSpy Enterprise Edition	

Installation and de-installation of Taxonomy Manager

Taxonomy Manager is installed automatically when you first install a new version of Altova Mission Kit Enterprise Edition or of any of Altova's XBRL-enabled applications (see table above).

Likewise, it is removed automatically when you uninstall the last Altova XBRL-enabled application from your computer.

Taxonomy Manager features

Taxonomy Manager provides the following features:

- Shows XBRL taxonomies installed on your computer and checks whether new versions are available for download.
- Downloads newer versions of XBRL taxonomies independently of the Altova product release cycle. (Altova stores taxonomies online, and you can download them via Taxonomy Manager.)
- Install or uninstall any of the multiple versions of a given taxonomy (or all versions if necessary).
- An XBRL taxonomy may have dependencies on other taxonomies. When you install or uninstall a particular taxonomy, Taxonomy Manager informs you about dependent taxonomies and will automatically install or remove them as well.
- Taxonomy Manager uses the XML catalog mechanism to map schema references to local files. In the
 case of large XBRL taxonomies, processing will therefore be faster than if the taxonomies were at a
 remote location.
- All major taxonomies are available via Taxonomy Manager and are regularly updated for the latest
 versions. This provides you with a convenient single resource for managing all your taxonomies and
 making them readily available to all of Altova's XBRL-enabled applications.
- Changes made in Taxonomy Manager take effect for all Altova products installed on that machine.

Custom XBRL Taxonomies

If you need to work with custom XBRL taxonomies that are not included with Taxonomy Manager, you can add these taxonomies to the set of custom packages that StyleVision can reference. Do this as follows:

- In Altova desktop applications: Select the **Tools | Options** menu command, and go to the XBRL | Taxonomy Packages section. Browse for the ZIP package of your custom XBRL taxonomy. For more information, see the description of this command in your desktop product documentation.
- In Altova server applications: When running commands from the command line that support custom taxonomies, provide the --taxonomy-package or --taxonomy-package-config-file option. For example: In RaptorXML+XBRL Server, these options are supported by XBRL validation commands such as valxbrl or valxbrltaxonomy; in MapForce, they are supported by run command.

How it works

Altova stores all XBRL taxonomies used in Altova products online. This repository is updated when new versions of the taxonomies are released. Taxonomy Manager displays information about the latest available

taxonomies when invoked in both its GUI form as well as on the CLI. You can then install, upgrade or uninstall taxonomies via Taxonomy Manager.

Taxonomy Manager also installs taxonomies in one other way. At the Altova website (https://www.altova.com/taxonomy-manager) you can select a taxonomy and its dependent taxonomies that you want to install. The website will prepare a file of type <code>.altova_taxonomies</code> for download that contains information about your taxonomy selection. When you double-click this file or pass it to Taxonomy Manager via the CLI as an argument of the install command, Taxonomy Manager will install the taxonomies you selected.

Local cache: tracking your taxonomies

All information about installed taxonomies is tracked in a centralized cache directory on your computer, located here:

Windows	C:\ProgramData\Altova\pkgs\.cache
Linux	/var/opt/Altova/pkgs\.cache
macOS	/var/Altova/pkgs

This cache directory is updated regularly with the latest status of taxonomies at Altova's online storage. These updates are carried out at the following times:

- Every time you start Taxonomy Manager.
- When you start StyleVision for the first time on a given calendar day.
- If StyleVision is open for more than 24 hours, the cache is updated every 24 hours.
- You can also update the cache by running the update 752 command at the command line interface.

The cache therefore enables Taxonomy Manager to continuously track your installed taxonomies against the taxonomies available online at the Altova website.

Do not modify the cache manually!

The local cache directory is maintained automatically based on the taxonomies you install and uninstall. It should not be altered or deleted manually. If you ever need to reset Taxonomy Manager to its original "pristine" state, then, on the command line interface (CLI): (i) run the reset Taxonomy Manager to its original "pristine" state, then, on the command line interface (CLI): (i) run the reset command, and (ii) run the initialize to option.)

HTTP proxy

You can use an HTTP proxy for Taxonomy Manager connections. The proxy settings will be taken from the system's proxy settings and/or StyleVision's local-network proxy settings (defined in the Options dialog (**Tools | Options | Network Proxy**)).

11.1.1 Run Taxonomy Manager

Graphical User Interface

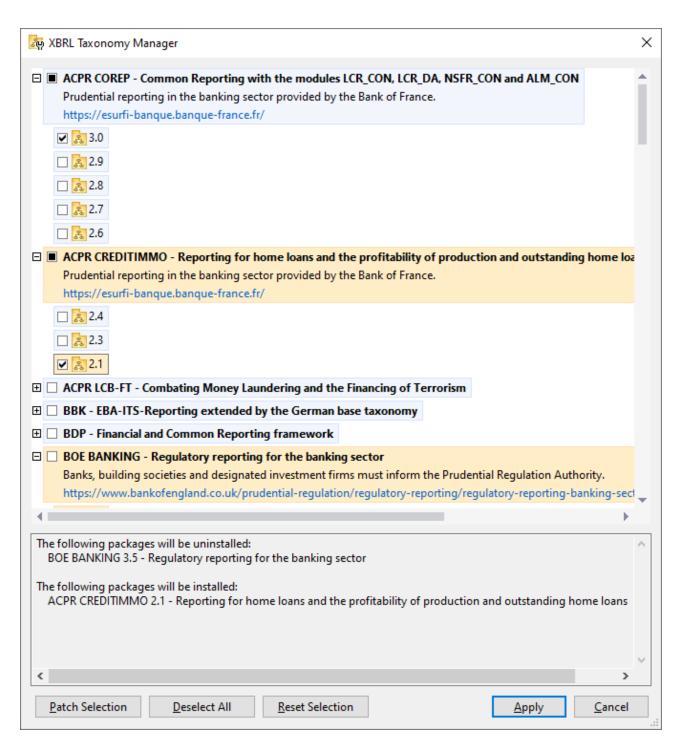

You can access the GUI of Taxonomy Manager in any of the following ways:

• During the installation of StyleVision: Towards the end of the installation procedure, select the check box Invoke Altova Taxonomy Manager to access the XBRL Taxonomy Manager GUI straight away. This will enable you to install taxonomies during the installation process of your Altova application.

- After the installation of StyleVision: After your application has been installed, you can access the Taxonomy Manager GUI at any time, via the menu command Tools | XBRL Taxonomy Manager.
- Via the .altova_taxonomies file downloaded from the Altova's XBRL Taxonomy Download Center:

 Double-click the downloaded file to run the Taxonomy Manager GUI, which will be set up to install the taxonomies you selected (at the website) for installation.

After the Taxonomy Manager GUI (*screenshot below*) has been opened, already installed taxonomies will be shown selected. If you want to install an additional taxonomy, select it. If you want to uninstall an already installed taxonomy, deselect it. After you have made your selections and/or deselections, you are ready to apply your changes. The taxonomies that will be installed or uninstalled will be highlighted and a message about the upcoming changes will be posted to the Messages pane at the bottom of the Taxonomy Manager window (*see screenshot*).

When you click **Apply**, the progress of the installation is displayed in a simplified Taxonomy Manager dialog. If there is an error (for example, a connection error), then an error message will be displayed in the dialog. In this case, fix the error and then click the **Advanced** button, check the taxonomy selection, and retry with **Apply**.

Command line interface

You can run Taxonomy Manager from a command line interface by sending commands to its executable file, taxonomymanager.exe.

The taxonomymanager.exe file is located in the following folder:

- On Windows: C:\ProgramData\Altova\SharedBetweenVersions
- On Linux or macOS (server applications only): %INSTALLDIR%/bin, where %INSTALLDIR% is the program's installation directory.

You can then use any of the commands listed in the CLI command reference section.

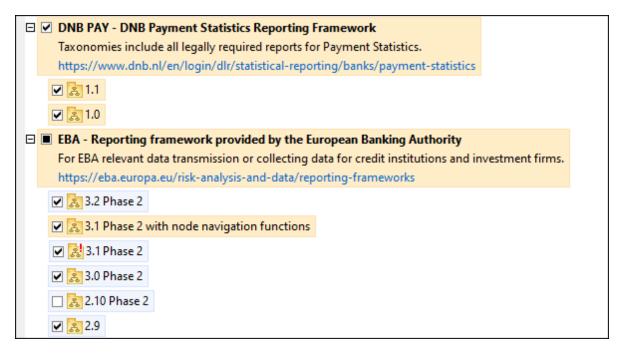

To display help for the commands, run the following:

- On Windows: taxonomymanager.exe --help
- On Linux or macOS (server applications only): sudo ./taxonomymanager --help

11.1.2 Status Categories

Taxonomy Manager categorizes the taxonomies under its management as follows:

- Installed taxonomies. These are shown in the GUI with their check boxes selected (in the screenshot below the checked versions of the DNB and EBA taxonomies are installed taxonomies). If all the versions of a taxonomy are selected, then the selection mark is a tick. If at least one version is unselected, then the selection mark is a solid colored square, as with EBA in the screenshot below. You can deselect an installed taxonomy to uninstall it.
- *Uninstalled available taxonomies.* These are shown in the GUI with their check boxes unselected. You can select the taxonomies you want to **install**.

• Upgradeable taxonomies are those which have been revised by their issuers since they were installed. They are indicated in the GUI by a icon (see screenshot above). You can patch an installed taxonomy with an available revision.

Points to note

• In the screenshot above, both DNB taxonomies and some of the EBA taxonomies are checked. Those with the blue background are already installed. Those with the yellow background are uninstalled and have been selected for installation. Note that (i) the EBA 2.10 Phase 2 taxonomy is not installed and has not been selected for installation, (ii) the EBA 3.1 Phase 2 taxonomy has been installed, but it has been patched by its issuer since it was installed and the patch has not yet been installed.

When running Taxonomy Manager from the command line, the <u>list</u> command is used with different options to list different categories of taxonomies:

taxonomymanager.exe list	Lists all installed and available taxonomies; upgradeables are also indicated
taxonomymanager.exe list	Lists installed taxonomies only; upgradeables are also indicated
taxonomymanager.exe list	Lists upgradeable taxonomies

Note: On Linux and macOS, use sudo ./taxonomymanager list

11.1.3 Patch or Install a Taxonomy

Patch an installed taxonomy

Occasionally, XBRL taxonomies may receive patches (upgrades or revisions) from their issuers. When Taxonomy Manager detects that patches are available, these are indicated in the taxonomy listings of Taxonomy Manager and you can install the patches quickly.

In the GUI

Patches are indicated by the icon. (Also see the previous topic about status categories.) If patches are available, the **Patch Selection** button will be enabled. Click it to select and prepare all patches for installation. In the GUI, the icon of each taxonomy that will be patched changes from to to and the Messages pane at the bottom of the dialog lists the patches that will be applied. When you are ready to install the selected patches, click **Apply**. All patches will be applied together. Note that if you deselect a taxonomy marked for patching, you will actually be uninstalling that taxonomy.

On the CLI

To apply a patch at the command line interface:

- 1. Run the <u>list -u</u> command. This lists any taxonomies where patch upgrades are available.
- 2. Run the upgrade 752 command to install all the patches.

Install an available taxonomy

You can install taxonomies using either the Taxonomy Manager GUI or by sending Taxonomy Manager the install instructions via the command line.

Note: If the current taxonomy references other taxonomies, the referenced taxonomies are also installed.

In the GUI

To install taxonomies using the Taxonomy Manager GUI, select the taxonomies you want to install and click **Apply**.

You can also select the taxonomies you want to install at the <u>Altova website</u> and generate a downloadable <u>.altova_taxonomies</u> file. When you double-click this file, it will open Taxonomy Manager with the taxonomies you wanted pre-selected. All you will now have to do is click **Apply**.

On the CLI

To install taxonomies via the command line, run the install (749) command:

taxonomymanager.exe install [options] Taxonomy+

where Taxonomy is the taxonomy (or taxonomies) you want to install or a .altova_taxonomies file. A taxonomy is referenced by an identifier of format <name>-<version>. (The identifiers of taxonomies are displayed when you run the list command.) You can enter as many taxonomies as you like. For details, see the description of the install command.

Note: On Linux or macOS, use the sudo ./taxonomymanager command.

Installing a required taxonomy

When you run an XBRL-related command in StyleVision and StyleVision discovers that a taxonomy it needs for executing the command is not present or is incomplete, Taxonomy Manager will display information about the missing taxonomy. You can then directly install any missing taxonomy via Taxonomy Manager.

In the Taxonomy Manager GUI, you can view all previously installed taxonomies at any time by running Taxonomy Manager from **Tools | Taxonomy Manager**.

11.1.4 Uninstall a Taxonomy, Reset

Uninstall a taxonomy

You can uninstall taxonomies using either the Taxonomy Manager GUI or by sending Taxonomy Manager the uninstall instructions via the command line.

Note: If the taxonomy you want to uninstall references other taxonomies, then the referenced taxonomies are also uninstalled.

In the GUI

To uninstall taxonomies in the Taxonomy Manager GUI, clear their check boxes and click **Apply**. The selected taxonomies and their referenced taxonomies will be uninstalled.

To uninstall all taxonomies, click Deselect All and click Apply.

On the CLI

To uninstall taxonomies via the command line, run the uninstall command:

taxonomymanager.exe uninstall [options] Taxonomy+

where each Taxonomy argument is a taxonomy you want to uninstall or a .altova_taxonomies file. A taxonomy is specified by an identifier that has a format of <name>-<version>. (The identifiers of taxonomies are displayed when you run the list of command.) You can enter as many taxonomies as you like. For details, see the description of the uninstall command.

Note: On Linux or macOS, use the sudo ./taxonomymanager command.

Reset Taxonomy Manager

You can reset Taxonomy Manager.

- In the GUI, click **Reset Selection**. This resets the the GUI to show what taxonomies are currently installed. Any selections or de-selections that the user has made in the current session will be canceled.
- On the CLI, run the <u>reset</u> command. This removes all installed taxonomies and the cache directory.

After running this command, make sure to run the <u>initialize</u> (748) command in order to recreate the cache directory. Alternatively, run the <u>reset</u> (750) command with the -i option.

Note that $\underline{reset} - \underline{i}$ restores the original installation of the product, so it is recommended that you run the \underline{update} command after performing a reset. Alternatively, run the \underline{reset} command with the -i and -u options.

11.1.5 Command Line Interface (CLI)

To call Taxonomy Manager at the command line, you need to know the path of the executable. By default, the Taxonomy Manager executable is installed here:

```
C:\ProgramData\Altova\SharedBetweenVersions\TaxonomyManager.exe
```

Note: On Linux and macOS systems, once you have changed the directory to that containing the executable, you can call the executable with sudo ./taxonomymanager. The prefix ./ indicates that the executable is in the current directory. The prefix sudo indicates that the command must be run with root privileges.

Command line syntax

The general syntax for using the command line is as follows:

```
<exec> -h | --help | --version | <command> [options] [arguments]
```

In the listing above, the vertical bar I separates a set of mutually exclusive items. The square brackets II indicate optional items. Essentially, you can type the executable path followed by either --h, --help, or --version options, or by a command. Each command may have options and arguments. The list of commands is described in the following sections.

11.1.5.1 help

This command provides contextual help about commands pertaining to Taxonomy Manager executable.

Syntax

```
<exec> help [command]
```

Where [command] is an optional argument which specifies any valid command name.

Note the following:

- You can invoke help for a command by typing the command followed by -h or --help, for example: <exec> list -h
- If you type -h or --help directly after the executable and before a command, you will get general help (not help for the command), for example: <exec> -h list

Example

The following command displays help about the list command:

```
taxonomymanager help list
```

11 1 5 2 info

This command displays detailed information for each of the taxonomies supplied as a Taxonomy argument. This information for each submitted taxonomy includes the title, version, description, publisher, and any dependent taxonomies, as well as whether the taxonomy has been installed or not.

Syntax

```
<exec> info [options] Taxonomy+
```

- The Taxonomy argument is the name of a taxonomy or a part of a taxonomy's name. (To display a taxonomy's package ID and detailed information about its installation status, you should use the list [49] command.)
- Use <exec> info -h to display help for the command.

Example

The following command displays information about the eba-2.10 and us-gaap-2020.0 taxonomies:

```
taxonomymanager info eba-2.10 us-gaap-2020.0
```

11.1.5.3 initialize

This command initializes the Taxonomy Manager environment. It creates a cache directory where information about all taxonomies is stored. Initialization is performed automatically the first time an XBRL-enabled Altova application is installed. You would not need to run this command under normal circumstances, but you would typically need to run it after executing the reset command.

Syntax

```
<exec> initialize | init [options]
```

Options

The initialize command takes the following options:

silent,s	Display only error messages. The default is false.
verbose,v	Display detailed information during execution. The default is false.
help,h	Display help for the command.

Example

The following command initializes Taxonomy Manager:

```
taxonomymanager initialize
```

11 1 5 4 install

This command installs one or more taxonomies.

Syntax

```
<exec> install [options] Taxonomy+
```

To install multiple taxonomies, add the Taxonomy argument multiple times.

The Taxonomy argument is one of the following:

- A taxonomy identifier (having a format of <name>-<version>, for example: eba-2.10). To find out the taxonomy identifiers of the taxonomies you want, run the 1ist
 749
 command. You can also use an abbreviated identifier if it is unique, for example eba. If you use an abbreviated identifier, then the latest version of that taxonomy will be installed.
- The path to a .altova_taxonomies file downloaded from the Altova website. For information about these files, see <u>Introduction to TaxonomyManager: How It Works</u> ⁷³⁷.

Options

The install command takes the following options:

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Example

The following command installs the latest eba (European Banking Authority) and us-gaap (US Generally Accepted Accounting Principles) taxonomies:

```
taxonomymanager install eba us-gaap
```

11.1.5.5 list

This command lists taxonomies under the management of Taxonomy Manager. The list displays one of the following

- All available taxonomies
- Taxonomies containing in their name the string submitted as a Taxonomy argument
- Only installed taxonomies
- Only taxonomies that can be upgraded

Syntax

```
<exec> list | ls [options] Taxonomy?
```

If no Taxonomy argument is submitted, then all available taxonomies are listed. Otherwise, taxonomies are listed as specified by the submitted options (see example below). Note that you can submit the Taxonomy argument multiple times.

<u>Options</u>

The list command takes the following options:

```
--installed, --i List only installed taxonomies. The default is false.

--upgradeable, --u List only taxonomies where upgrades (patches) are available. The default is false.

--help, --h Display help for the command.
```

Examples

- To list all available taxonomies, run: taxonomymanager list
- To list installed taxonomies only, run: taxonomymanager list -i
- To list taxonomies that contain either "eba" or "us-gaap" in their name, run: taxonomymanager list eba us-gaap

11.1.5.6 reset

This command removes all installed taxonomies and the cache directory. You will be completely resetting your taxonomy environment. After running this command, be sure to run the <u>initialize</u> command to recreate the cache directory. Alternatively, run the <u>reset</u> command with the <u>-i</u> option. Since <u>reset</u> <u>-i</u> restores the original installation of the product, we recommend that you run the <u>update</u> command after performing a reset and initialization. Alternatively, run the reset command with both the <u>-i</u> and <u>-u</u> options.

Syntax

```
<exec> reset [options]
```

Options

The reset command takes the following options:

```
--init, --i Initialize Taxonomy Manager after reset. The default is false.

--update, --u Updates the list of available taxonomies in the cache. The default is false.
```

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Examples

- To reset Taxonomy Manager, run: taxonomymanager reset
- To reset Taxonomy Manager and initialize it, run: taxonomymanager reset -i
- To reset Taxonomy Manager, initialize it, and update its taxonomy list, run: taxonomymanager reset i -u

11.1.5.7 uninstall

This command uninstalls one or more taxonomies. By default, any taxonomies referenced by the current one are uninstalled as well. To uninstall just the current taxonomy and keep the referenced taxonomies, set the option --k.

Syntax

```
<exec> uninstall [options] Taxonomy+
```

To uninstall multiple taxonomies, add the Taxonomy argument multiple times.

The Taxonomy argument is one of the following:

- A taxonomy identifier (having a format of <name>-<version>, for example: eba-2.10). To find out the taxonomy identifiers of the taxonomies that are installed, run the list -i command. You can also use an abbreviated taxonomy name if it is unique, for example eba. If you use an abbreviated name, then all taxonomies that contain the abbreviation in its name will be uninstalled.
- The path to a .altova_taxonomies file downloaded from the Altova website. For information about these files, see Introduction to TaxonomyManager: How It Works.

Options

The uninstall command takes the following options:

```
--keep-references, --k

Set this option to keep referenced taxonomies. The default is false.

--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Example

The following command uninstalls the eba-2.10 and us-gaap-2020.0 taxonomies and their dependencies:

```
taxonomymanager uninstall eba-2.10 us-gaap-2020.0
```

The following command uninstalls the eba-2.10 taxonomy but not the taxonomies it references:

```
taxonomymanager uninstall --k eba-2.10
```

11.1.5.8 update

This command queries the list of taxonomies available from the online storage and updates the local cache directory. You should not need to run this command unless you have performed a reset and initialize 748.

Syntax

```
<exec> update [options]
```

Options

The update command takes the following options:

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.

Display help for the command.
```

Example

The following command updates the local cache with the list of latest taxonomies:

```
taxonomymanager update
```

11.1.5.9 upgrade

This command upgrades all installed taxonomies that can be upgraded to the latest available *patched* version. You can identify upgradeable taxonomies by running the list -u⁷⁴⁹ command.

Note: The upgrade command removes a deprecated taxonomy if no newer version is available.

Syntax

```
<exec> upgrade [options]
```

Options

The upgrade command takes the following options:

```
--silent, --s

Display only error messages. The default is false.

--verbose, --v

Display detailed information during execution. The default is false.
```

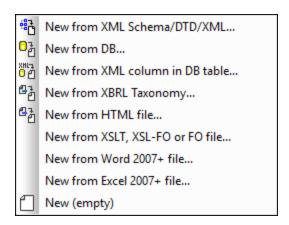

--help, --h

Display help for the command.

11.2 Creating an XBRL SPS File

To create a new SPS file based on an XBRL taxonomy, do the following:

1. Click the menu File, hover over the New command and, in the submenu that rolls out (screenshot below), click the command New from XBRL Taxonomy.

- 2. In the dialog that appears, browse for and select the required XBRL taxonomy, then click **Open**.
- 3. You will be prompted to assign a Working XBRL File. If you wish to assign one, click Browse and select the XBRL instance file you wish to use as the Working XBRL File. The data from the Working XBRL File will be used for the previews. Alternatively, you can choose to not assign a Working XBRL File by clicking the Skip button. It is useful to assign a Working XBRL File since you will then be able to preview different outputs with actual XBRL data and test your design more thoroughly.

A new SPS based on the XBRL taxonomy will be created.

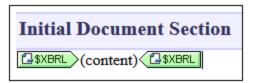

XSLT version and XSLT engine to use for XBRL-based SPS/stylesheet

To use the full range of StyleVision's XBRL functionality, set the XSLT version to XSLT 2.0 or XSLT 3.0 110. If you generate an XSLT stylesheet from an XBRL-based SPS, use Altova's XSLT engines to carry out the transformation. Altova XSLT engines are available in Altova products, including in StyleVision, StyleVision Server, XMLSpy, and RaptorXML Server.

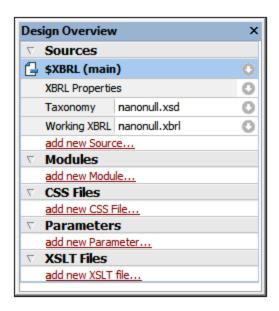

Main points about the XBRL SPS file

Note the following points about the newly created SPS file:

Design View displays a root XBRL template with a contents placeholder (screenshot below).

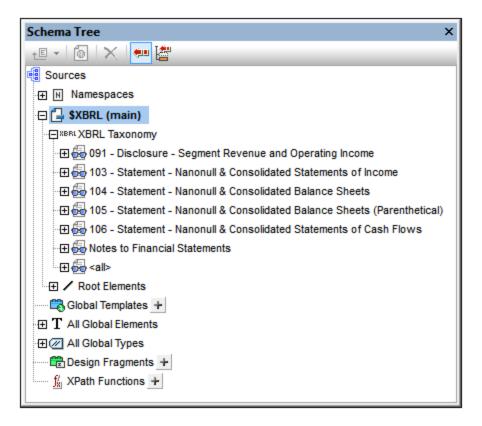

• The Design Overview sidebar (*screenshot below*) lists the taxonomy file (.xsd file) and Working XBRL File (.xbrl file). This window can be used to add other SPS elements as described in the Design Overview section 5. To set properties of the source taxonomy 760, right-click the XBRL Properties item or click its Context Menu icon and then select the command Edit XBRL Source Taxonomy Properties. The dialog that appears is described in the section, Taxonomy Source Properties 760.

• The Schema Tree sidebar displays the XBRL taxonomy in a tree form. This tree structure is derived from the taxonomy's presentation linkbase (the links specifying presentation relationships between concepts; typically, the presentation linkbase is in a separate XML file).

XBRL

The structure of the schema tree is described in the next section, <u>Taxonomy Structure</u> 151.

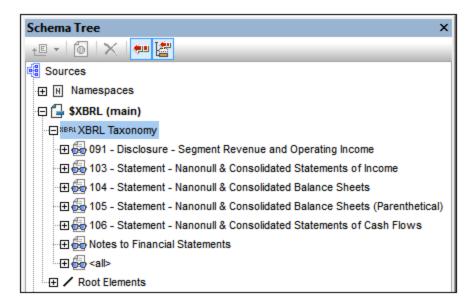

XBRL Taxonomy Structure 757

11.3 Taxonomy Structure

The structure of the taxonomy in the schema tree (see screenshot below) is derived from the taxonomy's presentation linkbase (the links specifying presentation relationships between concepts; typically, the presentation linkbase is in a separate XML file).

First level: presentation links

The taxonomy's tree structure organizes the taxonomy's concepts according to information in the presentation linkbase. In a presentation linkbase, a set of related concepts are grouped within a presentationLink element. The first level of the tree structure (*screenshot below*), therefore, represents the presentation links in the presentation linkbase. The screenshot below shows a taxonomy with six items representing the six presentation links in the taxonomy. Additionally on this first level, an item named <all> displays all the taxonomy concepts in a flat list. The <all> item contains all taxonomy concepts, including those that are not included in the presentation linkbase.

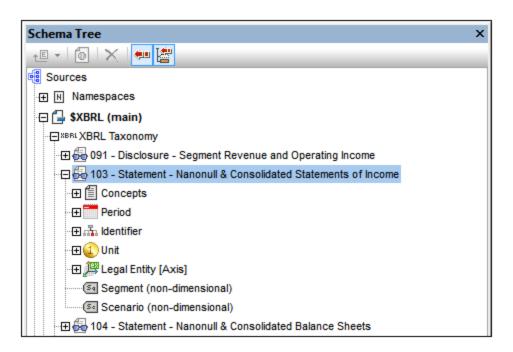

Second level: aspects

The second level within a single presentation link shows the link's aspects.

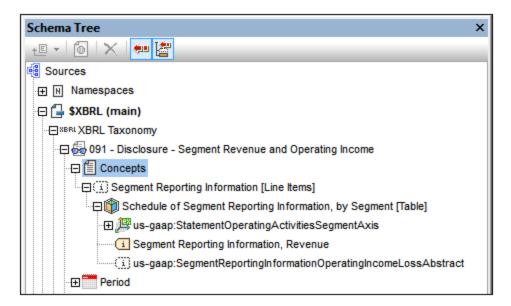

Aspects are: concepts, a period, an identifier, a unit, explicit dimensions, typed dimensions, non-dimensional segments, and non-dimensional scenarios (see screenshot below).

758 XBRL Taxonomy Structure

At the second level of the XBRL taxonomy, therefore, the following items appear:

• Concepts: A tree structure is created based on the presentation arcs within the presentation link. Each presentation arc is evaluated and the resultant relationships produced by the network of presentation arcs is represented in a tree (see screenshot below). The white icons in the tree are abstract items; these cannot occur in the instance file but are used in the presentation linkbase to group XBRL items.

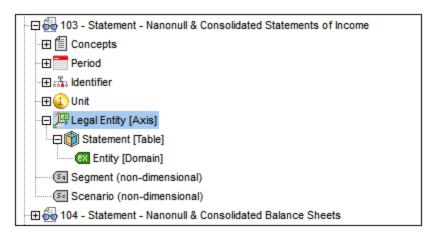

• **Periods:** Indicates the period of the presentation link. Lists the various period types that a fact in an instance document can have (xbrli:startDate, xbrli:endDate, xbrli:instant, and xbrli:forever). In the schema tree the xbrli:period element and its allowed children (the four period types listed above) are listed and can be inserted individually in the design.

XBRL Taxonomy Structure 759

• *Identifiers:* Shows the scheme attribute of the xbrli:identifier element. The xbrli:identifier element and its scheme attribute can be inserted in the design.

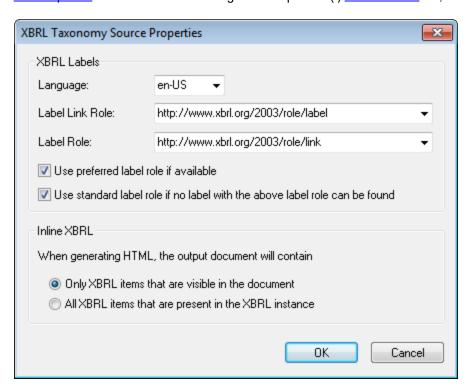

- Units: Specifies the unit of the presentation link.
- **Segments and scenarios:** These aspects contain explicit or typed dimensional information. They are indicated with yellow icons.
- **Non-dimensional (non-XDT) segments and scenarios:** These aspects constrain those child elements, respectively, of the segment and scenario elements that do not represent explicit or typed dimensional information. They are indicated with gray icons.
- **Dimensions:** If a concept in a presentation link has a dimension (dimensions are defined in the definitions linkbase), then that dimension is listed for that presentation link (*screenshot below*).
 - Dimensions are indicated in the tree with a three-dimensional axis (and in the case of US-GAAP taxonomies with an [Axis] label).
 - o Hypercubes are indicated with a cube icon (and, for US-GAAP, with the [Table] label).
 - o *Domains* are shown with an EX or TY icon indicating whether the dimension is explicit or typed. In US-GAAP taxonomies, the [Domain] label is also shown.
 - o Domain members are indicated in US-GAAP taxonomies with the [Member] label.

The <all> item in the schema tree

The <all> item in the schema tree contains a flat list of all concepts in the taxonomy, irrespective of whether they are included in the presentation linkbase or not. This enables access to concepts that are not present in the presentation linkbase. Such scenarios are possible, for example, when a taxonomy is extended to include a small number of new concepts that are not added to the presentation linkbase, or when no presentation linkbase is associated with the taxonomy. The <all> item additionally lists the period and identifier items, and optionally any dimensions that have been defined.

11.4 Taxonomy Source Properties

XBRL Labels

Items in a taxonomy can have multiple labels, but only one label of each set can be used in the design. Which one is used is specified in the XBRL Taxonomy Source Properties dialog (accessed via the <u>Properties item in the Design Overview window</u> 154). Using a combination of the options in this dialog (*screenshot below*), the desired label properties can be selected for the document as a whole.

The XBRL Taxonomy Source Properties dialog enables you to select the required label properties using the following options:

- Each of the three combo boxes (*Language*; *Label Link Role*; *Label Role*) lists all options in that category that are used in the taxonomy. For example, the combo box for the *Language* option lists every language that has been specified in the taxonomy. Select the language in which you require labels to appear. In the same way, select the desired label link role and label role.
- On presentation arcs, there is an optional attribute that specifies the preferred label role. If this is available on a presentation arc, it will be used if the *Preferred Label Role* check box is checked (the default setting).
- The standard label role is that named http://www.xbrl.org/2003/role/label and will be used if: (i) the label role specified in the dialog cannot be found, and (ii) the *Standard Label Role* option is checked. The *Standard Label Role* option is checked by default.

Overriding the document's label properties

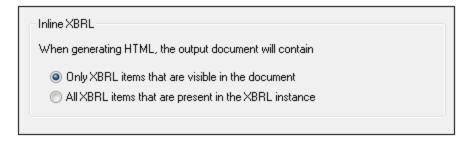

The label properties for the document (made in the XBRL Taxonomy Source Properties dialog as described above) can be overridden for specific taxonomy items by: (i) selecting the relevant item in the design, and (ii) setting properties for that item's label in the Properties sidebar (*screenshot below*).

Inline XBRL

XBRL items (facts) from the source XBRL instance document may or may not be displayed in the SPS design. The Inline XBRL options in the XBRL Taxonomy Source Properties dialog enables you to select whether:

- 1. Even source XBRL items that are not included in the SPS design are generated in the (X)HTML output, or
- 2. Only the XBRL items that are included in the SPS design are generated in the (X)HTML output. Items that are not displayed in the design will be output as hidden data inside the <HEAD> element of the (X) HTML document. (Note that fractions in hidden data do not include numerators and denominators.)

To specify what source XBRL items should be included in the output, select the appropriate radio button (All XBRL items in the XBRL instance or Only XBRL items in the design document).

762 XBRL XBRL XBRL Templates

11.5 XBRL Templates

The XBRL SPS design consists of one **\$XBRL** root template, which contains a hierarchy of templates. This is similar to SPS designs based on XML Schemas. One major difference, however, is that XBRL SPS designs can use **XBRL-specific templates** in addition to the schema node templates that are used in schema-based designs. These **"XBRL templates"** provide an abstraction layer that enables the SPS designer to think in XBRL terms as opposed to the XML structures used to express the XBRL data model.

XBRL templates for the different kinds of XBRL components can be placed in the design either by dragging a component from the <u>Schema Tree</u> or via the **Insert XBRL Element** command (of the **Insert** menu or Design View context menu). XBRL templates are useful because they provide a quick way to create the main XBRL components at desired locations in the design. XBRL templates can be edited just as any other template. For example, conditions or Design Fragments can be inserted within the template.

This section is organized as follows:

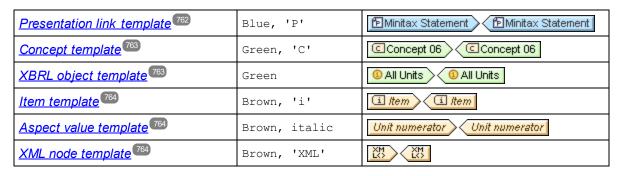

- <u>Types of Templates</u> (32): XBRL templates are grouped into different types, each of which has unique properties. Knowing these properties is important for working with the templates.
- A listing and description of the templates in the submenu of the Insert XBRL Element command.

Template location

When inserting an XBRL template, make sure that you understand the hierarchical context within which the node is being inserted.

11.5.1 Types of Template

XBRL templates are of the following types:

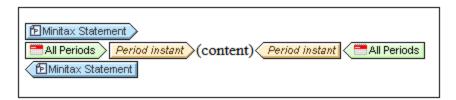

Schema node templates are brown and have a normal (non-italic) typeface.

XBRL SPS designs are created using a combination of <u>XBRL templates</u> (described on this page and the rest of this section, <u>XBRL tables</u> (such as <u>Auto-Calculations</u>), <u>XBRL tables</u> (such as <u>Auto-Calculations</u>) and <u>Conditions</u>)) (37)

Presentation link templates

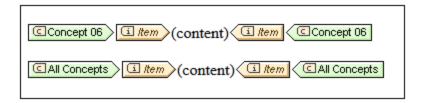

Presentation link templates are created when you drag a presentation link from the <u>Schema Tree</u> into the design and create it as an XBRL template. The name of the presentation link appears in the template tags. The screenshot below shows a presentation link template that has been created for the Minitax Statement presentation link.

The presentation link template selects the presentation link as its context. Template contents can then be defined within this context. It is mainly used for schema tree synchronization when selecting a concept template.

Concept templates

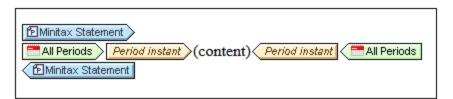

Concept templates are created when you drag a concept from the <u>Schema Tree</u> into the design and create the concept as an XBRL template. The concept is created as a <u>closed mode</u> Concept template, and the concept's name appears in the template tags. You can switch to <u>open mode</u> by selecting **Template Behavior | Open Mode** in the template's context menu.

A Concept template is created empty. You need to place an Item template within it to return facts related to the selected concept. The aspect value template, <u>Concept QName</u> 160, returns the concept's QName.

XBRL object templates

These are templates of certain XBRL elements (Periods, Identifiers, Units, and non-dimensional segments and scenarios) that are created as **XBRL objects**. If the template is specified to be in **open mode**, the XBRL object returns all the elements of the selected type (for example, all Periods; *the screenshot below shows an open-mode XBRL object template*). If the template is specified to be in **closed mode**, the XBRL object returns a specific element of the selected type (for example, one Period from among all Periods). To switch the behavior between open and closed modes, select the template, and, in the template's context menu (accessed by right-clicking the template), hover over the **Template Behavior** command and select the mode you want. See the section Open, Closed, and Classic Modes of the section Open, C

764 XBRL XBRL XBRL Templates

To insert an XBRL object template, right-click in the location where you wish to insert the template. Then hover over the Insert XBRL Element menu item. From the submenu that appears, select the XBRL element you wish to add as the XBRL object template.

The important point to note is that these templates each reference a specific XBRL object—and **not an XML node**. This means that, being an object rather an XML node, there will be no context node for XPath expressions created within the object. Mechanisms that require a context node, such as the contents placeholder, therefore will not be resolved. To access the XML node corresponding to the XBRL object, insert the XML Node template (see below 164) within the XBRL object. Alternatively, Altova XBRL extension functions 333 can be used in XPath expressions to access the required nodes.

To display information within an XBRL object template, use one of the following design mechanisms:

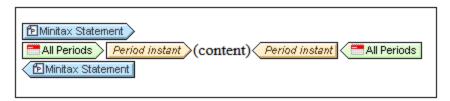

- An aspect value template (<u>see below</u> 164) that accesses a specific aspect of the XBRL component that was created as an XBRL object.
- An XML Node template (<u>see below</u> 164) that references the containing XBRL object as an XML node and allows XPath expressions to be used in this node's context.

Item templates

An Item template iterates over all XBRL facts that satisfy the constraints defined by the enclosing XBRL templates. See the <u>Item template</u> section for details.

Aspect value templates

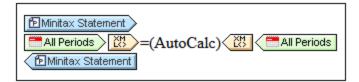

An aspect value template references a specification-defined value of the XBRL aspect represented by the containing XBRL object. To add an aspect value template, right-click within an XBRL object template (*see above*), hover over the <u>Insert XBRL Element</u> menu item, and, from the submenu that appears, select an aspect of the current XBRL component.

The screenshot above shows an aspect value template for the Instant value of the Period aspect. It is created within the XBRL Period template.

XML Node templates

An XML Node template references its nearest ancestor XBRL object as an XML node. This XML node will be the context node for XPath expressions created within the XML Node template. To add an XML Node template, right-click in the location where you wish to insert the template. Then hover over the Insert XBRL Element menu item. From the submenu that appears, select XML Node.

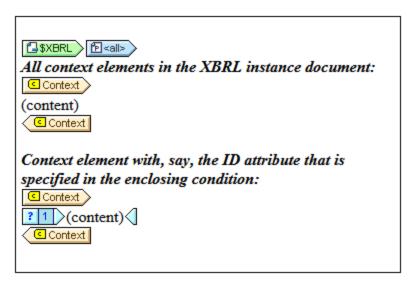

The screenshot above shows an XML Node template that has been created within the XBRL object template of the Period component.

Note: Not all XBRL templates can contain an XML Node template. For example, a <u>Concept template</u> cannot, since there is no XML node for a concept in the instance.

11.5.2 Context

The Context template returns XBRL context elements in the instance file (see listing below).

When the Context template is inserted in the design, it is created as an empty template. You must therefore insert a contents placeholder in the design if you wish to output the contents of the element.

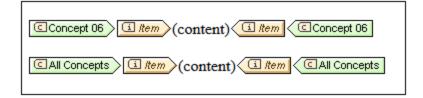

Note the following points:

- The location where the context template is inserted is significant. So you must ensure that you understand the <u>hierarchical context</u> within which the XBRL context node is inserted.
- The template returns all context elements at the hierarchical level at which the template is inserted.
- Within a Context template a particular context element in the instance file can be selected by creating a condition around the contents placeholder. This could be done, for instance by specifying the value of the id attribute of a context element (see screenshot above).

11.5.3 Concept

Concept templates are created when you drag a concept from the <u>Schema Tree</u> into the design and create the concept as an XBRL template. The concept is created as a <u>closed mode</u> Concept template, and the concept's name appears in the template tags. You can switch to <u>open mode</u> by selecting **Template Behavior | Open Mode** in the template's context menu.

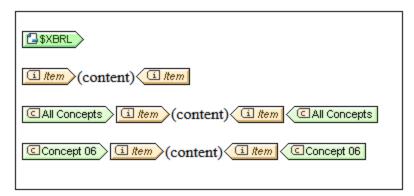

A Concept template is created empty. You need to place an Item template within it to return facts related to the selected concept. The aspect value template, <u>Concept QName</u>, returns the concept's QName.

11.5.4 Item

The Item template iterates over all XBRL facts that satisfy the constraints defined by the enclosing XBRL templates. For example:

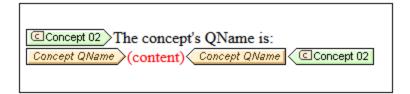

- If an Item template is placed within a Period, then it returns those facts that match the constraints which are in effect at that point.
- If an Item template is placed directly within the \$XBRL template, then all facts in the instance document are returned (see screenshot below).
- If it is placed within an XBRL object template (open or closed mode) then the facts addressed by the XBRL object template are returned. In the case of an open-mode XBRL object, all facts defined within the restrictions of the XBRL object are returned. In the case of a closed-mode XBRL object, the fact/s defined by the properties of the XBRL object are returned.

When the Item template is inserted in the design, it is created as an empty template. You must therefore insert a contents placeholder in the design if you wish to output the contents of the fact. The Item template has a property to allow additional dimensions (in the Properties entry helper), which takes a value of yes or no.

11.5.5 Concept QName

The Concept QName template is an aspect value template. It can be added within a <u>Concept template</u> (see screenshot below), and returns the QName of the XBRL fact/s addressed by the <u>Concept template</u> (see command to insert the Concept QName template (Insert XBRL Element | Concept QName) is enabled only when the cursor is placed within a <u>Concept template</u> (see

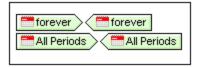

11.5.6 Periods

Period aspect

The Period template iterates over:

- (in open mode) the periods present in the XBRL instance;
- (in closed mode) a single given period, regardless of whether that period occurs in the XBRL instance.

The Period template is indicated with the following tags:

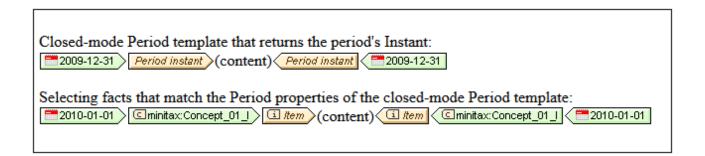

The period element can occur within an xbrli:context element, in a structure as shown below:

When you insert the Period template in the design, it is created as an empty template. You can then do the following:

- Access values of the period (for example, instant, start-date, end-date): Insert the Period aspect's aspect value templates (see below) to return the respective values of these aspects.
- Select Facts: An open or closed mode Period template can be used to select facts that match the properties of the Period.

768 XBRL Templates

Period values

Templates for the following period values can be inserted via the corresponding **Insert XBRL Element** command:

XBRL Element	Datatype	Command
instant	xs:dateTime	Period Instant DateTime
startDate	xs:dateTime	Period Start DateTime
endDate	xs:dateTime	Period End DateTime

The period aspect elements occur within an xbrli:period element. They are typically entered within a Period template. Each aspect value template is inserted with a contents placeholder; it returns the text content of the corresponding period aspect element.

11.5.7 Identifiers

Identifier aspect

The Identifier template iterates over:

- (in open mode) the XBRL identifier elements present in the XBRL instance. The identifier element occurs within an xbrli:context element;
- (in closed mode) a single given identifier, regardless of whether that identifier occurs in the XBRL instance.

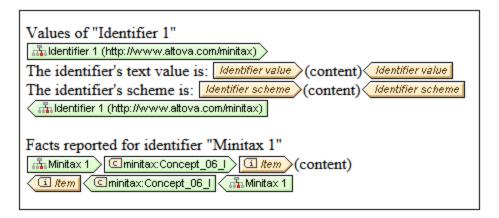

The Identifier template is indicated with the following tags:

When you insert an Identifier template in the design, it is created as an empty template. You can then do the following:

• Iterate over the Identifier's aspects (value and scheme), and return their values: An open or closed mode Identifier template will iterate over the Identifier aspects (value, scheme) that are specified as contents of the Identifier template, and return the values of these aspects.

• Select Facts: An open or closed mode Identifier template can be used to select facts that match the properties of the selected Identifier.

Identifier values

Aspect value templates for the following Identifier aspects can be inserted via the corresponding **Insert XBRL Element** commands:

XBRL Node	Command
@scheme	Identifier scheme
text()	Identifier text value

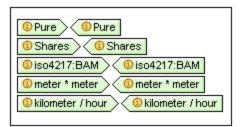

11.5.8 Units and Unitrefs

Unit aspect

The Unit template iterates over:

- (in open mode) the units present in the XBRL instance;
- (in closed mode) a single given unit.

The Unit template is indicated with the following tags. See the section <u>Unit Properties</u> for a detailed description of the different types of units.

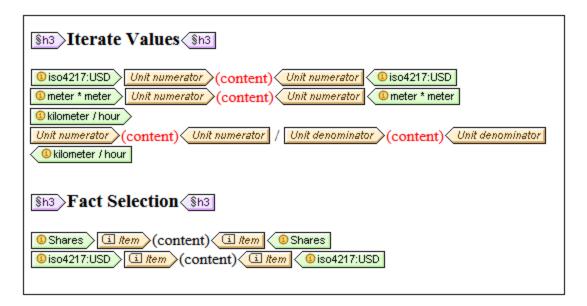

The unit element can have structures as shown below:

```
<xbrli:unit id="IdUnitShares">
```

```
<xbrli:measure>xbrli:shares
  </xbrli:unit>
  <xbrli:unit id="IdUnitSquareMeters">
   <xbrli:measure>minitax:meter</xbrli:measure>
    <xbrli:measure>minitax:meter</xbrli:measure>
  </xbrli:unit>
  <xbrli:unit id="IdUnitDollarsPerShare">
   <xbrli:divide>
     <xbrli:unitNumerator>
       <xbrli:measure</pre>
xmlns:iso4217="http://www.xbrl.org/2003/iso4217">iso4217:USD</xbrli:measure>
     </xbrli:unitNumerator>
     <xbrli:unitDenominator>
       <xbrli:measure>xbrli:shares</xbrli:measure>
     </xbrli:unitDenominator>
    </xbrli:divide>
</xbrli:unit>
```

When you insert a Unit template in the design, it is created as an empty template. You can then do the following (see screenshot below):

- Access values of the unit: Insert the Unit aspect's aspect value templates (see below) to return the respective values of these aspects.
- Select Facts: Select facts in the XBRL instance that contain the defined units. The Item aspect value template within each Unit template, will then return the facts that each closed-mode Unit template selects.

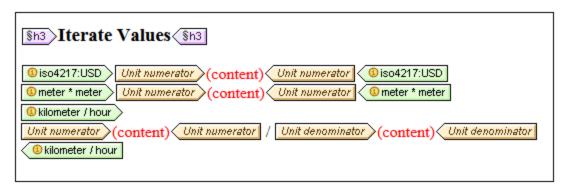

Unitref templates

The Unitref template iterates over all units in the instance, regardless of whether these are referenced by a reported fact or not. Unitref templates are inserted empty and with their tags collapsed. You can expand a collapsed Unit tag (by double-clicking it), and you can insert content within the tags.

Unit values (aspect value templates)

Aspect value templates for the following Unit aspects can be inserted via the **Insert XBRL Element** commands, **Unit Numerator** and **Unit Denominator**. Units can be thought of as ratios consisting of a numerator and denominator. Use **Unit Numerator** to generate the numerator part of a unit, and **Unit Denominator** to generate the denominator part. See the screenshot below.

11.5.9 Dimensions

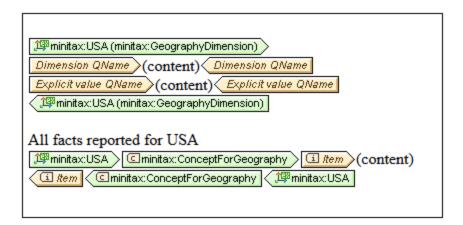

Dimension aspect

Templates of explicit/typed dimensions are created by dragging the element corresponding to the dimension from the schema tree (*see screenshot below*) into the design and creating the element as a Dimension template. The Dimension template iterates over:

- (in open mode) the XBRL dimension elements present in the XBRL instance;
- (in closed mode) a single given dimension.

When you insert an explicit or typed dimension template in the design, it is created as an empty template. You can then do the following:

- Iterate over the domain (of explicit dimensions) or typed element (of typed dimensions), and return their respective aspect values: An open or closed mode dimension template will iterate over the dimension. Aspect value templates within the dimension template (such as Dimension QName, Explicit Value QName, Typed Element) return the respective aspect values. The first template in the screenshot below shows an explicit dimension template containing aspect value templates.
- Select Facts: An open or closed mode dimension template can be used to select concepts that match the properties of the selected dimension. The second template in the screenshot below shows an explicit dimension template that selects concepts.

Dimension values

Aspect value templates for the following Dimension aspects can be inserted via the corresponding **Insert XBRL Element** commands:

Dimension	Aspect Value Template
Explicit	Dimension QName
Explicit	Explicit Value QName
Typed	Dimension QName
Typed	Typed Dimension Element

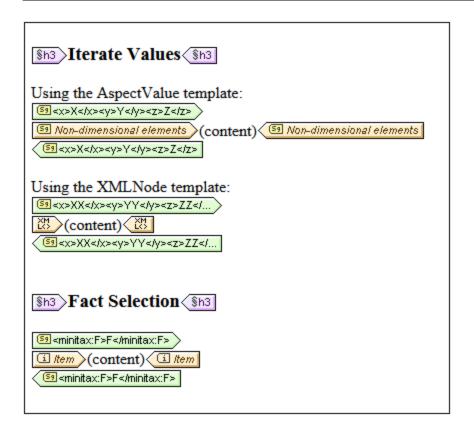

11.5.10 Non-XDT Segments and Scenarios

Templates of non-XDT segments and scenarios are created via the **Insert XBRL Element** command of the Design View context menu. The template is created as empty template in open mode. You can switch to closed mode via the **Template Behavior | Closed Mode** command of the template's context menu.

The non-XDT component template (segment or scenario) can then be used as follows:

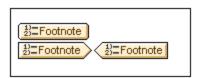

- The contents of the non-XDT component template can be returned by using either the aspect value template *Non-dimensional elements* (*first template in the screenshot below*) or the XML Node template.
- The third template in the screenshot below selects all facts that contain the non-dimensional data defined in the Non-XDT template.

XBRL Templates 773

11.5.11 Footnote

There are two parts to footnotes: (i) a footnote reference, and (ii) the actual footnote. The XBRL Footnote mechanism uses the TOC bookmarking and referencing system to create the footnotes. The Footnote template matches the XBRL footnote element and is created as an empty template. You can then design contents for the footnote and the footnote number. If the tag is collapsed, you can expand it by double-clicking the collapsed tag. The Footnote template is indicated with the following tags:

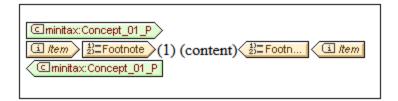

Note: The XBRL Table Wizard automatically creates footnotes if the Generate Footnotes option is checked.

Adding footnotes

A footnote can also be linked to a fact with a footnote arc. In such cases, the footnote can be inserted in the concept template that returns the relevant fact/s (see screenshot below). Use the Insert XBRL Element | Footnote command.

774 XBRL XBRL XBRL Templates

Sorting footnotes

If there are multiple footnotes that are linked to a single fact via footnote arcs, then the footnotes can be sorted. For example, sorting can be specified to be in ascending order of the character at any position in the footnote text. After adding the Footnote template (with the **Insert XBRL Element | Footnote** command), right-click the Footnote template, select the command **Sort By** and, in the Sort dialog that appears, enter the sorting criteria and click **OK**.

The order of the sorting (ascending/descending) is indicated by an icon in the template tag (see screenshot below).

Grouping footnotes

Multiple footnotes can be grouped according to a grouping key. For example, groups can be created on the basis of a grouping key that is the first three characters of the footnote text. To define the grouping key, right-click the Footnote template, select the command **Group By** and, in the Grouping dialog that appears, select the grouping criterion and key 389, and click **OK**.

That grouping has been specified is indicated by a g icon in the template tag (see screenshot above). To display the values of the footnotes by group, enter a user-defined template for the current group (by entering the XPath expression current-group () as the value of the user-defined template); see screenshot above.

Filtering footnotes

Multiple footnotes can be filtered by using an XPath expression. To do this, right-click the Footnote template, select the command **Edit XPath Filter** and, in the <u>Edit XPath Expression dialog</u> that appears, enter an XPath expression that evaluates to a boolean that will select the footnotes to display, and click **OK**. Note that the context node of the XPath expression will be the <u>footnote</u> element.

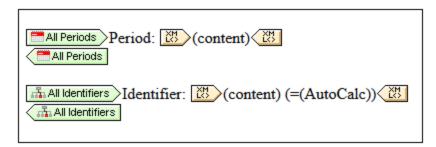

That filtering has been specified is indicated by an icon in the template tag (see screenshot above). (see screenshot below).

XBRL Templates 775

11.5.12 XML Node

The XML Node template is intended to be used within an XBRL object template 363. It accesses the XML node associated with the XBRL object template, and so enables regular XML access and operations within the XML Node template, especially using XPath. For example, Auto-Calculations 371 can be used and will have the element represented by the XBRL object as its context node.

In the screenshot above, both XBRL object templates contain XML Node templates.

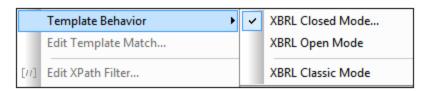

- The first XML Node template returns the contents of all the period elements that correspond to the Period XBRL objects that are generated.
- The second XML Node template returns the contents of all the identifier elements that correspond to the Identifier XBRL objects that are generated. In addition an Auto-Calculation is used. The context node for the Auto-Calculation will be the identifier element.

11.6 Open, Closed, and Classic Modes

The following XBRL templates (763) can be used in open or closed mode:

- Concept
- Period
- Identifier
- Unit
- Non-XDT segment
- Non-XDT scenario
- **Explicit dimension**
- Typed dimension

When one of the above templates is given a setting of open mode, the template iterates over all aspects of the selected type in the instance document. In closed mode, the aspect selection is restricted by the definition of the closed mode. To switch the behavior of a template between open and closed modes, select the template, and, in the template's context menu (obtained by right-clicking the template; screenshot below), hover over the Template Behavior command and select the mode you want.

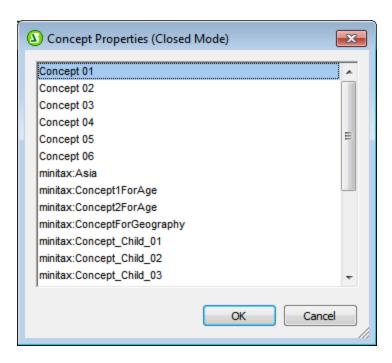

If you switch a template from open to closed mode, the template's closed-mode properties dialog appears, in which you can define the restrictions you want to apply in closed mode. If the template is already in closed mode, selecting the XBRL Closed Mode command displays the aspect's closed-mode properties dialog, in which you can modify the restrictions. Different types of aspects have different closed-mode dialogs. For example, the Concept aspect has a different closed-mode properties dialog than the Period aspect or Identifier aspect. Each of these dialogs is described in the subsections of this section.

Classic mode

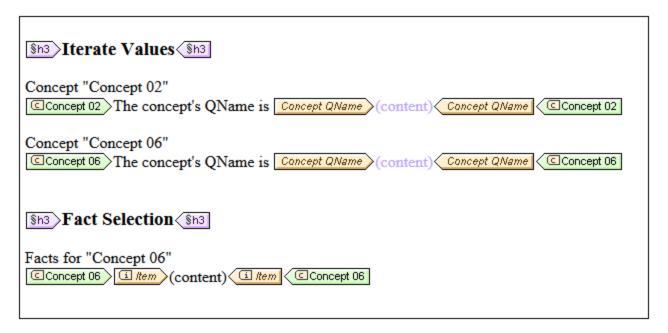

Some templates can also be given a setting of classic mode. This mode is a legacy mode that is similar to open mode. The difference between the two modes is this: In classic mode, an XBRL aspect template (for example, Period) restricts contexts (and the Item template returns facts reported for those contexts); In open mode, however, an XBRL aspect template restricts facts directly (and the Item template returns these facts).

11.6.1 **Concept Properties**

The Concept Properties dialog (screenshot below) appears when you click the Template Behavior | Closed Mode command of a Concept template's context menu. The dialog displays all the available concepts for which facts can be reported. You can select the concept over which you wish the closed-mode Concept template to iterate.

The closed mode template can then be used to display aspects of the selected Concept, such as Concept QName (by using the property's aspect value templates), or to select instance-document facts that are identified by the defined concept. The screenshot below shows both types of use.

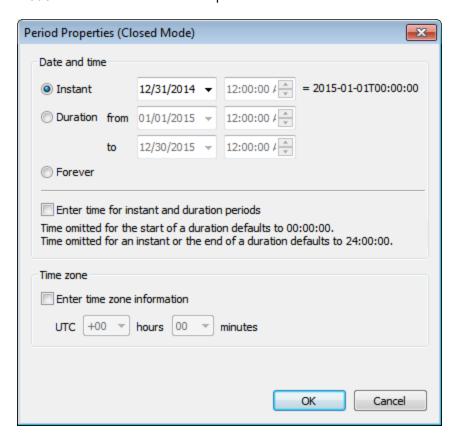

In the first type of use, shown in the *Iterate Values* section of the screenshot above, two closed-mode concepts are defined, and their Concept QName values are returned. In the second type of use, shown in the *Fact Selection* section of the screenshot above, facts are selected for the concept defined in the closed-mode template.

Note: Open mode templates behave similarly. However, they do not restrict the definition of the concept to a single concept. They iterate all concepts that satisfy the constraints in effect at that point in the design hierarchy.

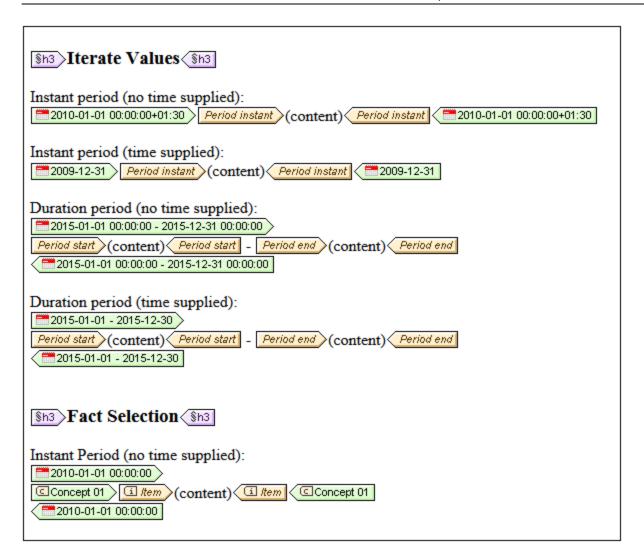

Period Properties 11.6.2

The Period Properties dialog (screenshot below) appears when you click the Template Behavior | Closed **Mode** command of the Period template's context menu.

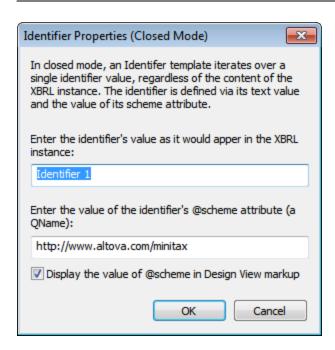

The dialog enables you to specify an Instant, Duration, or Forever value of the Period. Select the Period property you want to define (Instant, Duration, or Forever) by clicking its radio button. To enter a time value for an Instant or Duration, check the Enter time check box. Then select or enter the date (and time). Enter timezone information if this is required. Click **OK** when done. The Period elements that match the property defined in this dialog will be returned.

You can use the closed-mode template to display aspects of the Period, such as the Period Start (by using the Period's aspect value templates), or to select instance-document facts that contain the defined period. The screenshot below shows both types of use.

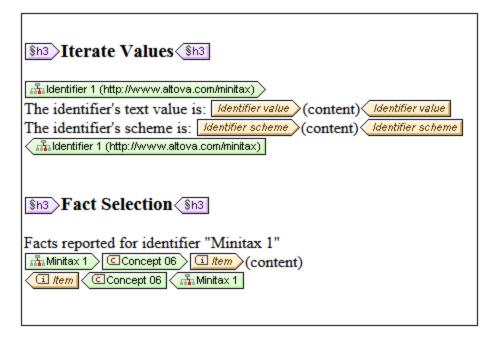

11.6.3 Identifier Properties

The Identifier Properties dialog (*screenshot below*) appears when you click the **Template Behavior | Closed Mode** command of the Identifier template's context menu.

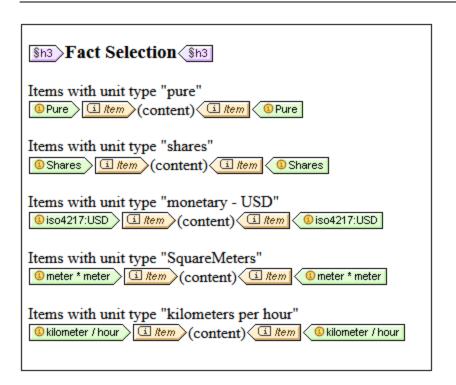

The dialog enables you to specify the Identifier over which the template will iterate. Enter the value of the instance document's Identifier element and @scheme attribute. To display the value of the @scheme attribute in the template tags, check the corresponding check box. For example, the screenshot below shows two different closed-mode Identifier templates.

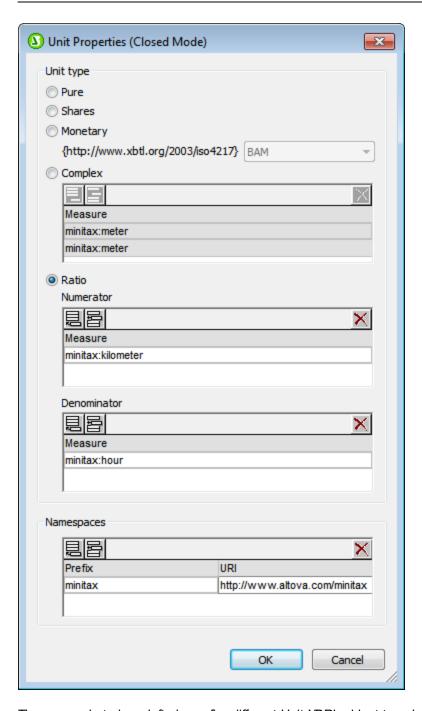

- The definition of the first Identifier template (Identifier 1) is shown in the screenshot at left. This template outputs the Identifier's value and scheme using the Identifier's aspect value templates.
- The second Identifier template selects all Concept 06 concepts that have an Identifier value of Minitax 1. The Item template within it returns that concept's value.

11.6.4 Unit Properties

The Unit Properties dialog (*screenshot below right*) appears when you click the **Template Behavior | Closed Mode** command of a Unit template's context menu.

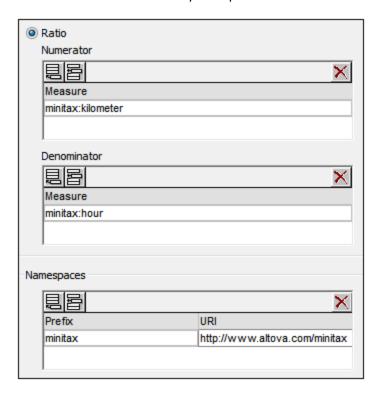

The screenshot above left shows five different Unit XBRL object templates (Pure, Shares, Monetary, Complex, and Ratio). The templates are defined (in the Properties dialog of each) to iterate over a specific type of Unit.

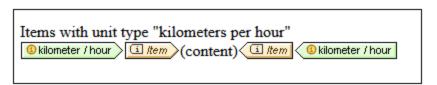

To specify a particular type of unit, in the Properties dialog, select one of the five unit types:

- Pure and Shares are in the namespace xmlns:xbrli="http://www.xbrl.org/2003/instance"
- The Monetary type is in the namespace xmlns:iso4217="http://www.xbrl.org/2003/iso4217"
- The Complex and Ratio types can be in any namespace that you define. The namespaces of measures used for these unit types must be specified in the *Namespaces* pane of the dialog

For example, if you wish to iterate over the kilometer/hour unit, define the closed mode template to be a ratio that has the appropriate numerator and denominator (see screenshot below). The namespace/s of the units must be defined in the Namespaces pane.

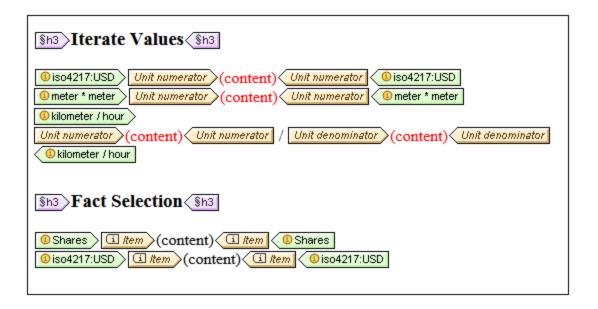

The Unit XBRL object template will automatically be named with the measures of the unit (see screenshot below).

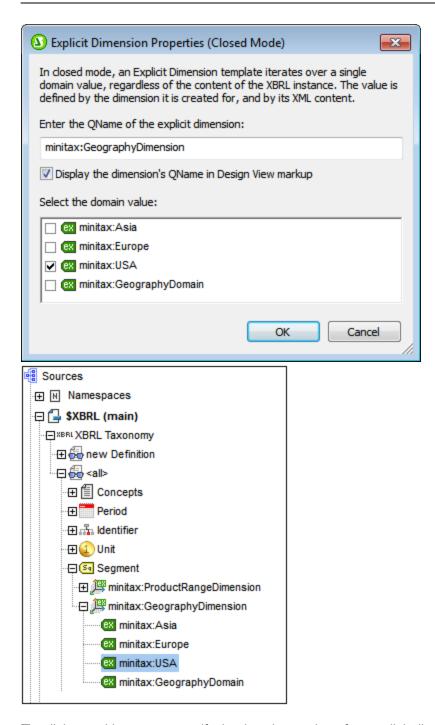

The Unit templates can be used in the following way (see screenshot below):

- To iterate over the aspect value templates inserted within the Unit XBRL object template, and return the values of these aspect value templates
- To select facts in the XBRL instance that contain the defined units. The Item aspect value template within each Unit template, will then return the facts that each closed-mode Unit template selects

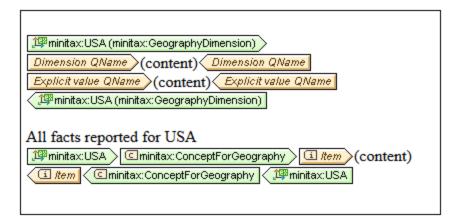

11.6.5 Explicit Dimension Properties

The Explicit Dimension Properties dialog (*screenshot below*) appears when you click the **Template Behavior** | **Closed Mode** command of the <u>explicit dimension</u> template's context menu.

The dialog enables you to specify the domain member of an explicit dimension over which the template will iterate. Enter the QName of the explicit dimension and then select the domain member from the list of domains that have been defined for the explicit dimension in the taxonomy. The screenshot above right shows the explicit dimension in the taxonomy structure. To display the dimension's QName in the template tags, check the Display QName option. The QName is displayed within parentheses (see first explicit dimension template in the screenshot below).

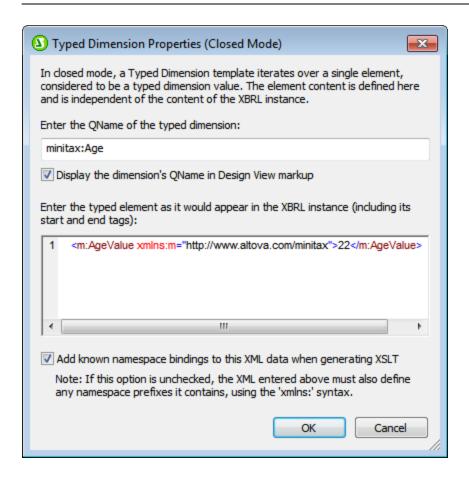

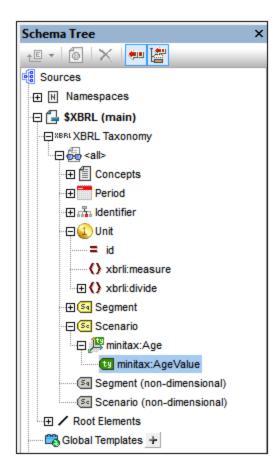

The screenshot above shows two closed-mode explicit dimension templates.

- The first template contains two aspect value templates (inserted via the context menu commands Insert XBRL Element | Dimension QName and Insert XBRL Element | Explicit Dimension Value QName).
- The second template selects all <code>ConceptForGeography</code> concepts that are linked to the <code>USA</code> domain of the <code>GeographyDimension</code> explicit dimension. The Item template within the concept template returns that concept's value.

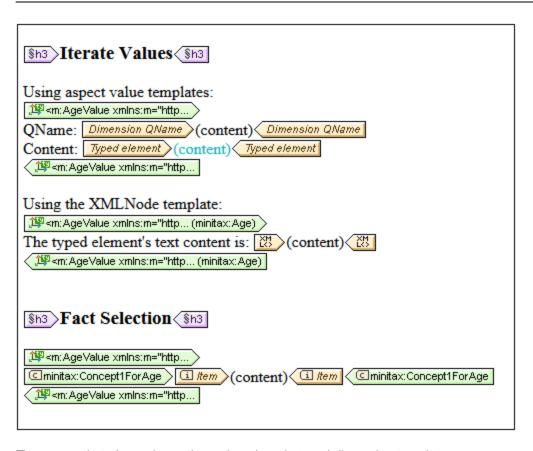

11.6.6 Typed Dimension Properties

The Typed Dimension Properties dialog (*screenshot below left*) appears when you click the **Template Behavior | Closed Mode** command of the <u>typed dimension</u> template's context menu.

The dialog enables you to specify the typed element of a typed dimension over which the template will iterate. First enter the QName of the typed dimension (see screenshot above left), and then enter the typed element as it would appear in the XBRL instance document, including the start and end tags. The screenshot above right shows the typed dimension in the taxonomy structure. To display the dimension's QName in the template tags, check the Display QName option. The QName is displayed within parentheses (see second typed dimension template in the screenshot below).

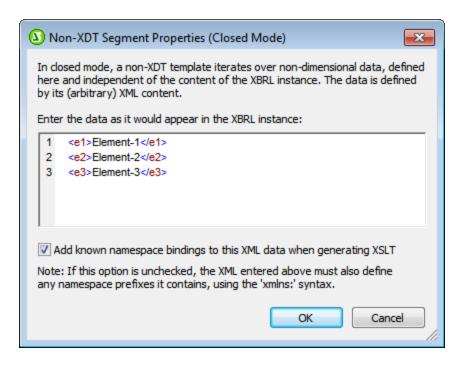

The screenshot above shows three closed-mode typed dimension templates.

- The first template contains two aspect value templates (inserted via the context menu commands Insert XBRL Element | Dimension QName and Insert XBRL Element | Typed Dimension
- In the second template, the XML Node template converts the XBRL object to an XML element and returns the contents of the element.
- The third template selects all Concept1ForAge concepts that have a typed element as defined in the typed dimension template. The Item template within the concept template returns that concept's value.

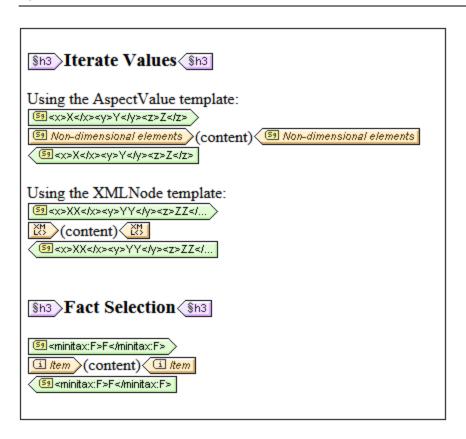

11.6.7 **Non-XDT Segment/Scenario Properties**

The Non-XDT Segment Properties dialog (screenshot below) and Non-XDT Scenario Properties dialog appear when you click the Template Behavior | Closed Mode command of the respective Non-XDT component template's context menu. The dialogs for Non-XDT segments and Non-XDT scenarios are similar.

The dialog enables you to specify additional, non-dimensional, XML data that is used to set a constraint on which reported facts are processed by the Item template. The Non-XDT component template (segment or scenario) can then be used as follows:

- The contents of the Non-XDT component template can be returned by using either the aspect value template Non-dimensional elements (first template in the screenshot below) or the XML Node template.
- The third template in the screenshot below selects all facts that contain the non-dimensional data defined in the Non-XDT template.

XBRL XBRL Tables 793

11.7 XBRL Tables

The XBRL Table Linkbase specification is designed to allow rendering of XBRL facts in a tabular form. A table linkbase provides the basic layout of a table (or several tables), leaving the table rendering details to the processing application. The layout as provided by the linkbase defines the appearance of the table's X and Y axes by assigning to each axis an arbitrarily complex structure of header cells. Each structure level corresponds to an XBRL aspect (concept, period, identifier, unit, segment, or scenario). The layout also defines the order of aspect values, filtering of aspect values, and other information.

The Table Wizard

StyleVision integrates table linkbases by reading the table linkbase information from the DTS and allowing the user to select a table definition from the table linkbase. The XBRL Table Wizard automatically fills its row and column breakdowns according to the definition of the selected table. Once the breakdowns are filled and the user completes the wizard, StyleVision generates the XBRL table. StyleVision also supports generating the XBRL table directly after the user selects a table definition, that is, without even opening the wizard.

Adding XBRL tables to the design

You can add an XBRL table to a design in any of the following ways (which are ordered by increasing level of user-friendliness):

- Manually add a table and all required design elements (XBRL templates, etc.) to the design.
- Use the XBRL Table Wizard to create the design elements; manually add/arrange breakdown items in the wizard as required.
- In the XBRL Table Wizard [794], fill the breakdown items automatically by selecting a table definition from the table linkbase. (The taxonomy must contain a table linkbase.)
- Completely auto-generate the table (without opening the wizard) by selecting a table definition from the table linkbase. (The taxonomy must contain a table linkbase.)

In the third case, the table definition in the table linkbase serves as a starting point for filling the breakdown items in the <u>Table Wizard</u> Test. The fact that the breakdown items originated in a table linkbase does not in any way restrict subsequent editing actions in the <u>Table Wizard</u> or in design view. Once a table has been selected and the breakdown items have been filled, the presence of a table linkbase no longer influences either the <u>Table Wizard</u>, subsequent design editing, or the XSL transformation.

Table Parameters

A table definition in a table linkbase might depend on parameters. For example, the linkrole of a relationship node might depend on a parameter. In such cases, different parameter values could produce fundamentally different table structures. This means that when a table is selected for filling the breakdown items, values must also be provided for any parameters defined in the table linkbase.

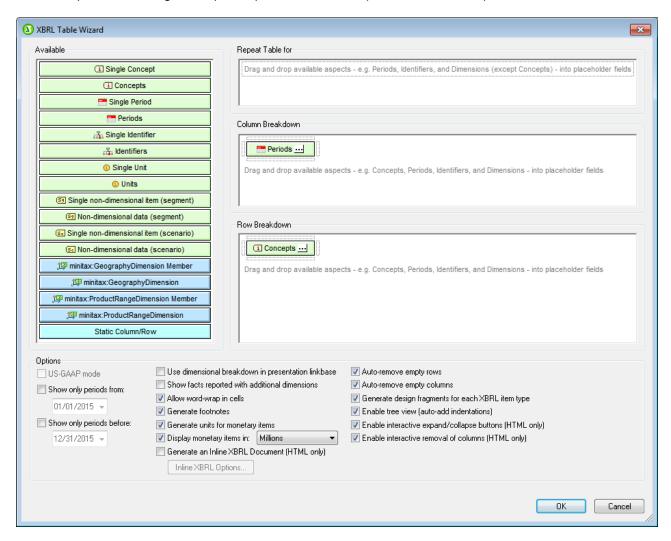

When selecting a table for filling the breakdown items, each table parameter can be assigned a single value only. This means that the resolution process results in a single table, which the user can subsequently customize in the wizard. The effect achieved by assigning multiple items to a parameter's value is reproduced by repeatedly using the <u>Table Wizard</u> 1941 to create a table, one for each desired parameter value item.

794 XBRL XBRL XBRL Table Wizard

11.8 XBRL Table Wizard

The XBRL Table Wizard is accessed when a concept is dragged from the source tree and dropped into the design. From the context menu that pops up select **Create XBRL Table**. The wizard helps you to quickly and easily create an XBRL report in the form of a table. The window of the XBRL Table Wizard consists of three parts:

- 1. An *Available* pane containing schema tree items that can be created as columns or rows of the table (see screenshot below);
- 2. Panes for defining the table structure (screenshot below, see XBRL Table Structure 1995 for details);
- 3. A pane for defining table options (see <u>XBRL Table Options</u> 600 for details) 600.

This section is organized into two parts:

- XBRL Table Structure describes how you create the XBRL table structure with the XBRL Table Wizard.
- XBRL Table Options (800) explains the various options that can be specified for the XBRL table.
- Component Properties describes the property-set of each components.

After specifying the design of the table, click the **OK** button to insert the table in the design. If you wish to change any of the table design settings after the table has been inserted in the design, delete the table and recreate it. When you drop the concept into the design and open the XBRL Table Wizard, the Wizard will have the settings that were made for the previous table. You can then modify these settings as required and press **OK** to insert the modified table in the design.

11.8.1 XBRL Table Structure

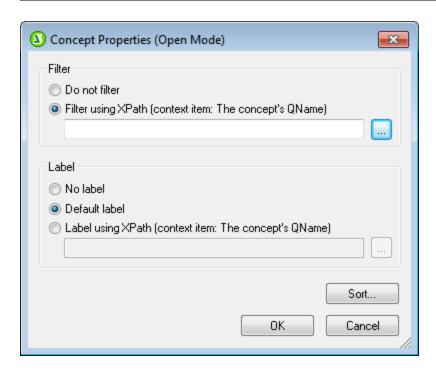

When a concept from the schema tree is created as an XBRL table, its descendant concepts, periods, identifiers, units, and non-XDT segments and scenarios become available (in the *Available* pane) for creation as rows and columns of the XBRL table. To create one of these items from the *Available* pane as columns or rows, drag it, respectively, into the *Column Breakdown* pane or *Row Breakdown* pane (*screenshot below*) and drop it into a placeholder field of the pane. In the screenshot below, the *Period* item has been created as columns while the *Concepts* item has been created as rows. To delete an item that has been dropped into a placeholder field of the table structure, select it and press the **Delete** key.

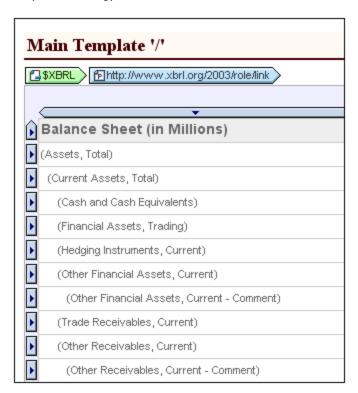

Concepts

When the Concepts item is dragged into, say the Row Breakdown pane, the descendant concepts (of the concept that is being created as the XBRL table) will be created as the rows of the table. By default all descendant concepts will be created as rows of the table. To deselect individual concepts or to modify the selection, click the Ellipsis icon of the Concepts item in the Row Breakdown pane of the XBRL Wizard. This displays the Concept Properties dialog (screenshot below), in which you can select the descendant concepts to be created as rows. Then click **OK**.

796 **XBRL** XBRL Table Wizard

Notice that the display of the descendant concepts in the Properties dialog is hierarchically structured. In the design, rows will be indented so as to reflect this structure (screenshot below, compare with structure in Properties dialog).

Additional options for the presentation of concepts in the design are available in the Table Options pane and in the <u>Table group of properties</u> 165 in the Properties sidebar.

XBRL XBRL Table Wizard 797

Periods

There are three types of periods that can be defined for a concept: *instants*, *durations*, and *forever*. What periods are displayed in the table can be specified in the Period Type pane of the <u>Periods Properties dialog</u> (screenshot below). To access the Periods Properties dialog, click the Ellipsis icon in the Periods item.

Note: If a date range is specified in the XBRL Table Options dialog, this range will be applied to periods; so only periods in this range will be processed.

Identifiers

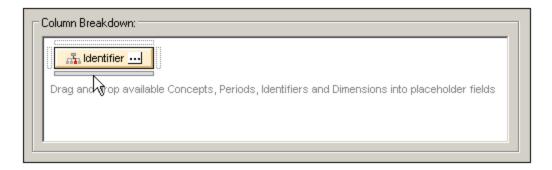

Inserting an Identifier item in a column or row causes each unique identifier value to receive a column or row, respectively. The contents of facts with a particular <code>identifier</code> value will be listed in the column/row for that identifier value. The screenshot below shows the HTML output of an XBRL instance file in which there is only one identifier value: <code>Nanonull Inc.</code>

Balance Sheet (in Millions)	Nanonull Inc
⊟ Assets, Total	€21.49€24.02
⊡ Current Assets, Total	€10.65€12.32
Cash and Cash Equivalents	€1.51€2.72
Trade Receivables, Current	€4.62€5.34
Tax Receivables, Current	€0.24€0.25
Inventories	€3.48€3.59
Other Assets, Current	€0.79€0.42
⊡ Non Current Assets, Total	€10.85€11.7
Property, Plant and Equipment	€1.21€1.42
Intangible Assets	€0.82€1.11
Goodwill	€6.27€6.65
Other Financial Assets, Non Current	€0.34€0.34
Deferred Tax Assets	€2.21€2.18

In the screenshot above, notice that entries in the *Nanonull Inc* column are a concatenation of two values. This is because, in the instance file, each fact (such as Assets, Total) occurs twice, each occurrence specified for the same identifier (Nanonull, Inc) but for different periods. See the next section, Periods and Identifiers, for a description of how to create separate columns for each unique identifier-period value.

Periods and identifiers

To create separate columns for each identifier's unique periods, do the following. In the XBRL Table Wizard, first drag the Identifier item into the *Column Breakdown* pane. Then drag the Periods item to the *Column Breakdown* pane, to the placeholder field below the Identifier item. The placeholder field becomes highlighted (see screenshot below).

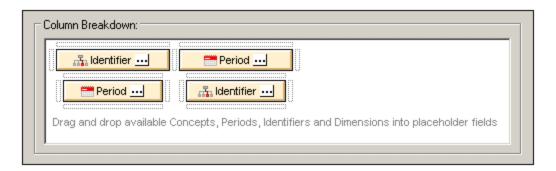

When the placeholder field becomes highlighted, drop the Periods item on it. The *Column Breakdown* pane will look something like this:

The effect of this is to create separate columns for each period of each identifier. The screenshot below shows a table with columns for two periods of the Nanonull, Inc identifier.

Balance Sheet (in Millions)	Nanonull Inc 2004-09-30	Nanonull Inc 2003-12-31
⊡ Assets, Total	€21.49	€24.02
⊡ Current Assets, Total	€10.65	€12.32
Cash and Cash Equivalents	€1.51	€2.72
Trade Receivables, Current	€4.62	€5.34
Tax Receivables, Current	€0.24	€0.25
Inventories	€3.48	€3.59
Other Assets, Current	€0.79	€0.42
⊡ Non Current Assets, Total	€10.85	€11.7
Property, Plant and Equipment	€1.21	€1.42
Intangible Assets	€0.82	€1.11
Goodwill	€6.27	€6.65
Other Financial Assets, Non Current	€0.34	€0.34
Deferred Tax Assets	€ 2.21	€2.18

In the *Column Breakdown* pane, available items can be dropped repeatedly in the placeholder fields. The screenshot below, for example, shows how the Identifier and Period items have been dropped into adjacent placeholder fields.

This results in output (*screenshot below*) where the Identifier-Period columns are displayed first (that is, on the left), and these columns are followed (on the right) by Period-Identifier columns.

Balance Sheet (in Millions)	Nanonull Inc 2004-09-30	Nanonull Inc 2003-12-31	2004-09-30 Nanonull Inc	2003-12-31 Nanonull Inc
⊡ Assets, Total	€21.49	€24.02	€21.49	€24.02
⊡ Current Assets, Total	€10.65	€12.32	€10.65	€12.32
Cash and Cash Equivalents	€1.51	€2.72	€1.51	€2.72
Trade Receivables, Current	€4.62	€5.34	€4.62	€5.34
Tax Receivables, Current	€0.24	€0.25	€0.24	€0.25
Inventories	€3.48	€3.59	€3.48	€3.59
Other Assets, Current	€0.79	€0.42	€0.79	€0.42

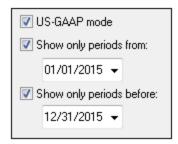

Repeating tables

The XBRL Table Wizard enables you to create a set of tables that repeat on a specific criterion. In the screenshot below, for example, a table is created with a structure in which concepts are rows and identifiers are columns. This table structure is repeated for each period (the Period item has been dropped into the *Repeat Table For* pane).

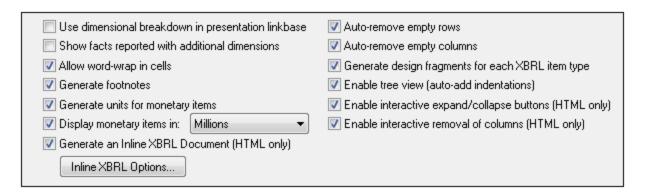

11.8.2 XBRL Table Options

At the bottom of the XBRL Table Wizard is a list of options for the table being created (*screenshots below*). Here, you can also switch to US-GAAP mode if your taxonomy is based on US-GAAP and draw on US-GAAP-specific information for use in creating the table. The range for which periods should be considered can also be set (*see screenshot below*).

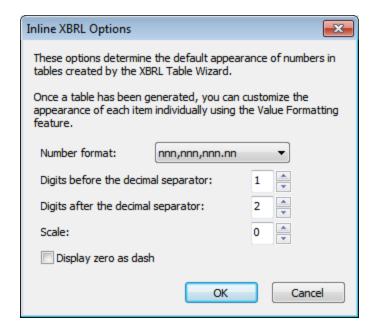

Other XBRL table options that may be set are as follows:

XBRL XBRL Table Wizard 801

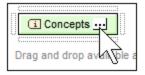

- Use dimensional breakdown in presentational linkbase: The dimensional structure specified in the presentation linkbase will be used to locate concepts in the table design.
- Show facts reported with additional dimensions: When facts have additional dimensions, these are reported.
- Allow word-wrap in cells: Word-wrapping in table cells can be switched on.
- Generate footnotes: Footnote templates will automatically be generated. There are two parts to footnotes: (i) footnote references are inserted for elements, and (ii) the actual footnotes are created at the bottom of the table.
- Generate units for monetary items: A Unit template is automatically inserted for monetary items in the design. This template applies the global template xbrli:measure. If this option is unchecked, the Unit template will not be inserted. However, it can be inserted at individual locations in the design at any time via the context menu. See XBRL Templates for details.
- Display monetary items in: You can select number units between Tens and Billions for monetary values. The selected unit will apply to the entire table. Monetary values in the table will be reported in these units, for example, in millions.
- Generate an Inline XBRL Document (HTML only): The HTML output document will contain the Inline XBRL namespace and all other requisites for containing Inline XBRL elements. Clicking the Inline XBRL Options button pops up the Inline XBRL Options dialog (screenshot below), which enables you to specify the default number-formatting of the output document. These options are explained in the Inline XBRL section, they are the same as the options for Non-fraction (regular numbers).

- Auto-remove empty rows: Empty rows in the output are removed.
- Auto-remove empty columns: Empty columns in the output are removed.
- Generate design fragments for each XBRL item: Default design fragments are generated for XBRL items (such as xbrli:monetaryItemType1). For the same XBRL item type used multiple times in the taxonomy, a new design fragment is generated for each instance of the XBRL item. Notice that the names of such generated design fragments has a counter appended to it. The counter is incremented by one each time a new design fragment is generated for the same XBRL item. Inline XBRL design fragments are given a prefix of ix.
- Enable tree view (auto-add indentation): In the output, concept rows will be set up in a hierarchy as specified in the presentation linkbase and indented accordingly.
- Enable interactive expand/collapse buttons (HTML only): Since the concepts constitute a hierarchy, concepts with descendants can be expanded or collapsed in HTML output. Expand/collapse buttons are created automatically in the HTML output, and the viewer can use these to customize the HTML display.
- Enable interactive removal of columns (HTML only): If checked, this option creates a remove button at the top of each column in the HTML output. By clicking this button, a viewer can remove a column in the HTML display.
- A time range can be specified for the report. Only facts within this time range will be displayed. Dates
 for the time range can be selected using the arrow keys. The Left Arrow and Right Arrow keys can
 be used to select a date component, the Up Arrow and Down Arrow keys can be used to change the
 value of the selected date component up and down, respectively.

11.8.3 Component Properties

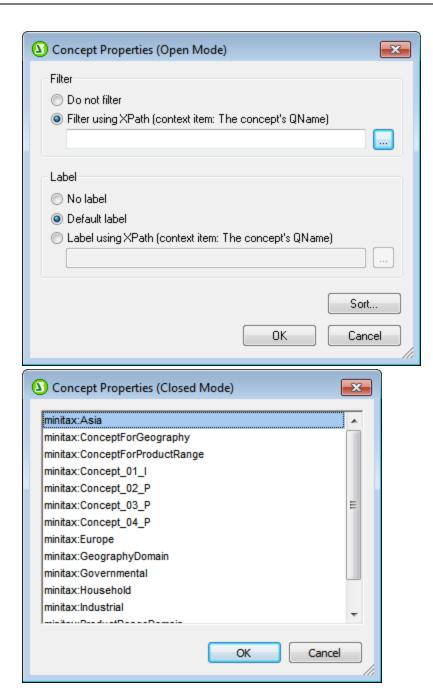

Each component has its individual set of properties. To edit a component's properties, in the XBRL Table Wizard or XBRL Chart Wizard, click the **Edit Properties** icon of the component (see screenshot below).

This displays the properties dialog of the respective component. The properties dialog of open mode and closed mode are different, since open mode returns multiple items while closed mode returns the single specified item. These dialogs are described below.

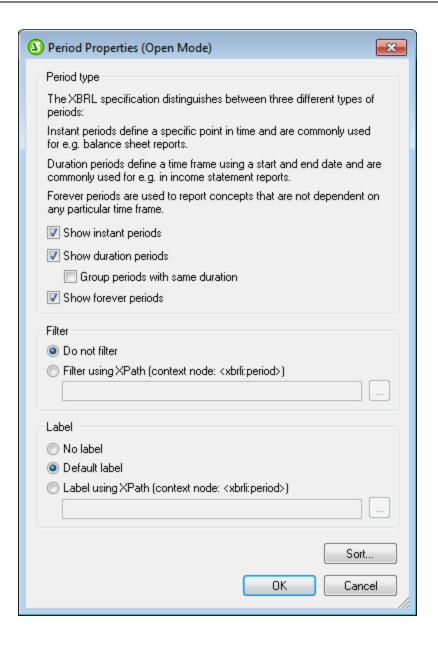

Concept properties

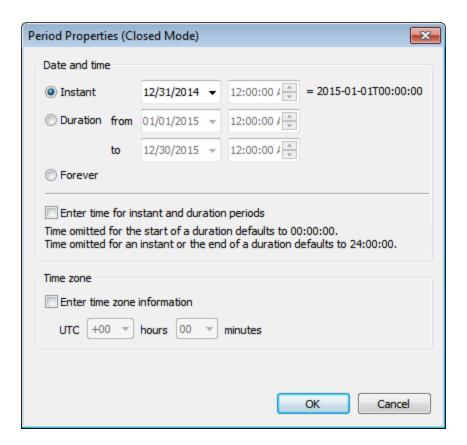

The Concept Properties dialogs are shown below: open mode concepts (left) and closed mode concepts (right). The open mode dialog provides options to filter, label, and sort the concepts being iterated over. The closed mode dialog enables you to select the concept to return. See the section Concept Properties (176) for detailed information.

Period properties

The Period Properties dialogs are shown below: open mode periods (*left*) and closed mode periods (*right*). The open mode dialog provides options to filter, label, and sort the periods being returned. The closed mode dialog provides options for entering the instant or duration of the period, with or without a timezone. See the section Period Properties (778) for detailed information.

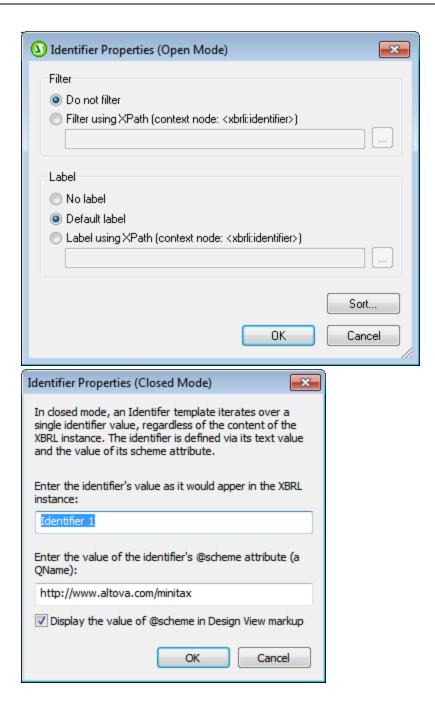

▼ Identifier properties

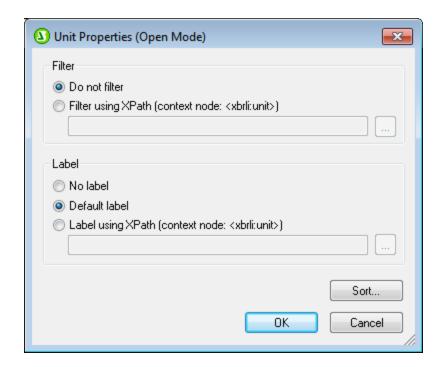

The Identifier Properties dialogs are shown below: open mode identifiers (left) and closed mode identifier (right). The open mode dialog provides options to filter, label, and sort the identifiers being iterated over. The closed mode dialog enables you to enter the value and scheme of the single specified identifier. See the section, Identifier Properties (right) for detailed information.

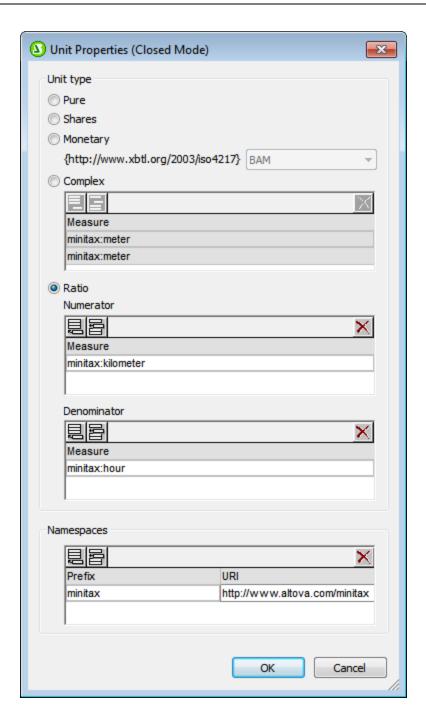

806 **XBRL** XBRL Table Wizard

Unit properties

The Unit Properties dialogs are shown below: open mode units (left) and closed mode units (right). The open mode dialog provides options to filter, label, and sort the units being returned. The closed mode dialog provides options for entering the unit type of the specified unit. See the section Unit Properties 181 for detailed information.

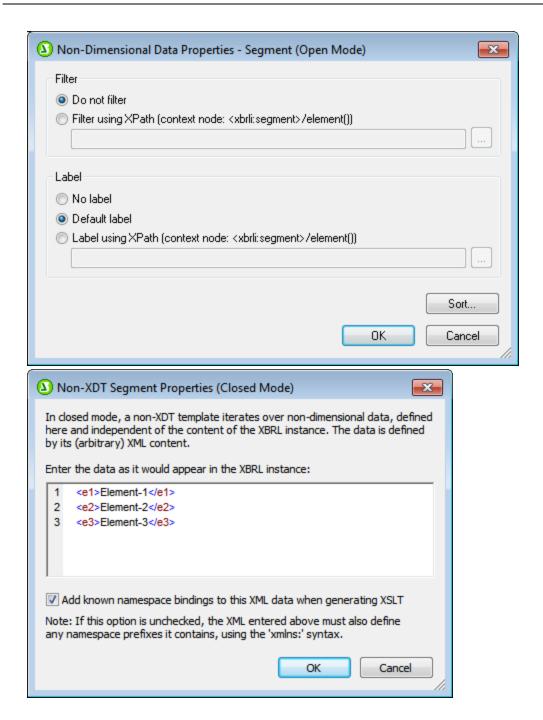

▼ Non-dimensional data (segment/scenario) properties

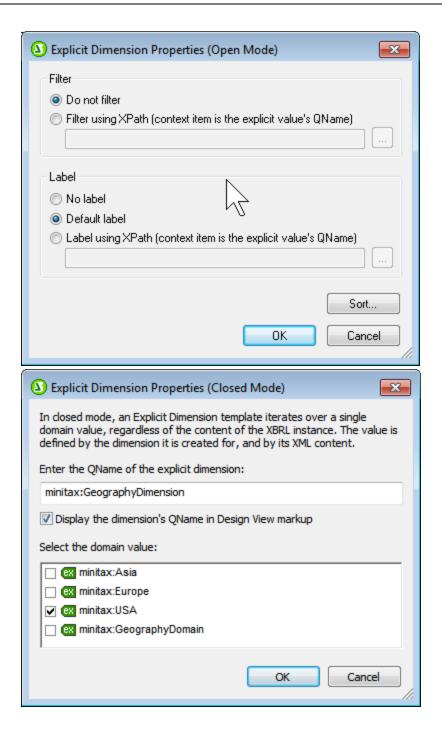

The Non-dimensional Data (Segment) and Non-dimensional Data (Scenario) Properties dialogs are shown below: open mode non-dimensional data (left) and closed mode non-dimensional data (right). The open mode dialog provides options to filter, label, and sort the non-dimensional data being returned. The closed mode dialog enables you to enter the XBRL instance data you require. See the section Non-XDT Segment/Scenario Properties for detailed information.

XBRL XBRL Table Wizard 809

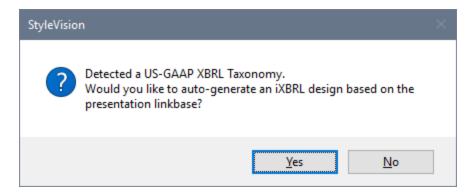

▼ Explicit dimension properties

The Explicit Dimension Properties dialogs are shown below: open mode explicit dimensions (left) and closed mode explicit dimensions (right). The open mode dialog provides options to filter, label, and sort the explicit dimensions being returned. The closed mode dialog enables you to select the dimension and domain you want. See the section Explicit Dimension Properties (185) for detailed information.

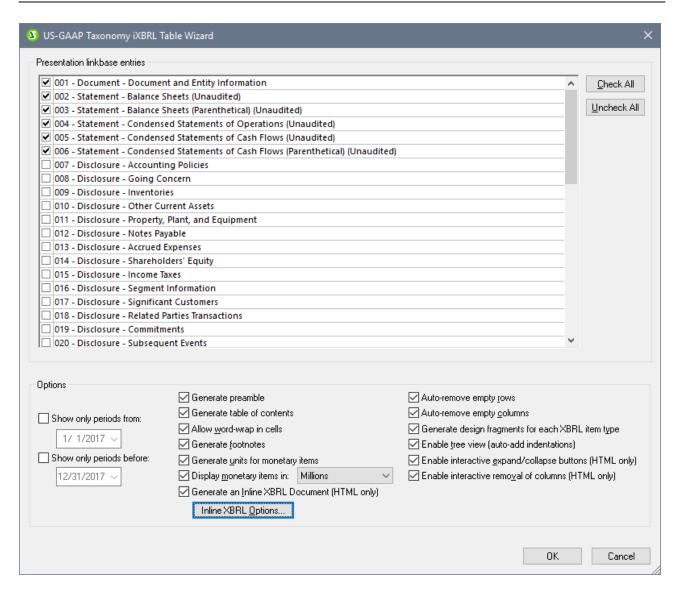

11.9 US-GAAP Table Wizard

When creating an SPS from an XBRL taxonomy, you will be prompted to select, first, a taxonomy, and then a Working XBRL File (needed if you want to generate previews). Next, you will be asked whether you wish to create a free-flowing document or a form-based document (see <u>File | New</u> 945). After you make this selection, if the taxonomy you selected is a US-GAAP taxonomy, the following dialog appears:

If you wish to automatically generate tables (one table for each item in the taxonomy's presentation linkbase), then select **Yes**. To create an empty SPS based on the selected taxonomy, select **No**.

If you select Yes, then the US-GAAP Table Wizard is displayed (screenshot below).

The wizard contains two panes:

- Presentation linkbase entries lists all the Statement entries and Disclosure entries present in the
 taxonomy's Presentation linkbase (see screenshot above). By default, the Statement entries are
 selected, the disclosure entries are not selected. You can select or deselect any entry for table
 generation. If you click Check All, then all the entries will be selected; in this event a dialog will appear
 that contains a standard warning about long document-generation times.
- Options, which enables you to select or deselect options related to the tables that will be generated. For details, see the section <u>Table Options</u> [814].

After you have made your selections in the wizard, click **OK**. The SPS will be generated with the selected entries appearing as tables.

You can edit the generated SPS in the usual way. To preview the output, select an output tab.

Note: The HTML tab is renamed to iXBRL.

Inline XBRL options

The US-GAAP Table Wizard enables you to generate <u>Inline XBRL</u> Table. To do this, in the wizard, select the *Generate Inline XBRL Document (HTML only)* option (*see screenshot above*). To specify Inline XBRL options, click **Inline XBRL Options** and set the options you want (described <u>here</u> 10.

If the Inline XBRL option is selected, then each entry of the Presentation linkbase that has been selected will be created in the SPS as an Inline XBRL template. You can subsequently modify the individual Inline XBRL templates and the SPS design as you like.

11.9.1 Main Features

While the topic <u>US-GAAP Table Wizard</u> describes the working of the wizard in broad outline, this section describes the following details:

- The report's preamble
 B13
- Generated templates ⁸¹⁴
- Warnings 814

Please read the previous section to get an overview of how the wizard works.

The report's preamble

The report's preamble is the header of the document (see screenshot below for an example). When the SPS is generated, a default preamble can be automatically added. It looks something like the preamble shown in the screenshot below.

UNITED STATES SECURITIES AND EXCHANGE COMMISSION WASHINGTON, D.C. 20549 FORM 10-Q

X_QUARTERLY REPORT PURSUANT TO SECTION 13 OR 15(d)
OF THE SECURITIES EXCHANGE ACT OF 1934

For the quarterly period ended February 29, 2017

OR

TRANSITION REPORT PURSUANT TO SECTION 13 OR 15(d) OF THE SECURITIES EXCHANGE ACT OF 1934

For the transition period from _____ to ____

COMMISSION FILE NUMBER 0-00000

NanoNull INC.

(Exact name of registrant as specified in its charter)

DELAWARE (State of Incorporation) 12-3456789 (I.R.S. Employer Identification No.)

You can choose from among the following three possibilities:

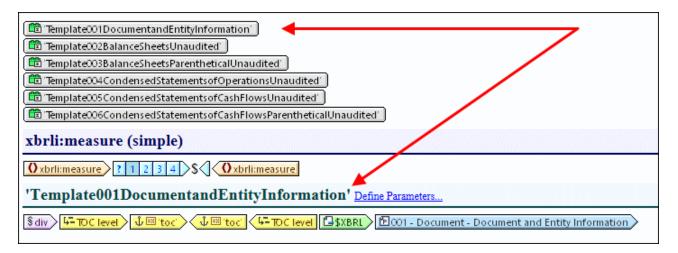

- To not generate a preamble, uncheck the Generate Preamble option in the wizard.
- To generate the default preamble, check the Generate Preamble option in the wizard.
- To generate a custom preamble, create the preamble in an XHTML file, and reference this file in the preamble's <u>User-Defined Template</u> (see screenshot below).

Do this as follows: (i) Right-click the preamble's <u>User-Defined Template</u> and select **Edit Template Match**; (ii) In the <u>Edit XPath Expression</u> that appears, enter a string value that is the URL of the XHTML file that contains your custom preamble. To go back to the default preamble, set this XPath expression to "template.html".

Generated templates

The entries of the Presentation linkbase are each created as a table in a separate <u>design fragment</u> so, and the design fragment is referenced by a template in the main document template (see screenshot below). The name of the template (and the design fragment) is automatically generated from the label of the entry in the Presentation linkbase.

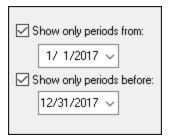

Warnings

When generating HTML/iXBRL output, XBRL validation warnings as well as warnings about content in Inline XBRL text blocks are displayed.

11.9.2 Table Options

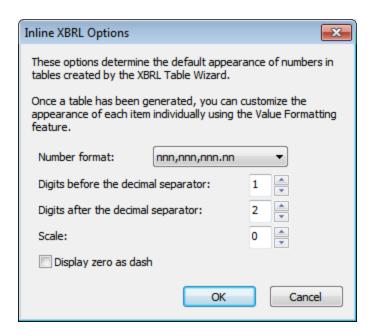

In the lower part of the US-GAAP iXBRL Table Wizard is a list of table options (*screenshots below*). The range of periods to be included can also be set (*see screenshot below*).

The table options that can be set are as follows:

☑ Generate preamble	✓ Auto-remove empty rows		
Generate table of contents	✓ Auto-remove empty columns		
✓ Allow <u>w</u> ord-wrap in cells	☑ Generate design fragments for each XBRL item type		
Generate footnotes	Enable tree view (auto-add indentations)		
Generate units for monetary items	Enable interactive expand/collapse buttons (HTML only)		
☑ Display monetary items in: Millions ✓	Enable interactive removal of columns (HTML only)		
☑ Generate an Inline XBRL Document (HTML only)			
Inline XBRL Options			

- *Generate preamble:* The preamble is the header of the document. This option determines whether a preamble is generated or not. For more information about how to choose between the default preamble and a custom preamble, see Main Features 813.
- Generate table of contents: A TOC will be automatically generated if this option is selected.
- Allow word-wrap in cells: Word-wrapping in table cells can be switched on.
- Generate footnotes: Footnote templates will automatically be generated. There are two parts to footnotes: (i) footnote references are inserted for elements, and (ii) the actual footnotes are created at the bottom of the table.
- Generate units for monetary items: A Unit template is automatically inserted for monetary items in the design. This template applies the global template xbrli:measure. If this option is unchecked, the Unit template will not be inserted. However, it can be inserted at individual locations in the design at any time via the context menu. See XBRL Templates for details.
- Display monetary items in: You can select number units between Tens and Billions for monetary values. The selected unit will apply to the entire table. Monetary values in the table will be reported in these units, for example, in millions.
- Generate an Inline XBRL Document (HTML only): The HTML output document will contain the Inline XBRL namespace and all other requisites for containing Inline XBRL elements. Clicking the Inline XBRL Options button pops up the Inline XBRL Options dialog (screenshot below), which enables you to specify the default number-formatting of the output document. These options are explained in the Inline XBRL section, they are the same as the options for Non-fraction (regular numbers).

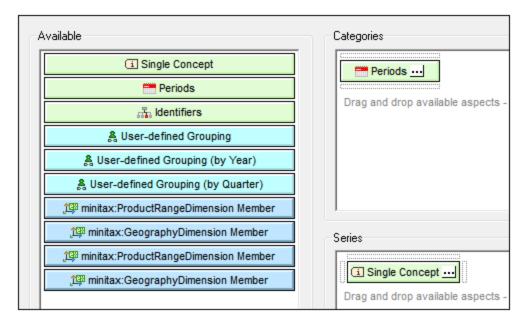

- Auto-remove empty rows: Empty rows in the output are removed.
- Auto-remove empty columns: Empty columns in the output are removed.
- Generate design fragments for each XBRL item: Default design fragments are generated for XBRL items (such as xbrli:monetaryItemType1). For the same XBRL item type used multiple times in the taxonomy, a new design fragment is generated for each instance of the XBRL item. Notice that the names of such generated design fragments has a counter appended to it. The counter is incremented by one each time a new design fragment is generated for the same XBRL item. Inline XBRL design fragments are given a prefix of ix.
- Enable tree view (auto-add indentation): In the output, concept rows will be set up in a hierarchy as specified in the presentation linkbase and indented accordingly.
- Enable interactive expand/collapse buttons (HTML only): Since the concepts constitute a hierarchy, concepts with descendants can be expanded or collapsed in HTML output. Expand/collapse buttons are created automatically in the HTML output, and the viewer can use these to customize the HTML display.
- Enable interactive removal of columns (HTML only): If checked, this option creates a remove button at the top of each column in the HTML output. By clicking this button, a viewer can remove a column in the HTML display.
- A time range can be specified for the report. Only facts within this time range will be displayed. Dates
 for the time range can be selected using the arrow keys. The Left Arrow and Right Arrow keys can
 be used to select a date component, the Up Arrow and Down Arrow keys can be used to change the
 value of the selected date component up and down, respectively.

11.10 XBRL Chart Wizard

The XBRL Chart Wizard is accessed when a concept is dragged from the source tree and dropped into the design. From the context menu that pops up select **Create XBRL Chart**. The wizard helps you to quickly and easily create chart representation of selected data. The window of the XBRL Chart Wizard consists of four panes:

- 1. A <u>Chart Settings pane</u> 187, in which the basic configuration of the chart is specified, for example, the chart's title, height, width, color scheme, label sizes, etc. Chart settings are described in detail in the <u>Charts section</u> 187 of the documentation.
- 2. An *Available* pane (*see screenshot below*) containing schema tree items that can be created as the categories and series of the chart;
- 3. A *Categories* pane, in which the X-Axis items of the chart can be specified. For example, the X-Axis of an annual sales chart could have items corresponding to the years of the period under consideration. To remove empty categories from the output, check the *Remove Empty Categories* check box at the bottom of the dialog.
- 4. A Series pane for selecting what concepts are to be plotted. For example, in an annual sales chart, if the series members were the revenue and net income concepts, then the facts of these two series members could be plotted for multiple periods. As a result, for each year on the X-Axis, the revenue and net income values would be represented on the Y-Axis (say as bars or as points on line graphs). To remove empty series from the output, check the Remove Empty Series check box at the bottom of the dialog.

This section of the documentation is organized into two parts:

- <u>Categories</u> ⁸¹⁸ describes how data for the Categories (X-Axis) is specified.
- Series 819 explains how members of the series are selected.
- <u>Component Properties</u> 822 describes the property-set of each components.

After specifying the settings and data for the chart, click the **OK** button to insert the chart in the design. If you wish to change any of the chart settings or data selections after the chart has been inserted in the design, right-click the chart and select **Edit Chart Settings**.

818 XBRL XBRL XBRL Chart Wizard

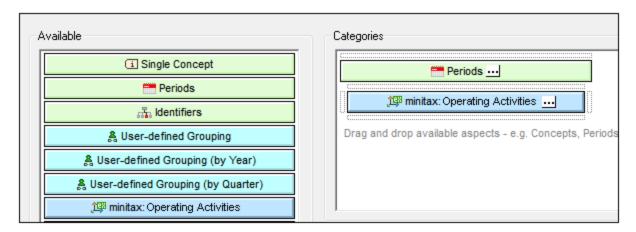

Example files

Examples of XBRL charts can be found in the Charts and XBRL folders in the Example project in the Project Window.

11.10.1 Categories

It is in the Categories pane of the <u>Chart Wizard</u> that the items displayed on the Category Axis are selected. (By default, the Category Axis is the X-Axis; the Y-Axis can be specified in the <u>Advanced Chart Settings</u> if you like. In pie charts, the Category Axis specifies which items are to form the segments of the chart.)

To select items for the Category Axis, first drag one or more components from the *Available* pane into the *Categories* pane. (In the screenshot below, the Period component and the explicit dimension for Statement have been dragged to the Categories pane.) Then click the Ellipsis icon of each component, to set its component's properties.

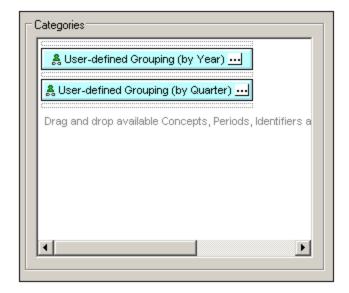

Properties of components

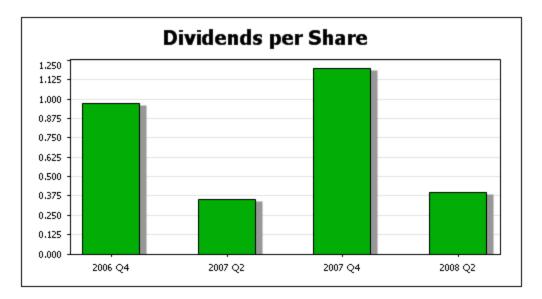

A component's properties include settings to set a filter on what is selected, to specify how labels are displayed on the Category Axis, and how to sort the selected Axis items. The section <u>Component Properties</u> contains a complete list of these properties.

User-defined groupings

Among the components in the *Available* tab, are predefined groupings for years and quarters (*see screenshot above*). These enable you to set up, for example, a category for individual quarters, as shown in the screenshot below.

The output of the category selection shown above would be something like that shown in the screenshot below: the category selection (shown on the X-Axis) are the years and quarters found in the XBRL instance document.

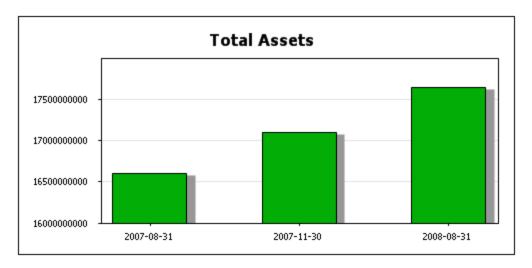

11.10.2 Series

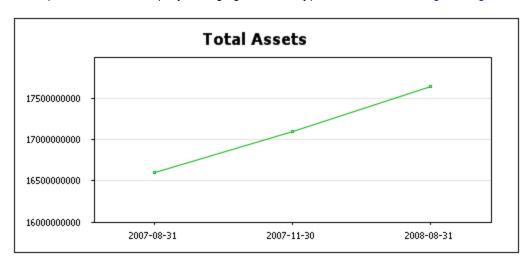

The Series Axis represents the value of selected data points. For example, you could select the Total Assets concept as one series of data points. In that case, the value of Total Assets facts will be output for every corresponding Category Axis selection (such as accounting dates).

Charts with single series

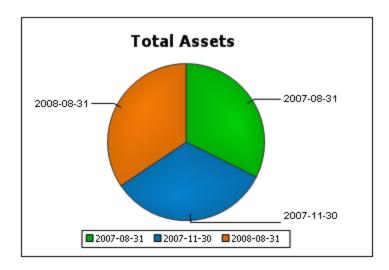

This kind of chart (with a single series selected as described above) is shown in the screenshot of the bar chart below.

This chart selects a single series, the Total Assets concept, and represents its value for the corresponding Category Axis dates. The bar chart can easily be changed into other chart types, such as a line chart or a pie chart (*screenshots below*), by changing the chart type in the Chart Settings dialog (137).

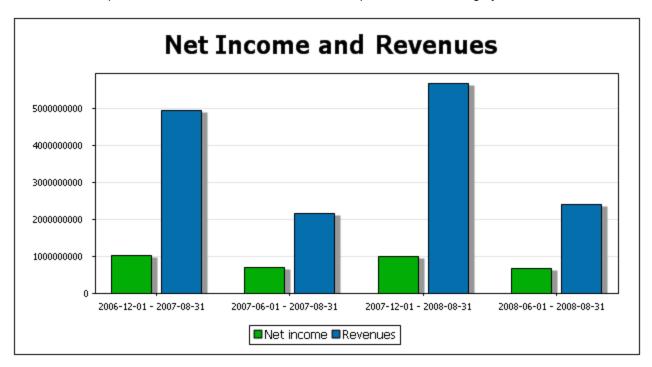

The points on the line chart are the values of the Total Assets concepts for the corresponding Category Axis dates. The pie chart shows the values of the Total Asset concepts for each Category Axis date as a segment of the pie.

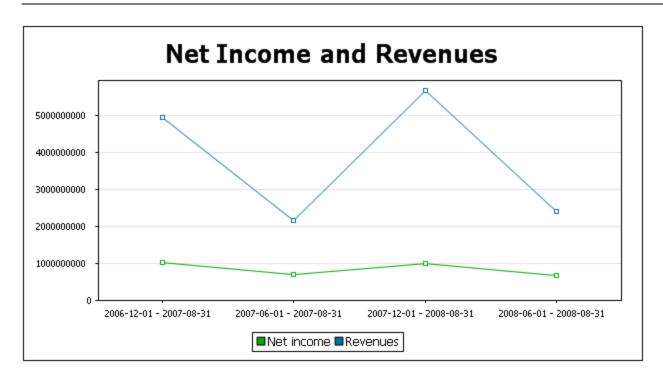

Charts with multiple series

In the single series example given above, charts were created for one series: the Total Assets concept. But a chart could have more than one series. In the example below, two series are specified: for the Net Income and Revenues concepts. Both series are shown for four duration periods on the Category Axis.

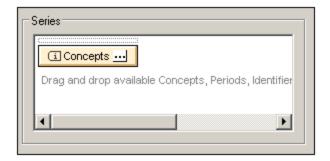

The bar chart above can be converted to other kinds of chart that can represent multiple series, such as line graph charts (*screenshot below*). But multiple series cannot be represented in charts such as pie charts—which are limited to one series.

Selecting the series

To select items for the Series Axis, first drag a component from the Available pane into the Series pane. (In the screenshot below, the Concepts component has been dragged to the Series pane.) Then click the Ellipsis icon of each component to set the component's properties.

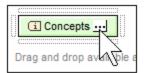

In the case of the Concepts component, the Concept Properties dialog enables you to select the concepts to display. Each selected concept in this dialog will become a series of the chart.

For details of the properties of the various components, see the section Component Properties 22.

11.10.3 **Component Properties**

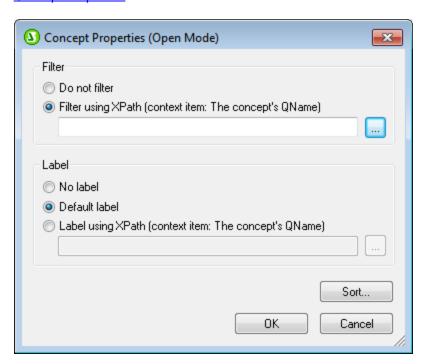

Each component has its individual set of properties. To edit a component's properties, in the XBRL Table Wizard or XBRL Chart Wizard, click the **Edit Properties** icon of the component (see screenshot below).

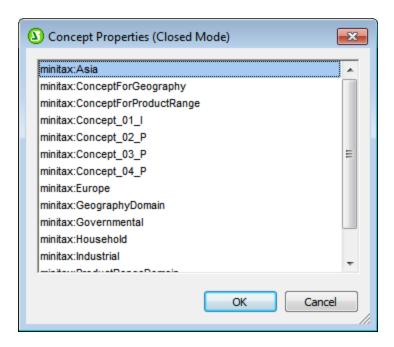

This displays the properties dialog of the respective component. The properties dialog of open mode and closed mode are different, since open mode returns multiple items while closed mode returns the single specified item. These dialogs are described below.

Concept properties

The Concept Properties dialogs are shown below: open mode concepts (left) and closed mode concepts (right). The open mode dialog provides options to filter, label, and sort the concepts being iterated over. The closed mode dialog enables you to select the concept to return. See the section Concept Properties (76) for detailed information.

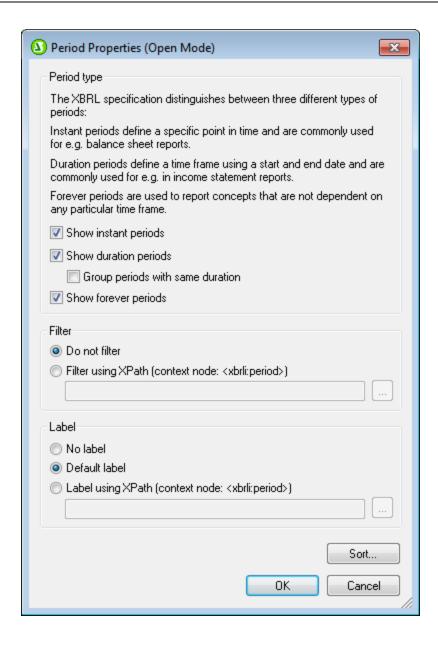

824 XBRL Chart Wizard

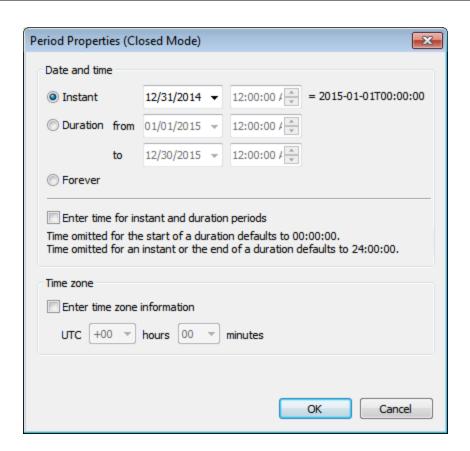

Period properties

The Period Properties dialogs are shown below: open mode periods (left) and closed mode periods (right). The open mode dialog provides options to filter, label, and sort the periods being returned. The closed mode dialog provides options for entering the instant or duration of the period, with or without a timezone. See the section Period Properties (778) for detailed information.

XBRL Chart Wizard 825

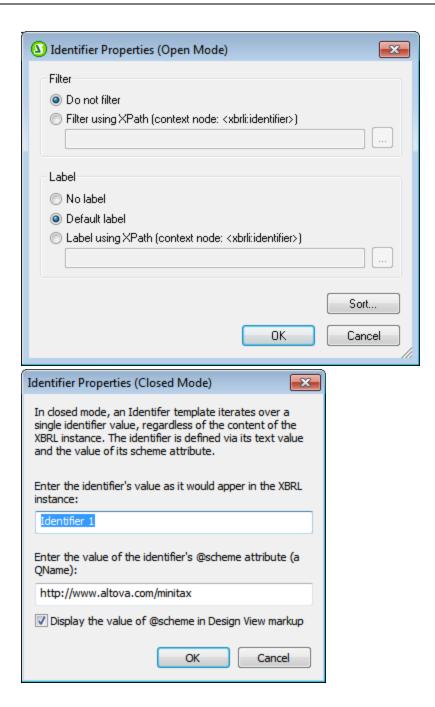

826 XBRL XBRL XBRL Chart Wizard

▼ Identifier properties

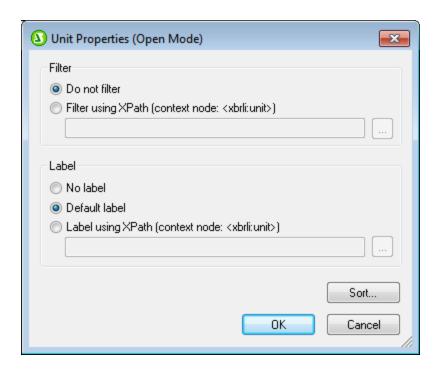

The Identifier Properties dialogs are shown below: open mode identifiers (left) and closed mode identifier (right). The open mode dialog provides options to filter, label, and sort the identifiers being iterated over. The closed mode dialog enables you to enter the value and scheme of the single specified identifier. See the section, Identifier Properties (right) for detailed information.

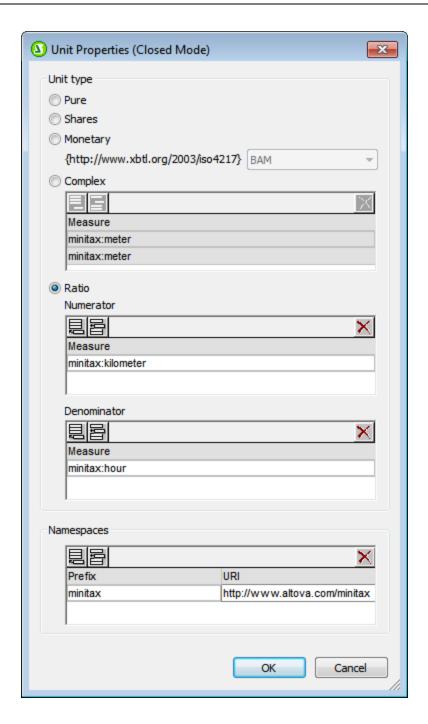

Unit properties

The Unit Properties dialogs are shown below: open mode units (*right*) and closed mode units (*right*). The open mode dialog provides options to filter, label, and sort the units being returned. The closed mode dialog provides options for entering the unit type of the specified unit. See the section Unit Properties (181) for detailed information.

828 XBRL Chart Wizard

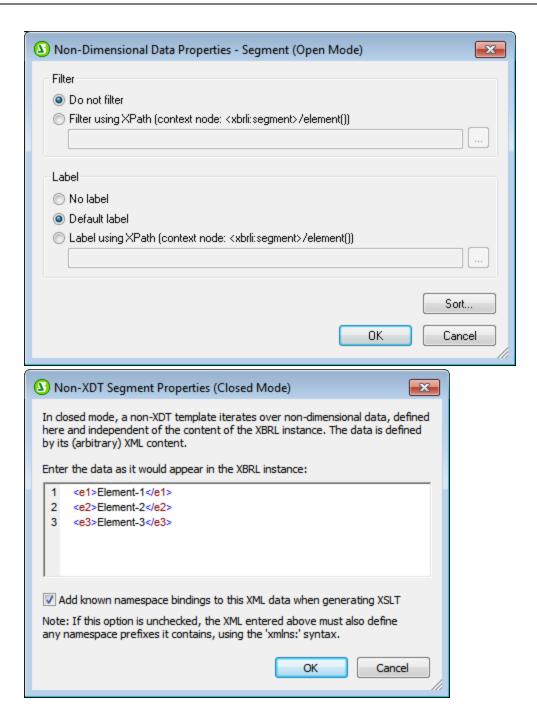

XBRL XBRL Chart Wizard 829

▼ Non-dimensional data (segment/scenario) properties

The Non-dimensional Data (Segment) and Non-dimensional Data (Scenario) Properties dialogs are shown below: open mode non-dimensional data (left) and closed mode non-dimensional data (right). The open mode dialog provides options to filter, label, and sort the non-dimensional data being returned. The closed mode dialog enables you to enter the XBRL instance data you require. See the section Non-XDT Segment/Scenario Properties for detailed information.

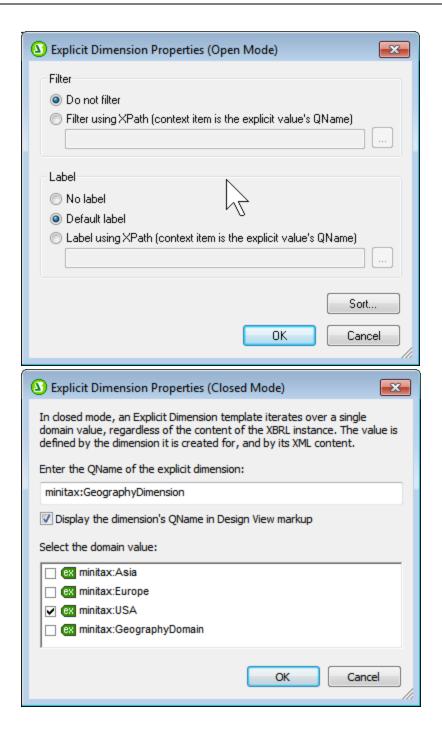

830 XBRL XBRL Chart Wizard

Explicit dimension properties

The Explicit Dimension Properties dialogs are shown below: open mode explicit dimensions (left) and closed mode explicit dimensions (right). The open mode dialog provides options to filter, label, and sort the explicit dimensions being returned. The closed mode dialog enables you to select the dimension and domain you want. See the section Explicit Dimension Properties (185) for detailed information.

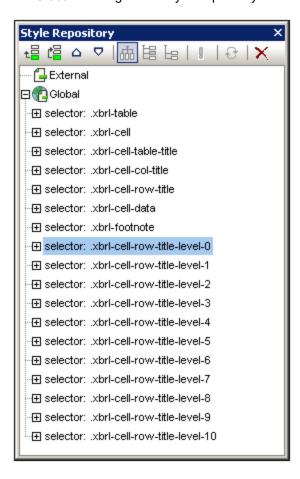

XBRL XBRL Chart Wizard 831

11.11 Properties and Formatting

When an XBRL table is created with the XBRL Table Wizard (794), it is created so that table properties and formatting can be applied via CSS. The mechanism works as follows:

- Table elements (for example, column headers, row headers, and cell contents) are assigned to distinct classes.
- Class selectors are created for these classes with certain default properties assigned to theses selectors. As a result, the table is displayed with the default CSS properties assigned to the various table element classes. The auto-generated class selectors and their properties can be viewed under the *Global* heading of the Style Repository sidebar (*screenshot below*).

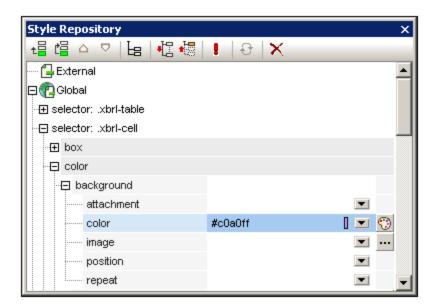

You can customize the formatting of the table by (i) modifying the default CSS properties of the StyleVision-generated class selectors; (ii) assigning your own classes and defining properties for these classes; (iii) setting additional styles in the Styles sidebar and Properties sidebar. How to do this in each of the three cases is described below.

Modifying properties of generated CSS class selectors

To modify properties of a CSS class selector that has been automatically generated, do the following:

1. In the Style Repository sidebar, expand that selector for which properties are to be modified (see screenshot below).

2. Select the required property group and then modify the value of the property you wish to change.

For more information about modifying CSS styles via the <u>Style Repository sidebar</u> see the section, <u>Working with CSS Styles</u> type you are not sure to what table element a particular selector applies, modify a property such as background-color and then check what element in the table design is affected.

Creating new classes and defining their properties

To insert a new class selector in the style repository, do the following:

- 1. Click the **Add** or **Insert** icon in the Style Repository toolbar.
- 2. Type in a name for the newly created selector item and press Enter.
- 3. In the expanded item box, define the required properties.

For more information about using CSS styles, see the section, Working with CSS Styles 465.

Properties via the Styles sidebar and Properties sidebar

Additionally, styles can be set directly on table components via the <u>Styles sidebar</u> and <u>Properties</u> sidebar that is without using class or id selectors. For a description of table-specific formatting see the sections, <u>Formatting Static and Dynamic SPS Tables</u> and <u>Row and Column Display</u> 165.

11.12 Inline XBRL

In an SPS design that <u>uses XSLT 2.0 or XSLT 3.0</u> (not XSLT 1.0), you can specify that content from an XBRL instance file be output to an (X)HTML file as an Inline XBRL element.

Inline XBRL elements are defined in the Inline XBRL specification and enable XBRL fragments to be embedded in an (X)HTML file. Internet browser applications typically render such elements as inline elements, and styling can be applied with CSS styles as required. The main advantage of having Inline XBRL elements in an (X)HTML file is that when the (X)HTML document is processed by an XBRL-generating application, the Inline XBRL markup in the (X)HTML document indicates the semantics of the XBRL fact, thus enabling the XBRL-generating application to extract the XBRL fact correctly and generate valid XBRL.

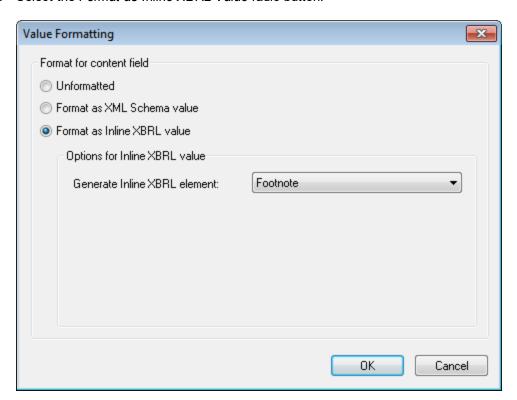

The version of the Inline XBRL that is generated can be selected in the Properties dialog 971.

Formatting content as Inline XBRL

In an SPS that is based on an XBRL taxonomy, create Inline XBRL elements as follows:

1. Right-click the design component (content placeholder or Auto-Calculation) and select **Edit Value**Formatting from the context menu. This pops up the Value Formatting dialog (see screenshot below).

3. In the *Generate Inline XBRL Element* combo box (see screenshot above), select the required Inline XBRL element. The options for each Inline XBRL element are described below.

Note: Inline XBRL is not supported for single-line or multi-line input field components in the SPS design. For multi-line input fields, although the Inline XBRL element is generated, Internet browsers will display the Inline XBRL element tags.

Specifying the XBRL facts to include

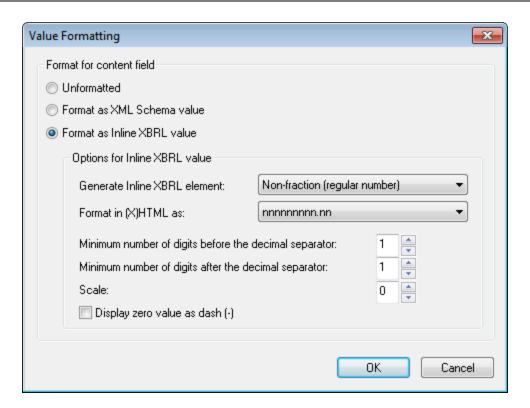

The XBRL instance document that will be used as the source document for the (X)HTML output document might contain more facts than you wish to present in the (X)HTML report. These additional facts can also be included as hidden data in the (X)HTML document. Such data can then be used by applications that generate valid XBRL from the (X)HTML document.

How additional document data from the XBRL instance is to be handled is specified in the <u>Taxonomy Source Properties</u> dialog (accessed via the Properties item in the Design Overview window). In this dialog, you can choose to include (i) only XBRL items that are displayed in the design, or (ii) all XBRL items in the source XBRL instance document. In the latter case, items that are not displayed in the design will be output as hidden data inside the <HEAD> element of the (X)HTML document.

Options for Inline XBRL values

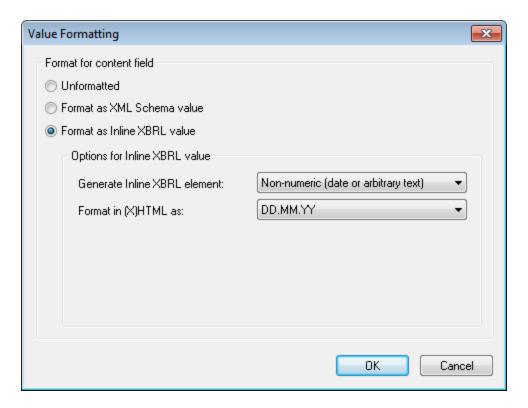

The following Inline XBRL elements can be generated. The various options for each element and important points to note about each element are listed below. You should note that the *Format in (X)HTML* option applies formatting only to the (X)HTML output.

• Non-fraction (regular number): The format in the (X)HTML output can be selected from the combo box of the Format item. The minimum number of digits before and after the decimal separator can be specified. The Scale option is the power of 10 by which the output value is multiplied. (10 to the power of 0 is 1; 10 to the power of 1 is 10; 10 to the power of 2 is 100, etc.) The Scale value is included in the Inline XBRL element. It will be used by the (X)HTML-to-XBRL generator application to multiply with the content of the Inline XBRL element and so obtain the XBRL item. You must note that, when generating the Inline XBRL element for (X)HTML from the source XBRL instance, the XBRL fact is not automatically modified by the value of the Scale element. You will need to modify the value of the XBRL fact according to the Scale value in an Auto-Calculation.

To display XBRL facts that have a value of zero as a dash, check the *Display Zero Value as Dash* check box.

- **Fraction (numerator, denominator):** The numerator and denominator of a fraction are formatted separately as regular numbers, and the formatting options for each are the same as for *Non-fraction (regular number)* described above.
- **Non-numeric (date or arbitrary text):** This option enables date values and text values to be formatted. In the *Format in (X)HTML* combo box (*screenshot below*), you can select the *Arbitrary Text* option or any other from a variety of date formats.

When the *Arbitrary Text* option is selected, you can additionally specify whether HTML elements inside the arbitrary text should be escaped in the generated XBRL instance. Check the *Escape Child Elements* check box to do this.

• Footnote: No options are required. A standard Inline XBRL element for footnotes is created.

11.13 Altova XBRL Extension Functions

Footnotes and Labels

```
altovaext:footnotes(node()) returns schema-element(link:footnote)*
altovaext:labels(xs:QName, xs:string) returns schema-element(link:label)*
```

Parse XML

```
axfi:parse-xml(xs:string) returns document-node(element(*))
axfi:parse-xml(xs:string, element(xbrli:xbrl)) returns document-node(element(*))
```

Aspects

```
axfi:aspect-type(item()) returns xs:string
axfi:aspect-to-base64Binary(item()) returns xs:base64Binary
axfi:aspect-from-base64Binary(xs:base64Binary) returns item()
axfi:aspect-from-base64Binary(xs:base64Binary, element(xbrli:xbrl)) returns item()
```

Concepts

```
axfi:create-concept-aspect(xs:QName) returns axfi:concept-aspect.type
axfi:create-concept-aspect(xs:QName, element(xbrli:xbrl)) returns axfi:concept-aspect.type
axfi:concept-aspect-concept(axfi:concept-aspect.type) returns xs:QName
axfi:concept-aspects-in-instance(element(xbrli:xbrl)) returns axfi:concept-aspect.type*
axfi:concept-aspects-in-facts(schema-element(xbrli:item)*) returns axfi:concept-aspect.type*
```

Location aspects

```
axfi:create-location-aspect(element()) returns axfi:location-aspect.type
axfi:location-aspect-element(axfi:location-aspect.type) returns element()
```

Identifiers

axfi:create-identifier-aspect(xs:string, xs:string) returns axfi:identifier-aspect.type

```
axfi:create-identifier-aspect(xs:string, xs:string, element(xbrli:xbrl)) returns
axfi:identifier-aspect.type

axfi:identifier-aspect-value(axfi:identifier-aspect.type) returns xs:string

axfi:identifier-aspect-scheme(axfi:identifier-aspect.type) returns xs:string

axfi:identifier-aspect-element(axfi:identifier-aspect.type, element(xbrli:xbrl)) returns element(xbrli:identifier)?

axfi:identifier-aspects-in-instance(element(xbrli:xbrl)) returns axfi:identifier-aspect.type*

axfi:identifier-aspects-in-facts(schema-element(xbrli:item)*) returns axfi:identifier-aspect.type*

axfi:identifier-aspects-in-contexts(schema-element(xbrli:context)*) returns
axfi:identifier-aspect.type*
```

Periods

```
axfi:create-period-aspect-instant(xbrli:dateUnion) returns axfi:period-aspect.type
axfi:create-period-aspect-instant(xbrli:dateUnion, element(xbrli:xbrl)) returns
axfi:period-aspect.type
axfi:create-period-aspect-start-end(xbrli:dateUnion, xbrli:dateUnion) returns axfi:period-
aspect.type
axfi:create-period-aspect-start-end(xbrli:dateUnion, xbrli:dateUnion, element(xbrli:xbrl))
returns axfi:period-aspect.type
axfi:create-period-aspect-forever() returns axfi:period-aspect.type
axfi:create-period-aspect-forever(element(xbrli:xbrl)) returns axfi:period-aspect.type
axfi:period-aspect-is-instant(axfi:period-aspect.type) returns xs:boolean
axfi:period-aspect-is-start-end(axfi:period-aspect.type) returns xs:boolean
axfi:period-aspect-is-duration(axfi:period-aspect.type) returns xs:boolean
axfi:period-aspect-is-forever(axfi:period-aspect.type) returns xs:boolean
axfi:period-aspect-instant(axfi:period-aspect.type) returns xs:dateTime
axfi:period-aspect-start(axfi:period-aspect.type) returns xs:dateTime
axfi:period-aspect-end(axfi:period-aspect.type) returns xs:dateTime
axfi:period-aspect-element(axfi:period-aspect.type, element(xbrli:xbrl)) returns
element(xbrli:period)?
axfi:period-aspects-in-instance(element(xbrli:xbrl)) returns axfi:period-aspect.type*
```

axfi:period-aspects-in-facts(schema-element(xbrli:item)*) returns axfi:period-aspect.type* axfi:period-aspects-in-contexts(schema-element(xbrli:context)*) returns axfi:periodaspect.type*

Non-XDT segments

```
axfi:create-non-xdt-segment-aspect(element()*) returns axfi:non-XDT-segment-aspect.type
axfi:create-non-xdt-segment-aspect(element()*, element(xbrli:xbrl)) returns axfi:non-XDT-
segment-aspect.type
axfi:non-xdt-segment-aspect-elements(axfi:non-XDT-segment-aspect.type) returns element()*
axfi:non-xdt-segment-aspects-in-instance(element(xbrli:xbrl)) returns axfi:non-XDT-segment-
aspect.type*
axfi:non-xdt-segment-aspects-in-facts(schema-element(xbrli:item)*) returns axfi:non-XDT-
segment-aspect.type*
axfi:non-xdt-segment-aspects-in-contexts(schema-element(xbrli:context)*) returns axfi:non-
XDT-segment-aspect.type*
```

Non-XDT scenarios

```
axfi:create-non-xdt-scenario-aspect(element()*) returns axfi:non-XDT-scenario-aspect.type
axfi:create-non-xdt-scenario-aspect(element()*, element(xbrli:xbrl)) returns axfi:non-XDT-
scenario-aspect.type
axfi:non-xdt-scenario-aspect-elements(axfi:non-XDT-scenario-aspect.type) returns element()*
axfi:non-xdt-scenario-aspects-in-instance(element(xbrli:xbrl)) returns axfi:non-XDT-
scenario-aspect.type*
axfi:non-xdt-scenario-aspects-in-facts(schema-element(xbrli:item)*) returns axfi:non-XDT-
scenario-aspect.type*
axfi:non-xdt-scenario-aspects-in-contexts(schema-element(xbrli:context)*) returns axfi:non-
XDT-scenario-aspect.type*
```

Dimensions (typed and explicit)

```
axfi:create-dimension-aspect-explicit(xs:QName, xs:QName?) returns axfi:dimension-
aspect.type
axfi:create-dimension-aspect-explicit(xs:QName, xs:QName?, element(xbrli:xbrl)) returns
axfi:dimension-aspect.type
axfi:create-dimension-aspect-typed(xs:QName, element()?) returns axfi:dimension-aspect.type
axfi:create-dimension-aspect-typed(xs:QName, element()?, element(xbrli:xbrl)) returns
axfi:dimension-aspect.type
```

```
axfi:dimension-aspect-is-explicit(axfi:dimension-aspect.type) returns xs:boolean

axfi:dimension-aspect-is-typed(axfi:dimension-aspect.type) returns xs:boolean

axfi:dimension-aspect-dimension(axfi:dimension-aspect.type) returns xs:QName

axfi:dimension-aspect-explicit-value(axfi:dimension-aspect.type) returns xs:QName?

axfi:dimension-aspect-typed-value(axfi:dimension-aspect.type) returns element()?

axfi:dimension-aspects-in-instance(element(xbrli:xbrl), xs:QName, xs:boolean) returns axfi:dimension-aspects-type*

axfi:dimension-aspects-in-facts(schema-element(xbrli:item)*, xs:QName, xs:boolean) returns axfi:dimension-aspects-in-contexts(schema-element(xbrli:context)*, xs:QName, xs:boolean) returns axfi:dimension-aspects-in-contexts(schema-element(xbrli:context)*, xs:QName, xs:boolean) returns axfi:dimension-aspects-in-contexts(schema-element(xbrli:context)*, xs:QName, xs:boolean) returns axfi:dimension-aspects-type*
```

Units

```
axfi:create-unit-aspect(xs:QName+, xs:QName*) returns axfi:unit-aspect.type
axfi:create-unit-aspect(xs:QName+, xs:QName*, element(xbrli:xbrl)) returns axfi:unit-aspect.type
axfi:unit-aspect-numerator(axfi:unit-aspect.type) returns xs:QName+
axfi:unit-aspect-denominator(axfi:unit-aspect.type) returns xs:QName*
axfi:unit-aspect-element(axfi:unit-aspect.type, element(xbrli:xbrl)) returns
element(xbrli:unit)?
axfi:unit-aspects-in-instance(element(xbrli:xbrl)) returns axfi:unit-aspect.type*
axfi:unit-aspects-in-facts(schema-element(xbrli:item)*) returns axfi:unit-aspect.type*
axfi:unit-aspects-in-units(schema-element(xbrli:unit)*) returns axfi:unit-aspect.type*
axfi:units-in-instance(element(xbrli:xbrl)) returns element(xbrli:unit)*
```

Facts and items

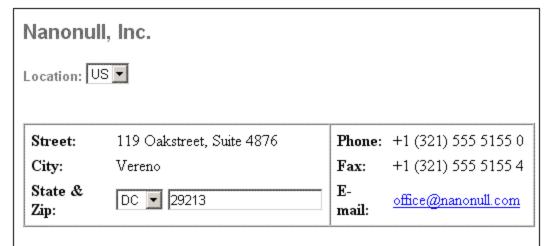

```
axfi:facts-in-instance(element(xbrli:xbrl), item()*, xs:boolean) returns element()*
axfi:items-in-instance(element(xbrli:xbrl), item()*, xs:boolean) returns element()*
axfi:tuples-in-instance(element(xbrli:xbrl), item()*) returns element()*
axfi:contexts-in-instance(element(xbrli:xbrl)) returns element(xbrli:context)*
```

axfi:contexts-in-instance(element(xbrli:xbrl), item()*, xs:boolean) returns element(xbrli:context)*

Authentic View 843

12 Authentic View

Authentic View (*screenshot below*) is a graphical representation of your XML document. It enables XML documents to be displayed without markup and with appropriate formatting and data-entry features such as input fields, combo boxes, and radio buttons. Data that the user enters in Authentic View is entered into the XML file.

Vereno Office Summary: 4 departments, 15 employees.

The company was established in Vereno in 1995 as a privately held software company. Since 1996, Nanonull has been actively involved in developing nanoelectronic software technologies. It released the first version of its acclaimed NanoSoft Development Suite in February 1999. Also in 1999, Nanonull increased its capital base with invesment from a consortium of private investment firms. The company has been expanding rapidly ever since.

Authentic Preview

In StyleVision, while editing an SPS, you are able to preview the Authentic View of the assigned Working XML File. If you click the Authentic View tab when no Working XML File has been assigned to the SPS, you are prompted to assign a Working XML File. In Authentic Preview, you can edit the XML document, similarly to standard Authentic View, and the editing changes can be saved to the Working XML File. This section describes Authentic View 444 and how to edit documents in Authentic View 555.

12.1 **Authentic View Interface**

Authentic Preview is enabled by clicking the Authentic tab of the active document. If no Working XML File has been assigned to the SPS, you are prompted to assign one.

This section provides:

- An overview of the interface
- A description of the toolbar icons specific to Authentic View
- A description of viewing modes available in the main Authentic Preview window
- A description of the context menus available at various points in the Authentic View of the XML document

Additional sources of Authentic View information are:

- An Authentic View Tutorial, which shows you how to use the Authentic View interface. This tutorial is available in the documentation of the Altova XMLSpy and Altova Authentic Desktop products (see the Tutorials section), as well as online.
- For a detailed description of Authentic View menu commands, see the User Reference section of your product documentation.

Altova website: ML content editing, XML authoring

Overview of the GUI 12.1.1

The Authentic Preview provides you with menu commands, toolbar icons, and context menus with which to edit the XML document that is displayed in the Main Window.

Menu bar

The menus available in the menu bar are described in detail in the User Reference section of your product documentation.

Toolbar

The symbols and icons displayed in the toolbar are described in the section, Authentic View toolbar icons [845].

Main window

This is the window in which the Working XML document is displayed and edited. It is described in the section, Authentic View main window 847.

Status Bar

The Status Bar displays the XPath to the currently selected node. In the Authentic Preview of StyleVision, the XPath to the currently selected node is indicated in the Schema Tree, where the currently selected node is highlighted in gray. The XPath in Authentic Preview is not displayed in a status bar.

Context menus

These are the menus that appear when you right-click in the Main Window. The available commands are context-sensitive editing commands, i.e. they allow you to manipulate structure and content relevant to the selected node. Such manipulations include inserting, appending, or deleting a node, adding entities, or cutting and pasting content.

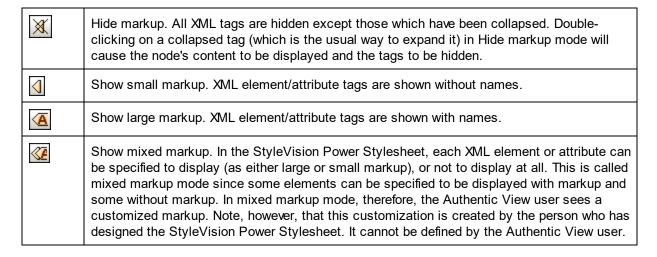

12.1.2 Authentic View Toolbar Icons

lcons in the Authentic View toolbar are command shortcuts. Some icons will already be familiar to you from other Windows applications or Altova products, others might be new to you. This section describes icons unique to Authentic View. In the description below, related icons are grouped together.

Show/hide XML markup

In Authentic View, the tags for all, some, or none of the XML elements or attributes can be displayed, either with their names (large markup) or without names (small markup). The four markup icons appear in the toolbar, and the corresponding commands are available in the **Authentic** menu.

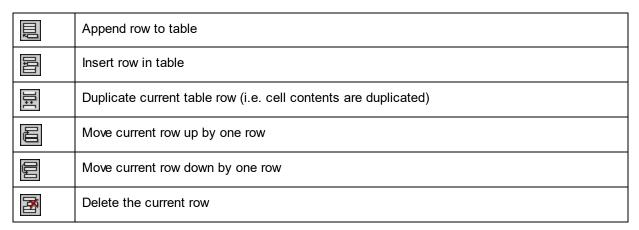

Editing dynamic table structures

Rows in a **dynamic SPS table** are repetitions of a data structure. Each row represents an occurrence of a single element. Each row, therefore, has the same XML substructure as the next.

The dynamic table editing commands manipulate the rows of a dynamic SPS table. That is, you can modify the number and order of the element occurrences. You cannot, however, edit the columns of a dynamic SPS table, since this would entail changing the substructure of individual element occurrences.

The icons for dynamic table editing commands appear in the toolbar, and are also available in the **Authentic** menu.

Note: These commands apply only to **dynamic SPS tables**. They should not be used inside static SPS tables.

DB Row Navigation icons

The arrow icons are, from left to right, Go to First Record; Go to Previous Record; Open the *Go to Record* # dialog; Go to Next Record; and Go to Last Record.

This icon opens the Edit Database Query dialog in which you can enter a query. Authentic View displays the queried record/s.

XML database editing

The **Select New Row with XML Data for Editing** command enables you to select a new row from the relevant table in an XML DB, such as IBM DB2. This row appears in Authentic View, can be edited there, and then saved back to the DB.

XML File commands

The following icons, from left to right, correspond to the commands listed below:

- Save Authentic XML Data: Saves the XML data file.
- Save Authentic XML Data As: Saves the XML data file as another file.

• Reload Authentic View. Reloads the saved XML data file. Any unsaved changes will be lost.

• Validate: Validates the XML data file.

12.1.3 Authentic View Main Window

There are four viewing modes in Authentic View: Large Markup; Small Markup; Mixed Markup; and Hide All Markup. These modes enable you to view the document with varying levels of markup information. To switch between modes, use the commands in the **Authentic** menu or the icons in the toolbar (see the previous section, <u>Authentic View toolbar icons</u> (845)).

Large markup

This shows the start and end tags of elements and attributes with the element/attribute names in the tags:

The element Name in the figure above is **expanded**, i.e. the start and end tags, as well as the content of the element, are shown. An element/attribute can be **contracted** by double-clicking either its start or end tag. To expand the contracted element/attribute, double-click the contracted tag.

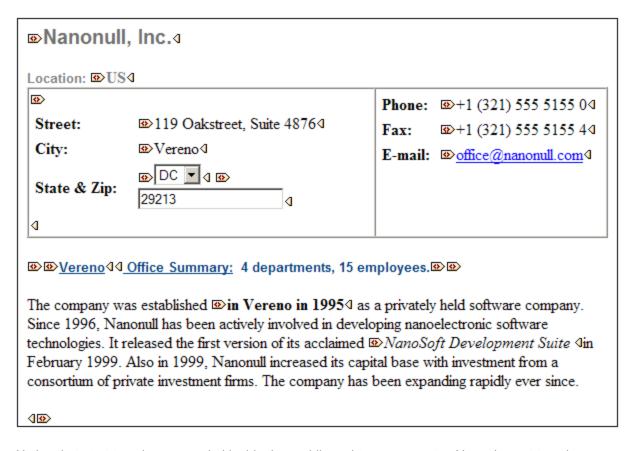

In large markup, attributes are recognized by the equals-to symbol in the start and end tags of the attribute:

Small markup

This shows the start and end tags of elements/attributes without names:

Notice that start tags have a symbol inside them while end tags are empty. Also, element tags have an angular-brackets symbol while attribute tags have an equals sign as their symbol (see screenshot below).

```
№ № 2006-04-014: № № Boston4, № USA444
```

To collapse or expand an element/attribute, double-click the appropriate tag. The example below shows a collapsed element (highlighted in blue). Notice the shape of the tag of the collapsed element and that of the start tag of the expanded element to its left.

```
® Office Summary: 4 departments, 15 employees. ® ®
```

Mixed markup

Mixed markup shows a customized level of markup. The person who has designed the StyleVision Power Stylesheet can specify either large markup, small markup, or no markup for individual elements/attributes in the document. The Authentic View user sees this customized markup in mixed markup viewing mode.

Hide all markup

All XML markup is hidden. Since the formatting seen in Authentic View is the formatting of the printed document, this viewing mode is a WYSIWYG view of the document.

Content display

In Authentic View, content is displayed in two ways:

• Plain text. You type in the text, and this text becomes the content of the element or the value of the attribute.

Data-entry devices. The display contains either an input field (text box), a multiline input field, combo
box, check box, or radio button. In the case of input fields and multiline input fields, the text you enter
in the field becomes the XML content of the element or the value of the attribute.

In the case of the other data-entry devices, your selection produces a corresponding XML value, which is specified in the StyleVision Power Stylesheet. Thus, in a combo box, a selection of, say, "approved" (which would be available in the dropdown list of the combo box) could map to an XML value of "1", or to "approved", or anything else; while "not approved" could map to "0", or "not approved", or anything else.

Optional nodes

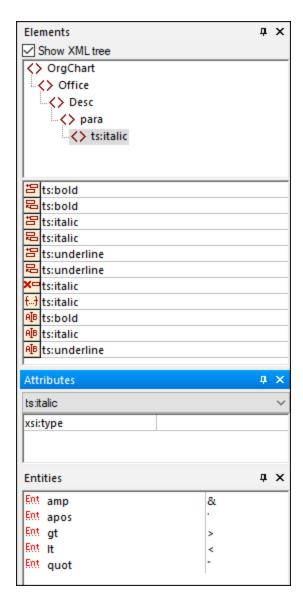

When an element or attribute is **optional** (according to the referenced schema), a prompt of type add [element/attribute] is displayed:

Clicking the prompt adds the element, and places the cursor for data entry. If there are multiple optional nodes, the prompt add... is displayed. Clicking the prompt displays a menu of the optional nodes.

12.1.4 Authentic View Entry Helpers

There are three entry helpers in Authentic View: for Elements, Attributes, and Entities. They are displayed as windows down the right side of the Authentic View interface (see screenshot below).

The Elements and Attributes Entry Helpers are context-sensitive, i.e. what appears in the entry helper depends on where the cursor is in the document. The entities displayed in the Entities Entry Helper are not context-sensitive; all entities allowed for the document are displayed no matter where the cursor is.

Each of the entry helpers is described separately below.

Elements Entry Helper

The Elements Entry Helper consists of two parts:

• The upper part, containing an XML tree that can be toggled on and off using the **Show XML tree** check box. The XML tree shows the ancestors up to the document's root element for the current element. When you click on an element in the XML tree, elements corresponding to that element (as described in the next item in this list) appear in the lower part of the Elements Entry Helper.

The lower part, containing a list of the nodes that can be inserted within, before, and after; removed; applied to or cleared from the selected element or text range in Authentic View. What you can do with an element listed in the Entry Helper is indicated by the icon to the left of the element name in the Entry Helper. The icons that occur in the Elements Entry Helper are listed below, together with an explanation of what they mean.

To use a node from the Entry Helper, click its icon.

Insert After Element

The element in the Entry Helper is inserted after the selected element. Note that it is appended at the correct hierarchical level. For example, if your cursor is inside a //sect1/para element, and you append a sect1 element, then the new sect1 element will be appended not as a following sibling of //sect1/para but as a following sibling of the sect1 element that is the parent of that para element.

Insert Before Element

The element in the Entry Helper is inserted before the selected element. Note that, just as with the Insert After **Element** command, the element is inserted at the correct hierarchical level.

Remove Element

Removes the element and its content.

Insert Element

An element from the Entry Helper can also be inserted within an element. When the cursor is placed within an element, then the allowed child elements of that element can be inserted. Note that allowed child elements can be part of an elements-only content model as well as a mixed content model (text plus child elements).

An allowed child element can be inserted either when a text range is selected or when the cursor is placed as an insertion point within the text.

- When a text range is selected and an element inserted, the text range becomes the content of the inserted element.
- When an element is inserted at an insertion point, the element is inserted at that point.

After an element has been inserted, it can be cleared by clicking either of the two Clear Element icons that appear (in the Elements Entry Helper) for these inline elements. Which of the two icons appears depends on whether you select a text range or place the cursor in the text as an insertion point (see below).

Apply Element

If you select an element in your document (by clicking either its start or end tag in the Show large markup view) and that element can be replaced by another element (for example, in a mixed content element such as para, an italic element can be replaced by the bold element), this icon indicates that the element in the Entry Helper can be applied to the selected (original) element. The **Apply Element** command can also be applied to a text range within an element of mixed content; the text range will be created as content of the applied element.

- If the applied element has a child element with the same name as a child of the original element and an instance of this child element exists in the original element, then the child element of the original is retained in the new element's content.
- If the applied element has no child element with the same name as that of an instantiated child of the original element, then the instantiated child of the original element is appended as a sibling of any child element or elements that the new element may have.

• If the applied element has a child element for which no equivalent exists in the original element's content model, then this child element is not created directly but Authentic View offers you the option of inserting it.

If a text range is selected rather than an element, applying an element to the selection will create the applied element at that location with the selected text range as its content. Applying an element when the cursor is an insertion point is not allowed.

This icon appears when text within an element of mixed content is selected. Clicking the icon clears the element from around the selected text range.

Clear Element (when insertion point selected)

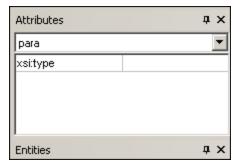

This icon appears when the cursor is placed within an element that is a child of a mixed-content element. Clicking the icon clears the inline element.

Attributes Entry Helper

The Attributes Entry Helper consists of a drop-down combo box and a list of attributes. The element that you have selected (you can click the start or end tag, or place the cursor anywhere in the element content to select it) appears in the combo box. The Attributes Entry Helper shown in the figures below has a para element in the combo box. Clicking the arrow in the combo box drops down a list of all the para element's **ancestors up to the document's root element**, which in this case is orgChart.

Below the combo box, a list of valid attributes for that element is displayed, in this case for para. If an attribute is mandatory on a given element, then it appears in bold. (In the example below, there are no mandatory attributes except the built-in attribute xsi:type.)

To enter a value for an attribute, click in the value field of the attribute and enter the value. This creates the attribute and its value in the XML document.

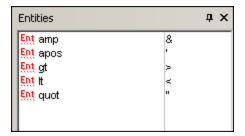

Note the following:

• In the case of the xsi:nil attribute, which appears in the Attributes Entry Helper when a nillable element has been selected, the value of the xsi:nil attribute can only be entered by selecting one of the allowed values (true or false) from the dropdown list for the attribute's value.

• The xsi:type attribute can be changed by clicking in the value field of the attribute and then either (i) selecting a value from the dropdown list that appears, or (ii) entering a value. Values displayed in the dropdown list are the available abstract types defined in the XML Schema on which the Authentic View document is based.

Entities Entry Helper

The Entities Entry Helper allows you to insert an entity in your document. Entities can be used to insert special characters or text fragments that occur often in a document (such as the name of a company). To insert an entity, place the cursor at the point in the text where you want to have the entity inserted, then double-click the entity in the Entities Entry Helper.

Note: An internal entity is one that has its value defined within the DTD. An external entity is one that has its value contained in an external source, e.g. another XML file. Both internal and external entities are listed in the Entities Entry Helper. When you insert an entity, whether internal or external, the entity—not its value—is inserted into the XML text. If the entity is an internal entity, Authentic View displays **the value of the entity**. If the entity is an external entity, Authentic View displays the entity—and not its value. This means, for example, that an XML file that is an external entity will be shown in the Authentic View display as an entity; its content does not replace the entity in the Authentic View display.

You can also **define your own entities** in Authentic View and these will also be displayed in the entry helper: see <u>Define Entities</u> in the Editing in Authentic View section.

12.1.5 Authentic View Context Menus

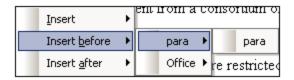

Right-clicking on some selected document content or node pops up a context menu with commands relevant to the selection or cursor location.

Inserting elements

The figure below shows the **Insert** submenu, which is a list of all elements that can be inserted at that current cursor location. The **Insert Before** submenu lists all elements that can be inserted before the current element. The **Insert After** submenu lists all elements that can be inserted after the current element. In the figure below, the current element is the para element. The bold and italic elements can be inserted within the current para element.

As can be seen below, the para and Office elements can be inserted before the current para element.

The node insertion, replacement (**Apply**), and markup removal (**Clear**) commands that are available in the context menu are also available in the <u>Authentic View entry helpers</u> and are fully described in that section.

Insert entity

Positioning the cursor over the **Insert Entity** command rolls out a submenu containing a list of all declared entities. Clicking an entity inserts it at the selection. See <u>Define Entities</u> for a description of how to define entities for the document.

Insert CDATA Section

This command is enabled when the cursor is placed within text. Clicking it inserts a CDATA section at the cursor insertion point. The CDATA section is delimited by start and end tags; to see these tags you should switch on large or small markup. Within CDATA sections, XML markup and parsing is ignored. XML markup characters (the ampersand, apostrophe, greater than, less than, and quote characters) are not treated as markup, but as literals. So CDATA sections are useful for text such as program code listings, which have XML markup characters.

Remove node

Positioning the mouse cursor over the **Remove** command pops up a menu list consisting of the selected node and all its removable ancestors (those that would not invalidate the document) up to the document element. Click the element to be removed. This is a quick way to delete an element or any removable ancestor. Note that clicking an ancestor element will remove all its descendants, including the selected element.

Clear

The **Clear** command clears the element markup from around the selection. If the entire node is selected, then the element markup is cleared for the entire node. If a text segment is selected, then the element markup is cleared from around that text segment only.

Apply

The **Apply** command applies a selected element to your selection in the main Window. For more details, see <u>Authentic View entry helpers</u> ⁸⁴⁹.

Copy, Cut, Paste

These are the standard Windows commands. Note, however, that the **Paste** command pastes copied text either as XML or as Text, depending on what the designer of the stylesheet has specified for the SPS as a whole. For information about how the **Copy as XML** and **Copy as Text** commands work, see the description of the **Paste As** command immediately below.

Paste As

The **Paste As** command offers the option of pasting as XML or as text an Authentic View XML fragment (which was copied to the clipboard). If the copied fragment is pasted as XML it is pasted together with its XML markup. If it is pasted as text, then only the text content of the copied fragment is pasted (not the XML markup, if any). The following situations are possible:

- An *entire node together with its markup tags* is highlighted in Authentic View and copied to the clipboard. (i) The node can be pasted as XML to any location where this node may validly be placed. It will not be pasted to an invalid location. (ii) If the node is pasted as text, then only the node's *text content* will be pasted (not the markup); the text content can be pasted to any location in the XML document where text may be pasted.
- A *text fragment* is highlighted in Authentic View and copied to the clipboard. (i) If this fragment is pasted as XML, then the XML markup tags of the text—even though these were not explicitly copied with the text fragment—will be pasted along with the text, but only if the XML node is valid at the location where the fragment is pasted. (ii) If the fragment is pasted as text, then it can be pasted to any location in the XML document where text may be pasted.

Note: Text will be copied to nodes where text is allowed, so it is up to you to ensure that the copied text does not invalidate the document. The copied text should therefore be: (i) lexically valid in the new location (for example, non-numeric characters in a numeric node would be invalid), and (ii) not otherwise invalidate the node (for example, four digits in a node that accepts only three-digit numbers would invalidate the node).

Note: If the pasted text does in any way invalidate the document, this will be indicated by the text being displayed in red.

Delete

The **Delete** command removes the selected node and its contents. A node is considered to be selected for this purpose by placing the cursor within the node or by clicking either the start or end tag of the node.

12.2 Editing in Authentic View

This section describes important features of Authentic View in detail. Features have been included in this section either because they are frequently used or because the mechanisms or concepts involved require explanation.

The section explains the following:

- The Date Picker is a graphical calendar that enters dates in the correct XML format when you click a date. See Date Picker ⁸⁷⁵.
- An entity is shorthand for a special character or text string. You can define your own entities, which allows you to insert these special characters or text strings by inserting the corresponding entities. See <u>Defining Entities</u> 876 for details.
- In the Enterprise and Professional editions of Altova products, Authentic View users can sign XML documents with <u>digital XML signatures</u> and verify these signatures.
- What <u>image formats</u> ⁸⁷⁹ can be displayed in Authentic View.

To learn how to use all the features of Authentic View, please do the Authentic View Tutorial using either XMLSpy or Authentic Desktop. The Authentic View Tutorial is available with these products.

Altova website: ML content editing, XML authoring

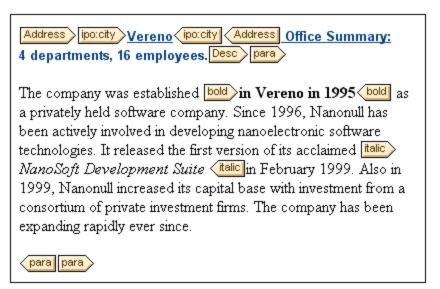

12.2.1 Basic Editing

When you edit in Authentic View, you are editing an XML document. Authentic View, however, can hide the structural XML markup of the document, thus displaying only the content of the document (*first screenshot below*). You are therefore not exposed to the technicalities of XML, and can edit the document as you would a normal text document. If you wish, you could switch on the markup at any time while editing (*second screenshot below*).

Vereno Office Summary: 4 departments, 16 employees.

The company was established in Vereno in 1995 as a privately held software company. Since 1996, Nanonull has been actively involved in developing nanoelectronic software technologies. It released the first version of its acclaimed NanoSoft Development Suite in February 1999. Also in 1999, Nanonull increased its capital base with investment from a consortium of private investment firms. The company has been expanding rapidly ever since.

An editable Authentic View document with no XML markup.

An editable Authentic View document with XML markup tags.

Inserting nodes

Very often you will need to add a new node to the Authentic XML document. For example, a new Person element might need to be added to an address book type of document. In such cases the XML Schema would allow the addition of the new element. All you need to do is right-click the node in the Authentic View document before which or after which you wish to add the new node. In the context menu that appears, select **Insert Before** or **Insert After** as required. The nodes available for insertion at that point in the document are listed in a submenu. Click the required node to insert it. The node will be inserted. All mandatory descendant nodes are also inserted. If a descendant node is optional, a clickable link, Add_NodeName, appears to enable you to add the optional node if you wish to.

If the node being added is an element with an abstract type, then a dialog (something like in the screenshot below) appears containing a list of derived types that are available in the XML Schema.

The screenshot above pops up when a Publication element is added. The Publication element is of type PublicationType, which is an abstract complex type. The two complex types BookType and MagazineType are derived from the abstract PublicationType. Therefore, when a Publication element is added to the XML document, one of these two concrete types derived from Publication's abstract type must be specified. The new Publication element will be added with an xsi:type attribute:

```
<Publication xsi:type="BookType"> ... </Publication>
<Publication xsi:type="MagazineType"> ... </Publication>
    ...
<Publication xsi:type="MagazineType"> ... </Publication>
```

Selecting one of the available derived types and clicking **OK** does the following:

- Sets the selected derived type as the value of the xsi:type attribute of the element
- Inserts the element together with the descendant nodes defined in the content model of the selected derived type.

The selected derived type can be changed subsequently by changing the value of the element's xsi:type attribute in the Attributes Entry Helper. When the element's type is changed in this way, all nodes of the previous type's content model are removed and nodes of the new type's content model are inserted.

Text editing

An Authentic View document will essentially consist of text and images. To edit the text in the document, place the cursor at the location where you wish to insert text, and type. You can copy, move, and delete text using familiar keystrokes (such as the **Delete** key) and drag-and-drop mechanisms. One exception is the **Enter** key. Since the Authentic View document is pre-formatted, you do not—and cannot—add extra lines or space between items. The **Enter** key in Authentic View therefore serves to append another instance of the element currently being edited, and should be used exclusively for this purpose.

Copy as XML or as text

Text can be copied and pasted as XML or as text.

- If text is pasted as XML, then the XML markup is pasted together with the text content of nodes. The XML markup is pasted even if only part of a node's contents has been copied. For the markup to be pasted it must be allowed, according to the schema, at the location where it is pasted.
- If text is pasted as text, XML markup is not pasted.

To paste as XML or text, first copy the text (**Ctrl+C**), right-click at the location where the text is to be pasted, and select the context menu command **Paste As | XML** or **Paste As | Text**. If the shortcut **Ctrl+V** is used, the text will be pasted in the default Paste Mode of the SPS. The default Paste Mode will have been specified by the designer of the SPS. For more details, see the section <u>Context Menus</u> [85].

Alternatively, highlighted text can be dragged to the location where it is to be pasted. When the text is dropped, a pop-up appears asking whether the text is to be pasted as text or XML. Select the desired option.

Text formatting

A fundamental principle of XML document systems is that content be kept separate from presentation. The XML document contains the content, while the stylesheet contains the presentation (formatting). In Authentic View, the XML document is presented via the stylesheet. This means that all the formatting you see in Authentic View is produced by the stylesheet. If you see bold text, that bold formatting has been provided by the stylesheet. If you see a list or a table, that list format or table format has been provided by the stylesheet. The XML document, which you edit in Authentic View contains only the content; it contains no formatting whatsoever. The formatting is contained in the stylesheet. What this means for you, the Authentic View user, is that you do not have to—nor can you—format any of the text you edit. You are editing content. The formatting that is automatically applied to the content you edit is linked to the semantic and/or structural value of the data you are editing. For example, an email address (which could be considered a semantic unit) will be formatted automatically in a certain way because it is an email. In the same way, a headline must occur at a particular location in the document (both a structural and semantic unit) and will be formatted automatically in the way the stylesheet designer has specified that headlines be formatted. You cannot change the formatting of either email address or headline. All that you do is edit the content of the email address or headline.

In some cases, content might need to be specially presented; for example, a text string that must be presented in boldface. In all such cases, the presentation must be tied in with a structural element of the document. For example, a text string that must be presented in boldface, will be structurally separated from surrounding content by markup that the stylesheet designer will format in boldface. If you, as the Authentic View user, need to use such a text string, you would need to enclose the text string within the appropriate element markup. For information about how to do this, see the Insert Element command in the Elements Entry Helper section of the documentation.

Using RichEdit in Authentic View

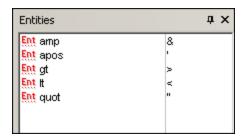

In Authentic View, when the cursor is placed inside an element that has been created as a RichEdit component, the buttons and controls in the RichEdit toolbar (*screenshot below*) become enabled. Otherwise they are grayed out.

Select the text you wish to style and specify the styling you wish to apply via the buttons and controls of the RichEdit toolbar. RichEdit enables the Authentic View user to specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of text. The text that has been styled will be enclosed in the tags of the styling element.

Inserting entities

In XML documents, some characters are reserved for markup and cannot be used in normal text. These are the ampersand (α), apostrophe (α), less than (α), greater than (α), and quote (α) characters. If you wish to use these characters in your data, you must insert them as entity references, via the Entities Entry Helper (screenshot below).

XML also offers the opportunity to create custom entities. These could be: (i) special characters that are not available on your keyboard, (ii) text strings that you wish to re-use in your document content, (iii) XML data fragments, or (iv) other resources, such as images. You can define your own entities within the Authentic View application. Once defined, these entities appear in the Entities Entry Helper and can then be inserted as in the document.

Inserting CDATA sections

CDATA sections are sections of text in an XML document that the XML parser does not process as XML data. They can be used to escape large sections of text if replacing special characters by entity references is undesirable; this could be the case, for example, with program code or an XML fragment that is to be reproduced with its markup tags. CDATA sections can occur within element content and are delimited by <!

[CDATA [and]] > at the start and end, respectively. Consequently the text string]] > should not occur within a CDATA section as it would prematurely signify the end of the section. In this case, the greater than character should be escaped by its entity reference (>). To insert a CDATA section within an element, place the cursor at the desired location, right-click, and select Insert CDATA Section from the context menu. To see the CDATA section tags in Authentic View, switch on the markup display. Alternatively, you could highlight the text that is to be enclosed in a CDATA section, and then select the Insert CDATA section command.

Note: CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). CDATA sections can only be entered within elements that are displayed in Authentic View as text content components.

Editing and following links

A hyperlink consists of two parts: the link text and the target of the link. You can edit the link text by clicking in the text and editing. But you cannot edit the target of the link. (The target of the link is set by the designer of the stylesheet (either by typing in a static target address or by deriving the target address from data contained in the XML document).) From Authentic View, you can go to the target of the link by pressing **Ctrl** and clicking the link text. (Remember: merely clicking the link will set you up for editing the link text.)

12.2.2 Tables in Authentic View

The three table types fall into two categories: SPS tables (static and dynamic) and CALS/HTML Tables.

SPS tables are of two types: static and dynamic. SPS tables are designed by the designer of the StyleVision Power Stylesheet to which your XML document is linked. You yourself cannot insert an SPS table into the XML document, but you can enter data into SPS table fields and add and delete the rows of dynamic SPS tables. The section on SPS tables section on SPS tables.

CALS/HTML tables are inserted by you, the user of Authentic View. Their purpose is to enable you to insert tables at any allowed location in the document hierarchy should you wish to do so. The editing features of CALS/HTML Tables and the CALS/HTML Table editing icons are described below.

12.2.2.1 SPS Tables

Two types of SPS tables are used in Authentic View: static tables and dynamic tables.

Static tables

Static tables are fixed in their structure and in the content-type of cells. You, as the user of Authentic View, can enter data into the table cells but you cannot change the structure of these tables (i.e. add rows or columns, etc) or change the content-type of a cell. You enter data either by typing in text, or by selecting from options presented in the form of check-box or radio button alternatives or as a list in a combo-box. After you enter data, you can edit it.

Nanonull, I	nc.	
Street:	119 Oakstreet, Suite 4876	Phone: +1 (321) 555 5155
City:	Vereno	Fax: +1 (321) 555 5155 - 9
State & Zip:	DC 29213	E-mail: office@nanonull.com

Note: The icons or commands for editing dynamic tables must not be used to edit static tables.

Dynamic tables

Dynamic tables have rows that represent a repeating data structure, i.e. each row has an identical data structure (not the case with static tables). Therefore, you can perform row operations: append row, insert row, move row up, move row down, and delete row. These commands are available under the **Authentic** menu and as icons in the toolbar (shown below).

To use these commands, place the cursor anywhere in the appropriate row, and then select the required command.

First Last		Title	Ext	EMail	Shares	Leave		
	Last					Total	Used	Left
Vегнон	Callaby	Office Manager	581	v.callaby@nanonull.com	1500	25	4	21
Frank	Further	Accounts Receivable	471	f.further@nanonull.com	0	22	2	20
Loby	Matise	Accounting Manager	963	1.matise@nanonull.com	add Shares	25	7	18
Employees: 3 (20% of Office, 9% of Company)				Shares: 1500 (13% of Office, 6% of Company)				

To move among cells in the table, use the Up, Down, Left, and Right arrow keys. To move forward from one cell to the next, use the **Tab** key. Pressing the **Tab** key in the last cell of the last row creates a new row.

12.2.2.2 CALS/HTML Tables

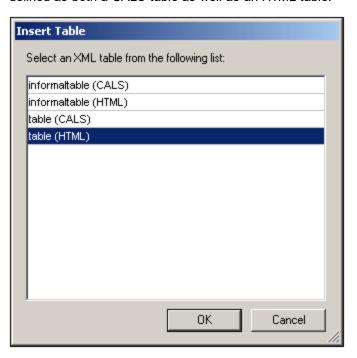

CALS/HTML tables can be inserted by you, the user of Authentic View, for certain XML data structures that have been specified to show a table format. There are three steps involved when working with CALS/HTML tables: inserting the table; formatting it; and entering data. The commands for working with CALS/HTML tables are available as icons in the toolbar (see <u>CALS/HTML table editing icons</u>).

Inserting tables

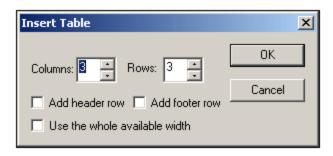

To insert a CALS/HTML table do the following:

1. Place your cursor where you wish to insert the table, and click the icon. (Note that where you can insert tables is determined by the schema.) The Insert Table dialog (screenshot below) appears. This

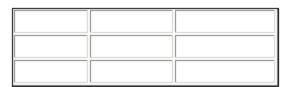

dialog lists all the XML element data-structures for which a table structure has been defined. For example, in the screenshot below, the informaltable element and table element have each been defined as both a CALS table as well as an HTML table.

- 2. Select the entry containing the element and table model you wish to insert, and click OK.
- 3. In the next dialog (*screenshot below*), select the number of columns and rows, and specify whether a header and/or footer is to be added to the table and whether the table is to extend over the entire available width. Click **OK** when done.

For the specifications given in the dialog box shown above, the following table is created.

By using the **Table** menu commands, you can add and delete columns, and create row and column joins and splits. But to start with, you must create the broad structure.

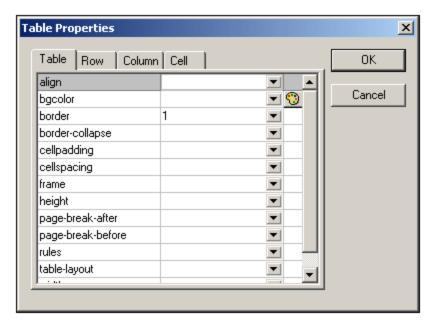

Formatting tables and entering data

The table formatting will already have been assigned in the document design. However, you might, under certain circumstances, be able to modify the table formatting. These circumstances are as follows:

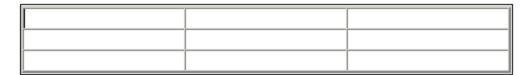

- The elements corresponding to the various table structure elements must have the relevant CALS or HTML table properties defined as attributes (in the underlying XML Schema). Only those attributes that are defined will be available for formatting. If, in the design, values have been set for these attributes, then you can override these values in Authentic View.
- In the design. no style attribute containing CSS styles must have been set. If a style attribute containing CSS styles has been specified for an element, the style attribute has precedence over any other formatting attribute set on that element. As a result, any formatting specified in Authentic View will be overridden.

To format a table, row, column, or cell, do the following:

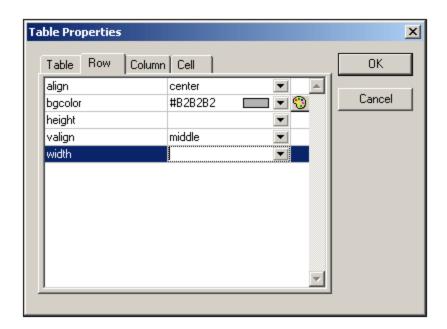

1. Place the cursor anywhere in the table and click the (Table Properties) icon. This opens the Table Properties dialog (see screenshot), where you specify formatting for the table, or for a row, column, or cell.

2. Set the cellspacing and cellpadding properties to "0". Your table will now look like this:

3. Place the cursor in the first row to format it, and click the (Table Properties) icon. Click the **Row** tab.

Since the first row will be the header row, set a background color to differentiate this row from the other rows. Note the Row properties that have been set in the figure above. Then enter the column header text. Your table will now look like this:

Name	Telephone	Email

Notice that the alignment is centered as specified.

4. Now, say you want to divide the "Telephone" column into the sub-columns "Office" and "Home", in which case you would need to split the horizontal width of the Telephone column into two columns. First, however, we will split the vertical extent of the header cell to make a sub-header row. Place the cursor in the "Telephone" cell, and click the (Split vertically) icon. Your table will look like this:

Name	Telephone	Email

5. Now place the cursor in the cell below the cell containing "Telephone", and click the horizontally) icon. Then type in the column headers "Office" and "Home". Your table will now look like this:

Name	Telephone		Email
	Office	Home	Eman

Now you will have to split the horizontal width of each cell in the "Telephone" column.

You can also add and delete columns and rows, and vertically align cell content, using the table-editing icons. The CALS/HTML table editing icons are described in the section titled, <u>CALS/HTML Table Editing Icons</u>

Moving among cells in the table

To move among cells in the CALS/HTML table, use the Up, Down, Right, and Left arrow keys.

Entering data in a cell

To enter data in a cell, place the cursor in the cell, and type in the data.

Formatting text

Text in a CALS/HTML table, as with other text in the XML document, must be formatted using XML elements or attributes. To add an element, highlight the text and double-click the required element in the Elements Entry Helper. To specify an attribute value, place the cursor within the text fragment and enter the required attribute value in the Attributes Entry Helper. After formatting the header text bold, your table will look like this.

Name	Telephone		Email
Ivaine	Office	Home	Ешап

The text above was formatted by highlighting the text, and double-clicking the element strong, for which a global template exists that specifies bold as the font-weight. The text formatting becomes immediately visible.

Note: For text formatting to be displayed in Authentic View, a global template with the required text formatting must have been created in StyleVision for the element in guestion.

12.2.2.3 CALS/HTML Table Editing Icons

The commands required to edit CALS/HTML tables are available as icons in the toolbar, and are listed below. Note that no corresponding menu commands exist for these icons. For a full description of when and how CALS/HTML Tables are to be used, see CALS/HTML Tables 852.

Insert table

The "Insert Table" command inserts a CALS/HTML table at the current cursor position.

Delete table

The "Delete table" command deletes the currently active table.

Append row

The "Append row" command appends a row to the end of the currently active table.

Append column

The "Append column" command appends a column to the end of the currently active table.

Insert row

The "Insert row" command inserts a row above the current cursor position in the currently active table.

Insert column

The "Insert column" command inserts a column to the left of the current cursor position in the currently active table.

Join cell left

The "Join cell left" command joins the current cell (current cursor position) with the cell to the left. The tags of both cells remain in the new cell, the column headers remain unchanged and are concatenated.

Join cell right

The "Join cell right" command joins the current cell (current cursor position) with the cell to the right. The contents of both cells are concatenated in the new cell.

Join cell below

The "Join cell below" command joins the current cell (current cursor position) with the cell below. The contents of both cells are concatenated in the new cell.

Join cell above

The "Join cell above" command joins the current cell (current cursor position) with the cell above. The contents of both cells are concatenated in the new cell.

Split cell horizontally

The "Split cell Horizontally" command creates a new cell to the right of the currently active cell. The size of both cells, is now the same as the original cell.

Split cell vertically

The "Split cell Vertically" command creates a new cell below the currently active cell.

Align top

This command aligns the cell contents to the top of the cell.

Center vertically

This command centers the cell contents.

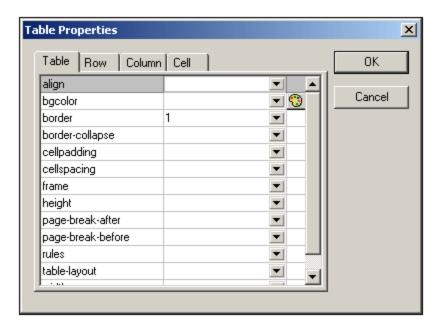

Align bottom

This command aligns the cell contents to the bottom of the cell.

Table properties

The "Table properties" command opens the Table Properties dialog box. This icon is only made active for HTML tables, it cannot be clicked for CALS tables.

12.2.3 Editing a DB

In Authentic View, you can edit database (DB) tables and save data back to a DB. This section contains a full description of interface features available to you when editing a DB table. The following general points need to be noted:

- The number of records in a DB table that are displayed in Authentic View may have been deliberately restricted by the designer of the StyleVision Power Stylesheet in order to make the design more compact. In such cases, only that limited number of records is initially loaded into Authentic View. Using the DB table row navigation icons (see Navigating a DB Table), you can load and display the other records in the DB table.
- You can guery the DB (89) to display certain records.
- You can add, modify, and delete DB records, and save your changes back to the DB. See Modifying a DB Table 873.

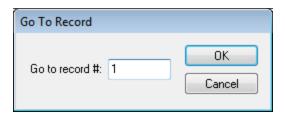

Note: In Authentic View, data coming from a SQLite database is not editable. When you attempt to save SQLite data in Authentic View, a message box will inform you of this known limitation.

12.2.3.1 Navigating a DB Table

The commands to navigate DB table rows are available as buttons in the Authentic View document. Typically, one navigation panel with either four or five buttons accompanies each DB table.

The arrow icons are, from left to right, Go to First Record in the DB Table; Go to Previous Record; Open the Go to Record dialog (see screenshot); Go to Next Record; and Go to Last Record.

To navigate a DB table, click the required button.

XML Databases

In the case of XML DBs, such as IBM DB2, one cell (or row) contains a single XML document, and therefore a single row is loaded into Authentic View at a time. To load an XML document that is in another row, use the **Authentic | Select New Row with XML Data for** menu command.

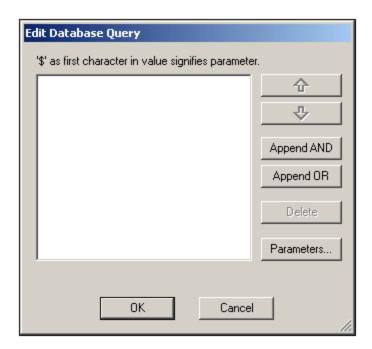

12.2.3.2 DB Queries

A DB query enables you to query the records of a table displayed in Authentic View. A query is made for an individual table, and only one query can be made for each table. You can make a query at any time while editing. If you have unsaved changes in your Authentic View document at the time you submit the query, you will be prompted about whether you wish to save **all** changes made in the document or discard **all** changes. Note that even changes made in other tables will be saved/discarded. After you submit the query, the table is reloaded using the query conditions.

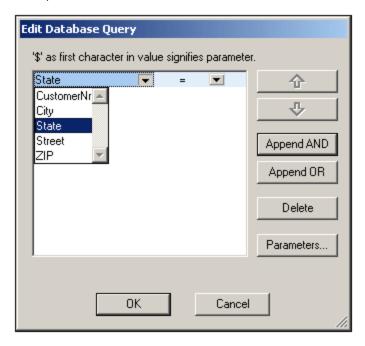

Note: If you get a message saying that too many tables are open, then you can reduce the number of tables that are open by using a query to filter out some tables.

To create and submit a query:

1. Click the Query button for the required table in order to open the Edit Database Query dialog (see screenshot). This button typically appears at the top of each DB table or below it. If a Query button is not present for any table, the designer of the StyleVision Power Stylesheet has not enabled the DB Query feature for that table.

2. Click the **Append AND** or **Append OR** button. This appends an empty criterion for the query (shown below).

- 3. Enter the expression for the criterion. An expression consists of: (i) a field name (available from the associated combo-box); (ii) an operator (available from the associated combo-box); and (iii) a value (to be entered directly). For details of how to construct expressions see the Expressions in criteria

 871
- 4. If you wish to add another criterion, click the **Append AND** or **Append OR** button according to which logical operator (AND or OR) you wish to use to join the two criteria. Then add the new criterion. For details about the logical operators, see the section <u>Re-ordering criteria in DB Queries</u> 872.

Expressions in criteria

Expressions in DB Query criteria consist of a field name, an operator, and a value. The **available field names** are the child elements of the selected top-level data table; the names of these fields are listed in a combo-box (see screenshot above). The **operators** you can use are listed below:

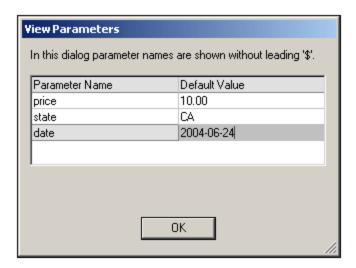

=	Equal to
<>	Not equal to
<	Less than
<=	Less than or equal to
>	Greater than
>=	Greater than or equal to
LIKE	Phonetically alike
NOT LIKE	Phonetically not alike
IS NULL	Is empty
NOT NULL	Is not empty

If IS NULL or NOT NULL is selected, the Value field is disabled. **Values** must be entered without quotes (or any other delimiter). Values must also have the same formatting as that of the corresponding DB field; otherwise the expression will evaluate to FALSE. For example, if a criterion for a field of the date datatype in an MS Access DB has an expression StartDate=25/05/2004, the expression will evaluate to FALSE because the date datatype in an MS Access DB has a format of YYYY-MM-DD.

Using parameters with DB Queries

You can enter the name of a **parameter** as the value of an expression when creating queries. Parameters are variables that can be used instead of literal values in queries. When you enter it in an expression, its value is used in the expression. Parameters that are available have been defined by the SPS designer in the SPS and can be viewed in the View Parameters dialog (see screenshot below). Parameters have been assigned a default value in the SPS, which can be overridden by passing a value to the parameter via the command line (if and when the output document is compiled via the command line).

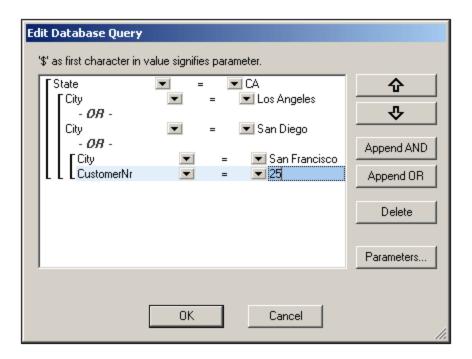

To view the parameters defined for the SPS, click the **Parameters** button in the Edit Database Query dialog. This opens the **View Parameters** dialog (see screenshot).

The View Parameters dialog contains **all** the parameters that have been defined for the stylesheet in the SPS and parameters must be edited in the stylesheet design.

Re-ordering criteria in DB Queries

The logical structure of the DB Query and the relationship between any two criteria or sets of criteria is indicated graphically. Each level of the logical structure is indicated by a square bracket. Two adjacent criteria or sets of criteria indicate the AND operator, whereas if two criteria are separated by the word OR then the OR operator is indicated. The criteria are also appropriately indented to provide a clear overview of the logical structure of the DB Query.

The DB Query shown in the screenshot above may be represented in text as:

State=CA AND (City=Los Angeles OR City=San Diego OR (City=San Francisco AND CustomerNr=25))

You can re-order the DB Query by moving a criterion or set of criteria up or down relative to the other criteria in the DB Query. To move a criterion or set of criteria, do the following:

- 1. Select the criterion by clicking on it, or select an entire level by clicking on the bracket that represents that level.
- 2. Click the Up or Down arrow button in the dialog.

The following points should be noted:

- If the adjacent criterion in the direction of movement is at the same level, the two criteria exchange places.
- A set of criteria (i.e. criterion within a bracket) changes position within the same level; it does not change levels.
- An individual criterion changes position within the same level. If the adjacent criterion is further
 outward/inward (i.e. not on the same level), then the selected criterion will move outward/inward, one
 level at a time.

To delete a criterion in a DB Query, select the criterion and click **Delete**.

Modifying a DB Query

To modify a DB Query:

- 1. Click the Query button . The Edit Database Query dialog box opens. You can now edit the expressions in any of the listed criteria, add new criteria, re-order criteria, or delete criteria in the DB Query.
- 2. Click **OK**. The data from the DB is automatically re-loaded into Authentic View so as to reflect the modifications to the DB Query.

12.2.3.3 Modifying a DB Table

Adding a record

To add a record to a DB table:

- 1. Place the cursor in the DB table row and click the licon (to append a row) or the icon (to insert a row). This creates a new record in the temporary XML file.
- 2. Click the **File | Save Authentic XML Data...** command to add the new record in the DB. In Authentic View a row for the new record is appended to the DB table display. The <code>AltovaRowStatus</code> for this record is set to <code>A</code> (for Added).

When you enter data for the new record it is entered in bold and is underlined. This enables you to differentiate added records from existing records—if existing records have not been formatted with these text formatting properties. Datatype errors are flagged by being displayed in red.

The new record is added to the DB when you click **File | Save Authentic XML Data...**. After a new record is saved to the DB, its <code>AltovaRowStatus</code> field is initialized (indicated with ---) and the record is displayed in Authentic View as a regular record.

Modifying a record

To modify a record, place the cursor at the required point in the DB table and edit the record as required. If the number of displayed records is limited, you may need to navigate to the required record (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see Navigating a DB Table (see <a href="Na

When you modify a record, entries in all fields of the record are underlined and the AltovaRowStatus of all primary instances of this record is set to U (for Updated). All secondary instances of this record have their AltovaRowStatus set to U (lowercase). Primary and secondary instances of a record are defined by the structure of the DB—and correspondingly of the XML Schema generated from it. For example, if an Address table is included in a Customer table, then the Address table can occur in the Design Document in two types of instantiations: as the Address table itself and within instantiations of the Customer table. Whichever of these two types is modified is the type that has been primarily modified. Other types—there may be more than one other type—are secondary types. Datatype errors are flagged by being displayed in red.

The modifications are saved to the DB by clicking **File | Save Authentic XML Data...**. After a modified record is saved to the DB, its <code>AltovaRowStatus</code> field is initialized (indicated with ---) and the record is displayed in Authentic View as a regular record.

Note the following points:

- If even a single field of a record is modified in Authentic View, the entire record is updated when the data is saved to the DB.
- The date value 0001-01-01 is defined as a NULL value for some DBs, and could result in an error message.

Deleting a record

To delete a record:

- 1. Place the cursor in the row representing the record to be deleted and click the icon. The record to be deleted is marked with a strikethrough. The AltovaRowStatus is set as follows: primary instances of the record are set to D; secondary instances to d; and records indirectly deleted to x. Indirectly deleted records are fields in the deleted record that are held in a separate table. For example, an Address table might be included in a Customer table. If a Customer record were to be deleted, then its corresponding Address record would be indirectly deleted. If an Address record in the Customer table were deleted, then the Address record in the Customer table would be primarily deleted, but the same record would be secondarily deleted in an independent Address table if this were instantiated.
- 2. Click File | Save Authentic XML Data to save the modifications to the DB.

Note: Saving data to the DB resets the Undo command, so you cannot undo actions that were carried out prior to the save.

12.2.4 Working with Dates

There are two ways in which dates can be edited in Authentic View:

- Dates are entered or modified using the <u>Date Picker</u> 875.
- Dates are entered or modified by typing in the value 876.

The method the Authentic View user will use is defined in the SPS. Both methods are described in the two sub-sections of this section.

Note on date formats

In the XML document, dates can be stored in one of several date datatypes. Each of these datatypes requires that the date be stored in a particular lexical format in order for the XML document to be valid. For example, the xs:date datatype requires a lexical format of YYYY-MM-DD. If the date in an xs:date node is entered in anything other than this format, then the XML document will be invalid.

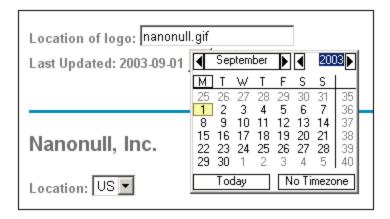

In order to ensure that the date is entered in the correct format, the SPS designer can include the graphical Date Picker in the design. This would ensure that the date selected in the Date Picker is entered in the correct lexical format. If there is no Date Picker, the Authentic View should take care to enter the date in the correct lexical format. Validating the XML document could provide useful tips about the required lexical format.

12.2.4.1 Date Picker

The Date Picker is a graphical calendar used to enter dates in a standard format into the XML document. Having a standard format is important for the processing of data in the document. The Date Picker icon appears near the date field it modifies (*see screenshot*).

To display the Date Picker (see screenshot), click the Date Picker icon.

To select a date, click on the desired date, month, or year. The date is entered in the XML document, and the date in the display is modified accordingly. You can also enter a time zone if this is required.

12.2.4.2 Text Entry

For date fields that do not have a Date Picker (see screenshot), you can edit the date directly by typing in the new value.

Invoice Number: 001

Invoice Amount: 40.00

2006-03-10

Customer: The ABC Company

Errors

The following types of error will be flagged:

• If you edit a date and change it such that it is out of the valid range for dates, the date turns red to alert you to the error. If you place the mouse cursor over the invalid date, an error message appears (see screenshot).

```
Invoice Number: 001
2006-03-32
Customer: ERROR: Invalid value for datatype date in element
Invoice Arthropics and the control of the control
```

• If you try to change the format of the date, the date turns red to alert you to the error. (In the screenshot below, slashes are used instead of hyphens).

Invoice Number: 001

2006/03/10

Customer: The ABC Company

Invoice Amount: 40.00

12.2.5 Defining Entities

About entities

You can define entities for use in Authentic View, whether your document is based on a DTD or an XML Schema. Once defined, these entities are displayed in the Entities Entry Helper and in the **Insert Entity** submenu of the context menu. When you double-click on an entity in the Entities Entry Helper, that entity is inserted at the cursor insertion point.

An entity is useful if you will be using a text string, XML fragment, or some other external resource in multiple locations in your document. You define the entity, which is basically a short name that stands in for the required data, in the Define Entities dialog. After defining an entity you can use it at multiple locations in your document. This helps you save time and greatly enhances maintenance.

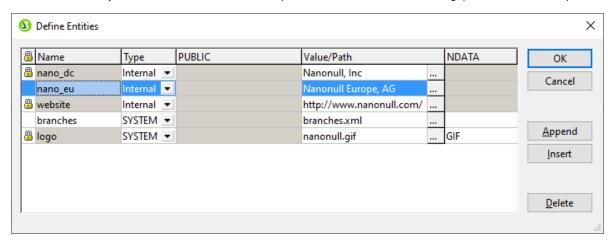

Types of entity

There are two broad types of entityyou can use in your document: a **parsed entity**, which is XML data (either a text string or a fragment of an XML document), or an **unparsed entity**, which is non-XML data such as a binary file (usually a graphic, sound, or multimedia object). Each entity has a name and a value. In the case of parsed entities the entity is a placeholder for the XML data. The value of the entity is either the XML data itself or a URI that points to a .xml file that contains the XML data. In the case of unparsed entities, the value of the entity is a URI that points to the non-XML data file.

Defining entities

To define an entity:

1. Click Authentic | Define XML Entities. This opens the Define Entities dialog (screenshot below).

- 2. Enter the name of your entity in the Name field. This is the name that will appear in the Entities Entry Helper.
- 3. Enter the type of entity from the drop-down list in the Type field. The following types are possible: An Internal entity is one for which the text to be used is stored in the XML document itself. Selecting PUBLIC or SYSTEM specifies that the resource is located outside the XML file, and will be located with the use of a public identifier or a system identifier, respectively. A system identifier is a URI that gives the location of the resource. A public identifier is a location-independent identifier, which enables some processors to identify the resource. If you specify both a public and system identifier, the public identifier resolves to the system identifier, and the system identifier is used.
- 4. If you have selected PUBLIC as the Type, enter the public identifier of your resource in the PUBLIC field. If you have selected Internal or SYSTEM as your Type, the PUBLIC field is disabled.
- 5. In the Value/Path field, you can enter any one of the following:
 - If the entity type is Internal, enter the text string you want as the value of your entity. Do not enter quotes to delimit the entry. Any quotes that you enter will be treated as part of the text string.
 - If the entity type is SYSTEM, enter the URI of the resource or select a resource on your local network by using the Browse button. If the resource contains parsed data, it must be an XML file (i.e., it must have a .xml extension). Alternatively, the resource can be a binary file, such as a GIF file.

- If the entity type is PUBLIC, you must additionally enter a system identifier in this field.
- 6. The NDATA entry tells the processor that this entity is not to be parsed but to be sent to the appropriate processor. The NDATA field must therefore contain some value to indicate that the entity is an unparsed entity.

Dialog features

You can do the following in the Define Entities dialog:

- Append entities
- Insert entities
- Delete entities
- Sort entities by the alphabetical value of any column by clicking the column header; clicking once sorts in ascending order, twice in descending order.
- Resize the dialog box and the width of columns.
- Locking. Once an entity is used in the XML document, it is locked and cannot be edited in the Define
 Entities dialog. Locked entities are indicated by a lock symbol in the first column. Locking an entity
 ensures that the XML document is valid with respect to entities. (The document would be invalid if an
 entity is referenced but not defined.)
- Duplicate entities are flagged.

Limitations of entities

- An entity contained within another entity is not resolved, either in the dialog, Authentic View, or XSLT output, and the ampersand character of such an entity is displayed in its escaped form, i.e. &
- External unparsed entities that are not image files are not resolved in Authentic View. If an image in the design is defined to read an external unparsed entity and has its URI set to be an entity name (for example: 'logo'), then this entity name can be defined in the Define Entities dialog (see screenshot above) as an external unparsed entity with a value that resolves to the URI of the image file (as has been done for the logo entity in the screenshot above).

12.2.6 XML Signatures

An SPS can be designed with an XML signature configured for Authentic View. When XML signatures are enabled in the SPS, the Authentic View user can digitally sign the Authentic XML file with the enabled signature. After the document has been signed, any modification to it will cause the verification of the signature to fail. Whenever a signed Authentic XML document is opened in the Authentic View of any Altova product, the verification process will be run on the document and the result of the verification will be displayed in a window.

Note: XML signatures can be used, and will be verified, in the Authentic View of Enterprise and Professional editions of the following Altova products: Authentic Desktop, Authentic Browser, XMLSpy, and StyleVision.

XML signature actions

The following Authentic View user actions for signatures are possible:

• Choosing the certificate/password: Signatures are authenticated with either a certificate or a password. The authentication object (certificate or password) is required when the signature is created and again

when it is verified. If an Authentic XML document has a signature-enabled SPS assigned to it, the SPS might specify a default certificate or password for the signature. Whether a default certificate or password has been specified or not, the signature can be configured to allow the Authentic View user to select an own certificate/password. The Authentic View user can do this at any time in the XML Signature dialog (screenshot below). Selecting an own certificate/password overrides the default certificate/password. The own certificate/password is stored in memory and is used for the current session. If, after an own certificate/password has been selected, the Authentic View user closes the file or the application, the SPS reverts to its default setting for the certificate/password.

- Signing the document: The Authentic XML document can be signed either automatically or manually. Automatic signing will have been specified in the signature configuration by the SPS designer and causes the Authentic XML document to be signed automatically when it is saved. If the automatic-signing option has not been activated, the document can be signed manually. This is done by clicking the XML Signature toolbar icon or the Authentic | XML Signature command, and, in the XML Signature dialog that then pops up (screenshot above), clicking the Sign Document button. Note that signing the document with an embedded signature would require the schema to allow the Signature element as the last child element of the root (document) element. Otherwise the document will be invalid against the schema. When signing the document, the authentication object and the placement of the signature are determined according to the signature configuration. You must ensure that you have access to the authentication information. For more information about this, consult your SPS designer.
- Verifying the Authentic XML document: If an SPS has XML Signatures enabled, the verification process will be run on the signature each time the Authentic View XML document is loaded. If the password or certificate key information is not saved with the SPS and signature, respectively, the Authentic View user will be prompted to enter the password or select a certificate for verification. Note that if an embedded signature is generated, it will be saved with the XML file when the XML file is saved. The generated signature must be explicitly removed (via the Remove Signature button of the XML Signature dialog; see screenshot above) if you do not wish to save it with the XML file. Similarly, if a detached signature is generated, it too must be explicitly removed if it is not required.

12.2.7 Images in Authentic View

Authentic View allows you to specify images that will be used in the final output document (HTML, RTF, PDF and Word 2007+). You should note that some image formats might not be supported in some formats or by some applications. For example, the SVG format is supported in PDF, but not in RTF and would require a browser add-on for it to be viewed in HTML. So, when selecting an image format, be sure to select a format that is supported in the output formats of your document. Most image formats are supported across all the output formats (see *list below*).

Authentic View is based on Internet Explorer, and is able to display most of the image formats that your version of Internet Explorer can display. The following commonly used image formats are supported:

- GIF
- JPG
- PNG
- BMP
- WMF (Microsoft Windows Metafile)
- EMF (Enhanced Metafile)
- SVG (for PDF output only)

Relative paths

Relative paths are resolved relative to the SPS file.

12.2.8 Keystrokes in Authentic View

The Enter key

In Authentic View the **Enter** key is used to append additional elements when it is in certain cursor locations. For example, if the chapter of a book may (according to the schema) contain several paragraphs, then pressing **Enter** inside the text of the paragraph causes a new paragraph to be appended immediately after the current paragraph. If a chapter can contain one title and several paragraphs, pressing **Enter** inside the chapter but outside any paragraph element (including within the title element) causes a new chapter to be appended after the current chapter (assuming that multiple chapters are allowed by the schema).

Note: The **Enter** key does **not** insert a new line. This is the case even when the cursor is inside a text node, such as paragraph.

Using the keyboard

The keyboard can be used in the standard way, for typing and navigating. Note the following special points:

- The Tab key moves the cursor forward, stopping before and after nodes, and highlighting node contents; it steps over static content.
- The add... and add Node hyperlinks are considered node contents and are highlighted when tabbed. They can be activated by pressing either the spacebar or the **Enter** key.

Authentic Scripting 881

13 Authentic Scripting

The **Authentic Scripting** feature provides more flexibility and interactivity to SPS designs. These designs can be created or edited in StyleVision Enterprise and Professional editions, and can be viewed in the Authentic View of the Enterprise and Professional editions of Altova products. A complete listing of support for this feature in Altova products is given in the table below.

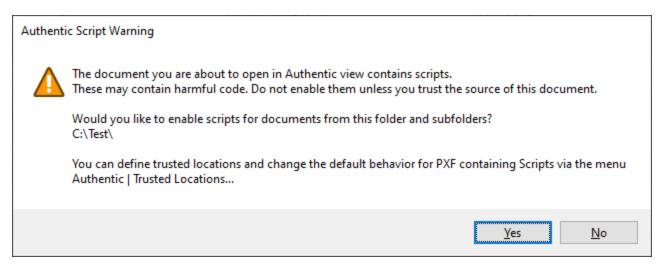

Altova Product	Authentic Scripts Creation	Authentic Scripts Enabled
StyleVision Enterprise	Yes	Yes
StyleVision Professional	Yes	Yes
StyleVision Basic *	No	No
XMLSpy Enterprise	No	Yes
XMLSpy Professional	No	Yes
Authentic Desktop Enterprise	No	Yes

- * No Authentic View
- ** Scripted designs displayed. No internal macro execution or event handling. External events fired.

Authentic Scripts behave in the same way in all Altova products, so no product-specific code or settings are required.

Authentic Script Warning Dialog

If a PXF file, or an XML file linked to an SPS, contains a script and the file is opened or switched to Authentic View (in Altova products other than StyleVision), then a warning dialog (*screenshot below*) pops up.

You can choose one of the following options:

• Click **Yes**. to add the folder containing the file to the Trusted Locations list for Authentic scripts. Subsequently, all files in the trusted folder will be opened in Authentic View without this warning dialog

- being displayed first. The Trusted Locations list can be accessed via the menu command **Authentic** | **Trusted Locations**, and modified.
- Click No to not add the folder containing the file to the Trusted Locations list. The file will be displayed
 in Authentic View with scripts disabled. The Authentic Script Warning dialog will appear each time this
 file is opened in Authentic View. To add the file's folder to the Trusted Locations list subsequently,
 open the Trusted locations dialog via the menu command Authentic | Trusted Locations, and add the
 folder or modify as required.

Note: When StyleVision is accessed via its COM interface (see <u>Programmers' Reference</u> to see how this can be done), **the security check is not done** and the **Authentic Script Warning dialog is not displayed**. The warning dialog described above appears in the Authentic View of Altova products other than StyleVision. You, as an SPS designer, should be aware of this.

How Authentic Scripting works

The designer of the SPS design can use Authentic Scripting in two ways to make Authentic documents interactive:

- By assigning scripts for user-defined actions (macros) to design elements, toolbar buttons, and context menu items.
- By adding to the design event handlers that react to Authentic View events.

All the scripting that is required for making Authentic documents interactive is done within the StyleVision GUI (Enterprise and Professional editions). Forms, macros and event handlers are created within the Scripting Editor interface of StyleVision and these scripts are saved with the SPS. Then, in the Design View of StyleVision, the saved scripts are assigned to design elements, toolbar buttons, and context menus. When an XML document based on the SPS is opened in an Altova product that supports Authentic Scripting (see table above), the document will have the additional flexibility and interactivity that has been created for it.

In this section

In this section we explain how Authentic Scripting works. The section is organized into the following subsections:

- <u>Scripting Editor</u> 833, which describes the interface in which a scripting project containing the scripts for the SPS are saved
- Macros ⁸³⁴, which shows how macros can be associated with design elements, Authentic toolbar buttons, and Authentic context menus
- Event Handlers (890), which shows how event handler scripts are created and used
- Scripting Options (891), which documents the options

Example files

Example SPS files with Authentic Scripting are in the Authentic\Scripting folder of the Examples project in the Project window of StyleVision.

Authentic Scripting Scripting Scripting Editor 883

13.1 Scripting Editor

StyleVision's Scripting Editor (*screenshot below*) enables you to add scripts for forms, macros, and event handlers to the SPS.

To start Scripting Editor select either the menu command **Authentic | Edit Authentic Scripts** or the **Authentic Scripts** or the

```
Scripting Editor - [ChangeAddressToEU]
                                                                                                               ×
∽ ○ | 从 🗙 🖺 🖺 | 🏥
                                      if ( confirm( "Are you sure to change address data to EU?\nAll existing a
s 🗖
                                2
                                    ■ {
□ ← Project (JScript, .NET 2.0)
                                3
                                          elemParent = StartChangingAddress( 'EU' );
 - ⊞ 🛅 .NET Assemblies
                                4
                               5
                                          // and now append all address elements in EU
   🧟 (GlobalDeclarations)
                                          elemChild = AuthenticView.CreateXMLNode( spyXMLDataElement );
                                6
   - 🧀 Forms
                                7
                                          elemChild.Name = 'Street';
 🕀 🗁 Events
                                8
                                          elemParent.AppendChild( elemChild );
  9
                              10
                                          elemChild = AuthenticView.CreateXMLNode( spyXMLDataElement );
 - ← Macros
                                          elemChild.Name = 'Citv':
     ChangeAddressToEU
                              11
                              12
                                          elemParent.AppendChild( elemChild );
     ChangeAddressToUS
                              13
   ---- S ClearAll
                                          elemChild = AuthenticView.CreateXMLNode( spyXMLDataElement );
                              15
                                          elemChild.Name = 'Country';
                                          elemParent.AppendChild( elemChild );
                              16
                              17
                              18
                                          elemChild = AuthenticView.CreateXMLNode( spyXMLDataElement );
                              19
                                          elemChild.Name = 'LocationDescription';
                              20
                                          elemParent.AppendChild( elemChild );
                              21
                              22
                               Source
                                                                                                  Ln 18, Col 46
                                                                         Save
                                                                                   Save & Close
                                                                                                  Revert Changes
```

The scripting language can be changed by doing the following:

- 1. Right-click the Project item, which is at the top of the Project Tree (see screenshot above).
- 2. In the context menu that pops up, select **Project Settings**.
- In the Project Settings dialog that appears, select either JScript or VBScript as the scripting language and specify the target .NET framework. The user can then access and use classes and extensions of the selected Microsoft .NET framework: for example, for creating forms.

The <u>Scripting Editor</u> and its features are described in detail in the <u>Programmers' Reference</u> (083).

Every SPS has a single scripting project, which is saved in the SPS. Clicking the **Save** button in Scripting Editor does not save the script to the SPS; it merely saves changes to the scripting project in memory. Changes in the scripting project are saved to the SPS only when the SPS is saved.

13.2 Macros

Macros are single programs that are executed when a user action occurs. Macros do not take a parameter, do not return a value, and do not call other macros directly. However, code that needs to be reused by multiple macros or event handlers can be put in a function in the Global Declarations area.

A macro that is not assigned to a specific user action will not be executed. Valid user actions may be an interaction with <u>a specific design element</u> 884, <u>a toolbar button click</u> 897, or the selection of <u>a user-defined</u> context menu item 886.

The EventContext property

An SPS design element can appear in multiple places. To determine in which context a macro is executed, the AuthenticView interface has a property called EventContext to hold the context. Via the EventContext property, a macro can query the XPath location where the macro was started, evaluate XPath expressions in the current node, and access variables defined in the scope of the location. For more details, see the section AuthenticView API.

Checking macro references

The designer might accidentally rename a macro or delete it from the script project, though it is still referenced in the design. To help prevent or correct such errors, the command **Authentic | Check Macro References** checks for invalid references. A dialog will pop up to help the user replace or delete the reference.

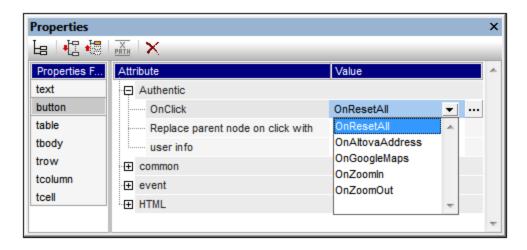

In this section

In this section we look at how macros can be associated with valid user actions:

- Macros on Design Elements 884
- Macros on Toolbar Buttons
- Macros on Context Menu Items
 Macros on Context Menu Items

13.2.1 Macros on Design Elements

Macros can be assigned to design elements via the Authentic Properties window. In the screenshot below the macro named <code>OnResetAll</code> has been selected from a list of available macros and assigned to a button's <code>OnClick</code> event:

Different design elements support different user actions for which macros can be assigned. The table below gives a complete list.

User action	Supported design element	Can cancel event
OnClick	Button, Image	No
OnBeforeLinkClick	Link	Yes
OnBeforeChange	Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox	Yes
OnAfterChange	Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox	No
OnSetFocus	Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox	No
OnKillFocus	Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox	No

Macros assigned to these user actions will be called only on primary user input. They are not called on an undo action, or when the action was from outside Authentic View (for example, from a COM API call). If a macro is to be used to cancel further event processing, the user needs to place a COM API call

AuthenticView.DoNotPerformStandardAction() in the macro where it is required. For example, it can be put in the macro BeforeChangeToEU (listing below) which has been assigned to a OnBeforeChange event for a radio button:

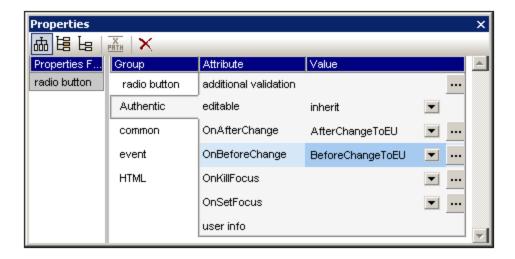

```
if ( !confirm( "Are you sure to change address data to EU?\nAll existing address data will be deleted!") )
```

AuthenticView.DoNotPerformStandardAction();

This will prevent the changing of the radio button value if the user canceled the confirm dialog. This example is in the file <code>OnChange.sps</code> is in the <code>Authentic\Scripting</code> folder of the <code>Examples</code> project in the Project window. You can open this file and see how the macro works.

Useful features

After a macro has been assigned in the Properties window (*screenshot below*), it can be quickly accessed for editing in the Scripting Editor by clicking the **Edit Macro** button to the right of its name (*see screenshot below*).

13.2.2 Macros on Context Menu Items

Macros can also be used to customize Authentic context menus. This enables the SPS designer to add custom menu items that each execute a macro.

There is no GUI to aid in this process. The SPS designer must add an event handler for the On_AuthenticContextMenuActivated event, and then manipulate the menu via the AuthenticView API. This can be seen in the example file OnContextMenu.sps which is in the Authentic\Scripting folder of the Examples project in the Project window. The screenshot below shows the On AuthenticContextMenuActivated event handler script in the Scripting Editor.

```
function On AuthenticContextMenuActivated(
                                             2
Project (JScript)
 objContextMenu = AuthenticView.ContextMenu;
   🧟 (GlobalDeclarations)
                                             5
                                                         // First, we do not want user to be able to remove any elements
  - Forms
                                             6
                                                         // and therefore we are searching for the "Remove" menu and delete it
 - Events
                                                         nItem = 0;
  □ ← AuthenticView Events
                                             8
                                                         while ( nItem < objContextMenu.CountItems() )</pre>
       On_AuthenticBeforeCopy
       On_AuthenticBeforeCut
                                                             if ( objContextMenu.GetItemText( nItem ).indexOf( 'Remove' ) >= 0 )
                                             10
       On_AuthenticBeforeDelete
                                             11
                                                                 objContextMenu.DeleteItem( nItem );
       On_AuthenticBeforeDrop
                                             12
                                                              else.
                                             13
                                                                 nItem++;
       On_AuthenticBeforePaste
                                             14
      4 On AuthenticBeforeSave
                                             15
      On AuthenticContextMenuActivated
                                                         // Now we also want to add our own menu entries depending on location
                                             16

On_AuthenticDragOver

                                                         sFieldName = GetCurrentEditFieldName();
      On AuthenticKeyboardEvent
                                                         if ( sFieldName != ''
                                             18
       On_AuthenticLoad
                                             19
       On_AuthenticMouseEvent
                                             20
                                                             objContextMenu.InsertItem( 0, 'Erase ' + sFieldName, 'OnEraseEditField' );
       On_AuthenticSelectionChanged
                                             21
                                                              objContextMenu.InsertItem( 1, 'Set ' + sFieldName + ' to default', 'OnSetEditFieldToDefault' );
      On_AuthenticToolbarButtonClicked
                                             22
       On AuthenticToolbarButtonExecuted
                                             23
       On_AuthenticUserAddedXMLNode
 - 🔁 ि Macros
    OnEraseEditField
```

The event handler for the <code>On_AuthenticContextMenuActivated</code> event creates two menu items and assigns macros to them. This example file also contains an event handler for the <code>On-AuthenticLoad</code> event, which disables entry helpers and markup buttons when AuthenticView is loaded.

```
function On AuthenticLoad(
 1
 2
     □ {
 3
           // We are disabling all entry helpers in order to prevent user from manipulating XML tree
 4
           AuthenticView.DisableElementEntryHelper();
 5
           AuthenticView.DisableAttributeEntryHelper();
 6
 7
           // We are also disabling the markup buttons for the same purpose
           AuthenticView.SetToolbarButtonState( 'AuthenticMarkupSmall', authenticToolbarButtonDisabled );
 8
           AuthenticView.SetToolbarButtonState( 'AuthenticMarkupLarge', authenticToolbarButtonDisabled );
 9
10
           AuthenticView.SetToolbarButtonState( 'AuthenticMarkupMixed', authenticToolbarButtonDisabled );
11
12
```

13.2.3 Custom Buttons

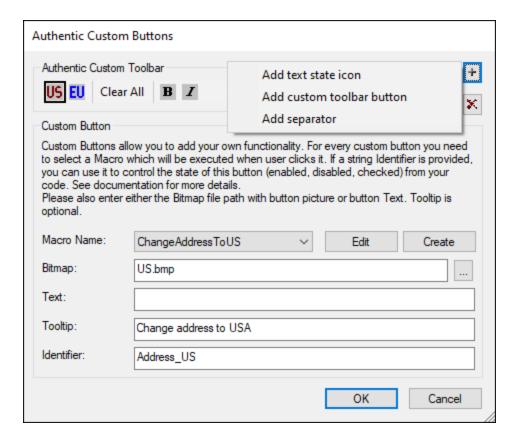

In the SPS design you can create a custom button to add to the Authentic toolbar and specify what macro it will trigger. To add a custom button to the Authentic toolbar, first select the command **Authentic | Custom Toolbar Buttons**, then click the **Add** button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select the type of custom button you want.

There are two types of custom buttons:

• Text State Icons are buttons that change the style of text (say, to bold or italic) and are associated with a particular element. Such elements would typically occur within elements of mixed-content type (that is, in elements that can contain both text and child elements). For example, a para element would be of mixed context because it can contain text, and, say, bold child elements, and italic child elements. In such a case, you can associate a Text State Icon (which is a bitmap image) to a child element of the mixed-content element. So, the bold element, for example, could be assigned a specific button image (its Text State Icon). A global template for the bold element is then defined to

provide the bold formatting of the bold element. In Authentic View, the Text State Icon for the bold element will appear as a toolbar button. When the Authentic View user selects text within a para element of the example cited above and clicks the bold element's toolbar button, the selected text will be enclosed with the bold element tags and the bold formatting of the bold element's global template will be applied to the text.

• Custom toolbar buttons are associated with a particular macro.

Custom buttons take the following parameters:

- The location of an image for the button (in the Bitmap field) or text for the button (in the Text field).
- In the *Element Name* field (available for Text State Icons), enter the name of the element with which you wish to associate the Text State Icon,
- In the *Macro Name* combo box (available for Custom Toolbar Buttons), select the macro from the dropdown list that you wish to associate with the Custom Toolbar Button. The macros listed here are those that have been saved with the SPS. When you click the **Create** button, the <u>Scripting Editor</u> of StyleVision opens in its own window, enabling you to quickly and easily create a macro. Clicking the **Edit** button opens the selected macro for editing in the <u>Scripting Editor</u>.
- You can optionally enter a tooltip (in the *Tooltip* field) as a guide for the Authentic View user when he or she mouses over the custom button.
- In the *Identifier* field enter a text string that will be used as the identifier of the custom button. This identifier can then be used in scripting code if the designer wishes to control the button state via the AuthenticView API.

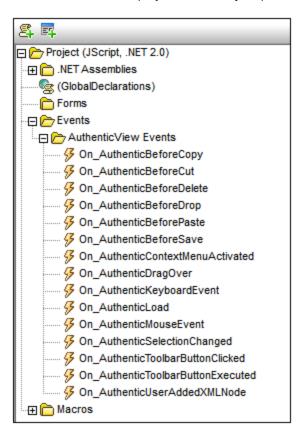

The screenshot above shows the the custom button **US** has the <code>ChangeAddressToUS</code> macro assigned to it. This custom button uses an image named <code>US.bmp</code>. Text for the button can be entered as a fallback. A tooltip has been entered and the custom button has the identifier <code>Address_US</code>. This example is from the file <code>ToolbarButtons.sps</code> is in the <code>Authentic\Scripting</code> folder of the <code>Examples</code> project in the Project window.

890 Authentic Scripting Event Handlers

13.3 Event Handlers

Authentic Scripting offers the possibility to define event handlers to react to general—not design-element-specific—user actions. They represent the same mechanism as adding COM listeners for AuthenticView events in external applications, but they can be more conveniently edited and stored within the design.

To add an event handler script, start the Scripting Editor (**Authentic | Edit Authentic Scripts**). The available event handlers are displayed in the Project pane under the AuthenticView Events node.

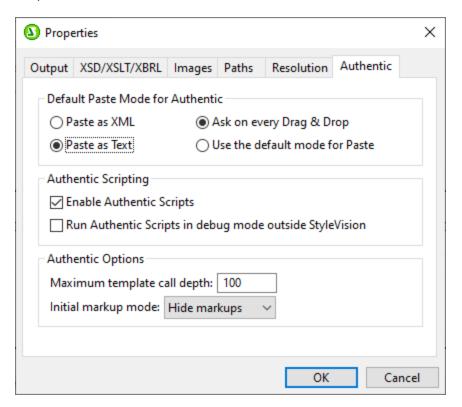

Double-click an event to access its script template in the scripting window. In the scripting window, edit the event handler script template as required. See the section <u>Macros on Context Menu Items</u> for an example of how event handlers can be used.

Authentic Scripting Scripting Scripting Options 891

13.4 Scripting Options

In order to enable Authentic scripting in an SPS, select the menu command **File | Properties**,. In the Properties dialog that appears (*screenshot below*), select the Authentic tab and check *Enable Authentic Scripts*.

Another scripting option you can specify is whether macros can be run in debug mode in the Authentic View of other Altova products. This feature is useful if you wish to test and debug a macro outside the StyleVision environment.

14 Automated Processing

The functionality of StyleVision together with the various XSLT and output files generated by StyleVision provide powerful automation possibilities. This section describes these capabilities.

StyleVision's file-generation functionality

After you have created an SPS design with StyleVision, you can generate several kinds of XSLT and output files from within the GUI, depending on which edition of StyleVision you are using (Enterprise, Professional, or Basic). The following files can be generated with the **File | Save Generated Files** command:

- XSLT files for HTML, Text, RTF, FO, and Word 2007+ output.
- FO files, which can be passed to an FO processor (such as Apache's FOP) for creation of PDF output.
- HTML, Text, RTF, PDF, and Word 2007+ output.

As you will notice from the list above, the files that can be saved with StyleVision are of two types:

- 1. The XSLT files generated by the SPS design, and
- 2. The final output files (such as HTML).

Note: Additionally, if database sources are used, XML Schema and XML data files can be generated based on the database structure and content.

The processes to generate the final HTML, Text, RTF, and Word 2007+ output files are all one-step processes in which the XML document is transformed by an XSLT stylesheet to the output format. The PDF-generation process, however, requires two steps:

- 1. Transformation of XML to FO by using an XSLT stylesheet. StyleVision can generate both the XSLT file and the FO file.
- 2. Processing of the FO file with an FO processor (such as Apache's FOP) to produce PDF output. If an FO processor is set up to be used with StyleVision, then StyleVision can generate PDF output by first transforming the XML to FO using the built-in Altova XSLT Engines, and then processing the FO to PDF with the FO processor you have set up.

FOP and XSLT

One FOP option enables you to specify an input XML file, an input XSLT file, and an output PDF file:

```
fop -xml input.xml -xslt input.xslt -pdf output.pdf
```

In this situation, FOP uses its built-in XSLT engine to carry out the first-step XML-to-FO transformation. It then passes the result FO document to FOP for the second-step FO-to-PDF processing.

You should be aware, however, that FOP's built-in engine might not support all the XSLT features that StyleVision and RaptorXML support. Consequently, there could errors if an XSLT stylesheet generated by StyleVision is specified as an input for an XML transformation using FOP's built-in XSLT engine. In such cases, use the XSLT engine of RaptorXML+XBRL) Server to transform to FO, and then supply the FO file to FOP for processing to PDF.

Automated Processing 893

StyleVision Server and RaptorXML: generating files from outside the GUI

Additionally to generating XSLT stylesheets and the required output formats via the StyleVision GUI (<u>File | Save Generated Files</u> command), you can generate output files using two other methods:

- 1. With StyleVision Server, which calls StyleVision's file generation functionality without opening the GUI, you can produce various kinds of output.
- 2. With RaptorXML [897], a standalone Altova application that contains Altova's XML(+XBRL) Validator, and XSLT and XQuery Engines. The XSLT Engines in RaptorXML can be used for transformations of XML to an output format by processing XML documents with XSLT stylesheets. The XSLT file will have to be created in advance so that it can be used by RaptorXML. (RaptorXML does not take an SPS as an input parameter.) The advantages of using RaptorXML are: (i) speed, as a result enabling fast transformations of large files; and (ii) in addition to a command line interface, RaptorXML provides interfaces for COM, Java, and .NET, and can therefore be easily called from within these environments. How to use RaptorXML for transformations is explained in the sub-section RaptorXML [897].
- 3. Multiple transformations can be carried out according to pre-set triggers (such as a daily time) using Altova StyleVision Server within an Altova FlowForce Server workflow. This is described in the section Automation with FlowForce Server.

14.1 Command Line Interface

StyleVision functionality can be called from the command line in two ways:

- By calling the <u>StyleVision executable</u> 894. This provides a access to StyleVision's XSLT-file-generation functionality. The XSLT files are generated from the SPS file.
- By using <u>StyleVision Server are solutions</u> to generate output files (HTML, etc). The output files are generated from a PXF file, which is a package of an SPS file with its related files (XML, XSD, image files, etc). The PXF file is generated from StyleVision.

How to use the command line

894

There are two ways you can use the command line:

- Commands can be entered singly on the command line and be executed immediately. For example, in a command prompt window, you can enter a command for StyleVision or <u>StyleVision Server</u> and press **Enter** to execute the command.
- A series of commands can be entered in a **batch file** for batch processing. For example:

```
@ECHO OFF
CLS
StyleVision TestEN.sps -outxslt=HTML-EN.xslt
StyleVision TestDE.sps -outxslt=HTML-DE.xslt
StyleVision TestES.sps -outxslt=HTML-ES.xslt
```

When the batch file is processed, the commands are executed and the files are generated.

StyleVision functionality in scheduled tasks

Using the Scheduled Tasks tool of Windows, StyleVision commands can be set to execute according to a predefined schedule. Either a single command or a batch file can be specified as the task to be executed. How to create such commands is described in <u>How to Automate Processing</u> 901.

14.1.1 StyleVision

The syntax for command line use is:

```
StyleVision [<SPS File>] [<options>]
```

where

styleVision calls StyleVision, which is located in the StyleVision application folder specifies the SPS file coptions>

calls StyleVision, which is located in the StyleVision application folder specifies the SPS file coptions listed below.

When a command is executed StyleVision runs silently (i.e. without the GUI being opened), generates the required output files, and closes. If an error or warning is encountered, the GUI is opened and the corresponding message is displayed in a message box.

Automated Processing Command Line Interface 895

Note: For the SPS to load correctly in StyleVision, the XSD and Working XML files that the SPS uses must be at the locations specified for them in the SPS.

Options

Options may be entered in any order.

• XSLT file output

```
-OutXSLT=<file> Writes XSLT-for-HTML to the specified file
-OutXSLRTF=<file> Writes XSLT-for-RTF to the specified file
-OutXSLText=<file> Writes XSLT-for-Text to the specified file
-OutXSLFO=<file> Writes XSLT-for-FO to the specified file
-OutXSLWord2007=<file> Writes XSLT-for-Word 2007+ to the specified file
```

DB data output

```
-OutDBXML=<file> Writes XML generated from DB to the specified file.

-OutDBSchema=<file> Writes XML Schema generated from DB to the specified file.
```

Examples

```
StyleVision "QuickStart.sps" -outxslt="QuickStartHTML.xslt"
StyleVision "C:\Test\QuickStart.sps" -outxslt="C:\Test\QuickStartHTML.xslt"
```

Points to note

Note the following points:

- Paths may be absolute or relative and should use backslashes.
- If the filename or the path to it contains a space, then the entire path should be enclosed in quotes. For example: "c:\My Files\MyXML.xml" or "c:\MyFiles\My XML.xml".
- Commands, paths, and folder and file names are case-insensitive.

14.1.2 StyleVision Server

StyleVision Server can be used via its command line interface (CLI) on Windows, Linux. and Mac OS systems to transform XML files into output HTML, PDF, RTF, and DOCX documents. The StyleVision Server CLI's generate command takes an XML file and a $\frac{PXF file}{622}$ as its two arguments, and the desired output formats as its parameters. The XSLT stylesheets for the transformation are obtained from the $\frac{PXF file}{622}$ submitted as input.

896 Automated Processing Command Line Interface

An advantage of using StyleVision Server's CLI over RaptorXML Server's CLI is that StyleVision Server can take PXF files as its input (RaptorXML takes an XSLT file as its input). StyleVision Server is however best used when used as part of an Altova FlowForce workflow. A FlowForce workflow can start transformation jobs according to preset triggers: Multiple files can be transformed automatically within a network when the FlowForce job is triggered. See the section Automation with FlowForce Server for more information.

For more information about the StyleVision Server CLI, see the StyleVision Server documentation.

Output files

StyleVision Server can generate one or more of the following files from the specified PXF file:

- HTML (.html) file/s using the XML and XSLT-for-HTML files specified in the PXF, or using alternative XML files
- Text file using the text document and XSLT-for-Text files specified in the PXF
- RTF file using the XML and XSLT-for-RTF files specified in the PXF, or using alternative XML files
- FO file using the XML and XSLT-for-FO files specified in the PXF, or using alternative XML files
- PDF file using XML and XSLT-for-FO specified in the PXF, or using alternative XML files
- Word 2007+ file using the XML and XSLT-for-Word 2007+ files specified in the PXF, or using alternative XML files

Automated Processing Using RaptorXML 897

14.2 Using RaptorXML

Altova RaptorXML is Altova's third-generation, hyper-fast XML and XBRL processor XBRL processing is available only in RaptorXML+XBRL Server. It has been built to be optimized for the latest standards and parallel computing environments. Designed to be highly cross-platform capable, the engine takes advantage of today's ubiquitous multi-core computers to deliver lightning fast processing of XML and XBRL data.

RaptorXML is available in two editions:

- RaptorXML Server edition, which can be accessed over a network and can transform multiple files at a time
- RaptorXML+XBRL Server edition, which can be accessed over a network, can transform multiple files at a time, and additionally supports XBRL validation.

For more information about RaptorXML, see the Altova website.

Typical use-cases

The functionality of RaptorXML that would be most relevant to StyleVision users is the XSLT transformation functionality. Typically, this functionality would be used as follows:

- 1. An XSLT stylesheet is generated from an SPS with the <u>File | Save Generated Files</u> command. Note that RaptorXML cannot be used to generate XSLT stylesheets from an SPS file.
- 2. The generated XSLT stylesheet is used to transform XML documents with RaptorXML. With RaptorXML you can generate HTML, Text, RTF, FO, and Word 2007+ output.

Advantages of RaptorXML

The advantages of using RaptorXML are as follows:

- RaptorXML provides very fast validation and XSLT transformation, and is therefore useful for dealing with large files.
- Easy use with command line, COM, Java, and .NET interfaces.
- Automation and scheduling (901) with the use of batch files and the scheduling processes such as the Scheduled Tasks process of Windows.

For a description of how RaptorXML can be used to automate the production of output documents (such as HTML) from XML source documents, see the section <u>How to Automate Processing</u> ⁽⁹⁰¹⁾.

For additional and more detailed information about using RaptorXML, including how to use RaptorXML's COM, Java, and .NET interfaces, see the RaptorXML user documentation.

14.2.1 PDF Output

To generate PDF output from an XML document requires two steps:

1. The XML document is transformed by an XSLT stylesheet. An XSLT transformation engine (such as that of RaptorXML) is used for this transformation. The result is an FO document.

898 Automated Processing Using RaptorXML

2. The FO document is processed by an FO processor (such as Apache's FOP) to generate the PDF output. StyleVision can be set up to pass the FO result of an XSLT transformation to an FO processor. In StyleVision, the result of PDF generation is displayed in the PDF Preview window or can be saved as a file (via the File | Save Generated Files command).

RaptorXML and PDF

Since RaptorXML does not provide parameters to direct the FO output of an XSLT transformation to an FO processor, you will be left with an FO document as the result of the XSLT transformation step (the first step of the two-step PDF-generation process).

The FO document must now be passed to an FO processor for second-step processing from FO to PDF. The instructions for carrying out this step vary according to the processor being used. For example, in the case of the Apache FOP processor, the following simple command can be used to identify the input FO document and specify the name and location of the output PDF document:

```
fop -fo input.fo -pdf output.pdf
```

FOP offers other parameters, and these are listed in the FOP user reference.

FOP and XSLT

One FOP option enables you to specify an input XML file, an input XSLT file, and an output PDF file:

```
fop -xml input.xml -xslt input.xslt -pdf output.pdf
```

In this situation, FOP uses its built-in XSLT engine to carry out the first-step XML-to-FO transformation. It then passes the result FO document to FOP for the second-step FO-to-PDF processing.

You should be aware, however, that FOP's built-in engine might not support all the XSLT features that StyleVision and RaptorXML support. Consequently, there could errors if an XSLT stylesheet generated by StyleVision is specified as an input for an XML transformation using FOP's built-in XSLT engine. In such cases, use the XSLT engine of RaptorXML+XBRL) Server to transform to FO, and then supply the FO file to FOP for processing to PDF.

Batch processing to PDF

A quick and simple way to generate PDF by using RaptorXML for the first-step XSLT transformation and FOP for the second-step FO processing would be to write a batch file that combines the two commands. For example:

```
raptorxmlserver xslt --input=Test.xml --output=Test.fo Test.xslt
fop -fo Test.fo -pdf Test.pdf
```

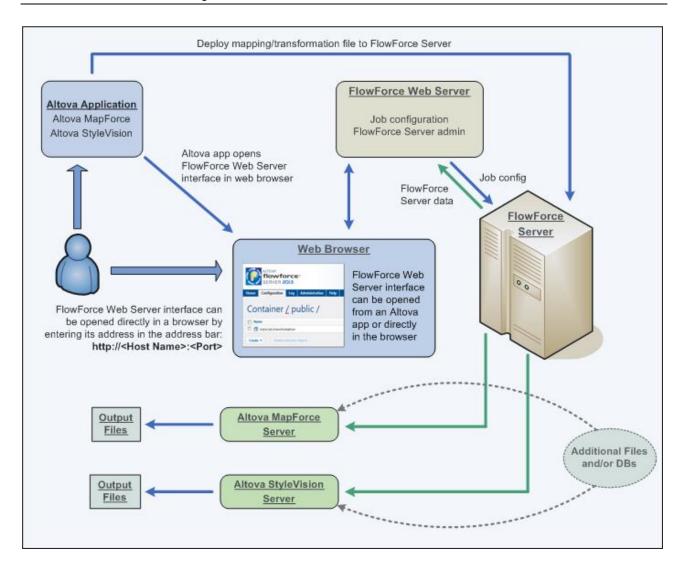

The first command calls RaptorXML and produces <code>test.fo</code> as output. The second command passes <code>test.fo</code> to the FOP processor, which generates the PDF file <code>test.pdf</code>. For more information about batch processing and how batch files can be used to automate processes, see the following section: How to Automate Processing

14.3 Automation with FlowForce Server

Transformations can be automated over a network by using Altova's FlowForce Server, which is available on Windows, Linux, and Mac OS systems. The process works as follows:

- 1. From StyleVision, a PXF file 222 is deployed to FlowForce Server 3659 (with the File | Deploy to FlowForce command) as a .transformation file. The .transformation file contains all the files and information required to carry out transformations as designed in the SPS. (In the diagram below, the deployment is represented by the connector line running along the top.)
- 2. After the .transformation file has been deployed to FlowForce Server, jobs can be created in FlowForce that use the .transformation file to generate transformations according to triggers specified in the job definition. (A trigger could be, for example, a specific time every day.) Flow Force jobs are created in the FlowForce Web Server interface (shown in the center of the diagram below), which can be accessed from StyleVision or via an HTTP address. For information about creating FlowForce jobs, see the FlowForce documentation.
- 3. At execution time, FlowForce Server passes the transformation instructions and relevant files to StyleVision Server, which then carries out the transformation (*see diagram below*).

The role of StyleVision Server in the FlowForce workflow is shown in the diagram below. (The role of MapForce Server in the workflow is also displayed since FlowForce jobs can be created that send Altova MapForce mappings to the Altova MapForce Server for execution.)

Note that additionally to being invoked by a FlowForce job, StyleVision Server can also be invoked via its command line. Usage is described in the <u>StyleVision Server documentation</u>.

14.4 How to Automate Processing

A batch file (a text file saved with the file extension .bat) contains a sequence of commands that will be executed from the command line. When the batch file is executed, each command in the batch file will be executed in turn, starting with the first and progressing through the sequence. A batch file is therefore useful in the following situations:

- Executing a series of commands automatically (see below).
- Creating a chain of processing commands, where a command requires input produced by a preceding command. (For example, an XML file produced as output of one transformation is used as the input of a subsequent transformation.)
- Scheduling a sequence of tasks to be executed at a particular time.

Batch file with sequence of commands

A sequence of commands to be executed is entered as follows:

```
@ECHO OFF
CLS
StyleVision TestEN.sps -outxslt=HTML-EN.xslt
StyleVision TestDE.sps -outxslt=HTML-DE.xslt
StyleVision TestES.sps -outxslt=HTML-ES.xslt
```

When the batch file is processed, the commands are executed and the files generated. The batch file above uses StyleVision to generate three XSLT files from an SPS file.

Batch processing to PDF

A quick and simple way to generate PDF by using RaptorXML for the first-step XSLT transformation and FOP for the second-step FO processing would be to write a batch file that combines the two commands. (For the sake of simplicity, assume that the calls to RaptorXML and FOP correctly locate the executables.)

```
raptorxml xslt --input=Test.xml --output=Test.fo Test.xslt
fop -fo test.fo -pdf test.pdf
```

The first command calls RaptorXML and produces test.fo as output. The second command passes test.fo to the FOP processor, which generates the PDF file test.pdf. For more information about RaptorXML, see Using RaptorXML 897.

15 StyleVision in Visual Studio

StyleVision can be integrated into the Microsoft Visual Studio 2012/2013/2015/2017/2019/2022. This unifies the best of both worlds, integrating advanced SPS file creation capabilities with the advanced development environment of Visual Studio.

In this section, we describe:

- The <u>broad installation process</u> and the integration of the StyleVision plugin in Visual Studio.
- <u>Differences</u> between the Visual Studio version and the standalone version.

15.1 Installing the StyleVision Plugin

To install the StyleVision Plug-in for Visual Studio, take the steps below:

- 1. Install Microsoft Visual Studio 2012/2013/2015/2017/2019/2022. Note that from Visual Studio 2022 onwards, Visual Studio is being made available only as a 64-bit application.
- 2. Install StyleVision (Enterprise or Professional Edition). If you have installed Visual Studio 2022+, then you must install the 64-bit version of StyleVision.
- 3. Download and run the StyleVision integration package for Microsoft Visual Studio. This package is available on the StyleVision (Enterprise and Professional Editions) download page at www.altova.com.

Once the integration package has been installed, you will be able to use StyleVision in the Visual Studio environment.

Important

You must use the integration package corresponding to your StyleVision version (current version is 2025). The integration package is not edition-specific and can therefore be used for both Enterprise and Professional editions.

15.2 Differences with StyleVision Standalone

This section lists the ways in which the Visual Studio versions differ from the standalone versions of StyleVision.

Entry helpers (Tool windows in Visual Studio)

The entry helpers of StyleVision are available as Tool windows in Visual Studio. The following points about them should be noted. (For a description of entry helpers and the StyleVision GUI, see the section, <u>User Interface</u> 34.)

- You can drag entry helper windows to any position in the development environment.
- Right-clicking an entry helper tab allows you to further customize your interface. Entry helper configuration options are: dockable, hide, floating, and auto-hide.

StyleVision commands as Visual Studio commands

Some StyleVision commands are present as Visual Studio commands in the Visual Studio GUI. These are:

- Undo, Redo: These Visual Studio commands affect all actions in the Visual Studio development environment.
- Projects: StyleVision projects are handled as Visual Studio projects.
- **Customize Toolbars, Customize Commands:** The Toolbars and Commands tabs in the Customize dialog (**Tools | Customize**) contain both visual Studio commands as well as StyleVision commands.
- **Views:** In the **View** menu, the command **StyleVision** contains options to toggle on entry helper windows and other sidebars, and to switch between the editing views, and toggle certain editing guides on and off.
- StyleVision Help: This StyleVision menu appears as a submenu in Visual Studio's Help menu.

Note: In Visual Studio 2019 and later, StyleVision functionality can be accessed in the **Extensions** menu of Visual Studio. In earlier versions of Visual Studio, StyleVision features are available in top-level menus of Visual Studio.

StyleVision in Eclipse 905

16 StyleVision in Eclipse

Eclipse is an open source framework that integrates different types of applications delivered in the form of plugins. The StyleVision Integration Package for Eclipse enables you to integrate and access the functionality of StyleVision in the Eclipse Platform for Windows. Supported Eclipse versions are: 2024-12 (4.34), 2024-09 (4.33), 2024-06 (4.32), 2024-03 (4.31).

In this section, we describe the following:

- How to install the Integration Package for Eclipse and integrate StyleVision in Eclipse

16.1 Install the Integration Package for Eclipse

Prerequisites

- Eclipse 2024-12 (4.34), 2024-09 (4.33), 2024-06 (4.32), 2024-03 (4.31) (http://www.eclipse.org), 64-bit.
- A Java Runtime Environment (JRE) or Java Development Kit (JDK) for the 64-bit platform.
- StyleVision Enterprise or Professional Edition 64-bit.

Note: All the prerequisites listed above must have the 64-bit platform. Integration with older Eclipse 32-bit platforms is no longer supported, although it may still work.

After the prerequisites listed above are in place, you can install the StyleVision Integration Package (64-bit) to integrate StyleVision in Eclipse. The integration can be carried out either during the installation of the Integration Package or manually from Eclipse after the Integration Package has been installed. The StyleVision Integration Package is available for download at https://www.altova.com/components/download.

Note: Eclipse must be closed while you install or uninstall the StyleVision Integration Package.

Integrate StyleVision during installation of the Integration Package

You can integrate StyleVision in Eclipse during the installation of the StyleVision Integration Package. Do this as follows:

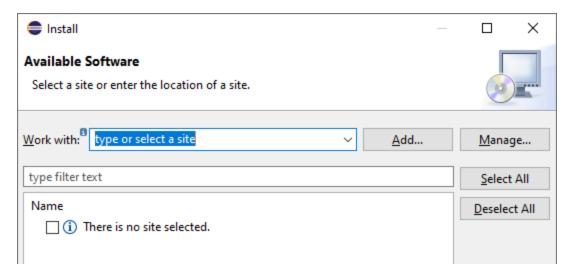

- 1. Run the StyleVision Integration Package to start the installation wizard.
- 2. Go through the initial steps of the installation with eth wizard.
- 3. In the Integration step, select *Let this wizard integrate Altova StyleVision plug-in into Eclipse*, and browse for the directory where the Eclipse executable (eclipse.exe) is located.
- 4. Click **Next** and complete the installation.

The StyleVision perspective and menus will be available in Eclipse the next time you start it.

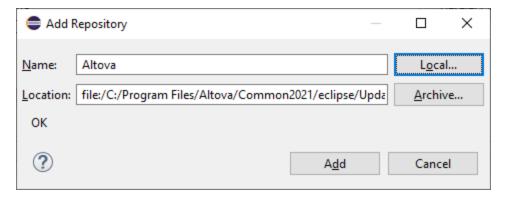

Integrate StyleVision in Eclipse manually

After you have installed the StyleVision Integration Package, you can manually integrate StyleVision in Eclipse as follows:

- 1. In Eclipse, select the menu command Help | Install New Software.
- 2. In the Install dialog box, click **Add**.

3. In the Add Repository dialog box, click Local. Browse for the folder C:\Program
Files\Altova\Common2025\eclipse\UpdateSite, and select it. Provide a name for the site (such as "Altova").

- 4. Repeat the steps 2-3 above, this time selecting the folder C:\Program Files\Altova\<% APPNAMESHORT%>\eclipse\UpdateSite and providing a name such as "Altova StyleVision".
- 5. On the Install dialog box, select *Only Local Sites*. Next, select the "Altova category" folder and click **Next**.
- 6. Review the items to be installed and click **Next** to proceed.
- 7. To accept the license agreement, select the respective check box.
- 8. Click **Finish** to complete the installation.

Note: If there are problems with the plug-in (missing icons, for example), start Eclipse from the command line with the -clean flag.

16.2 StyleVision Perspective in Eclipse

In Eclipse, a perspective is a GUI view that is configured with the functionality of a specific application. After StyleVision has been integrated in Eclipse, a new perspective, named StyleVision, becomes available in Eclipse. This perspective is a GUI that resembles the StyleVision GUI and includes a number of its components.

When a file having a filetype associated with StyleVision is opened (.sps, for example), this file can be edited in the StyleVision perspective. Similarly, a file of another filetype can be opened in another perspective in Eclipse. Additionally, for any active file, you can switch the perspective (see below), thus allowing you to edit or process that file in another environment.

There are therefore two main advantage of perspectives:

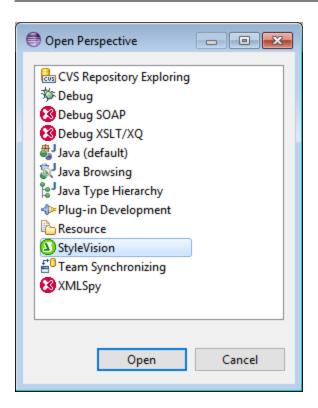

- 1. Being able to quickly change the working environment of the active file, and
- 2. Being able to switch between files without having to open a new development environment (the associated environment is available in a perspective)

Working with the StyleVision perspective involves the following key procedures, which are described further below:

- Switching to the StyleVision perspective.
- Setting preferences for the StyleVision perspective.
- Customizing the StyleVision perspective.

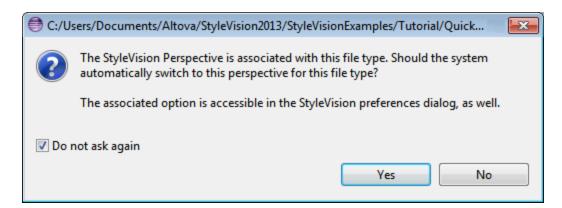

Switch to the StyleVision perspective

In Eclipse, select the command **Window | Perspective | Open Perspective | Other**. In the dialog that appears (*screenshot below*), select **StyleVision**, and click **Open**.

The empty window or the active document will now have the StyleVision perspective. This is how the user switches the perspective via the menu. To access a perspective faster from another perspective, you can set the required perspective to be listed in the **Open Perspective** submenu, above the **Other** item. This setting is in the customization dialog (see *further below*).

Perspectives can also be switched when a file is opened or made active. The perspective of the application associated with a file's filetype will be automatically opened when that file is opened for the first time. Before the perspective is switched, a dialog appears asking whether you wish to have the default perspective automatically associated with this filetype (*screenshot below*).

Check the *Do Not Ask Again* option if you wish to associate the perspective with the filetype without having to be prompted each time a file of this filetype is opened and then click **OK**.

Preferences for the StyleVision perspective

To access the Preferences of a perspective, select the command **Window | Preferences**. In the list of perspectives in the left pane, select StyleVision, then select the required preferences. Finish by clicking **OK**.

The preferences of a perspective include:

- To automatically switch to the StyleVision perspective when a file of an associated filetype is opened (see above)
- Options for including or excluding individual StyleVision toolbars
- Access to StyleVision options.

Customize the StyleVision perspective

The customization options enable you to determine what shortcuts and commands are included in the perspective. To access the Customize Perspective dialog of a perspective, make that perspective the active perspective and select the command **Window | Perspective | Customize Perspective**.

- In the *Toolbar Visibility* and *Menu Visibility* tabs, you can specify which toolbars and menus are to be displayed.
- In the *Action Set Availability* tab, you can add action sets to their parent menus and to the toolbar. If you wish to enable an action group, check its check box.
- In the Shortcuts tab of the Customize Perspective dialog, you can set shortcuts for submenus. Select the required submenu in the Submenus combo box. Then select a shortcut category, and check the shortcuts you wish to include for the perspective.

Click Apply and Close to complete the customization and for the changes to take effect.

16.3 Other Stylevision Entry Points in Eclipse

In addition to the StyleVision perspective, two other entry points in Eclipse can be used to access StyleVision functionality:

- StyleVision menu
- StyleVision toolbar

StyleVision menu in Eclipse

The **StyleVision** menu of Eclipse contains StyleVision commands that provide key StyleVision functionality. These commands occur in various menus of the standalone version of StyleVision.

StyleVision toolbar in Eclipse

The StyleVision toolbar in Eclipse (screenshot below) contains two buttons.

These buttons do the following:

- Open the StyleVision Help
- Provide access to StyleVision commands (as an alternative to accessing them from the **StyleVision** menu, see above).

Note: Toolbar commands are not supported. If you have set up a toolbar command in StyleVision that runs a command or script, then this toolbar command will not be available in the plug-in.

17 Menu Commands and Reference

This section contains a complete description of StyleVision toolbars, Design View symbols, and menu commands. It is divided into the following broad parts:

- An explanation of <u>symbols used in Design View</u>⁹¹³
- A description of the <u>Edit XPath Expression dialog</u> 917.
- A description of all the <u>toolbars with their icons</u> (934), as well as a description of how to customize the views of the toolbars.
- All menu commands.

While the User Reference section contains a description of individual commands, the mechanisms behind various StyleVision features are explained in detail in the relevant sections. The mechanisms have been organized into the following groups::

- SPS File Content 130
- SPS File Structure
 SPS File Structure
- SPS File Advanced Features 370
- SPS File Presentation 450
- SPS File and Databases 628
- SPS File and XBRL 735

For command line usage, see Command Line Interface: StyleVisionBatch 894.

- See also
- User Interface 34
- Quick Start Tutorial 66

17.1 **Design View Symbols**

An SPS design will typically contain several types of component. Each component is represented in the design by a specific symbol. These symbols are listed below and are organized into the following groups:

- Nodes in the XML document 913
- XML document content
- Data-entry devices
- Predefined formats
- XPath objects
- URI objects

Each of these component types can:

- be moved using drag and drop;
- be cut, copied, pasted, and deleted using (i) the commands in the Edit menu 979, or (ii) the standard Windows shortcuts for these commands;
- · have formatting applied to it;
- have a context menu pop up when right-clicked.

Nodes in the XML document

Element and attribute nodes in the XML document are represented in the SPS design document by tags. Each node has a start tag and end tag. Double-clicking either the start or end tag collapses that node. When a node is collapsed all its contents are hidden. Double-clicking a collapsed node expands it and displays its content.

The following types of node are represented:

Document node

The document node (indicated with \$XML) represents the XML document as a whole. It is indicated with a green \$XML tag when the schema source is associated with an XML document, and with \$DB when the schema source is associated with a DB. The document node in the screenshot at left is expanded and contains the OrgChart element, which is collapsed. The document node in the screenshot at right is collapsed; its contents are hidden.

Element node

An **element node** is inserted together with all its ancestor elements if the ancestors are not present at the insertion point. In the screenshot above, the Name element node is shown expanded (left) and collapsed (right).

Attribute node

An **attribute node** is inserted together with all its ancestor elements if the ancestors are not present at the insertion point. Attribute names contain the prefix =. In the screenshot above, the href attribute node is shown expanded (*left*) and collapsed (*right*).

Nodes are included in the design as node templates. For information on the various kind of templates that can be included in the design, see the section, <u>Templates and Design Fragments</u> 344.

XML document content

XML document content is represented by two placeholders:

- (contents)
- (rest-of-contents)

The contents placeholder represents the contents of a single node. All the text content of the node is output. If the node is an attribute node or a text-only element node, the value of the node is output. If the node is an element node that contains mixed content or element-only content, the text content of all descendants is output. In XSLT terms, the contents placeholder is equivalent to the xsl:apply-templates element with its select attribute set for that node..

Note: When applied to an element node, the contents placeholder does not output the values of attributes of that element. To output attribute nodes, you must explicitly include the attribute in the template (main or global).

The rest-of-contents placeholder applies templates to the rest of the child elements of the current node. The template that is applied for each child element in this case will be either a global template (if one is defined for that element) or the default template for elements (which simply outputs text of text-only elements, and applies templates to child elements). For example, consider an element book, which contains the child elements: title, author, isbn, and pubdate. If the definition of book specifies that only the title child element be output, then none of the other child elements (author, isbn, and pubdate) will be output when this definition is processed. If, however, the definition of book includes the rest-of-contents placeholder after the definition for the title element, then for each of the other child elements (author, isbn, and pubdate), a global template (if one exists for that element), or the default template for elements, will be applied.

Data-entry devices

In order to aid the Authentic View user edit the XML document correctly and enter valid data, data-entry devices can be used in the design. You can assign any of the following data-entry devices to a node:

Input fields (single line or multi-line)

Combo boxes

Check boxes

Radio buttons

These tags can be collapsed and expanded by double-clicking an expanded and the collapsed tag, respectively. For a detailed description of how each of these data-entry devices is used, see <u>Data-Entry Devices</u>.

Predefined formats

Predefined formats are shown in mauve tags, which can be expanded/collapsed by double-clicking.

The screenshot above shows tags for the predefined format p (para), expanded (at left) and collapsed (at right). To apply a predefined format, highlight the items around which the predefined format is to appear (by clicking a component and/or marking text), and insert the predefined format (45).

XPath objects

StyleVision features two mechanisms that use XPath expressions:

Conditional templates

Condition tags are blue. The start tag contains cells. The leftmost cell contains a question mark. Other cells each contain either (i) a number, starting with one, for each when condition; and/or (ii) an asterisk for the optional otherwise condition. A condition branch can be selected by clicking it. The number of the selected condition branch is highlighted in the start tag, and the template for that branch is displayed (within the start and end tags of the condition). The XPath expression for the selected condition branch is also highlighted in the Design Tree. Note that tags for conditions cannot be expanded/collapsed.

• Auto-Calculations

Auto-Calculations are represented in Design View by the = (AutoCalc) object (see screenshot above). The XPath expression for the selected Auto-Calculation is highlighted in the Design Tree. The dialog to edit the Auto-Calculation is accessed via the Properties sidebar (371).

URI objects

There are three URI-based objects that can be inserted in a design:

Images

If an image is inserted in the SPS design and can be accessed by StyleVision, it becomes visible in Design View. If it cannot be accessed, its place in the SPS is marked by an image placeholder.

• Bookmarks (Anchors)

Bookmark tags are yellow and indicated with the character A (*screenshots above*). A bookmark is created with the command **Insert | Insert Bookmark**, and can be empty or contain content. Content must always be inserted after the anchor is created. Anchor tags can be expanded (*screenshot above left*) or collapsed (*screenshot above right*).

Links

Link tags are yellow and indicated with the character A (*screenshots above*). A link is created with the command **Insert | Hyperlink**. The object around which the link is created can be inserted in the design before or after the link is created. If an item is to be created as a link, it should be selected and the link created around it. Link tags can be expanded (*screenshot above left*) or collapsed (*screenshot above right*).

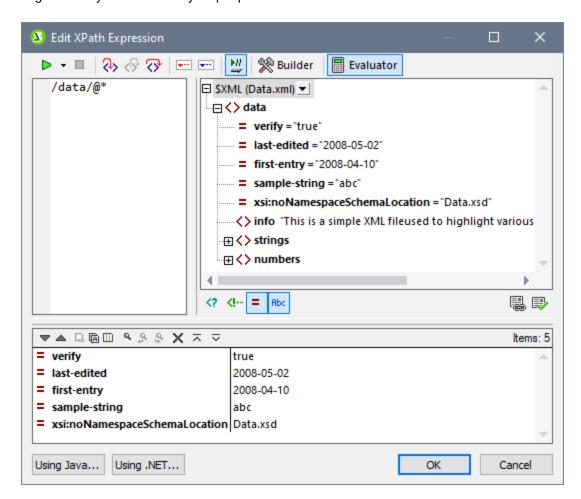

17.2 Edit XPath Expression Dialog

The **Edit XPath Expression** dialog (*screenshot below*) is used to build, test, and edit XPath expressions. It is accessible at all places in Design View where an XPath expression may be entered, such as when entering expressions for <u>conditional processing</u> or the values of <u>Styles</u> and <u>Properties</u>.

The dialog automatically supports the **XPath version** that corresponds to the <u>XSLT version</u> of the SPS (XPath 1.0 for XSLT 1.0; XPath 2.0 for XSLT 2.0; and XPath 3.1 for XSLT 3.0). To switch the XPath version, switch the <u>XSLT version</u> of the SPS 110.

Dialog layout

The Edit XPath Expression dialog contains the following panes (see screenshot below): (i) an Expression pane (top left); (ii) a Sources pane (top right); (iii) a Results pane (bottom). In Builder Mode, the Results pane is augmented by additional entry helper panes.

Evaluation Mode and Debug Mode

The Edit XPath Expression dialog has two modes:

- <u>Evaluation Mode ⁽⁹¹⁸⁾</u>, in which an XPath expression is evaluated with respect to the assigned Working XML File/s. The expression is entered in the **Expression pane**, and the result is displayed in the **Results pane**. You can click nodes in the result to go to that node in the Sources pane of the dialog.
- <u>Debug Mode</u> [92], in which you can debug an XPath expression as it applies to the assigned Working XML File/s. You can set breakpoints and tracepoints, and go step-by-step through the evaluation. At each step you can see the content of variables, as well as set custom Watch expressions to check additional aspects of the evaluation.

To switch between the two modes, select the appropriate command in the **Start Evaluation/Debugging** dropdown menu that is located in the left-hand corner of the window's toolbar *(see screenshot below)*.

How to use the two modes is described in the sub-sections of this section.

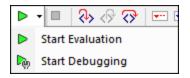

XPath/XQuery Expression Builder

In both modes, the Expression Builder 22 can be used to help you construct syntactically correct expressions.

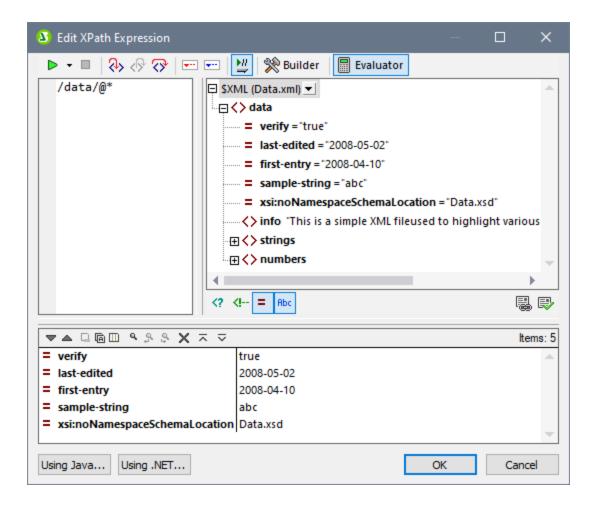

Switch Expression Builder on/off with the Builder Mode button of the main toolbar

17.2.1 Evaluator

Select Evaluation Mode by selecting **Start Evaluation** in the **Start Evaluation/Debugging** dropdown menu (see screenshot below).

In Evaluation Mode, click the **Evaluator** button (see screenshot below). The evaluator has the following panes (see screenshot below): (i) an Expression pane (top left); (ii) a Sources pane (top right); (iii) a Results pane (bottom).

The XPath expression and its evaluation

The XPath expression is entered in the Expression pane. The results of the evaluation are displayed in the Results pane (see screenshot above).

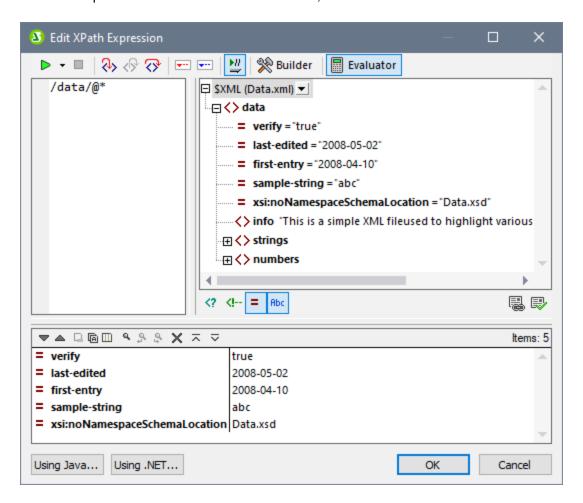

Note the following points:

- In order for an expression to be evaluated against an XML file, that file must be assigned as the Working XML file of one of the sources of the SPS 107.
- Results can be displayed even as you type the expression (select the Evaluate on Typing icon in the
 toolbar), or they can be displayed when you click the toolbar button Start Evaluation/Debugging (F5)
 (located at top left of the toolbar).
- To enter the XPath locator expression of a node in a source tree, double-click that node in the Sources pane.
- In the Sources pane, you can switch on/off the display of: (i) processing instructions, (ii) comments, (iii) attributes, and (iv) elements. Do this via the buttons below the Sources pane.
- The context node is that of the design component within which the expression is being created. To set another node as the context node of the expression: (i) select the node in the Sources pane, and (ii) click **Set Evaluation Context** (located below the Sources pane). To save this context node for the expression, click the toggle command button **Remember Evaluation Context** (located below the

- Sources pane). Note, however, that the actual context node for the expression will be the context node of the current design component, and this is the context node that will be used at runtime.
- You can use the functions of the Java and .NET programming languages in the XPath expression. The buttons **Using Java** and **Using .NET** at the bottom of the dialog display info boxes with explanations about how to use Java and .NET extension functions in XPath expressions. For more information about this, see the Extension Functions 1974 section of this **documentation**.
- To create the expression over multiple lines (for easier readability), use the Return key.
- To increase/decrease the size of text in the expression field, click in the expression field, then press **Ctrl** and turn the scroll wheel. **Note that this also applies in the Results pane.**
- Instead of manually entering the locator path expression of a node, you can do the following: (i) Place the cursor at the point in the XPath expression where you want to enter the locator path; (ii) In the Sources tree, double-click the node you want to target. This enters the locator path of the selected node in the expression. The locator path will be an absolute path starting at the root node of the document.

Results pane

The Results pane is shown in the screenshot below, at bottom. Note that it has its own toolbar.

The Results pane has the following functionality:

• The result list consists of two columns: (i) a node name or a datatype; (ii) the content of the node.

- If the XPath expression returns nodes (such as elements or attributes), you can select whether the entire contents of the nodes should be shown as the value of the node. To do this, switch on the toggle Show Complete Result.
- When the result contains a node (including a text node)—as opposed to expression-generated literals
 —clicking that node in the Results pane highlights the corresponding node in the XML document in the
 Sources tree.
- You can copy both columns of a result sub-line, or only the value column. To copy all columns, right-click a sub-line and toggle on **Copying Includes All Columns**. (Alternatively you can toggle the command on/off via its icon in the toolbar of the Results pane.) Then right-click the sub-line you want to copy and select either **Copy Subline** (for that subline) or **Copy All** (for all sublines).

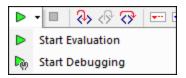

Toolbar of the Results pane

The toolbar of the Results pane contains icons that provide navigation, search, and copy functionality. These icons, starting from the left, are described in the table below. The corresponding commands are also available in the context menu of result list items.

Icon	What it does
Next, Previous	Selects, respectively, the next and previous item in the result list
Copy the selected text line to the clipboard	Copies the value column of the selected result item to the clipboard. To copy all columns, toggle on the Copying includes all columns command (see below)
Copy all messages to the clipboard	Copies the value column of all result items to the clipboard, including empty values. Each item is copied as a separate line
Copying includes all columns	Switches between copying (i) all columns, or (ii) only the value column. The column separator is a single space
Find	Opens a <i>Find</i> dialog to search for any string, including special characters, in the result list
Find previous	Finds the previous occurrence of the term that was last entered in the Find dialog
Find next	Finds the next occurrence of the term that was last entered in the Find dialog
Expand with children	Expands the selected item and all its descendants
Collapse with children	Collapses the selected item and all its descendants
Clear	Clears the result list

17.2.2 Debugger

The Debugger enables you to debug an XPath expression in the context of a Working XML File to access the Debugger, selecting **Start Debugging** in the **Start Evaluation/Debugging** dropdown menu (*screenshot below*). This sets the mode to Debug Mode. You can then switch between the Builder (for help with building the expression) and Evaluator (for debugging the expression). To start debugging, click **Start Evaluation/Debugging (F5)**

After you have entered an expression, you can start debugging by clicking **Start Evaluation/Debugging (F5)** (after making sure that you are in Debug Mode).

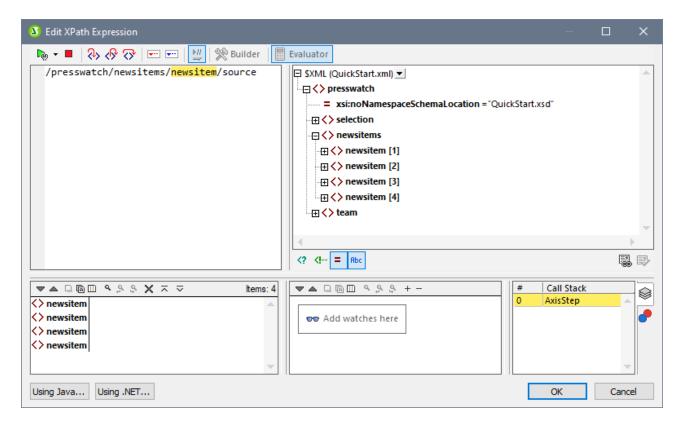

■ Buttons for setting up Debug Mode

D ₀	Start Evaluation/Debugging (F5)	Starts the debugger
%	Switch to Builder	Switches to Expression Builder mode, which provides context- sensitive entry helpers to help construct expressions
	Evaluation on typing	Switches on the evaluation of expressions while the expression is being typed

Layout of Debug Mode

In Debug Mode, two additional panes are added to the Results pane (see screenshot below):

- the Call Stack and Debug Points pane, each of which has a separate tab in the pane
- the Variables and Watch Expressions pane; both watch expressions and variables are shown in the same pane.

Debugger Mode offers the following features:

- Enables you to step into the XPath evaluation process, one step at a time to see how the XPath expression is being evaluated. Use the **Step Into (F11)** toolbar button for this. At each evaluation step, the part of the expression being currently evaluated is highlighted in yellow (see screenshot above), while the result of evaluating that step is shown in the Results pane. For example, in the screenshot above, all the section descendant elements of the book element have been selected.
- Set breakpoints where you want to pause the evaluation and check results at these points. You can step through the evaluation by pausing only at breakpoints. Use the **Start Debugging (F5)** toolbar button for this. This is quicker than pausing at every step with **Step Into (F11)**.
- Set tracepoints to see a report of results at the steps marked as tracepoints. The evaluation will not pause (except at breakpoints), but the tracepoint results will be displayed in a list in the Results pane.
- Watch expressions can be used to check information (such as document data or aspects of the evaluation). This is especially useful at breakpoints.
- Variables that are in scope, including their values, are displayed in the Variables and Watch Expressions pane.
- Processor calls of an evaluation step are shown in the Call Stack tab of the Call Stack and Debug Points pane.
- If breakpoints and tracepoints have been set, then these are displayed in the Debug Points tab of the Call Stack and Debug Points pane.

For more information about these features, see their descriptions below.

Running the Debugger

The broad steps for debugging an XPath expression are as follows:

- 1. Enter the XPath expression in the expression pane.
- 2. Set any breakpoints or tracepoints you want. A breakpoint is a point at which the evaluation is paused. A tracepoint is a point in the evaluation that is recorded; tracepoints thus provide a traceable path of evaluation results.
- 3. If you click **Start Debugger**, evaluation is carried out in one step to the end unless a breakpoint has been marked in the expression. Click **Start Debugger** repeatedly to progress through each breakpoint to the end of the evaluation.
- 4. Use the Step Into/Out/Over functionality to go step-by-step through the evaluation.

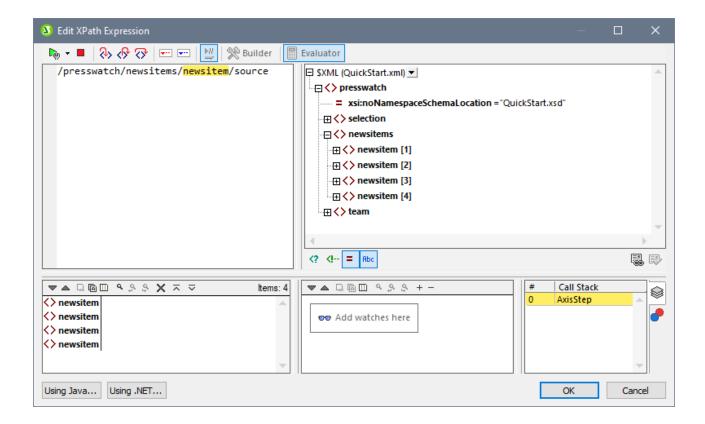

Buttons for debugging

₽	Start Debugger (F5)	Starts the debugger. Evaluation goes directly to the end, stopping only for breakpoints
	Stop Debugger (Shift+F5)	Exits the evaluation and stops the debugger
₹>	Step Into (F11)	Proceeds through the evaluation, one step at a time.
⟨ ⟩	Step Out (Shift+F11)	Steps out of the current evaluation step, and goes to the parent step
₹	Step Over (Ctrl+F11)	Steps over descendant steps
▼…	Insert/Remove Breakpoint (F9)	Inserts/removes a breakpoint at the expression step where you place the cursor
▼…	Insert/Remove Tracepoint (Shift+F9)	Inserts/removes a tracepoint at the expression step where you place the cursor

Stepping in, out, and over evaluation steps

The *Step Into* functionality enables you to go step-by-step through the evaluation. Each click of this command takes you through the next step of the evaluation; the current step is shown by the highlighting in the expression (see screenshot below). The *Step Out* functionality takes you to a step on a higher level as the current step, whereas the *Step Over* functionality steps over lower-level steps and takes you to the next step on the same level. You can try out the *Stepping* functionality by using the expression shown in the screenshot below and clicking the three *Step* buttons to see how they work.

The screenshot below shows the evaluation when processing has been paused on reaching the locator step newsitem. At this step, the result shows the four newsitem node.

Breakpoints

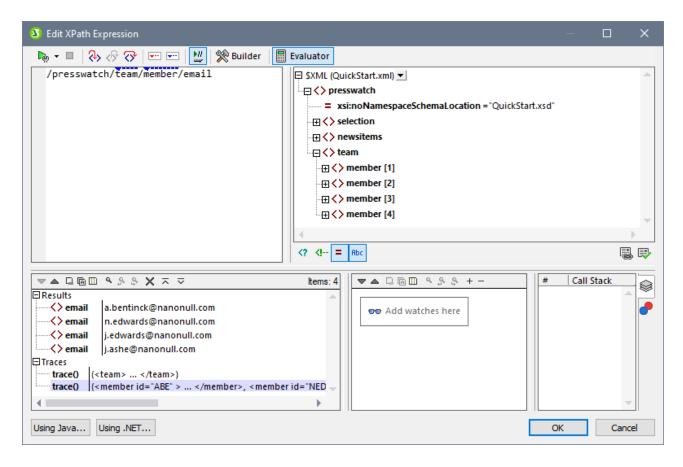

Breakpoints are points where you want the Debugger to stop after it has been started with **Start Debugger**. They are useful if you wish to analyze a specific part of the expression. When the Debugger stops at the breakpoint, you can check the result and could then use the **Step Into** functionality to display the results of the next steps of the evaluation. To set a breakpoint, place the cursor in the expression at the point where you want the breakpoint, and click the **Insert/Remove Breakpoint (F9)** toolbar button. The breakpoint will be marked with a dashed red overline. To remove a breakpoint, select it and click **Insert/Remove Breakpoint (F9)**.

Also see Debug Points 928 below.

Tracepoints

Tracepoints are points at which the results are recorded. These results are displayed in the *Traces* tree of the *Result* tab (see screenshot below). This enables you to see all the evaluation results of particular parts of the expression. For example, in the screenshot below, tracepoints have been set on the team node and member node. The results at these tracepoints are shown in the *Traces* tree.

To set a tracepoint, place the cursor at the point where you want the tracepoint, and click the toolbar button **Insert/Remove Tracepoint (Shift+F9)**. The tracepoint will be marked with a dashed blue overline (see screenshot below). To remove a tracepoint, select it and click **Insert/Remove Tracepoint (F9)**.

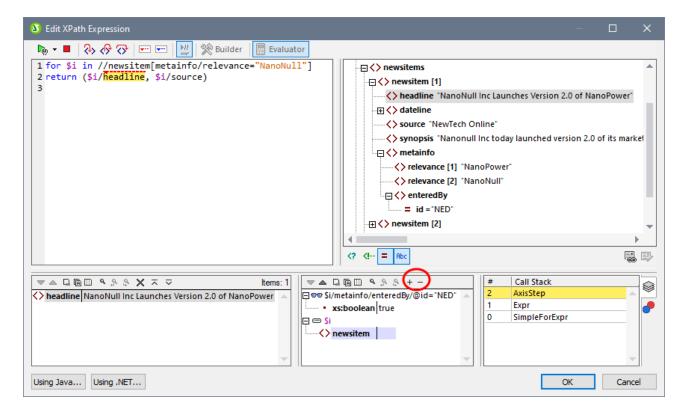

Note: If both a breakpoint and a tracepoint are set on a part of the expression, then the overline is composed of alternating red and blue dashes.

Also see Debug Points 928 below.

Variables, Watch Expressions, and Call Stack

Variables and watch expressions are displayed in the Variables and Watch Expressions pane (bottom center pane in the screenshot below).

Variables

Variables that have been declared in the expression and that are in scope in the current evaluation step will be displayed together with their respective current values. For example, in the screenshot above, processing has been paused at the breakpoint on headline. The \$i variable is in scope at this evaluation step. So \$i is displayed with its current value, which in the screenshot above is the first newsitem node.

Watch expressions

Watch expressions are expressions that you can enter, either before evaluation starts or during a pause in evaluation. They can be used for the following purposes:

- To test specific conditions. For example in the screenshot above, the watch expression \$i/metainfo/enteredBy/@id="NED" is used to test whether this news item has been entered by the team member with the id of NED. The result true in the case of the first news item tells us that this condition has been met.
- To find data within a certain context. For example, within the context of a company element, we could enter a watch expression @id to look up that company's customer code in the target XML document.
- To generate additional data. For example, a suitable string can be generated to indicate the total number of news items..

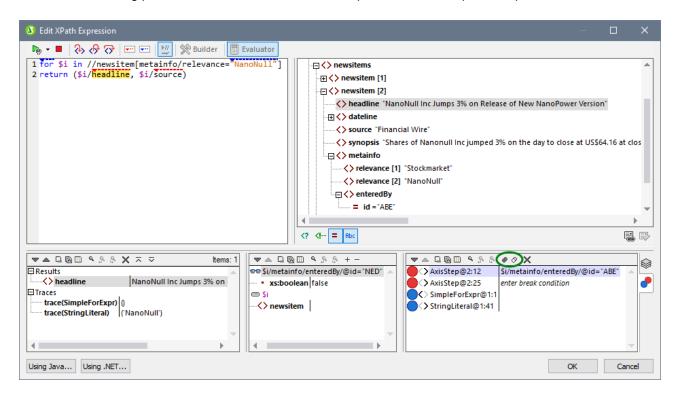

To enter a watch expression, click **Add Watch Entry** in the pane's toolbar (encircled in red in the screenshot above), then enter the expression and click **Enter** when done. To remove a watch expression, select it and click **Remove Selected Watch Entry** in the toolbar. If, during debugging, the expression cannot be correctly evaluated for some reason (for example, if one of its variables is out of scope), then the watch expression turns red.

Call stack

The *Call Stack* tab of the Call Stack and Debug Points pane (bottom right pane in the screenshot above) displays the processor calls up to that point in the debugging. The current processor call is highlighted in yellow. Note that only the calls that directly led to the current evaluation step are displayed.

Debug Points

The Debug Points tab of the Call Stack and Debug Points pane (bottom right pane in the screenshot below) shows the breakpoints (with solid red circles) and tracepoints (solid blue circles) that you have set on the expression. Each debug point is listed with its line and character number. For example, AxisStep@2:12 means that there is a debug point on line 2, character 12 of the expression in the Expression pane.

Note the following features:

- For breakpoints, you can enter a **break condition** by (i) double-clicking *Enter break condition* in the Debug Points pane, (ii) entering the expression for the condition, and (iii) pressing **Enter**. That breakpoint will be enabled only when the condition evaluates to true. For example, in the screenshot above, the break condition \$i/metainfo/enteredBy/@id="ABE" will enable the breakpoint on the headline of each news item that was entered by the team member with the id ABE. The screenshot shows the evaluation paused at this breakpoint. (Notice also that the Watch expression at this breakpoint returns false.)
- You can enable/disable all debug points by clicking their respective toolbar buttons: Enable All
 Debug Points and Disable All Debug Points (buttons encircled in green in the screenshot above).
 When a debug point is disabled, it is deactivated for all evaluations till it is enabled again.
- You can enable/disable individual breakpoints in their respective context menus.

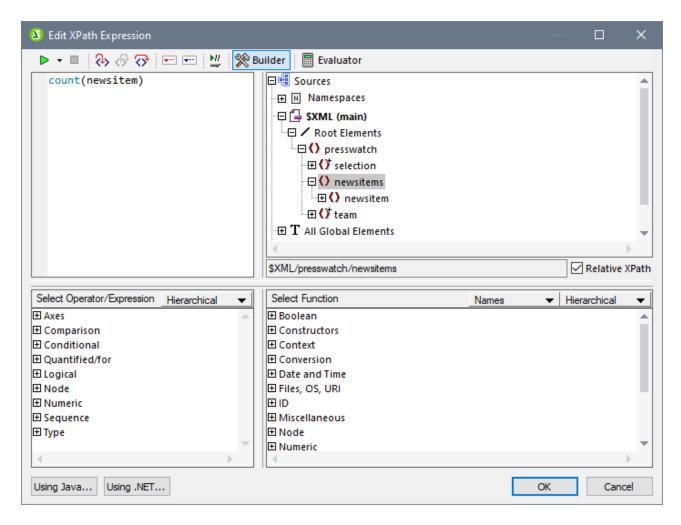

Toolbar commands in panes

The panes of the Edit XPath Expression dialog in Debug Mode (see screenshot above) contain buttons that provide navigation, search, and copy functionality. These buttons, starting from the left, are described in the table below. The corresponding commands are also available in the context menu of listed items.

Icon	What it does
Next, Previous	Selects, respectively, the next and previous item in the result list
Copy the selected text line to the clipboard	Copies the value column of the selected result item to the clipboard. To copy all columns, toggle on the Copying includes all columns command (see below)
Copy all messages to the clipboard	Copies the value column of all result items to the clipboard, including empty values. Each item is copied as a separate line
Copying includes all columns	Switches between copying (i) all columns, or (ii) only the value column. The column separator is a single space
Find	Opens a <i>Find</i> dialog to search for any string, including special characters, in the result list
Find previous	Finds the previous occurrence of the term that was last entered in the Find dialog
Find next	Finds the next occurrence of the term that was last entered in the Find dialog
Expand with children	Expands the selected item and all its descendants
Collapse with children	Collapses the selected item and all its descendants
Clear	Clears the result list

17.2.3 Expression Builder

When the **Builder** button in the Edit XPath Expression dialog is clicked (*see screenshot below*), entry helper panes to help you build an XPath expression become visible. Double-click an entry in any of these entry helpers to enter it at the current cursor point in the XPath expression.

There are three entry helper panes:

- A schema tree for entering element and attribute nodes in the XPath expression. If the Relative XPath
 check box is checked, then the location path to the selected node is entered relative to the context
 node (the node in the design within which the XPath expression is being built). The context node is
 shown below the schema tree pane. An absolute XPath expression starts at the document root, and is
 used for the selected node if the Relative XPath check box is unchecked.
- An entry helper pane for operators and expressions. These include: (i) axes (ancestor::, parent::, etc), (ii) operators (for example eq and div), and (iii) expressions (for # in # return #, etc). The items of the pane can be either listed alphabetically or grouped by functional category. Select the option you want by choosing *Hierarchical* or *Flat* from the dropdown menu in the title bar of the pane.
- An entry helper with the functions of the active XPath version either listed alphabetically or grouped by functional category. Select the option you want by choosing *Hierarchical* or *Flat* from the dropdown menu in the title bar of the pane. The *Names/Types* option enables you to choose whether the arguments of functions are displayed as names or datatypes.

Features of the Builder

• To view a text description of an item in either pane, hover over the item.

- Each function is listed with its signature (that is, with its arguments, the datatypes of the arguments, and the datatype of the function's output).
- Signatures are listed using either the names or datatypes of the function's arguments and output. Select *Names* or *Types* from the dropdown menu in the title bar of the pane.
- Double-clicking an item in any of the panes(operator, expression, or function), inserts that item at the cursor location in the expression. Functions are inserted with their arguments indicated by placeholders (the # symbol).
- If (i) text is selected in the XPath expression's edit field, and (ii) an expression or function that contains a placeholder is double-clicked to insert it, then the text that was selected is inserted instead of the placeholder.

After you have entered a function in the expression, hovering over the function name displays the function's signature and a text description of the function. If different signatures exist for a function having the same name, these are indicated with an overload factor at the bottom of the display. If you place the cursor within the parentheses of the function and press **Ctrl+Shift+Spacebar**, you can view the signatures of the various overloads of that function name.

Building XPath expressions

The Edit XPath Expression dialog helps you to build XPath expressions in the following ways.

• Context node and schema tree

The *Selection* text box in the *Sources* pane immediately shows you the context node. The expression will be inserted at a location within this context node, and it will be evaluated with this node as its context.

• Inserting a node from the schema tree

In the *Sources* pane, the entire schema is displayed. Double-click a node in the schema tree to insert it in the *XP*ath expression. If the *Relative XPath* check box is checked, the selected node will be inserted with a location path expression that is relative to the context node.

• Namespace information

The schema tree in the *Sources* pane contains a Namespace item. Expanding this item displays all the namespaces declared in the stylesheet. This information can be useful for checking the prefixes of a namespace you might want to use in an XPath expression.

• Inserting XPath axes, operators and expressions

The Select Operator/Expression pane lists the XPath axes (ancestor::, parent::, etc), operators (for example, eq and div), and expressions (for # in # return #, etc) for the XPath version selected as the XSLT version for the SPS. The display can be toggled between an alphabetical listing and a hierarchical listing (which groups the items according to functionality). To insert an axis, operator, or axis in the XPath expression, double-click the required item.

• Inserting XPath functions

The *Select Function* pane lists XPath functions alphabetically or grouped according to functionality (click the respective icon at the top of the pane to switch between the two arrangements). Each function is listed with its signature. If a function has more than one signature, that function is listed as many times as the number of signatures. Arguments in a signature are separated by commas, and each argument can have an occurrence indicator (? indicates a sequence of zero or one items of the specified type; * indicates a sequence of zero or more items of the specified type). The arguments can be displayed as names or as datatypes; select *Names* or *Types* in the title bar of the pane. Each function also specifies the return type of that function. For example: => date? indicates that the

expected return datatype is a sequence of none or one date item. Placing the mouse over a function displays a brief description of the function. To insert a function in the XPath expression, double-click the required function.

Java and .NET extension functions can be used in XPath expressions, enabling you to access the functions of these programming languages. The Java and .NET buttons at the bottom of the dialog, pop up info boxes with explanations about how to use Java and .NET extension functions in XPath expressions. For more information about this, see the Extension Functions section of this documentation.

Intelligent editing during direct text entry

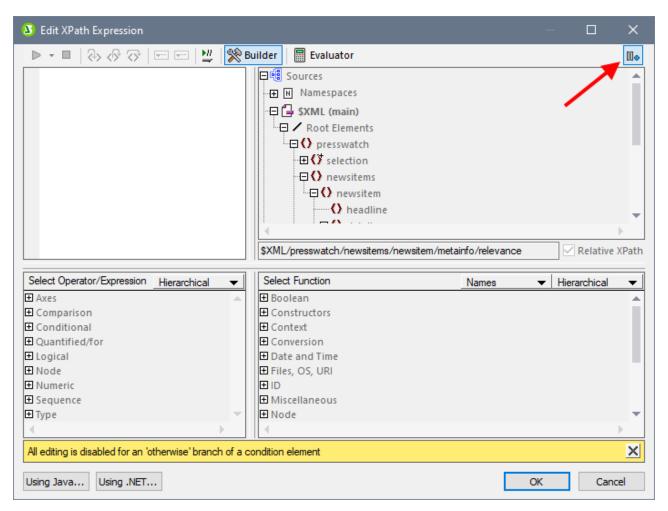

If you type an expression directly in the *Expression* text box, options that are available at that point are displayed in a popup (see screenshot below).

These include elements, XPath functions, and XPath axes. Go up and down the list of options using the **Up** and **Down** keys, and press **Enter** if you wish to select an option and enter it in the expression.

The Otherwise check box

The Otherwise toggle (see the red arrow in the screenshot below) adds an Otherwise branch to a conditional template as its last branch. Only one Otherwise branch may be present in a conditional template. When a conditional template is evaluated, the first branch to evaluate to true is executed. If no branch evaluates to true, then, the Otherwise branch is executed if present, otherwise the conditional template is exited without any of its branches being executed. Since the Otherwise branch is triggered only in the event that no preceding branch evaluates to true, it does not need to have a condition defined for it. As a result, when the Otherwise check box is selected, the entry field of the XPath expression is disabled.

For details of how to use the Otherwise condition, see <u>Conditional Templates</u> ⁽³⁸¹⁾.

17.3 Toolbars

A number of StyleVision commands are available as toolbar shortcuts, organized in the following toolbars:

- Formatting 936
- <u>Table</u> 937
- Authentic 938
- RichEdit
- Insert Design Elements 940
- Design Filter 943
- Global Resources

 944
- Standard 944

The icons in each toolbar are listed in the sub-sections of this section, each with a brief description of the corresponding command.

Positioning the toolbars

A toolbar can float freely on the screen or can be placed in a toolbar area along any edge of the GUI. Toolbars are most commonly placed along the top edge of the GUI, just below the Menu bar. However, they can also be placed along the side or bottom edges of the GUI.

To position a toolbar in a toolbar area, do the following:

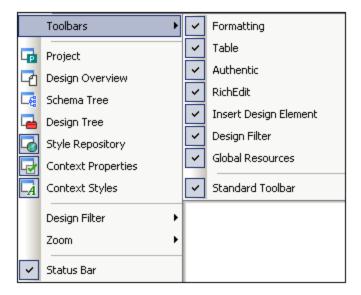

- 1. Grab the toolbar by its handle (if the toolbar is already in a toolbar area) or by its title bar (if the toolbar is floating).
- 2. Drag the toolbar to the desired toolbar area, if it exists, and drop it at the desired location in that toolbar area. If no toolbar area exists at the edge along which you wish to place the toolbar, dragging the toolbar to that edge will automatically create a toolbar area there when the toolbar is dropped.

To make a toolbar float freely grab it by its handle, drag it away from the toolbar area, and drop it anywhere on the screen except at an edge or in an existing toolbar area.

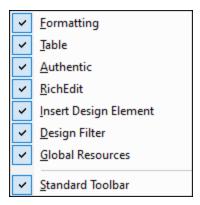

Switching the display of toolbars on and off

The display of individual toolbars can be switched on and off using any of the following three methods:

 In the View | Toolbars menu (screenshot below), select or deselect a toolbar to, respectively, show or hide that toolbar.

• Right-click any toolbar area to display a context menu (*screenshot below*) that allows you to toggle the display of individual toolbars on and off.

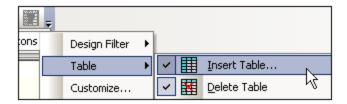

• In the Toolbars tab of the <u>Customize dialog</u> (<u>Tools | Customize</u>), toggle the display of individual toolbars on or off by clicking a toolbar's check-box. When done, click the **Close** button to close the dialog.

Adding and removing toolbar buttons

Individual toolbar buttons can be added to or removed from a toolbar, that is, they can be made visible or be hidden. To add or remove a button from a toolbar, do the following:

- In the toolbar where the button to be added or removed is, click the More Buttons button (if the toolbar is in a toolbar area) or the Toolbar Options button (if the toolbar is a floating toolbar). The More Buttons button is an arrowhead located at the right-hand side of the toolbar (in horizontal toolbar areas) or at the bottom of the toolbar (in vertical toolbar areas). The Toolbar Options button is an arrowhead located at the right-hand side of the floating toolbar.
- 2. In the **Add or Remove Buttons** menu that pops up, place the cursor over the **Add or Remove Buttons** menu item (*screenshot below*). This rolls out a menu which contains the names of the toolbars in that toolbar area plus the **Customize** menu item (*screenshot below*).

- 3. Place the cursor over the toolbar that contains the toolbar button to be added or removed (*screenshot above*).
- 4. In the menu that rolls out (*screenshot above*), click on the name of the toolbar button to add or remove that button from the toolbar.
- 5. Clicking the Customize item pops up the <u>Customize dialog</u> (1058).

The **Reset Toolbar** item below the list of buttons in each toolbar menu resets the toolbar to the state it was in when you downloaded StyleVision. In this state, all buttons for that toolbar are displayed.

Note: The buttons that a toolbar contains are preset and cannot be disassociated from that toolbar. The process described above displays or hides the button in the toolbar that is displayed in the GUI.

17.3.1 Format

The **Format toolbar** (*screenshot below*) is enabled in Design View and contains commands that assign commonly used inline and block formatting properties to the item/s selected in the SPS design.

Predefined HTML formats

The HTML format selected from the dropdown list is applied to the selection in Design View. For example, a selection of div applies HTML's Block (div) element around the current selection in Design View. The HTML format is converted to the corresponding RTF, PDF and Word 2007+ properties for the RTF, PDF and Word 2007+ outputs, respectively.

Text properties

The bold, italic, underline, and strikethrough inline text properties can be directly applied to the current selection in Design View by clicking on the appropriate button. Font style, font size, foreground and background color can also be applied via toolbar buttons.

<u>Alignment</u>

Alignment properties (left-aligned, centered, right-aligned, and justified) can be directly applied to the selection in Design View.

<u>Lists</u>

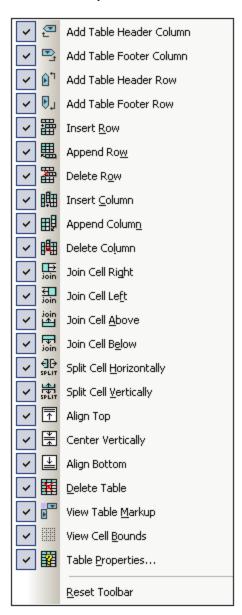

Lists can be inserted at the cursor insertion point, or the selection in the SPS can be converted to a list.

<u>Hyperlinks</u>

Inserts a hyperlink at the cursor insertion point. See <u>Hyperlink</u> for a description of how to use this command

17.3.2 Table

The **Table toolbar** contains commands to structure and format static and dynamic tables in Design View. These commands are shown in the screenshot below (which is that of the Table toolbar customization menu, available when you click the **Customize** button at the right of the toolbar).

Row and Column operations

Rows and columns in any SPS table (static or dynamic) can be inserted, appended, or deleted with reference to the cursor location. Rows and columns are inserted before the current cursor location or appended after all rows/columns. The row/column in which the cursor is can also be deleted. These operations are achieved with the Insert Row/Column, Append Row/Column, or Delete Row/Column buttons. You can also add table headers and footers as either columns or rows Add Table Header/Footer Column/Row.

Cell operations

An SPS table cell in which the cursor is located can be joined to any one of the four cells around it. The joining operation is similar to that of spanning table cells in HTML. The buttons to be used for these operations are **Join Cell Right/Left/Above/Below**. Also, an SPS table cell in which the cursor is located can be split, either horizontally or vertically, using the **Split Cell Horizontally** and **Split Cell Vertically** buttons, respectively. SPS table cell content can be aligned vertically at the top, in the middle, and at the bottom. The display of cell borders can be switched on and off with the **View Cell Bounds** toggle.

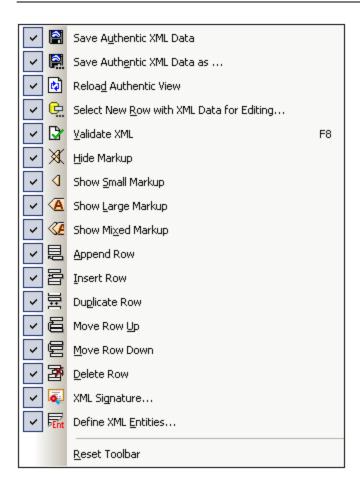

Table operations, properties, display

Placing the cursor in a static or dynamic table and clicking **Delete Table** deletes that table. Table markup can be toggled on and off with the View Table Markup command. The Table Properties command pops up the Table Properties dialog, in which properties of the table can be defined.

17.3.3 Authentic

The **Authentic toolbar** contains commands for customizing Authentic View and editing XML documents in Authentic View. These commands are shown in the screenshot below (the customization menu for <u>adding and removing Authentic toolbar buttons</u> available when you click the **Customize** button at the right of the toolbar).

All these features are available to the Authentic View user. They enable you, as the SPS designer, to test the SPS using features at the Authentic View users's disposal.

Validating, saving, and reloading XML documents

While editing an XML document in Authentic View, you can check the validity of the Working XML File by using the Validate XML button. Editing changes can be saved to the Working XML File with the Save Authentic **XML Data** button. The XML document can also be reloaded at any time from the last saved version.

Select new row with XML data for editing

This command is enabled only in SPSs that are based on an XML DB. The command enables a new row from the XML column to be loaded into Authentic View for editing. See the description of the command to some formula to to so details.

Markup tags in Authentic View

In Authentic View, the display of markup tags can be customized. Markup tags can be hidden (Hide Markup), can be shown with node names (Show Large Markup), without node names (Show Small Markup), or with any of these three options for individual nodes (Show Mixed Markup).

Editing of dynamic tables in Authentic View

In Authentic View, row operations can be performed on dynamic tables. Rows can be inserted, appended, and duplicated, as well as be moved up and down, using the appropriate toolbar buttons (Insert Row, Append Row, Duplicate Row, Move Row Up, Move Row Down, and Delete Row).

Defining XML Entities

Entities can be defined at any time while editing the Working XML File in Authentic View. Clicking the Define XML Entities button pops up the Define XML Entities dialog. (See Authentic | Define Entities for details of usage.)

17.3.4 RichEdit

The RichEdit toolbar contains commands for marking up text in Authentic View with text-styling properties.

In Authentic View, when the cursor is placed inside an element that has been <u>created as a RichEdit</u> <u>component</u> the buttons and controls in the RichEdit toolbar (*screenshot below*) become enabled. Otherwise they are grayed out.

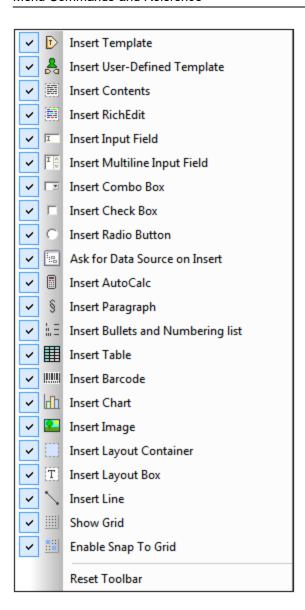

RichEdit enables the Authentic View user to specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of text. Select the text you wish to style in Authentic View and specify the styling you wish to apply via the buttons and controls of the RichEdit toolbar. The text that has been styled will be enclosed in the tags of the styling element apply and the styling element apply to the styling element

17.3.5 Insert Design Elements

The **Insert Design Elements toolbar** contains icons for commands to insert design elements in the SPS design, and for related commands. The various design elements that can be inserted via these toolbar icons are shown in the screenshot below. There are three types of items in the toolbar:

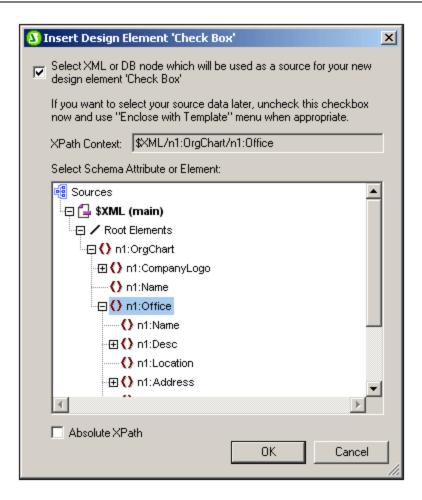

- 1. <u>Design elements</u> ⁹⁴¹, which are context-node-sensitive (the majority of elements in the toolbar),
- 2. <u>Layout elements</u> 942, which are independent of node context, and
- 3. Grid-related toggles 943 to aid design.

Design elements

The design elements are the context-node-sensitive elements that are available in the **Insert** menu. To insert a design element using its toolbar icon, do the following:

- 1. Select the toolbar icon for the element you wish to insert.
- 2. Click the location in the design where the element is to be inserted. A Insert Design Element for the selected design element (*screenshot below*) pops up. This displays the schema tree with the context node highlighted. The context node is the node within which the cursor has been placed for the insertion of the design element.

- 3. If you wish to insert the design element within the currently selected context node, click **OK**. If you wish to select another context node, do so in the schema tree and then click **OK**.
- 4. In the case of some design elements, such as Auto-Calculations, a further step is required, such as the definition of an Auto-Calculation. In other cases, such as the insertion of a user-defined template, the Insert Design Element dialog is skipped. In such cases, another dialog, such as the Edit XPath Expression dialog will pop up. Carry out the required step and press the dialog's **OK** button.

The design element will be inserted at the end of Step 3 or Step 4, depending on the kind of design element being inserted.

Layout elements

There are three layout element commands in the Insert Design Elements toolbar: to insert (i) a layout container; (ii) a layout box; and (iii) a line. Note that layout boxes and lines can only be inserted within a layout container.

To insert a layout container, select the **Insert Layout Container** icon and then click at the location in the design where you wish to insert the layout container. You will be prompted about the size of the layout container, on selecting which the layout container will be inserted. To insert a layout box, click the **Insert Layout Box** icon, then move the cursor to the location within the layout container at which you wish to insert the layout box and click. The layout box is inserted. Click inside the layout box to start typing. To insert a line, click the **Insert Line** icon, then move the cursor to the location within the layout container at which you wish to start drawing the line. Click to define the start point of the line and then drag the cursor to the desired endpoint.

Release the cursor at the end point. The line is inserted and extends from the indicated start point to the indicated end point.

To re-size layout containers and layout boxes, place the cursor over the right or bottom border of the layout container or layout box and drag the border so as to obtain the desired size. To move a layout box, place the cursor over the top or left border of the layout box and, when the cursor turns to a cross, drag the layout box to the new location.

Grid-related toggles

The **Show Grid** command toggles the display of the drawing grid on and off. When the **Snap to Grid** command is toggled on, elements created within the layout container, such as layout boxes and lines, snap to grid lines and grid line intersections. The properties of the grid can be set in the Design tab of the Options dialog (**Tools | Options**).

17.3.6 Design Filter

The **Design Filter toolbar** (*screenshot below*) contains commands that enable you to filter which templates are displayed in the design. Each icon in the toolbar is explained below.

Icon	Command	Description	
Ğ	Show only one template	Shows the selected template only. Place the cursor in a template and click to show that template only.	
	Show all template Shows all templates in the SPS (main, global, named, and layout) . types		
	Show imported templates Toggles the display of imported templates on and off.		
	Show/Hide main template	Toggles the display of the main template on and off.	
	Show/Hide global Toggles the display of global templates on and off.		
	Show/Hide Design Toggles the display of Design Fragments on and off. Fragments		

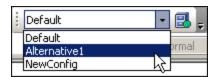

The Design Filter combo box (screenshot below) displays a list of all the templates in the SPS.

Selecting a template in the combo box causes the template to be selected in the design. The combo box, therefore, enables you to quickly navigate to the desired template in the design, which is useful if the design has several templates, some of which might be currently hidden.

17.3.7 Global Resources

The **Global Resources toolbar** (*screenshot below*) enables you: (i) to select the active configuration for the application, and (ii) to access the <u>Altova Global Resources dialog</u> ⁵⁴².

Select the active configuration from among the options in the dropdown list of the combo box. Click the Manage Global Resources icon to access the Altova Global Resources dialog.

17.3.8 Standard

The **Standard toolbar** contains buttons for commands that provide important file-related and editing functionality. These icons are listed below with a brief description. For a fuller description of a command, click the command to go to its description in the Reference section.

Icon	Command	Shortcut	Description
₹ 1	New from XML Schema / DTD (946)	Ctrl+N	Creates a new SPS document based on a schema. Clicking the dropdown arrow enables you to create the SPS from a DB or an HTML document, or an empty SPS.
	Open 952	Ctrl+O	Opens an existing SPS document.
	Reload		Reloads the SPS from the last saved version.
	Save Design 957	Ctrl+S	Saves the active SPS document.
	Save All 957	Ctrl+Shift+S	Saves all open SPS documents.
	Print 977	Ctrl+P	Prints the Authentic View of the Working XML file.
<u> </u>	Print Preview 977		Displays a print preview of the Authentic View of the Working XML File.

Icon	Command	Shortcut	Description
X	Cut 979	Shift+Del	Cuts the selection and places it in the clipboard.
	<u>Copy</u> ⁹⁷⁹	Ctrl+C	Copies the selection to the clipboard.
	Paste 979	Ctrl+P	Pastes the clipboard item to the cursor location.
×	Delete 979	Del	Deletes the selection.
N	Undo 979	Alt+ Backspace	Undoes an editing change. An unlimited number of Undo actions can be performed at a time.
2	Redo 979	Ctrl+Y	Redoes an undo.
**	Find 979	Ctrl+F	Finds text in Authentic View and Output Views.
4	Find Next 979	F3	Finds the next occurrence of the searched text.
	Zoom 996		Sets the Zoom Factor of Design View.
4	Show Small Design Markup		Switches markup tags to small markup format.
A	Show Large Design Markup		Switches markup tags to large markup format.
XSLT 1.0	XSLT 1.0 110		Sets XSLT 1.0 as the stylesheet language.
XSLT 20	XSLT 2.0 110		Sets XSLT 2.0 as the stylesheet language.
XSLT 3.0	XSLT 3.0 110		Sets XSLT 3.0 as the stylesheet language.
ABC	Spelling 1052		Runs a spelling check on the SPS document.
	Toggle DB Query 1047		Shows/hides the Database Query dialog.

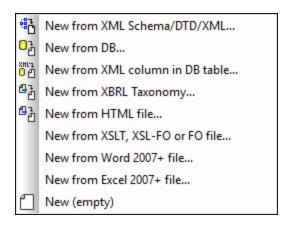

17.4 File Menu

The **File** menu contains commands for working with SPSs and related files. The following commands are available:

- New 946, to create a new SPS from a variety of sources.
- Open, Reload, Close, Close All 952, to open and close the active file, and to reload the active file.
- Save Design, Design As, All 957, which are commands to save the active SPS and all open SPS files.
- Export as MobileTogether Design File 955, to generate a MobileTogether design from the active SPS file.
- Save Authentic XML Data, Save As 965, enabled in Authentic View, it saves changes to the Working XML File 31.
- <u>Save Generated Files</u> ⁹⁶⁶, to save output files that can be generated using the SPS.
- Web Design an ASPX application, in the folder location you specify.
- Properties (971), to set the encoding of the output documents, the CSS compatibility mode of the
 browser, how relative image paths in Authentic View should be resolved, and whether images should
 be embedded or linked in the RTF (Enterprise and Professional editions) and Word 2007+ (Enterprise
 edition only) outputs.
- <u>Print Preview, Print (1777)</u>, enabled in Authentic View and output views, these commands print what is displayed in the previews.
- Most Recently Used Files, Exit ⁹⁷⁸, respectively, to select a recently used file to open, and to exit the program.

17.4.1 New

Placing the cursor over the **New** command pops out a submenu (*screenshot below*) that enables you to create a new SPS document of one of different types:

• A new SPS file based on an XML Schema or DTD or XML Schema generated from an XML file (New from XML Schema / DTD / XML). The selected schema is added to the Design Overview sidebar and a graphical tree representation is added to the schema tree (in the Schema Tree sidebar and Design View schema or XML) is created with an empty main template. A new SPS can also be created from a file (schema or XML) via a URL or global resource (see below).

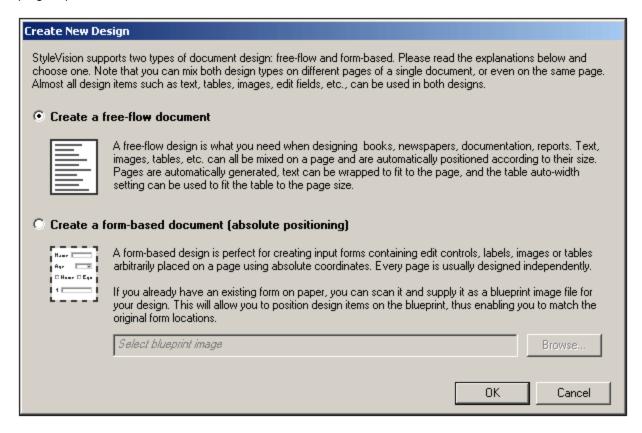

- A new SPS file based on an XML Schema generated from a DB you select (**New from DB** or **New from XML Column in IBM DB2**). The connection process is described in the section <u>Connecting to a DB and Setting up the SPS 633</u>. The SPS is created in <u>Design View 36</u> with an empty main template.
- A new SPS file based on an XBRL taxonomy 301.
- A new SPS based on a user-defined schema you create node-by-node from an <a href="https://ht
- An SPS can be created from an XSLT-for-HTML or an XSLT-for-FO or an FO file. Template structure
 and styling in the XSLT will be created in the SPS. You can then modify the SPS components and add
 content and formatting to the SPS. See New from XSLT for details.
- A new SPS that contains the content of a MS Word document as the design's static text [138].
- A new SPS that contains the content of a MS Excel document as the design's static text [141].
- A new empty SPS (**New (empty)**). No schema is added to either the Design Overview sidebar or the schema tree. An empty main template will be created in Design View 33.

Note: A global resource 542 can be used to locate a file or DB resource.

Selecting the type of design

After you have selected (XSD and XML) sources files, if required, the Create New Design dialog appears.

The Create New Design dialog (*screenshot below*) prompts you to select either: (i) a free-flowing document design, or (ii) a form-based document design (in which components are positioned absolutely, as in a layout program).

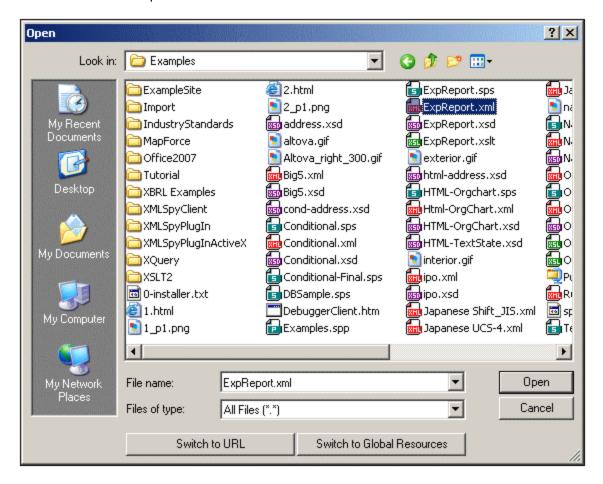

In a free-flowing document design, document content is laid out to fit the output media object or viewer (paper or

screen). Items in the document content can only be placed relative to each other, and not absolutely. This kind of design is suited for documents such as reports, articles, and books.

In a form-based document, a single <u>Layout Container</u> is created, in which design components can be positioned absolutely. The dimensions of the Layout Container are user-defined, and Layout Boxes can be positioned absolutely within the Layout Container and document content can be placed within individual Layout Boxes. If you wish the design of your SPS to replicate a specific form-based design, you can use an image of the original form as a <u>blueprint image</u>. The blueprint image can then be included as the background image of the Layout Container. The blueprint image is used to help you design your form; it will not be included in the output.

Selecting files via URLs and Global Resources

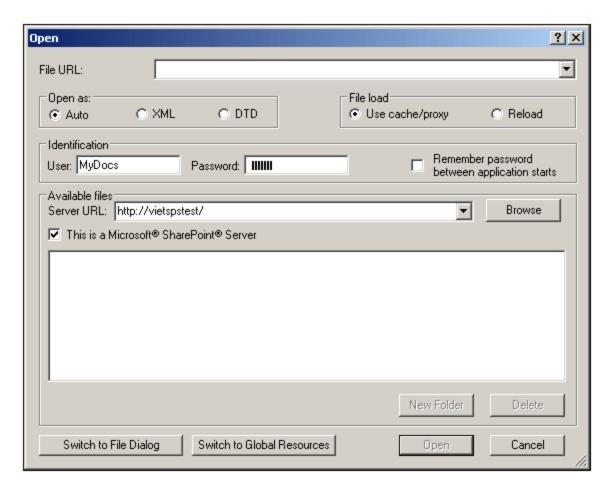

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Select the **Switch to URL** or **Switch to Global Resource** to go to one of these selection processes.

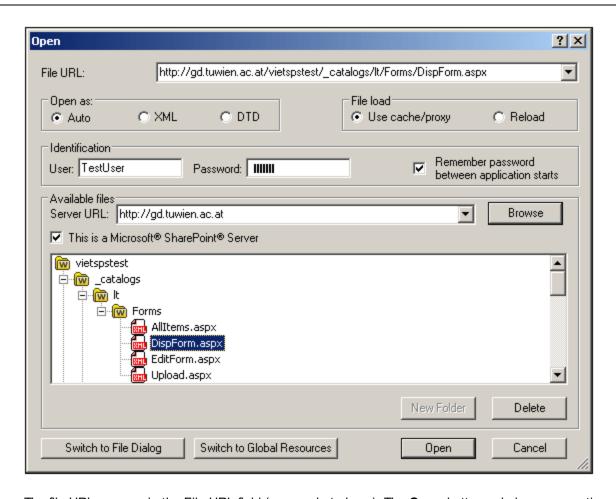

Selecting files via URLs

To select a file via a URL, do the following:

1. Click the **Switch to URL** command. This switches to the URL mode of the Open dialog (*screenshot below*).

- 2. Enter the URL you want to access, in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.
- 3. If the server is password protected, enter your User-ID and password in the *User* and *Password* fields.
- 4. Click **Browse** to view and navigate the directory structure of the server.
- 5. In the folder tree, browse for the file you want to load and click it.

The file URL appears in the File URL field (*screenshot above*). The **Open** button only becomes active at this point.

6. Click the **Open** button to load the file. The file you open appears in the main window.

Note: The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.

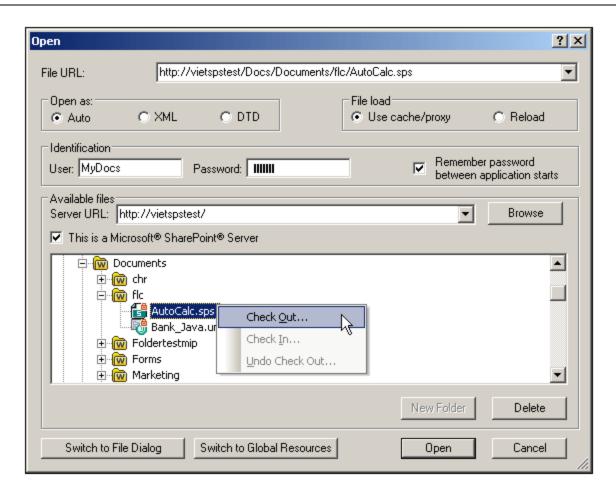

Note: To give you more control over the loading process, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case

Microsoft® SharePoint® Server Notes

Note the following points about files on Microsoft® SharePoint® Servers:

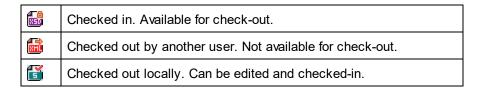

• In the directory structure that appears in the Available Files pane (*screenshot below*), file icons have symbols that indicate the check-in/check-out status of files.

951

Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

The various file icons are shown below:

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot above), or via the context menu that pops up when you click the file tab in the Main Window of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out command in the context menu. This has the effect of returning the file unchanged to the server.
- If you check out a file in one Altova application, you cannot check it out in another Altova application.

The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: **Check In** and **Undo Check Out**.

Opening and saving files via Global Resources

To open or save a file via a global resources, click **Switch to Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, <u>Using Global Resources</u> 553. For a general description of Global Resources, see the <u>Global Resources</u> 542 section in this documentation.

17.4.2 Open, Reload, Close, Close All

The **Open** (**Ctrl+O**) command allows you to open an existing SPS or PXF file. The familiar <u>Open dialog</u> of Windows systems is opened and allows you to select a file with an extension of .sps.

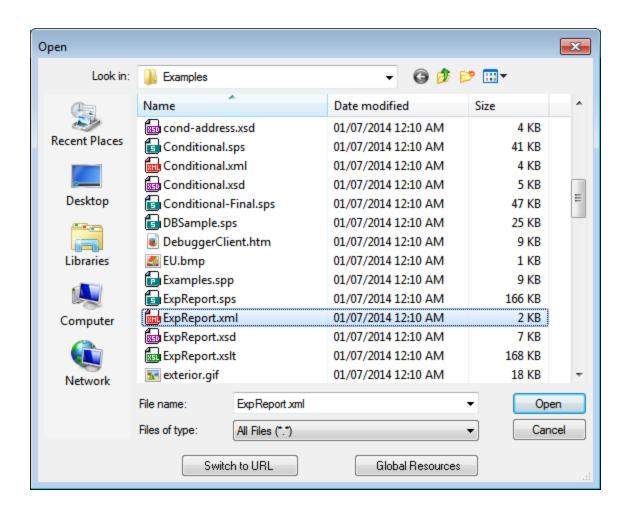

The **Reload** command reloads the SPS file from the file saved to disk. Any changes made since the file was last saved will be lost. The Working XML file will also be reloaded, enabling you to update the Working XML File it it has been changed externally.

The **Close** command closes the currently active SPS document. Note that while several files can be open, only one is active. The active document can also be closed by clicking the **Close** button at the top right of the <u>Main Window</u> If you have unsaved changes in the document, you will be prompted to save these changes.

The **Close All** command closes all the open SPS documents. If you have unsaved changes in an open document, you will be prompted to save these changes.

Selecting and saving files via URLs and Global Resources

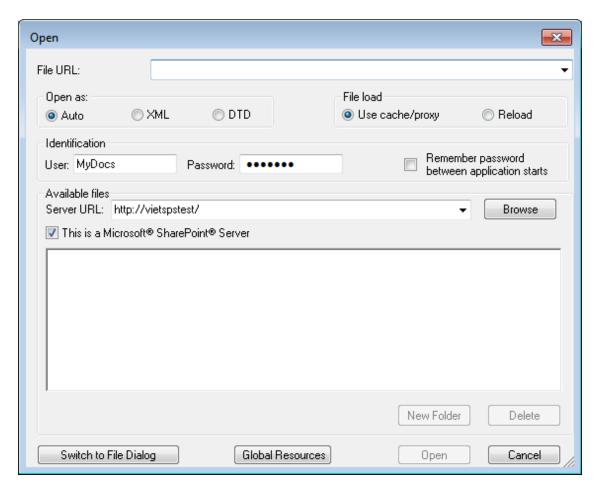

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Click **Switch to URL** or **Global Resource** to go to one of these selection processes.

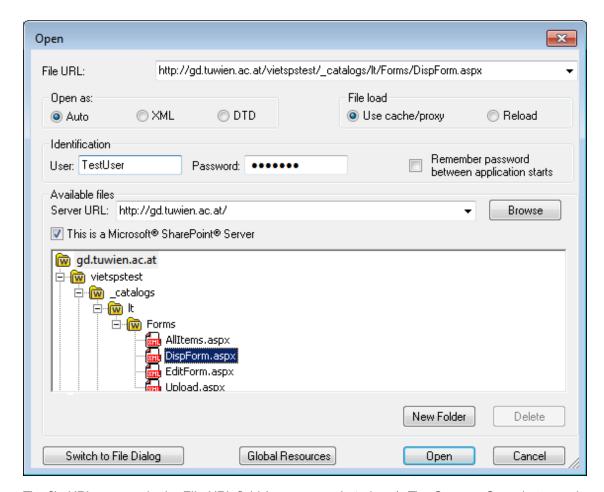

Selecting files via URLs

To select a file via a URL (either for opening or saving), do the following:

1. Click the **Switch to URL** command. This switches to the URL mode of the Open or Save dialog (the screenshot below shows the Open dialog).

- 2. Enter the URL you want to access in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.
- 3. If the server is password protected, enter your User-ID and password in the *User* and *Password* fields
- 4. Click **Browse** to view and navigate the directory structure of the server.
- 5. In the folder tree, browse for the file you want to load and click it.

The file URL appears in the File URL field (see screenshot above). The **Open** or **Save** button only becomes active at this point.

6. Click **Open** to load the file or **Save** to save it.

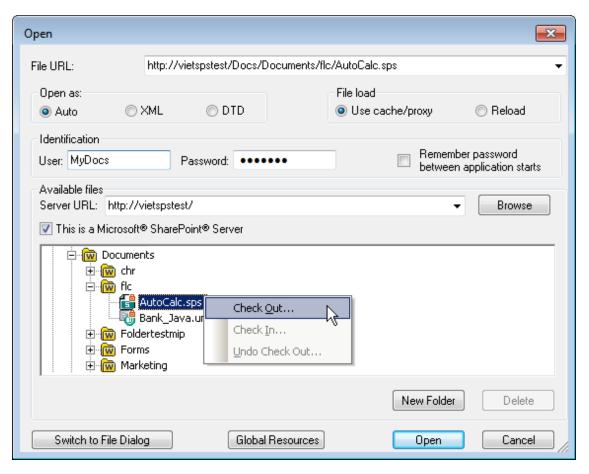

Note the following:

- The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.
- To give you more control over the loading process when opening a file, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

Microsoft® SharePoint® Server Notes

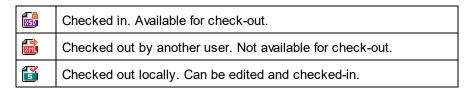

Note the following points about files on Microsoft® SharePoint® Servers:

• In the directory structure that appears in the Available Files pane (*screenshot below*), file icons have symbols that indicate the check-in/check-out status of files.

Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

The various file icons are shown below:

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot
 above), or via the context menu that pops up when you right-click the file tab in the Main Window
 of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out

- command in the context menu. This has the effect of returning the file unchanged to the server.
- If you check out a file in one Altova application, you cannot check it out in another Altova application. The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: Check In and Undo Check Out.
- Opening and saving files via Global Resources

To open or save a file via a global resources, click **Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, <u>Using Global Resources</u>

For a general description of Global Resources, see the <u>Global Resources</u>

Section in this documentation.

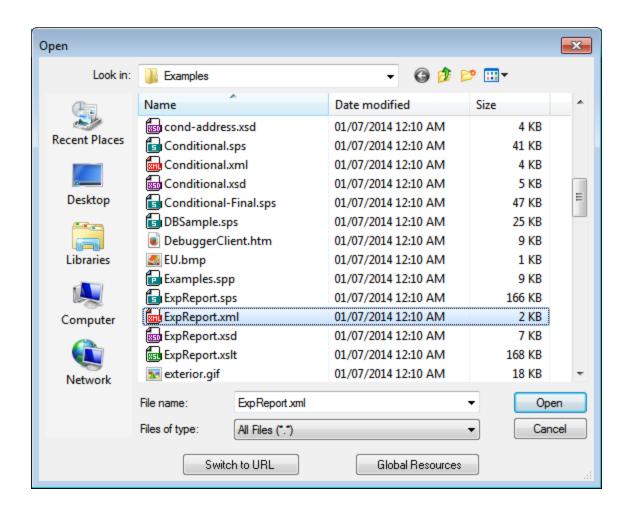

17.4.3 Save Design, Save All

The **Save Design (Ctrl+S)** command saves the currently open document as an SPS file (with the file extension .sps).

The Save All (Ctrl+Shift+S) command saves all the open SPS documents.

Selecting and saving files via URLs and Global Resources

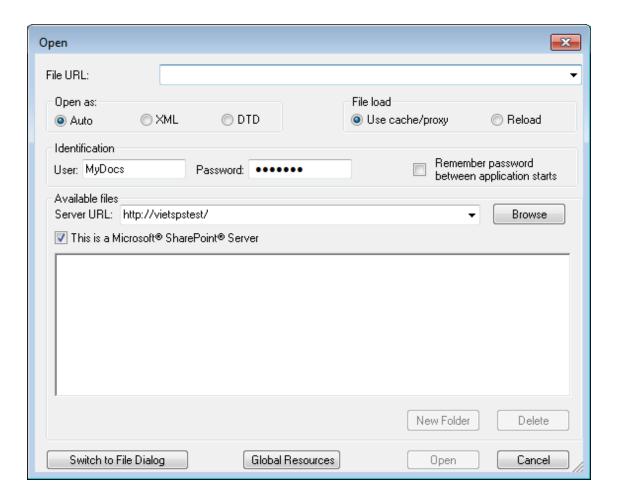

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Click **Switch to URL** or **Global Resource** to go to one of these selection processes.

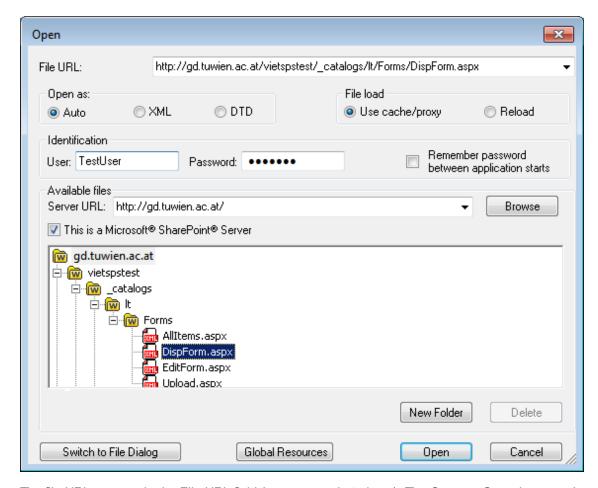

Selecting files via URLs

To select a file via a URL (either for opening or saving), do the following:

1. Click the **Switch to URL** command. This switches to the URL mode of the Open or Save dialog (the screenshot below shows the Open dialog).

- 2. Enter the URL you want to access in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.
- 3. If the server is password protected, enter your User-ID and password in the *User* and *Password* fields
- 4. Click **Browse** to view and navigate the directory structure of the server.
- 5. In the folder tree, browse for the file you want to load and click it.

The file URL appears in the File URL field (see screenshot above). The **Open** or **Save** button only becomes active at this point.

6. Click **Open** to load the file or **Save** to save it.

Note the following:

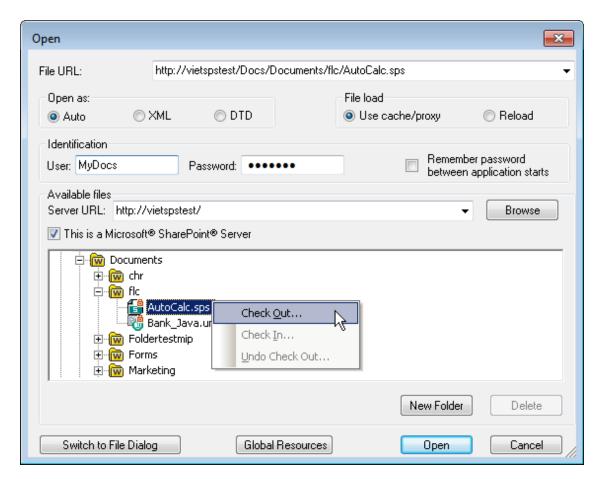

- The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.
- To give you more control over the loading process when opening a file, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

Microsoft® SharePoint® Server Notes

Note the following points about files on Microsoft® SharePoint® Servers:

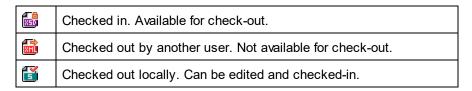

• In the directory structure that appears in the Available Files pane (*screenshot below*), file icons have symbols that indicate the check-in/check-out status of files.

© 2019-2025 Altova GmbH

Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

The various file icons are shown below:

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot
 above), or via the context menu that pops up when you right-click the file tab in the Main Window
 of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out

- command in the context menu. This has the effect of returning the file unchanged to the server.
- If you check out a file in one Altova application, you cannot check it out in another Altova application. The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: Check In and Undo Check Out.
- Opening and saving files via Global Resources

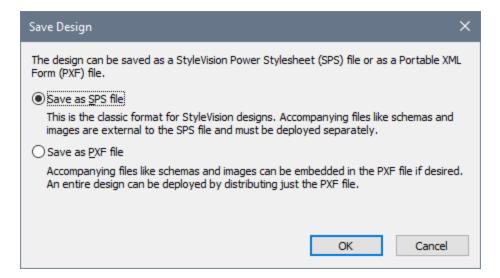

To open or save a file via a global resources, click **Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, <u>Using Global Resources</u>

For a general description of Global Resources, see the <u>Global Resources</u>

Section in this documentation.

17.4.4 Save As

The **Save As** command enables the design to be saved: (i) as an SPS file or (ii) as a PXF file (Portable XML Form file). Clicking the command pops up the Save Design dialog (*screenshot below*). Select the required format and click **OK**.

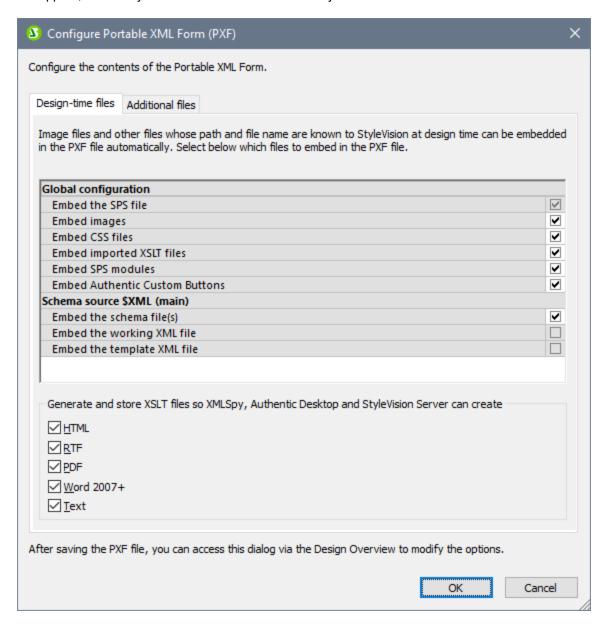

The **SPS format** is the standard Altova format for StyleVision designs. The **PXF format** is an Altova format that allows all files related to the design (schema files, XML files, images files, generated XSLT stylesheets, etc) to be embedded with the design. This format is very useful for transporting all the files required to open the design in Authentic View and/or to generate HTML, Text, RTF, PDF and/or Word 2007 output based on the design.

Save as SPS

Selecting the SPS option causes the familiar Save As dialog of Windows systems to pop up. Saving works exactly as described for the <u>Save Design</u> <u>solution</u>. The advantage of using the **Save As** command is that files that have already been saved with a filename can be saved with another filename.

Save as PXF

Selecting the PXF option causes the familiar Save As dialog of Windows systems to pop up. Saving works exactly as described for the <u>Save Design</u> command with the additional step of selecting the files you wish to include in the PXF file. After you specify the PXF filename, the Configure PXF dialog (*screenshot below*) will appear, in which you can select/deselect the files you wish to embed.

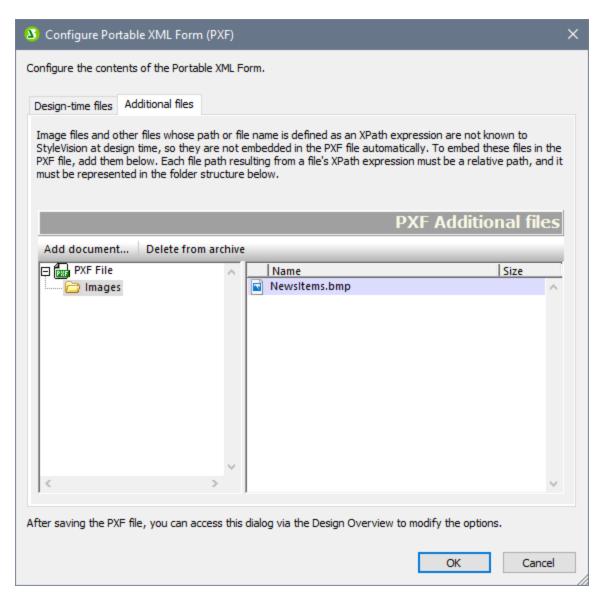

In the Global Configuration pane of the Design-time Files tab, you can select/deselect the design-related

source files to be embedded/omitted. You can additionally choose to embed XSLT files generated from the design. In the XSLT files pane, select the output formats for which you wish to generate and embed XSLT files. If an XSLT file is included in the PXF file and the PXF file is opened in the Authentic View of an Altova product, then the toolbar button to generate and view that output format is enabled in Authentic View (*screenshot below*).

In the Additional Files tab (screenshot below), you can specify any additional files you wish to include that are not design-time files. These could be, for example, image files referenced in the design by a URL generated with an XPath expression. In the screenshot below, the image file <code>NewsItems.bmp</code> located in the <code>Images</code> folder is selected for inclusion in the PXF file.

To include an additional file in the PXF file, click the **Add Document** button and then browse for the file you want. The Open dialog (in which you browse for the required file) opens the folder in which the SPS is located.

Files from this folder or any descendant folder may be selected. After an additional file has been added to the PXF file, it and the folder structure leading to it are displayed. The screenshot above indicates that the additional file <code>NewsItems.bmp</code> is in a folder named <code>Images</code>, which is itself contained in the folder in which the SPS file is located.

If a file is selected from a folder located in any level above the folder containing the SPS file, an error is reported.

In the SPS design, any reference to an additional file must be made with a relative path and must use the folder structure shown in the *Additional Files* pane. For example, <code>NewsItems.bmp</code> in the screenshot above must be referenced with the relative path: <code>Images/NewsItems.bmp</code>.

Note: In order to save PXF files, the option *Embed Images for RTF and Word 2007*+ (**File | Properties | Images**) must be selected.

17.4.5 Export as MobileTogether Design File

This command generates an Altova MobileTogether design file from the active SPS design. A MobileTogether design file is used to execute solutions in the MobileTogether app for mobile devices. For example, a MobileTogether solution can be opened in a mobile device, such as a smartphone, to view and edit the contents of a database. A MobileTogether solution is designed in Altova MobileTogether Designer. This command enables you to convert an SPS design into a MobileTogether design that can be edited in MobileTogether Designer. For more information, see the MobileTogether web page and MobileTogether Designer documentation. Conversions options are available in the MobileTogether Design tab of the Options dialog (Tools | Options (100)).

Note: Not all SPS design features have correspondences in MobileTogether designs. After running this command, you should therefore open the generated file in MobileTogether Designer to review it and, if necessary, correct it. The following design features are known not to be exported to MobileTogether designs: (i) Sources beyond the first one listed in the StyleVision design (see here (ii) global templates (iii) modules (iii)

17.4.6 Save Authentic XML Data, Save As

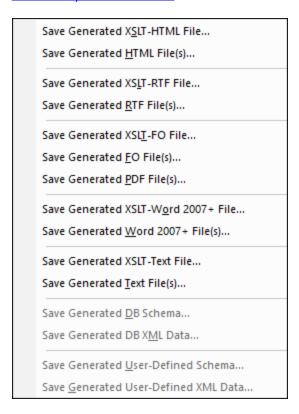

In Authentic View, you can edit the Working XML File or DB related to the SPS. The **Save Authentic XML Data** command saves these modifications to the Working XML File or DB. Alternatively to editing the XML file in StyleVision, you can edit an XML document or DB in the Authentic View of Altova XMLSpy or Altova Authentic Desktop.

The **Save Authentic XML Data As** command enables you to save the Authentic XML document as another file.

17.4.7 Save Generated Files

The **Save Generated Files** command pops up a submenu which contains options for saving the following files (*screenshot below*). For perspective on how the generated files fit into the general usage procedure, see <u>Usage Procedure | Generated Files</u> 116.

Save Generated XSLT-HTML File

The Save Generated XSLT-HTML File command generates an XSLT file for HTML output from your SPS. You can use this XSLT file subsequently to transform an XML document to HTML.

Save Generated HTML File(s)

The Save Generated HTML File(s) command generates an HTML file or files. Multiple HTML files will be generated if <u>multiple document output</u> has been specified in the design. This operation requires two input files:

- The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, the **Save Generated HTML File** command is disabled. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see <u>The DB Schema and DB XML files</u> Tor); you do not assign a Working XML File.
- An XSLT file, which is automatically generated from the currently active SPS file.

Save Generated XSLT-RTF File

The Save Generated XSLT-RTF File command generates an XSLT file for RTF output from your SPS. You can use this XSLT file subsequently to transform an XML document to RTF.

Save Generated RTF File(s)

The Save Generated RTF File(s) command generates an RTF file. Multiple RTF files will be generated if <u>multiple</u> document output has been specified in the design. This operation requires two input files:

- The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, the command is disabled. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see The DB Schema and DB XML files); you do not assign a Working XML File.
- An XSLT-for-RTF file, which is automatically generated from the currently active SPS file.

Save Generated XSLT-FO File

The XSL-FO File command generates an XSLT-for-FO (XSL-FO) file from your SPS. You can use this XSL-FO file subsequently to transform an XML document to an FO document.

Save Generated FO File

The Save Generated FO File command generates an FO file. This operation requires two input files:

- The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, an error message saying the XML file could not be loaded is displayed. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB Schema and DB XML files (see The DB XML files (see The DB Schema and DB XML files (see The DB XML files (see The DB XML files (see The DB XML files (see The DB XML files (see The DB XML files (see The DB XML files (see The DB XML files (see <a href
- An XSLT-for-FO file, which is generated from the currently active SPS file.

Save Generated PDF File(s)

The Save Generated PDF File(s) command generates a PDF file. Multiple PDF files will be generated if multiple document output see been specified in the design. It requires the following inputs and settings:

- A Working XML File. If no Working XML File has been assigned, an error message saying the XML file could not be loaded is displayed. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see <u>The DB Schema and DB XML files</u> ⁷⁰⁷); you do not have to assign a Working XML File.
- An XSLT-for-FO file, which is generated from the currently open SPS file.
- The path to the FO processor must be set in the XSL-FO tab of the Options dialog (Tools | Options).

Save Generated XSLT-Word2007+ File

The Save Generated XSLT-Word 2007+ File command generates an XSLT file for Word 2007+ output from your SPS. You can use this XSLT file subsequently to transform an XML document to a Word 2007+ document.

Save Generated Word 2007+ File(s)

The Save Generated Word 2007+ File(s) command generates a Word 2007+ file. Multiple Word 2007+ files will be generated if <u>multiple document output</u> has been specified in the design. This operation requires two input files:

- The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, the command is disabled. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see The DB Schema and DB XML files); you do not assign a Working XML File.
- An XSLT-for-Word 2007+ file, which is automatically generated from the currently active SPS file.

Save Generated XSLT-Text File

The Save Generated XSLT-Text File command generates an XSLT file for Text output from your SPS. You can use this XSLT file subsequently to transform an XML document to a text document.

Save Generated Text File(s)

The Save Generated Text File(s) command generates a text file. Multiple text files will be generated if <u>multiple</u> document output aben specified in the design. This operation requires two input files:

- The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, the command is disabled. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see <u>The DB Schema and DB XML files</u> ⁷⁰⁷); you do not assign a Working XML File.
- An XSLT-for-Text file, which is automatically generated from the currently active SPS file when this
 command is executed.

Save Generated DB Schema

When you connect to a DB in order to create a DB-based SPS, StyleVision generates and loads a temporary XML Schema based on the DB structure. The Save Generated DB Schema command enables you to save this generated XML Schema. Note that for XML DBs, StyleVision does not generate a schema file; it uses a schema file from the DB or some other external file location. Consequently, this command is not enabled for XML DBs.

Save Generated DB XML Data

The Save Generated DB XML Data command generates and saves an XML file that contains data from the DB in an XML structure conformant with the structure of the XML Schema generated from the DB. If DB Filters have been defined in the StyleVision Power Stylesheet, these are applied to the data import. Note that for XML DBs, StyleVision does not generate an XML file, but uses XML data in the XML columns of the XML DB. Consequently, this command is not enabled for XML DBs.

Save Generated User-Defined Schema

This command is activated when the SPS involves a user-defined schema. The schema you create in the Schema Tree sidebar is saved as an XML Schema with the .xsd extension.

Save Generated User-Defined XML Data

The data in the imported HTML file that corresponds to the user-defined schema is saved as an XML file. The corresponding data are the nodes in the HTML document (in Design View) that have been created as XML Schema nodes.

17.4.8 Deploy to FlowForce

The **Deploy to FlowForce** command enables you to deploy a .transformation file to your Altova FlowForce Server. The .transformation file contains all the files and information required to carry out transformations as designed in the SPS. After the .transformation file has been deployed to the FlowForce Server, you can create jobs in Altova FlowForce that use the .transformation file to generate transformations according to triggers specified in the job definition. For information about creating FlowForce jobs, see the FlowForce documentation.

A .transformation file is generated from a Portable XML Format (PXF) file. So, the **Deploy to FlowForce** command can be used when a PXF file is active. (If an SPS file is active, the **Deploy to FlowForce** command will be active, but clicking it will prompt you to save the SPS file as a PXF file. To create a PXF file from an SPS file, use the **File | Save As** command and select PXF as the format to save as.)

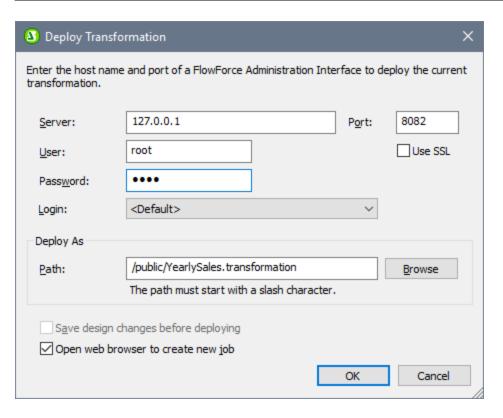

Note the following points:

- When a PXF file is saved, an option is provided for including external files (such as image files) in it. If an external file is not included in the PXF file but is required for the transformation, then the external file must be saved on the FlowForce Server. Since the external files will be accessed from the working directory (specified in the FlowForce job definition), they should be placed relative to the working directory, in such a way that links originating in the working directory will correctly access them.
- When a FlowForce job requiring a StyleVision transformation is executed, the job is passed to StyleVision Server, and StyleVision Server will extract the contents of the PXF file to the working directory that was specified in the job's parameters. To ensure that there is no filename collision when this extraction occurs, there should be no file in the working directory that has the same name as a file contained in the PXF file.

Before running the **Deploy to FlowForce** command, make sure that Altova FlowForce Server and Altova StyleVision Server are correctly licensed and running. See the Altova FlowForce documentation for more information about setting up FlowForce Server. (StyleVision Server is packaged with FlowForce Server.)

The Deploy command

The **Deploy to FlowForce** command pops up the Deploy Transformation dialog (*screenshot below*).

In this dialog, you specify the following:

- The address and port number of the FlowForce Web Server (not the FlowForce Server), together with access details (user and password) for the FlowForce Server.
- The filename of the transformation file and the location on the FlowForce Server where it is to be saved. The filepath must start with a slash, which represents the root directory of the FlowForce Server.
- If changes have been made to the design since the file was last saved, the Save design changes before deploying check box will be enabled. Check the box if you wish to save these changes; otherwise uncheck the box.
- To deploy the mapping through a SSL-encrypted connection, select the Use SSL check box. This
 assumes that FlowForce Server is already configured to accept SSL connections. For more
 information, refer to FlowForce Server documentation.

On clicking **OK**, the .transformation file is deployed to the FlowForce Server at the location specified. If you have checked the *Open web browser to create new job* check box (see screenshot above), the FlowForce Web Server interface is opened in a web browser, and the job created during the deployment step can be edited directly in the browser.

Multiple versions of StyleVision Server

If the server where you deploy the .transformation file has multiple versions of StyleVision Server running under FlowForce Server management (applicable to Windows servers only), then a *Select StyleVision Server* dialog appears, in which you are prompted to specify the version of Stylevision Server with which you want this mapping to be executed. You can select the version you want to use manually, or let the server select the most suitable version automatically.

This dialog appears when the FlowForce Server installation directory contains a .tool file for each StyleVision Server version which runs under FlowForce Server management. By default, a StyleVision Server .tool file is added automatically to this directory when you install StyleVision Server as part of a FlowForce Server

installation. The path where the .tool files are stored in FlowForce is: c:\Program
Files\Altova\FlowForceServer2025\tools. If you have additional versions of StyleVision Server which you want to run under FlowForce Server management, their .tool files may need to be copied manually to the directory above. The .tool file of StyleVision Server can be found at: c:\Program
Files\Altova\StyleVisionServer2025\etc.

Note: For information about how to work with FlowForce Server, see the <u>FlowForce documentation</u>.

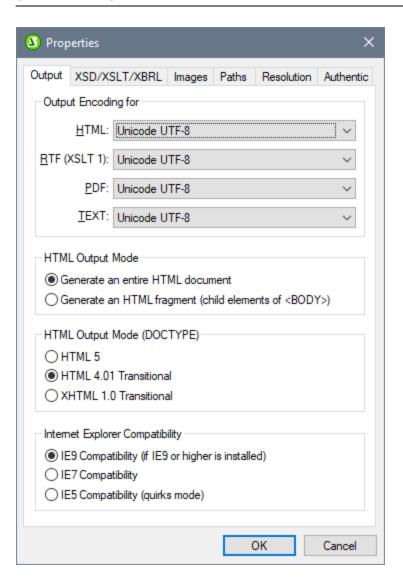

17.4.9 Web Design

The **Web Design** command rolls out a submenu containing the **Generate ASPX Web Application** command. This latter command generates all the files required to run an ASPX application, in the folder location you specify. A web browser will read the ASPX file that is the output document. C# code in this file will start a process whereby data in the source database or XML file will be transformed dynamically using an XSLT file in the ASPX package. The ASPX file (the output document of the transform process) will be updated with the latest data in the source database or XML file.

For more information, see <u>ASPX Interface for Web Applications</u> ⁶¹⁹.

17.4.10 Properties

The **Properties** command pops up the Properties dialog (*screenshot below shows the dialog in the Enterprise Edition*), in which you can set various properties for the active SPS.

Output

The following properties can be set in the Output tab:

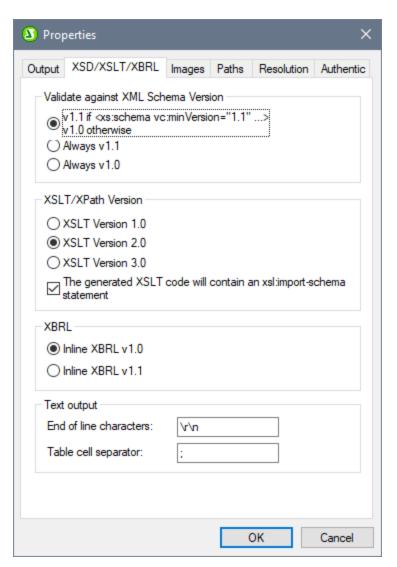

- **Output Encoding:** In the Output Encoding pane you can select the encoding of your output documents. Changing the encoding in this dialog changes the encoding for the currently active SPS. You can also specify the application-wide <u>default encoding</u> for all SPS documents in the Encoding tab of the Options dialog.
- **HTML output mode:** You can select whether an entire HTML document or only the child elements of the HTML body element are output. The child elements are output parallel to each other—that is, on the same level—and will contain all descendants recursively. As a result, the output documents can be fragments of HTML code. If multiple document output is enabled, HTML fragments can be created in separate documents..
- **HTML output mode (DOCTYPE):** You can select whether an HTML5, HTML 4.01 Transitional document, or XHTML 1.0 Transitional document is generated for the HTML output. This setting can be changed at any time while creating or editing the SPS document.

• Internet Explorer Compatibility and CSS support: CSS support in versions of Internet Explorer (IE) prior to IE 6 was incomplete and in some respects incorrectly interpreted. CSS support was enhanced and corrected in IE 6, and further improved and extended in IE 7, IE 9, and higher.

In an SPS, you can select the desired compatibility mode in the Properties dialog (*screenshot above*). You can select either IE 5, IE 7, or IE 9. (Note that for IE 9 compatibility to apply, IE 9 or higher must be installed.) The specified level of IE support is immediately available in Authentic View and HTML Preview. Note that new SPS documents are created with IE7 compatibility selected. SPS documents created in earlier versions of Altova StyleVision can be re-saved in the required Compatibility Mode (selected in the Properties along).

XSD/XSLT/XBRL

In this tab (screenshot below shows the dialog in the Enterprise Edition), you can specify which XSD validator to use for XML validation and which XSLT version to use in the SPS.

StyleVision has both an XSD 1.0 validator and an XSD 1.1 validator. You can choose from among the following options:

- Use the XSD 1.1 validator if the XSD document's /xs:schema/@vc:minVersion attribute is set to 1.1; otherwise use the XSD 1.0 validator.
- Always use the XSD 1.1 validator.
- Alawys use the XSD 1.0 validator.

Select the XSLT version for the active document in this tab. Checking the option about the xsl:import-schema statement causes the xsl:import-schema element of the XSLT 2.0 and 3.0 specifications to be included in the XSLT document generated by StyleVision. It is recommended that you select this option in order for datatypes to be read from the schema in the event that there is no xsi:schemaLocation attribute in the XML document.

If you use a design based on an XBRL schema source and the source data contains data that is selected for output as Inline XBRL 834, then the version of the Inline XBRL that is generated is that which is selected here.

For Text output, you can specify the following:

- The end-of-line characters to use. The default is \r\n (which indicates the carriage-return and linefeed characters on Windows systems).
- The character to indicate the end of a table cell. The default is the semicolon character.

Images

This tab provides settings for selecting the following:

- In the RTF and Word 2007+ output: Whether images are linked to or embedded.
- In HTML output: Whether images (currently chart, barcode and inline images) are embedded by means of the Data URI scheme.

These settings are made for each SPS individually, and they are available when the XSLT version of the SPS is either 2.0 or 3.0.

Embedding images in RTF and Word 2007+ output

To embed images, do the following:

- 1. With the required SPS active, open the Properties dialog (File | Properties).
- 2. Check the *Embed Images for RTF and Word 2007*+ check box (default setting is checked). Note that images will only be embedded if XSLT 2.0 or 3.0 is set as the XSLT version of the active SPS.
- 3. Click **OK** and save the SPS. The setting is saved for the active SPS.

If the *Embed Images* check box is not checked, images will be linked according to the image file path specified in the image's properties (select the image and select URL in the <u>Properties entry helper</u> 3). For information about how paths are resolved, see the section <u>Image URIs</u> 176.

This setting must be selected in order to save PXF files 622.

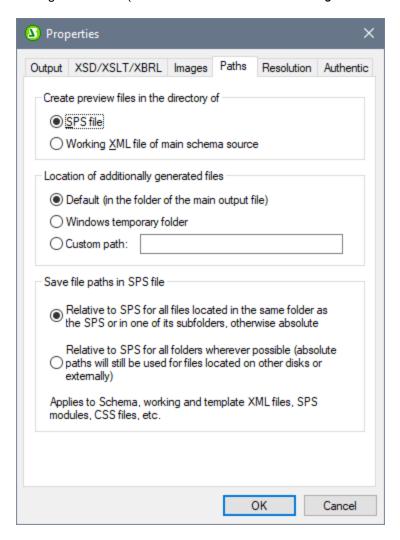

Note: The RTF format supports embedded images only for EMF, JPG, and PNG files.

Embedding images in HTML output

Chart, barcode, and inline images can be embedded in HTML output. If this checkbox is selected, the image data is converted to a Base64 string that is stored in the src attribute of the HTML img element using the Data URI scheme. This kind of embedding is available only when the XSLT version of the SPS is 2.0 or 3.0.

Paths

Default paths for various files created by the SPS file and for paths saved in the SPS file are specified in the settings of this tab (*screenshot below shows the dialog in the Enterprise Edition*).

The following defaults are set in the Paths tab:

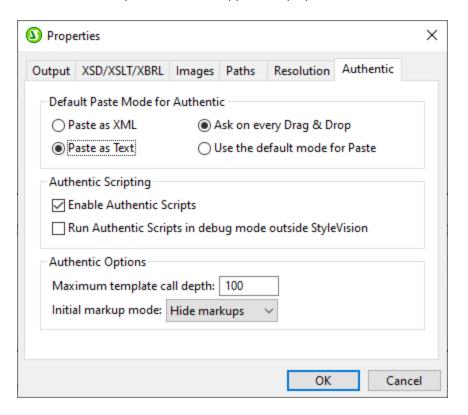

- Whether preview files are created in the directory of the SPS file or the Working XML File of the main schema source.
- Where additionally generated files (image files, barcode image files, chart image files, etc) are created.
- Whether file paths in the SPS are relative only when the target directory is in the directory tree of the SPS file, or relative even when the target directory is outside the directory tree of the SPS file.

Resolution

The resolution factor resolves how lengths that are specified as pixels in the design are to be converted to non-screen (print) units of length. You can select 72dpi, 96dpi, or 120dpi from the dropdown list of the combo box. The higher the dpi, the smaller will each pixel and the corresponding absolute length be. The conversion factors (for obtaining the number of points from the number of pixels) for each dpi are, respectively, 1.0, 0.75, and 0.6. For a complete explanation, see Pixel Resolution 512.

Authentic

The Authentic tab (screenshot below) provides properties for Authentic View:

Default paste mode for Authentic

Specifies whether an Authentic View selection that has been saved to the clipboard will be pasted, by default, as XML or text in Authentic View. If it is pasted as XML, it will be pasted with markup (XML tags), if the copied selection contains markup. Otherwise the default paste mode copies the text content of nodes without markup. The default paste mode can be overridden in Authentic View by right-clicking at the insertion point and, in the context menu that appears, selecting the command **Paste As | XML** or **Paste As | Text**, as required. The default paste mode can be changed at any time while editing the SPS document.

You can also specify whether, when text is dragged and dropped in Authentic View, the user is given the option of selecting how to paste the text or whether the default paste mode is used. To give the user the choice of deciding the past mode, select the radio button *Ask on every drag-and-drop*; to use the default paste mode without consulting the user, select the radio button *Use default mode for paste*.

Authentic scripting

These are options for scripts that are saved with an SPS: (i) Scripts can be enabled or not; (ii) Events in the scripts can be processed or can be disabled; (iii) Macros in the scripts can be run in debug mode from outside StyleVision (that is in the Authentic View of other Altova products) or can be disallowed. This feature is useful if you wish to test and debug a macro outside the StyleVision environment.

Authentic options

The *maximum template call depth* option specifies the maximum number of template calls that can be made recursively. If the number of calls exceeds the number specified here, an error is returned. This option can be used to prevent Authentic View from entering an unending loop.

The *Initial markup mode* option specifies the default markup mode of the active SPS.

17.4.11 Print Preview, Print

The Print Preview command is enabled in Design View and Authentic View (Authentic View is supported in the Enterprise and Professional editions only). The Print Preview command opens a window containing a preview of the SPS design (when Design View is active) or of the Authentic View of the Working XML File when Authentic View is active). The preview will show the design with or without tags according to what is on screen.

You can do the following in the Print Preview window, via the toolbar commands at the top of the page (*screenshot above*) and the page navigation icons at the bottom of the page. The commands in the Print Preview toolbar are as follows, starting from the left.

- Print the page using the Print button.
- Set paper orientation to portrait or landscape.
- Set page properties by clicking the Page Setup button to get the Page Setup dialog.
- Toggle on/off the display and printout of headers and footers.
- Set the view so that either the page width or page height occupies, respectively, the full screen width or full screen height.
- Set how many pages are to fit within the screen.
- Change the zoom factor of the preview pages using the Zoom In and Zoom Out buttons or the combo box to select a zoom factor.

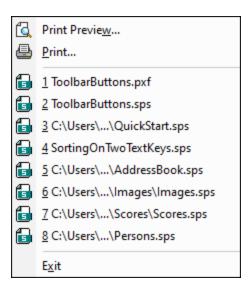

To navigate the pages of the preview, use the page navigation buttons at the bottom of the preview or by entering the page number in the Page text-box.

The Print command is enabled in the Authentic View and output preview tabs. It prints out the selected view of the Working XML File according to the page setup for that view. Note that the page setup for Authentic View can be edited in the Page Setup dialog, which you access via the Print Preview window.

Note: To enable background colors and images in Print Preview, do the following: (i) In the **Tools** menu of Internet Explorer, click **Internet Options**, and then click the Advanced tab; (ii) In the Settings box, under Printing, select the *Print background colors and images* check box, and (iii) Then click **OK**.

17.4.12 Most Recently Used Files, Exit

The list of most recently used files, shows the file name and path information for the nine most recently used files. Clicking one of these entries, causes that file to be opened in a new tab in the Main Window.

To access these files using the **keyboard**, press **ALT+F** to open the File menu, and then the number of the file you wish to open; for example, pressing **1** will open the first file in the list, **2** the second file, and so on.

The **Exit** command is used to quit StyleVision. If you have an open file with unsaved changes, you will be prompted to save these changes.

17.5 Edit Menu

The **Edit** menu contains commands that aid the editing of SPS and Authentic View documents. Besides the standard editing commands, such as **Cut** (Shift+Del or Ctrl+X), **Copy** (Ctrl+C), **Paste** (Ctrl+V), and **Delete** (Del), which are not described in this section, the following commands are available:

- Undo, Redo, Select All ⁹⁷⁹, to undo or restore your previous actions, and to select all content of the SPS.
- <u>Find, Find Next, Replace</u> ⁹⁷⁹, to find text in the SPS, Authentic View, and XSLT stylesheet previews, and to replace text in Authentic View.
- Collapse/Expand Markup 985, to collapse and expand SPS design component tags.

Commands are also available via the context menu which appears when you right-click a component or right-click at a cursor insertion point. Additionally, some commands are available as keyboard shortcuts and/or toolbar icons. Note, however, that commands which are not applicable in a particular document view or at a given location are grayed out in the menu.

17.5.1 Undo, Redo, Select All

The **Undo (Ctrl+Z)** command enables you to undo an editing change. An unlimited number of Undo actions is supported. Every action can be undone and it is possible to undo one command after another till the first action that was made since the document was opened.

The **Redo (Ctrl+Y)** command allows you to redo any number of previously undone commands. By using the Undo and Redo commands, you can step backward and forward through the history of commands.

The **Select All** command selects the entire contents of the Design Document window.

17.5.2 Find, Find Next, Replace

The **Find (Ctrl+F)** command enables you to find text strings in Design View, JavaScript Editor, Authentic View, and XSLT stylesheets.

The Find & Replace dialog that is displayed depends on which view is currently active.

- When Design View is active, clicking the Find or Replace command will set the focus to the Find & Replace sidebar 64. The search and replace functionality of Design View is described in the topic Find & Replace sidebar 64.
- The search and replace functionality in JavaScript Editor, Authentic View, and XSLT stylesheets is described in this topic.

XSLT stylesheets and JavaScript Editor

Clicking the **Find** command in the XSLT-for-HTML, XSLT-for-RTF, XSLT-for-PDF, XSLT-for-Word 2007+, or JavaScript Editor tab displays the following dialog:

You can select from the following options:

- Match case: Case-sensitive search when toggled on (Address is not the same as address).
- *Match whole word*: Only the exact words in the text will be matched. For example, for the input string fit, with *Match whole word* toggled on, only the word fit will match the search string; the fit in fitness, for example, will not be matched.
- Regular expression: If toggeld on, the search term will be read as a regular expression. See <u>Regular</u> expressions below for a description of how regular expressions are used.
- Find anchor: When a search term is entered, the matches in the document are highlighted and one of these matches will be marked as the current selection. The Find anchor toggle determines whether that first current selection is made relative to the cursor position or not. If Find anchor is toggled on, then the first currently selected match will be the next match from the current cursor location. If Find anchor is toggled off, then the first currently selected match will be the first match in the document, starting from the top.
- Find in selection: When toggled on, locks the current text selection and restricts the search to the selection. Otherwise, the entire document is searched. Before selecting a new range of text, unlock the currently selection by toggling off the Find in Selection option.
- Replace: In the JavaScript Editor tab, click the Down Arrow button, which is located at the top left of
 the dialog, to open the Replace field. Here you can enter the string that you want to substitute for the
 found string.

HTML Preview and Authentic View

Clicking the **Find** command in HTML Preview or Authentic View opens a simple Find and Replace 4 dialog.

Note the following:

- To match the entry with whole words, check "Match whole word only". For example, an entry of soft will find only the whole word soft; it will not find, for example, the soft in software.
- To match the entry with fragments of words, leave the "Match whole word only" check box unchecked. Doing this would enable you, for example, to enter soft and software.
- To make the search case-insensitive, leave the "Match case" checkbox unchecked. This would enable you to find, say, Soft with an entry of soft.
- In Authentic View, the dynamic data (XML data) is searched, not text from the static (XSLT) input.
- The **Replace** functionality in Authentic View is straightforward, enabling you to replace a chosen text string with another. Available options are: (i) the matching of whole words only (not words in the text that contain the searched-for string), and (ii) the matching of words that have the same casing as the searched-for string.

Find Next command

The **Find Next (F3)** command repeats the last Find command to search for the next occurrence of the requested text. See Find repeats the last Find command to search for the next occurrence of the requested text.

Using regular expressions

You can use regular expressions (regex) to find a text string. To do this, first, switch the *Regular expression* option on (*see above*). This specifies that the text in the search term field is to be evaluated as a regular expression. Next, enter the regular expression in the search term field. For help with building a regular expression, click the **Regular Expression Builder** button, which is located to the right of the search term field. Click an item in the Builder to enter the corresponding regex metacharacter/s in the search term field. See below for a brief description of metacharacters.

Regular expression metacharacters

Given below is a list of regular expression metacharacters.

•	Matches any character. This is a placeholder for a single character.		
(Marks the start of a tagged expression.		
)	Marks the end of a tagged expression.		
(abc)	The (and) metacharacters mark the start and end of a tagged expression. Tagged expressions may be useful when you need to tag ("remember") a matched region for the purpose of referring to it later (back-reference). Up to nine expressions can be tagged (and then back-referenced later, either in the Find or Replace field).		
	For example, (the) \1 matches the string the the. This expression can be literally explained as follows: match the string "the" (and remember it as a tagged region), followed by a space character, followed by a back-reference to the tagged region matched previously.		
\n	Where n is a variable that can take integer values from 1 through 9. The expression refers to the first through ninth tagged region when replacing. For example, if the find string is Fred([1-9]) xxx and the replace string is Sam\1 YYY, this means that in the find string there is one tagged expression that is (implicitly) indexed with the number 1; in the replace string, the tagged expression is referenced with \1. If the find-replace command is applied to Fred2xxx, it would generate Sam2YYY.		
\<	Matches the start of a word.		
\>	Matches the end of a word.		
\x	Allows you to use a character x , which would otherwise have a special meaning. For example, \setminus [would be interpreted as [and not as the start of a character set.		
[]	Indicates a set of characters. For example, [abc] means any of the characters a, b or c. You can also use ranges: for example [a-z] for any lower case character.		
[^]	The complement of the characters in the set. For example, [^A-Za-z] means any character except an alphabetic character.		
^	Matches the start of a line (unless used inside a set, see above).		
\$	Matches the end of a line. Example: A+\$ to find one or more A's at end of line.		
*	Matches 0 or more times. For example, Sa*m matches Sm, Sam, Saam, Saam and so on.		
+	Matches 1 or more times. For example, Sa+m matches Sam, Saam, Saaam and so on.		

Representation of special characters

Note the following expressions.

\r	Carriage Return (CR). You can use either CR (\r) or LF (\n) to find or create a new line
\n	Line Feed (LF). You can use either CR (\r) or LF (\n) to find or create a new line
\t	Tab character
\\	Use this to escape characters that appear in regex expression, for example: \\\n

Regular expression examples

This example illustrates how to find and replace text using regular expressions. In many cases, finding and replacing text is straightforward and does not require regular expressions at all. However, there may be instances where you need to manipulate text in a way that cannot be done with a standard find and replace operation. Consider, for example, that you have an XML file of several thousand lines where you need to rename certain elements in one operation, without affecting the content enclosed within them. Another example: you need to change the order of multiple attributes of an element. This is where regular expressions can help you, by eliminating a lot of work which would otherwise need to be done manually.

Example 1: Renaming elements

The sample XML code listing below contains a list of books. Let's suppose your goal is to replace the <category> element of each book to <Genre>. One of the ways to achieve this goal is by using regular expressions.

```
<?xml version="1.0" encoding="UTF-8"?>
<books xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
xsi:noNamespaceSchemaLocation="books.xsd">
  <book id="1">
     <author>Mark Twain</author>
     <title>The Adventures of Tom Sawyer</title>
     <category>Fiction</category>
     <year>1876
  </book>
   <book id="2">
     <author>Franz Kafka</author>
     <title>The Metamorphosis</title>
     <category>Fiction</category>
      <year>1912
  </book>
   <book id="3">
     <author>Herman Melville</author>
     <title>Moby Dick</title>
     <category>Fiction</category>
      <year>1851
   </book>
</books>
```

To solve the requirement, follow the steps below:

1. Press **Ctrl+H** to open the Find and Replace dialog box.

- 2. Click Use regular expressions
- 3. In the Find field, enter the following text: <category>(.+)</category> . This regular expression matches all category elements, and they become highlighted.

```
<?xml version="1.0" encoding="UTF-8"?>
                                                            <category>(.+)</category>
                                                                                                   ∨ | * | ×
      <books xmlns:xsi="http://www.w3.org/2001/XMLSc"</pre>
2
       books.xsd">
          <book id="1">
 3
                                                            Aa <u>Abc</u> ⋅* (♦ II <u>=</u>
                                                                                      1 de 3
                                                                                                  4 | ▶
             <author>Mark Twain</author>
 4
5
              <title>The Adventures of Tom Sawver</tit
 6
              <category>Fiction</category>
              <year>1876</year>
          </book>
8
          <book id="2">
9
10
              <author>Franz Kafka</author>
              <title>The Metamorphosis</title>
11
12
              <category>Fiction</category>
13
             <year>1912
14
          </hook>
15
          <book id="3">
16
             <author>Herman Melville</author>
              <title>Moby Dick</title>
17
18
             <category>Fiction</category>
19
             <year>1851</year>
20
           </book>
       </books>
21
```

To match the inner text of each element (which is not known in advance), we used the tagged expression (.+) . The tagged expression (.+) means "match one or more occurrences of any character, that is .+, and remember this match". As shown in the next step, we will need the reference to the tagged expression later.

- 4. In the Replace field, enter the following text: <genre>\1</genre> . This regular expression defines the replacement text. Notice it uses a back-reference \1 to the previously tagged expression from the Find field. In other words, \1 in this context means "the inner text of the currently matched <category> element".
- 5. Click **Replace All** and observe the results. All category elements have now been renamed to genre, which was the intended goal.

Example 2: Changing the order of attributes

The sample XML code listing below contains a list of products. Each product element has two attributes: id and a size. Let's suppose your goal is to change the order of id and size attributes in each product element (in other words, the size attribute should come before id). One of the ways to solve this requirement is by using regular expressions.

To solve the requirement, follow the steps below:

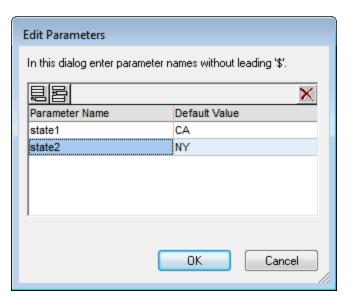

- 1. Press Ctrl+H to open the Find and Replace dialog box.
- 2. Click Use regular expressions **

```
<?xml version="1.0" encoding="UTF-8"?>
                                                          duct id="(.+)" size="(.+)"/>
                                                                                               ∨|| *|| ×|
    cproducts xmlns:xsi="http://www.w3.org/2001/XML
      products.xsd">
                                                          cproduct size="\2" id="\1"/>
                                                                                              te tap
         oduct id="1" size="10"/>
3
         oduct id="2" size="20"/>
                                                          Aa <u>Abc</u> •* ♦ I <u>=</u>
                                                                                  2 of 6
                                                                                              4
         oduct id="3" size="30"/>
5
         cproduct id="4" size="40"/>
7
         oduct id="5" size="50"/>
8
         cproduct id="6" size="60"/>
9
      </products>
```

6. Click **Replace All** and observe the results. All product elements have now been updated so that attribute size comes before attribute id.

17.5.3 Stylesheet Parameters

The **Stylesheet Parameters** command enables you to declare and edit parameters and their default values. The command is available in both the Design Document view and the Authentic Editor View. When you click this command, the Edit Parameters dialog (*shown below*) pops up.

985

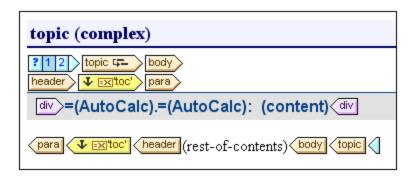

The following points should be noted:

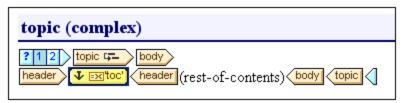

- You can insert, append, edit and delete parameters for the entire stylesheet and for the DB Filters.
- Parameter names must begin with a letter, and can contain the characters A to Z, a to Z, 0 to 9, and the underscore.
- The Edit Parameters dialog contains all the user-defined parameters in an SPS.
- Parameters can also be declared in the <u>Design Overview sidebar</u> 45.

17.5.4 **Collapse/Expand Markup**

The Collapse/Expand Markup command is a toggle command, which collapses and expands the selected tag. It can be applied to any kind of tag: node, predefined format, SPS mechanism, etc. To collapse/expand a tag, double-click the tag; the end tag of an expanded tag may also be double-clicked to collapse that tag.

The screenshots below show how a series of tags are collapsed. Double-clicking a collapsed tag expands it.

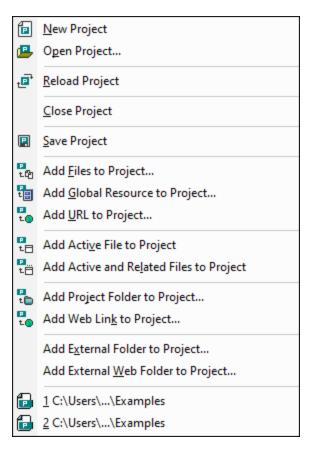

Collapsing a tag can be useful for optimizing the display according to your editing needs.

17.6 **Project Menu**

The Project menu (screenshot below) enables you to create, structure, and modify projects. You can quickly set up a project, specify files in the project, and organize files by file type into separate folders. A project is displayed graphically in the Project sidebar, from where files can be accessed for use in the SPS design.

The **Project** menu contains the following commands, which are explained in detail in the sub-sections of this section:

- New Project 988, for creating a new project
- Open Project 988, for opening an existing project
- Reload Project 933, for refreshing a project in the Projects sidebar Close Project 933, for closing a project in the Project sidebar
- Save Project 988, for saving and naming a project
- Add Files to Project 989, for adding files to a project in the Project sidebar
- Add Global Resource to Project (889), for adding Altova Global Resources to a project in the Project
- Add URL to Project 989, for adding a file via a URL to a project in the Project sidebar
- Add Active File to Project (991), for adding the currently active SPS file to a project
- Add Active and Related Files to Project [991], for adding the currently active SPS file and its related
- Add Project Folder to Project 991, for adding folders to a project in the Project sidebar
- Add External Folder to Project 991, for adding local folders to a project in the Project sidebar
- Add External Web Folder to Project 991, for adding folders via URL to a project in the Project sidebar

Recent projects

At the bottom of the Project menu, the file names of the nine most recently used projects are listed, thus allowing quick access to these files.

Drag-and-drop

In the Project window, a folder can be dragged to another folder or to another location within the same folder. A file can be dragged to another folder, but cannot be moved within the same folder (within which files are arranged alphabetically). Additionally, files and folders can be dragged from Windows File Explorer to the Project sidebar.

17.6.1 New Project, Open Project, Reload Project

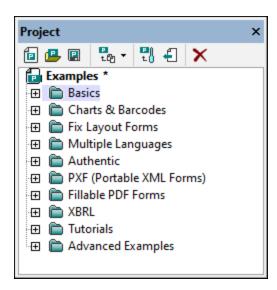

The **New Project** command creates a new project. The new project replaces the previous project (if any) in the Projects sidebar. If the project you have been working on has unsaved changes, a prompt appears asking whether you wish to save changes to the project. Note that the **New Project** command only creates a new project without saving it; you have to explicitly save the project using the **Save Project** command.

The **Open Project** command opens an existing project and displays it in the Projects sidebar. If a project was previously open in the Projects sidebar, it is replaced by the opened project. If the previous project has unsaved changes, a prompt appears asking whether you wish to save changes to that project before it is replaced in the Projects sidebar.

The **Reload Project** command reloads the current project. This command is especially useful if you are working in a multi-user environment, where other users might make changes to the project.

17.6.2 Close Project, Save Project

The **Close Project** command closes the active project. If the project contains unsaved changes, a prompt appears asking whether you wish to save the project before closing it. A project with unsaved changes is indicated with an asterisk after the project name in the Project sidebar (*screenshot below*).

The **Save Project** command saves the current project. Note that it is when a project is saved for the first time that it is named. A project can only be renamed outside StyleVision; for example, by using Windows File Explorer to locate and rename the file.

17.6.3 Add Files / Global Resource / URL to Project

Add Files to Project

The **Add Files to Project** command adds files to the current project. The command pops up an Open dialog box, in which you select a single file or a group of files to add to the project. The file/s will be added to subfolders within the project folder according to the file type extensions defined for each sub-folder. If the same file type extension has been defined for more than one folder, then a file with that file type extension will be added to the first folder (in the Projects sidebar) having that file type extension.

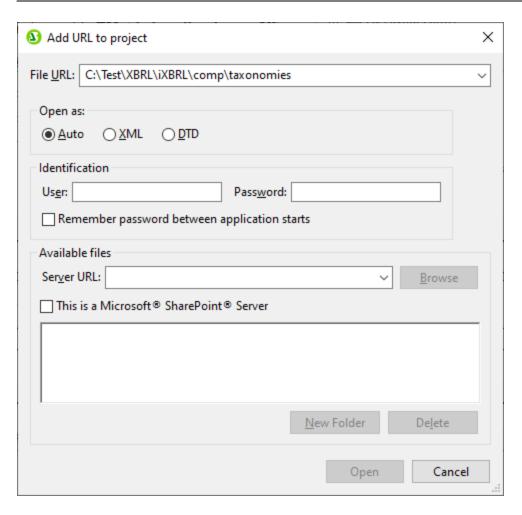

To add a file to a folder or sub-folder within the main project folder, right-click that folder, select the command **Add Files**, and then browse for the required file/s.

Add Global Resource to Project

The **Add Global Resource to Project** command pops up a dialog that lists global resources in the currently active Global Resources XML File and enables you to select one of these resources to add to the active project. Select the required global resource and click **OK**.

Add URL to Project

The **Add URL to Project** command adds a URL to the current project. URLs in a project cause the target object of the URL to be included in the project. The command pops up the Add URL to Project dialog (screenshot below).

You can enter either a file URL (with or without the file: \\ protocol) or a server URL. For the server URL, enter your user name and password, then enter the server URL. Click **Browse** to connect to the server, then, from the list that appears in the Available Files display, click the file you wish to add to the project folder.

Note that URLs can also be added to folders and sub-folders of the main project folder. To do this, right-click the project folder and select the command **Add URL**. This pops up the Add URL dialog. Proceed as described above.

Drag-and-drop

A file can be dragged to another folder, but cannot be moved within the same folder (within which files are arranged alphabetically). Additionally, files can be dragged from Windows File Explorer to the Project window.

Deleting Files, Resources, and URL

To delete a file, Altova Resource, or URL, select that object in the Project sidebar, right-click, and, from the context menu, select **Delete**.

17.6.4 Add Active (and Related) Files to Project

Add Active File to Project

The Add Active File to Project command adds the active SPS file to the current project. This file is added to the first folder defined for the .sps file type extension. If you wish to add not just the SPS but the related schema, Working XML, Template XML, CSS and image files, use the Add Active and Related Files to **Project** command (see below). To add the active file to a folder or sub-folder within the main project folder. right-click that folder, select the command Add Active File.

Add Active and Related Files to Project

The Add Active and Related Files to Project command adds the currently active SPS file as well as the related schema files, and, if any, the Working XML, Template XML, CSS and image files. Each file is added to the first folder defined for that particular file type extension. To add the active file and related files to a folder or sub-folder within the main project folder, right-click that folder, select the command Add Active and Related Files.

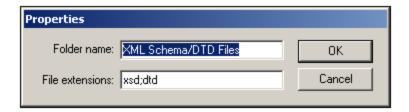

Deleting Files

To delete a file, select the file in the Project sidebar, right-click, and, from the context menu, select Delete.

Add Project and External Folders to Project 17.6.5

Add Project Folder to Project

The Add Project Folder to Project command adds a new folder to the current project. When you click the command, the Properties dialog (screenshot below) pops up, in which you enter the name and file type extensions for the folder (file type extensions are separated by a semi-colon). When a file having the file type extension defined for the folder is added to the project, the file will automatically be added to this folder. The newly added project folder is appended to the list of project folders in the Project sidebar.

To create a sub-folder of any given project folder, right-click the folder for which the sub-folder is required. In the context-menu that pops up, select Add Project Folder. In the Properties dialog, enter the folder name and the file type extensions for the folder.

Add External Folder to Project

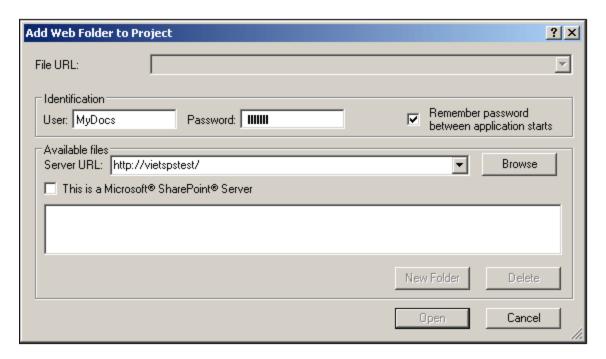

The Add External Folder to Project command adds a new external folder to the current project. The command adds a local or network folder, with all its contents, to the current project. The added external folder can be expanded and collapsed. To add an external folder to a project folder as a sub-folder, right-click the project folder and, from the context menu, select the command Add External Folder.

Add External Web Folder to Project

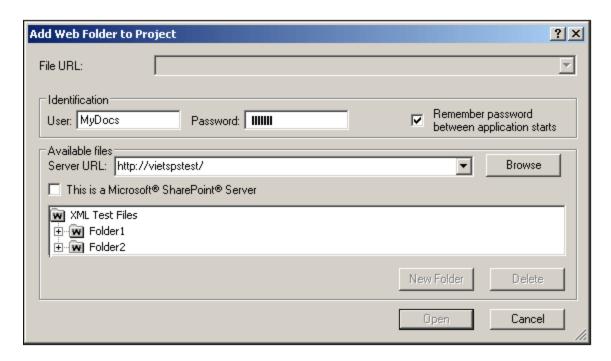

The **Add External Web Folder to Project** command adds a new external folder via a URL to the current project. The added external folder can be expanded and collapsed. To add an external web folder to a project folder as a sub-folder, right-click the project folder and, from the context menu, select the command **Add External Web Folder**.

On clicking the command, the Add Web Folder dialog pops up (screenshot below). Do the following:

1. Click in the Server URL field to enter the server URL, and enter the login ID in the User and Password fields

2. Click **Browse** to connect to the server and view the folders available there.

- 3. Click the folder you want to add to the project view. The **OK** button only becomes active once you do this. The folder name and server URL now appear in the File URL field.
- 4. Click **OK** to add the folder to the project.
- 5. Click the plus icon to view the folder contents.
- 6. To define the file types to display for the web folder, right-click, select **Properties** from the context menu, and enter the required file type extensions.

Drag-and-drop

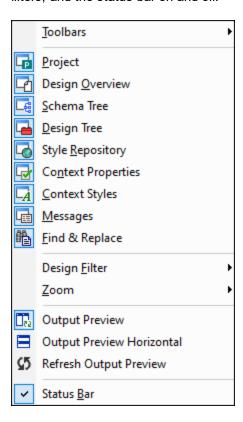

In the Project window, a folder can be dragged to another folder or to another location within the same folder. Additionally, folders can be dragged from Windows File Explorer to the Project window.

Deleting Folders

To delete a folder or multiple folders, select the file in the Project sidebar, right-click, and, from the context menu, select **Delete**.

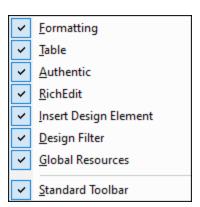

17.7 View Menu

The **View** menu (*screenshot below*) enables you to change the look of the GUI and to toggle on and off the display of GUI components. You can switch the display of individual toolbars, individual design sidebars, design filters, and the status bar on and off.

17.7.1 Toolbars and Status Bar

Placing the cursor over the **Toolbars** item pops out a submenu (*screenshot below*), which enables you to turn on and off the display of the different toolbars.

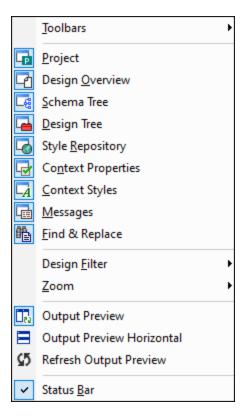

When a toolbar is checked, it is displayed. In the screenshot above all the toolbars are displayed. To toggle on or off the display of a toolbar, click the appropriate toolbar. For a complete description of toolbars, see the section Reference | Toolbars 934.

Status Bar

The display of the Status Bar, which is located at the bottom of the application window, can be switched on or off by clicking the **Status Bar** toggle command.

17.7.2 Design Sidebars

The **View** menu contains toggle commands to switch the display of each sidebar on and off (*screenshot below*).

When a sidebar is toggled on (the command's icon is framed) it is displayed in the GUI. Click a sidebar to set its display on or off, as required. This command is also used to make a hidden sidebar visible again. The display setting specified for a sidebar is View-specific: a setting made in a particular View (Design View, Authentic View, Output View, no document open) is retained for that particular View till changed.

17.7.3 Design Filter, Zoom

Design Filter

The **Design Filter** menu item rolls out a sub-menu containing commands that enable you to filter the templates that are displayed in Design View. This is useful if your design is very long or contains several templates. Using the Design Filter mechanism, you can specify what kinds of template to display. The following filter options are available:

Icon	Command	Description
Ġ	Show only one template	Shows the selected template only. Place the cursor in a template and click to show that template only.
	Show all template types	Shows all templates in the SPS (main, global, named, and layout) .
	Show imported templates	Toggles the display of imported templates on and off.
<u> </u>	Show/Hide main template	Toggles the display of the main template on and off.
	Show/Hide global templates	Toggles the display of global templates on and off.
	Show/Hide Design Fragments	Toggles the display of Design Fragments on and off.

Note that these commands are also available as toolbar icons in the <u>Design Filters</u> ⁹⁴³ toolbar.

Zoom

The **Zoom** command enables you to select a Zoom factor from the submenu that rolls out. You can also zoom in or out by changing the Zoom factor in the Zoom combo box (in the Standard toolbar), or by pressing the **Ctrl** key and scrolling with the mouse.

17.7.4 Output Previews

There are three Output Preview commands:

- Output Preview, which switches Output Preview on/off
- Output Preview Horizontal, which is enabled when Output Preview has been switched on. The
 command switches from a vertical split view to a horizontal split view. When the output preview
 becomes available in a horizontal split, the command automatically changes to Output Preview
 Vertical, which switches the split view back to a vertical split view.
- **Refresh Output Preview**, which immediately refresh the output preview with any changes in the design or Authentic View.

17.8 Insert Menu

The **Insert** menu provides commands enabling you to insert a variety of design components into the SPS. Some of these commands are available as <u>toolbar icons</u> Additionally, **Insert** menu commands are also available via **context menus** which appear when, in the SPS design, you right-click a cursor insertion point. In the context menus, commands that are not available at that location in the SPS are disabled.

Note: Since the **Insert** commands are used for constructing the SPS, they are available in Design View only.

17.8.1 Contents

The **Contents** command inserts a (content) placeholder at the cursor location point. There (content) placeholder can be inserted within two types of node, **element** and **attribute**, and it indicates that all children of the current node will be processed.

- If the current node is an element node, the node's children element nodes and text nodes will be processed. For the processing of children element nodes, global templates will be used if these exist. Otherwise the built-in template rule for elements will be used. For the processing of text nodes, the built-in template rule for text nodes will be used, the effect of which is to output the text. Effectively, the built-in template rule for elements, outputs the text of all descendant text nodes. It is important to note that the values of attributes will not be output when the (content) placeholder is used—unless a global template is defined for the attribute's parent element or one of its ancestors and the attribute is explicitly output, using either the (content) placeholder or any other content-rendering component.
- If the current node is an attribute node, the built-in template rule for the attribute's child text node will be used. This template copies the text of the text node to the output, effectively outputting the attribute's value.

The (content) placeholder can also be inserted for a node by placing the cursor inside the node tags, right-clicking, and selecting **Insert | Contents** or by clicking the **Insert Contents** icon in the <u>Insert Design Elements</u> toolbar (and then clicking the location in the design where the element is to be inserted.

Styling the contents

The (content) placeholder can be formatted by selecting it and using a predefined format and/or properties in Styles sidebar. This formatting is visible in the design, and, in the output, it will be applied to the contents of the node.

Replacing contents

If another node from the schema tree is dropped into a node containing a (content) placeholder, then the existing (content) placeholder is replaced by the new node.

Deleting contents

The (content) placeholder can be deleted by selecting it and pressing the Delete key on the keyboard.

Note: You can create an **empty template rule** by deleting the (content) placeholder of a node. An empty template rule is useful if you wish to define that some node have no template applied to it, i.e. produce no output.

17.8.2 Rest of Contents

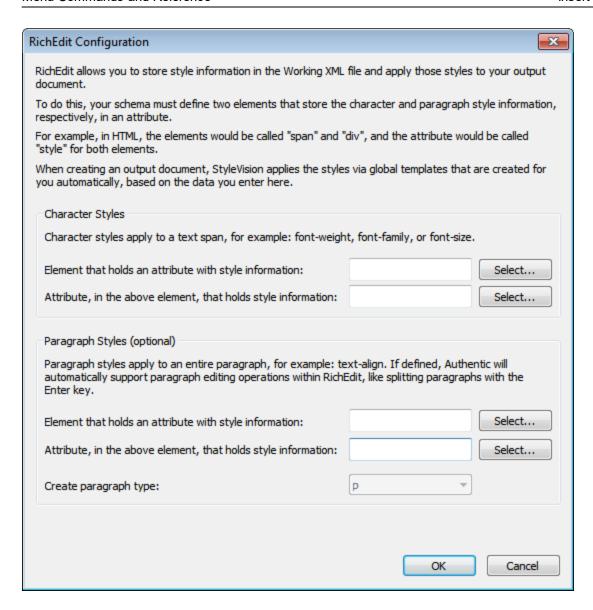

The **Rest of Contents** command inserts the (rest-of-contents) placeholder for that node. This placeholder represents the content of **unused child nodes** of the current node; it corresponds to the xsl:apply-templates rule of XSLT applied to the unused elements and text nodes of the current element. Note that templates are not applied for child attributes. The (rest-of-contents) placeholder can also be inserted for an element by placing the cursor inside the element tags, right-clicking, and selecting **Insert Rest of Contents**.

Use the (rest-of-contents) placeholder in situations where you wish to process one child element in a specific way and apply templates to its siblings. It is important to apply templates to siblings in order to avoid the possibility that the siblings are not processed. This enables you to reach elements lower down in the document hierarchy.

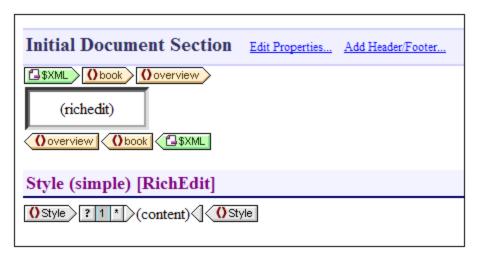

The (rest-of-contents) placeholder can be deleted by selecting it and pressing the **Delete** key on the keyboard.

17.8.3 RichEdit

The **RichEdit** command inserts a RichEdit component at the cursor location. For the first RichEdit component, the RichEdit Configuration dialog (*screenshot below*) pops up. This RichEdit configuration is valid for all RichEdit components in the document. As a result, for RichEdit components inserted subsequently, the RichEdit Configuration dialog does not appear.

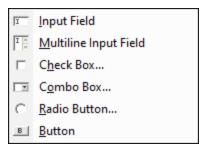

In the RichEdit Configuration dialog, enter the name of the styling element and its attribute that is to contain the RichEdit styling properties. You can also select the required element and attribute from the schema tree. Click the respective **Select** buttons to open the schema tree. When done, click **OK**. The RichEdit component is created (see screenshot below), and an **uneditable** RichEdit global template having the name of the styling element (Style in the screenshot below) is created in the design.

For more information about the RichEdit feature in context, see <u>Text-Styling Flexibility in Authentic</u> 483.

17.8.4 Form Controls

Mousing over the **Form Controls** command rolls out a submenu (*screenshot below*) containing commands to insert various form controls (<u>data-entry devices</u> (2005).

How to create each of these form controls is described in the section <u>Using Data-Entry Devices</u>. After a form control has been created, its properties can be edited by selecting it and then editing the required property in the <u>Properties sidebar</u>.

Form controls can also be inserted in the design by right-clicking at the insertion point and selecting **Insert | Form Controls**, or by clicking the respective Form Control icon in the <u>Insert Design Elements toolbar</u> and then clicking the location in the design where the element is to be inserted.

Note: CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). CDATA sections can only be entered within elements that are displayed in Authentic View as text content components.

17.8.5 DB Control

Mousing over the **DB Controls** command rolls out a submenu containing commands to insert controls in Authentic View that enable the Authentic View user to navigate the display of records in Authentic View and to

query the DB. These control can be inserted in the design and will appear in the Authentic View document at the corresponding locations.

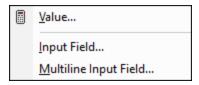

The list of commands is as follows.

- Navigation
- Navigation + Goto
- Query Button

For details about how these controls are created and what they do, see the section <u>SPS Design Features for DB</u> 715.

17.8.6 Auto-Calculation

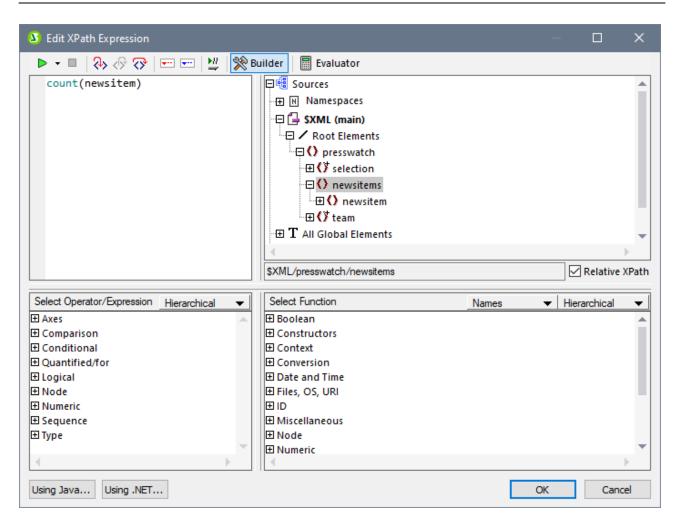

An **Auto-Calculation** uses an XPath expression to calculate a value. This value is displayed at the point where the Auto-Calculation is inserted. An Auto-Calculation can be inserted in the SPS as a text value, input field, or multiline input field. Place the cursor at the location where the Auto-Calculation is to be inserted, then either right-click or use the command in the **Insert** menu. When the cursor is placed over **Insert | Auto-Calculation**, a menu pops out (*screenshot below*), enabling you to choose how the Auto-Calculation should be inserted. Alternatively, you can use the Auto-Calculation icon in the <u>Insert Design Elements toolbar</u> (40).

The value of the Auto-Calculation will be displayed accordingly in Authentic View and the output document.

The XPath expression for the Auto-Calculation

On selecting how the Auto-Calculation should be represented, the Edit XPath Expression dialog (screenshot below) pops up.

The context node for the expression being built is highlighted in the schema tree in the pane at extreme left. You can enter the XPath expression directly in the text box, or you can double click an item (in any of the three panes) to insert that item. Nodes inserted from the schema tree in the left-hand pane are inserted relative to the context node (if the *Relative XPath* check box is checked) or as an absolute expression starting from the document node (if the *Relative XPath* check box is unchecked).

After completing the XPath expression, click **OK** to finish inserting the Auto-Calculation.

Updating an XML node with an Auto-Calculation

A node in an XML document can be updated with the result of an Auto-Calculation. How to do this is described in the section, <u>Updating Nodes with Auto-Calculations</u> 374.

17.8.7 Date Picker

The **Date Picker** command inserts a Date Picker at the current cursor position. It will be enabled only when the cursor is within an xs:date or xs:dateTime node and if the element has been created as (contents) or an input field.

17.8.8 Paragraph, Special Paragraph

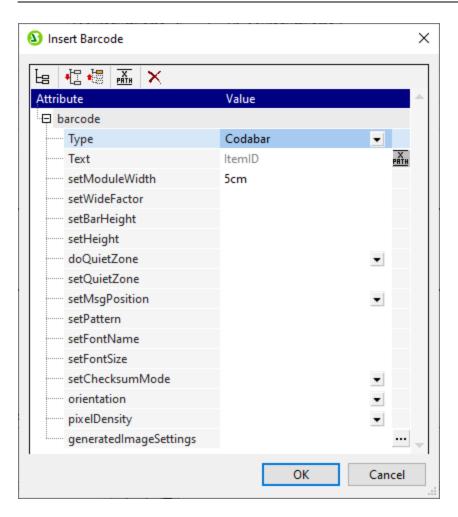

The **Paragraph** command inserts an HTML paragraph element around the selected component. A component is considered selected for this purpose when the entire node is selected (by clicking either of its tags) or when static text is selected. If the cursor is placed within static text, the paragraph element is inserted (start and end tags) at this point. A paragraph can also be inserted by using the **Insert Paragraph** icon in the Insert Design Elements toolbar.

The **Special Paragraph** command allows you to assign a predefined format to the selected node. The available predefined formats can also be selected from the combo box in the toolbar.

Each paragraph type has particular formatting features that can be used to advantage. Note that the pre format type enables carriage returns to be output as such instead of them being normalized to whitespace.

17.8.9 **Barcode**

The Insert Barcode command pops up the Insert Barcode dialog (screenshot below).

Two properties, *Type* and *Text*, are mandatory; the others are optional and/or have appropriate default values. After entering values for the mandatory properties and any other properties you wish to set, click **OK**. The barcode you have specified (such as that for the ISBN shown below) will be inserted in the design. For detailed information about the various barcode properties, see the section, <u>Barcodes</u> 274.

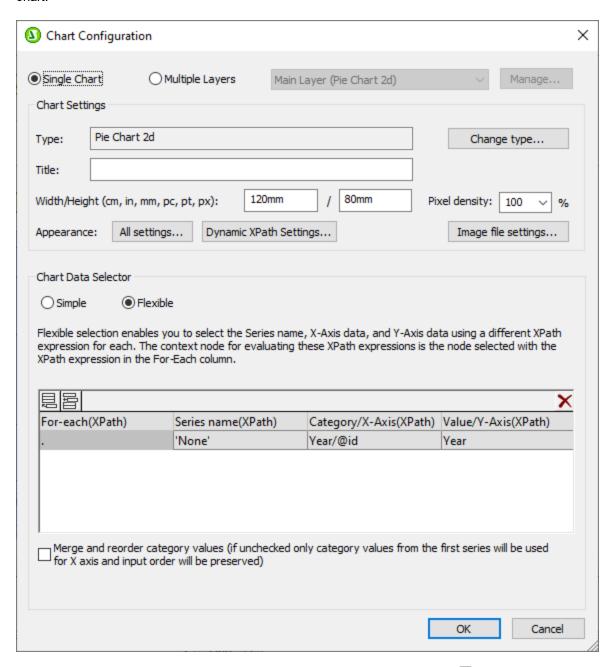

Important: For barcodes to work, a Java Runtime Environment must be installed. This must be version 1.4 or later in a bit version that corresponds to the bit version of the StyleVision package installed on your system: 32-bit or 64-bit.

Important: For barcodes to be generated in the output, you must use Altova's XSLT processor to generate the output. This is because the barcodes in an SPS are generated by calling special Java extension functions that are not part of the XSLT standard. Altova's XSLT processors support these specific extension functions, whereas other XSLT processors very probably do not. As a result, barcodes will not be generated if processed with a non-Altova XSLT processor. The Altova XSLT processor is packaged with StyleVision, and is automatically called when you generate output via the **Generate** commands in the **File** menu. Alternatively, you can use RaptorXML Server, which is a Altova's standalone XSLT processor.

17.8.10 Chart

The **Insert Chart** command pops up the Chart Configuration dialog (*screenshot below*), in which you can specify the settings for the chart and make the data selection that determines what data is represented in the chart.

For a detailed description of how to work with charts, see the section Charts (182).

17.8.11 Image

The **Image** command pops up the Insert Image dialog (see screenshots below), in which you can specify the image to insert. The **Insert Image** icon in the <u>Insert Design Elements toolbar</u> also pops up the Insert Image dialog.

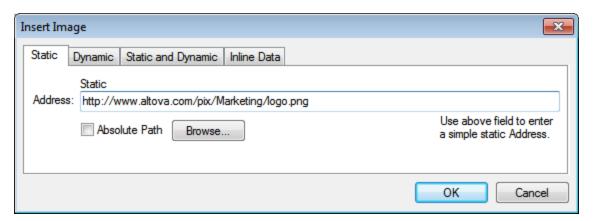

The Insert Image dialog has four tabs, each of which provides a different way to specify the image location. These are:

- Static: for entering the image URI directly
- Dynamic: for obtaining the image URI from the XML document or generating it with an XPath expression
- Static and dynamic: for combining the static and dynamic methods
- Inline data: for selecting an image that is stored in an XML file as Base-16 or Base-64 encoded text

The tabs are described in detail below.

Static

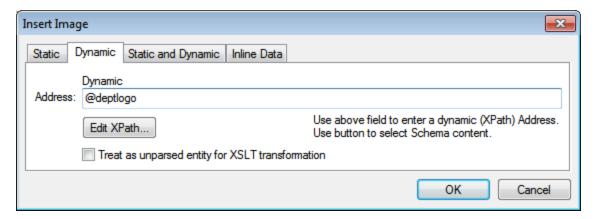

The image URI is entered directly in the *Address* field (see screenshot below). In the screenshot below the image URI is: http://www.altova.com/pix/Marketing/logo.png.

You can specify whether the URI is absolute (*Absolute* check box checked) or relative (*Absolute* check box unchecked). If a relative URI is entered, it will be resolved relative to the SPS file location. To enter the (absolute or relative) URI automatically, click **Browse** and browse for the image file.

Dynamic

An XPath expression returns the image URI. In the screenshot below, the XPath expression is <code>@deptlogo</code>. This assumes that the image URI is stored in the <code>deptlogo</code> attribute of the context node. The context node is the node within which the image is being created.

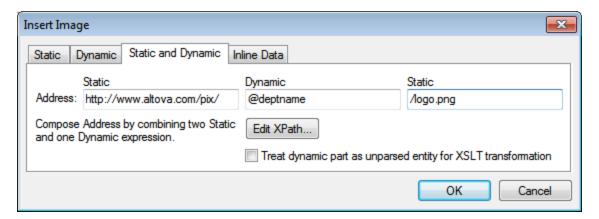

Click the **Edit XPath** button to pop up the <u>XPath Expression Builder</u> (929). In the schema tree of the XPath Expression Builder, the context node will be highlighted.

If the SPS is DTD-based and uses **unparsed entities**, then, an unparsed entity that references the image URI can be used. First, check the *Treat as unparsed entity* checkbox. Then enter an XPath expression that selects the node containing the unparsed entity. For details of how to use unparsed entities, see <u>Unparsed Entity</u> URIs

Static and Dynamic

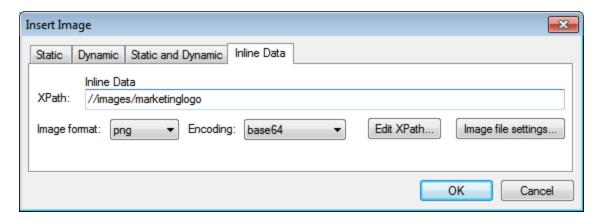

Use both the static and dynamic mechanisms together to generate the URI.

If the deptname attribute of the context node has a value of Marketing, then the image URI composed in the screenshot above will be: http://www.altova.com/pix/Marketing/logo.png. Note that you can use the XPath Expression Builder [929] for the dynamic part.

Inline data

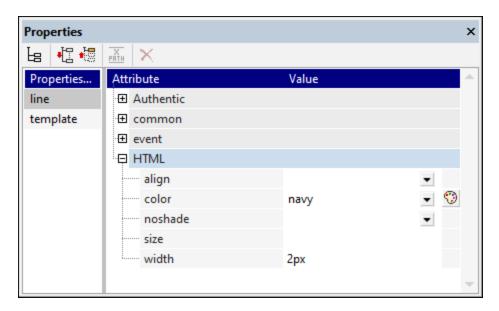

An image can be stored in an XML file as Base-16 or Base-64 encoded text. The XPath expression in the Insert Image dialog (see screenshot below) selects the node containing the encoded text. The Encoding combo box specifies the encoding used in the source XML so that StyleVision can correctly read the encoded text. And the Image Format combo box indicates in what format the image file must be generated. (An image file is generated from the encoded text data, and this file is then used in the output document.)

The Image File Settings dialog (accessed by clicking the **Image File Settings** button) enables you to give a name for the image file that will be created. You can choose not to provide a name, in which case StyleVision will generate a name.

17.8.12 Horizontal Line

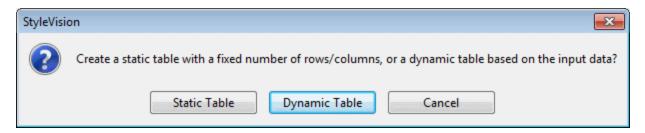

The **Horizontal Line** command inserts a horizontal line at the cursor insertion point. This command is not available when an SPS component is selected. To set properties for the horizontal line, select the line in the design, and in the Properties sidebar, select *line*, and specify values for properties in the *HTML* group (see screenshot below).

You can specify the following properties for the line: its color, size (thickness), width (in the design), alignment, and the noshade property.

17.8.13 Table

The Insert Table command pops up the Create Table dialog (screenshot below).

According to whether you wish to create a static table or a dynamic table, select the appropriate button. How to proceed with each type of table is described in the section: <u>Static SPS Tables</u> and <u>Dynamic SPS</u> Tables 153.

Note that tables can also be created by using the **Table** | **Insert Table** menu command and the **Insert Table** icon in the Insert Design Elements toolbar.

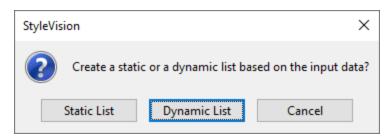

17.8.14 Bullets and Numbering

The **Bullets and Numbering** command allows you to create a list, either static or dynamic. The list items of a static list are entered in the SPS, while those of dynamic lists are the values of sibling nodes in the XML document.

To create a list do the following:

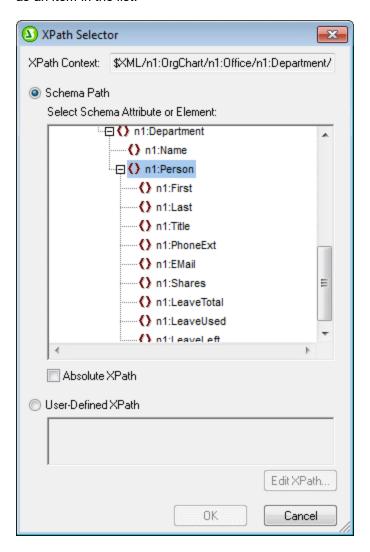

Place the cursor at the location where you wish to insert the list and click the **Bullets and** Numbering command. This pops up a dialog asking whether you wish to create a static list or dynamic list (screenshot below).

If you click **Static List**, the Bullets and Numbering dialog described in Step 3 pops up. If you click **Dynamic List**, the XPath Selector dialog pops up (*screenshot below*).

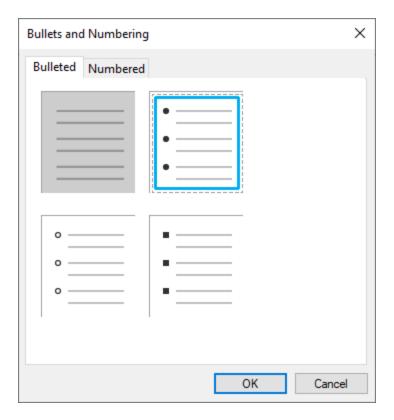

2. In the XPath Selector dialog, notice that the XPath Context is the context of the insertion location, and that it cannot be changed in the dialog. Select the node that is to be created as the dynamic list. In the screenshot below, the context node is n1:Department, and the n1:Person node has been selected as

the node to be created as a list. This means that the content of each n1:Person node will be created as an item in the list.

If you select the User-defined XPath option, then you can enter an XPath expression to select the node to be created as the dynamic table. Clicking **OK** pops up the Bullets and Numbering dialog described in the next step.

3. In the the Bullets and Numbering dialog, select the kind of list you wish to create. You can choose from a bulleted list (with a bullet, circle, or square as the list item marker), or a numbered list. Clicking **OK** creates the list with the type of list item marker you selected.

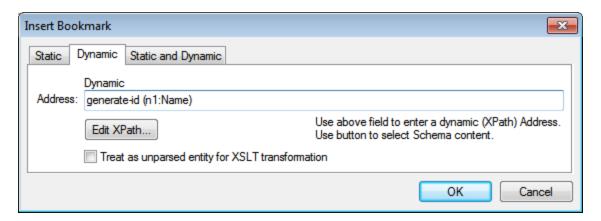

Note: A static list can also be created by placing the cursor at the location where the list is to be created and then clicking the Bulleted List icon or Numbered List icon in the <u>Insert Design Elements toolbar</u> as required. A dynamic list can also be created by dragging a node from the Schema Tree into the design.

17.8.15 **Bookmark**

The **Bookmark** command allows you to insert a bookmark (or anchor) anywhere in the SPS. A bookmark can be referenced by a <u>Hyperlink</u> 1012.

To insert a bookmark, do the following:

- 1. Place the cursor at the location where you wish to create the bookmark.
- 2. Select **Insert | Bookmark**, or right-click and select **Insert | Bookmark**. The Insert Bookmark dialog appears.

- 3. In the Insert Bookmark dialog (40), select a tab according to whether the name of the bookmark should be static (Static tab), dynamically obtained from the XML document (Dynamic), or composed of both static and dynamic parts (Static and Dynamic). In the screenshot above a dynamic bookmark is created, which has a name that is a unique ID for each Name child of the context node.
- 4. Click **OK**. The bookmark is defined.

Note: Bookmarks are created at the location specified in the design. If that location is within an element that repeats, a bookmark is created within each instance of that repeating element. If a static name is given, then each bookmark will have the same name. Therefore, it is better in such cases (of repeating elements) to give a dynamic name, which can be, for example, the name of a child element of the context node (the element within which the bookmark is created). If the node selected for the dynamic name might have the same content across multiple instances, then the uniqueness of the bookmark name can be ensured by using the generate-id() function to generate the name (see screenshot above). To reference such a bookmark, the same ID can be generated as the href value of a hyperlink (In this case make sure you use the fragment-identifier # in front of the generate-id() function. The XPath expression would be: concat('#', generate-id(nodeXXX)).

You can edit the name of a bookmark after it has been created. Do this by right-clicking the bookmark and selecting the **Edit Bookmark Name** command from the context menu that appears. Alternatively, in the Properties sidebar, in the *Bookmark* group of properties for the bookmark, you can click the **Edit** button of the bookmark name attribute and make the required changes.

Deleting a bookmark

To delete a bookmark, select it in the design and press the **Delete** key.

17.8.16 Hyperlink

The **Hyperlink** command enables you to insert a link from any part of the output document (HTML, RTF, PDF, or Word 2007+) to an anchor within the output document or to an external document or document fragment. Note that links are created only in the output document; linking is not available in Authentic View.

To insert a hyperlink, do the following:

- 1. A hyperlink can be created around an existing design component or inserted at any point in the document (with the link text inserted subsequently). Select the SPS component or text fragment to be made into a hyperlink or place the cursor at the point where the link is to be inserted.
- 2. Click the Hyperlink icon in the toolbar, or select **Insert | Hyperlink**, or right-click and select **Insert | Hyperlink** (when no design component is selected) or **Enclose With | Hyperlink** (when a design component is selected). A hyperlink can also be inserted by using the **Insert Hyperlink** icon in the <u>Insert Design Elements toolbar</u> (940).
- 3. In the <u>Insert Hyperlink dialog</u> that appears, specify the document or document fragment you wish to link to. If you are linking to a document fragment (that is, to a bookmark within a document), remember to include the # symbol. The URI for the hyperlink is specified in one of the following forms:
 - As a static address (entered directly; you can select an HTML file via the **Browse** button, and a fragment in the current document via the **Bookmark** button). Examples would be: http://www.altova.com (static Web page URI); U:\documentation\index.html (via Browse button); or #top of page (via Bookmark button).
 - As a dynamic address (which comes from a node in the XML document; you specify the node). An example would be a node such as //otherdocs/doc1. If the name of a bookmark has been generated using the generate-id() function, then the href of the hyperlink should be generated using the same generate-id() function. For information, see Defining Hyperlinks 445.
 - As a combination of static and dynamic text for an address (you specify the static text and the XML document node). An example would be www.altova.com -- department/name -- #intropara.
- 4. Click **OK**. The hyperlink is created.

Note: When specifying the node for a dynamic hyperlink entry, you can enter the XPath expression as an absolute XPath expression by checking the *Absolute Path* check box. If this check box is not checked, the XPath expression will be relative to the context node, which is the node within which the hyperlink is being inserted.

Using unparsed entities

If you are using a DTD as your schema, then in the dynamic part of a hyperlink address, you can use the URI declared for an unparsed entity in the DTD. For details of how to use unparsed entities, see <u>Using unparsed</u> entity <u>URIs</u> 566.

Editing a hyperlink

You can edit the href of a hyperlink after it has been created. Do this by right-clicking the hyperlink and selecting the **Edit URL** command. Alternatively, in the Properties sidebar, in the *Link* group of properties for the link, you can click the **Edit** button of the URL attribute and make the required changes.

Deleting a hyperlink

To delete a hyperlink, select it in the design and press the **Delete** key.

17.8.17 **Footnote**

You can insert footnotes in a document by adding the Footnote component (**Insert | Insert Footnote**) at the location where you want the footnote number to be. Footnotes are available in paged media output (PDF, RTF, and Word 2007+ in the *Enterprise Edition*; and RTF in the *Professional Edition*).

Note the following points:

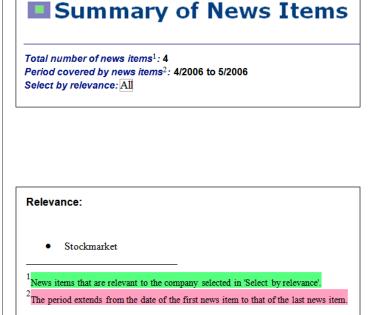

- The text of the footnote must be placed within the tags of the footnote component, and the footnote text can be formatted.
- In the output, the footnote number appears at the location where the footnote was added. The footnote text appears at the bottom of the page, together with the corresponding footnote number.
- In the output, footnote text will be formatted according to the formatting of the text within the footnote component in the design.
- In the output, footnotes are numbered automatically through to the end of the document.
- In the case of multiple output documents, numbering is re-started for each output document.

In the screenshot below, two footnote components (**Insert | Insert Footnote**) have been inserted. The footnote text has been placed within the tags of the component, and the text has been formatted.

The screenshots below show the output. The screenshot at left shows the complete page, while the screenshots at right show closeups of the footnote numbers (*top*) and footnote texts (*bottom*).

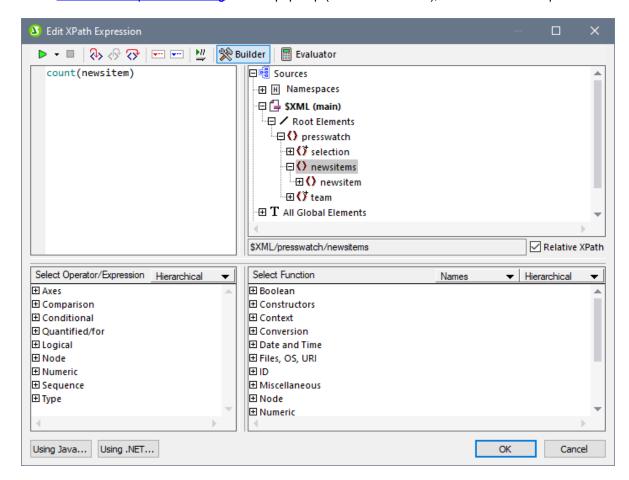

Note: Formatting of footnote numbers is not supported.

17.8.18 Condition, Output-Based Condition

The **Condition** command enables you to insert a condition at the cursor point or around the selection. A condition consists of one or more branches, with each branch containing a specific set of processing rules. In this way, different sets of processing rules can be specified for different branches. For example, if the content of a node is the string <code>Stop</code>, the branch can test this, and specify that the contents of the node be colored red; a second branch can test whether the contents of the node is the string <code>Go</code>, and, if yes, color the contents of the node green; a third branch can specify that if the contents of the node is neither the string <code>Stop</code> nor the string <code>Go</code>, the contents of the node should be colored black.

To insert a condition, do the following:

- Place the cursor at the desired location in the design or select the component around which the condition is to be inserted.
- 2. Select the menu command **Insert | Condition** or right-click and select the context menu command **Insert | Condition**.
- 3. In the Edit XPath Expression dialog 917 that pops up (screenshot below), enter the XPath expression.

The context node for the expression being built is highlighted in the schema tree in the pane at extreme left. You can enter the XPath expression directly in the text box, or you can double click an item (in any of the three panes) to insert that item. Nodes inserted from the schema tree in the left-hand pane are inserted relative to the context node (if the *Relative XPath* check box is checked) or as an absolute expression starting from the document node (if the *Relative XPath* check box is unchecked).

4. Click **OK** to finish inserting the condition. The condition is created with one branch, the test for which is the XPath expression you entered.

Insert Output-Based Condition

This command inserts an output based-condition at the cursor location or around the selected component. Each branch of the condition represents a single output (Authentic View, RTF, PDF, Word 2007, Text or HTML). To determine which branch represents which output, mouseover the branch tag or check the XPath expression of the selected branch (in the Properties sidebar, in the Condition Branch entry, click the Edit button 333). If the output-based condition was created at a cursor insertion point, all branches will be empty and content will have to be inserted for each branch. If the output-based condition was created around a component, each branch will contain that component. For more details about output-based conditions, see Output-Based Conditions 335. You can edit, move, and delete output-based conditions in the same way you would with a standard condition.

Editing the XPath expressions of branches

To edit the XPath expression of a branch, select the branch in Design View. Then, in the Properties sidebar, select condition branch | when. Click the **Edit** button for the XPath item. This pops up the Edit XPath Expression dialog (*screenshot above*), in which you can edit the expression. Click ok when done.

Adding branches, changing the order of branches, and deleting branches

To add new branches, change the order of branches, and delete branches, right-click the required branch and select the relevant item from the context menu.

17.8.19 **Disabled**

The **Disabled** command inserts a Disabled component at the cursor location (*screenshot below*). (To put the Disabled component around selected content, use the **Enclose With | Disabled** command.)

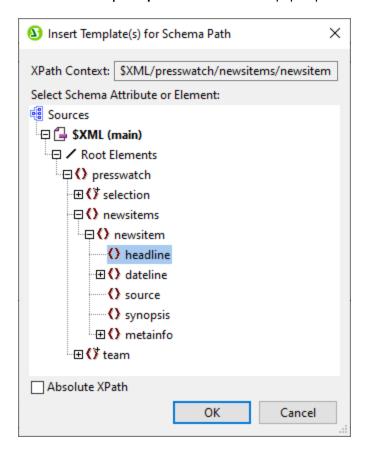

Content inside a Disabled component is ignored in the output. So you can add content that you want to ignore to the Disabled component. The Disabled component thus serves as a way to comment out content.

When you want to reinstate disabled content, simply remove the Disabled tags from around the content. To do this, select the Disabled component, right-click, and select **Remove Tag Only**.

17.8.20 Template

The **Template** command inserts, at the cursor insertion point, an empty template for the schema tree node you select. Insert a template as follows.

- 1. Place the cursor in the design at the location where the template is to be inserted.
- 2. Click the Insert | Template command. This pops up the Insert Template dialog (screenshot below).

- 3. The XPath Context field contains the context node of the cursor insertion point. This node will be the context node of the template when it is created. In the dialog, select the node for which you want to create the template. In the screenshot above the headline node is selected. So we will be creating a template for the headline node in the context of the newsitem element.
- 4. Click **OK** to finish.

An empty template for the selected node will be created. In the screenshot below, an empty template for the headline node has been created.

17.8.21 User-Defined Template

The **User-Defined Template** command inserts, at the cursor insertion point, an empty template that selects a node the user specifies in an XPath expression. Insert a user-defined template as follows.

- 1. Place the cursor in the design at the location where the template is to be inserted.
- 2. Click the **Insert | User-Defined Template** command. This pops up the <u>Edit XPath Expression</u> dialog ⁹¹⁷.
- 3. Enter the XPath expression to select the node you want. There are a few points to note in this connection: (i) The XPath expression will be evaluated in the context of the node within which the user-defined template is being created; (ii) The XPath expression can select any node anywhere in the document as well as in another XML document.
- 4. After you have entered the XPath expression, click **OK** to finish.

An empty user-defined template for the targeted node will be created.

For more detailed information, see the section, SPS File: Contents | User-Defined Templates 143.

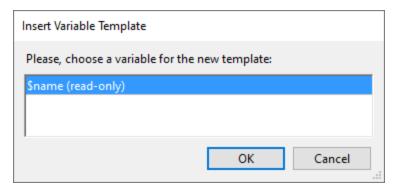

17.8.22 Variable Template

A **Variable Template** is a template that targets a variable and, by default outputs its content. It is inserted with the **Insert | Variable Template** or **Enclose with | Variable** command, which inserts, at the cursor insertion point, a template for a variable defined in the SPS. The variable template (*screenshot below*) contains a content placeholder by default, and this serves to output the contents of the variable. You can insert additional content (static as well as dynamic) in the variable template as required, or modify it as you would any other template. A variable template is indicated with a dollar symbol in its start and end tags.

To insert a variable template, do the following:

- 1. Place the cursor in the design at the location where the template is to be inserted.
- 2. Right-click and select the **Insert | Variable Template** command. This pops up the Insert Variable Template dialog (*screenshot below*).

- 3. The dialog contains a list of all the <u>user-declared parameters and variables</u> defined in the SPS. Select the variable for which you wish to add a variable template.
- 4. Click **OK** to finish.

17.8.23 Design Fragment

Mousing over the **Design Fragment** command rolls out a submenu containing all the Design Fragments currently in the design. Clicking a Design Fragment in the submenu inserts it at the cursor insertion point.

17.8.24 Layout Container, Layout Box, Line

The Insert | Layout Container command enables a Layout Container to be inserted anywhere in the design. A Layout Box and a Line can be inserted in a Layout Container, and both these commands are enabled only when a Layout Container is selected.

Layout Containers, Layout Boxes, and Lines can also be inserted via the respective icons in the <u>Insert Design</u> <u>Elements toolbar</u>. To insert via the toolbar icons, you must first select the appropriate toolbar icon and then click in the design at the location where you wish to insert the layout item.

For a detailed description of Layout modules and how to insert and use them in the design, see the section <u>Layout Modules</u> 278.

17.8.25 Table of Contents

Mousing over the **Table of Contents** command rolls out a submenu containing commands to insert various commands relating to the creation of a Table of Contents (TOC) template, TOC bookmarks, and a design document structure for the TOC.

The list of commands is as follows. For the details of how to use them click on the respective links, which will take you to the section on how to use that particular TOC component.

- Insert Table of Contents
- TOC Bookmark 420

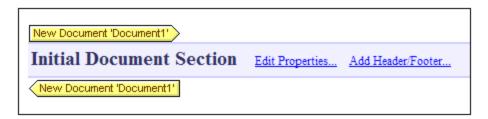

- TOC Bookmark (Wizard)

 416
- TOC Reference 426
- Hierarchical Numbering 426
- Sequential Numbering 426
- Level 417
- <u>Level Reference</u> 425
- Template Serves as Level 417

Note: These commands are also available as commands in a context menu, depending on where you right click in the design.

17.8.26 New Document

The **Insert New Document** command inserts a New Document template (*screenshot below*) at the cursor insertion point.

The New Document template contains an empty Initial Document Section. Content can now be entered in the Initial Document Section. If desired, additional Document Sections can be appended to the Initial Document Section via the Insert | Insert | Insert | Column / Document Section command.

A New Document template creates a new document in the output. As a result, the output will consist of multiple output-documents.

For a detailed description of how to work with multiple output-documents, see the section, <u>Multiple Document</u> Output .

17.8.27 Page / Column / Document Section

With the **Page / Column / Document Section** command you can insert, for paged media output, a page break (HTML printouts, RTF, PDF, and Word 2007+ outputs) and page number (RTF, PDF, and Word 2007+ outputs). Such insertions are possible only at cursor insertion points.

New Page

Click **New Page** to insert a page break at the cursor insertion point. The page break is displayed as a dashed line across the whole of the Design window. In HTML output, while the page break has no effect in the browser view, a page break will be inserted when the browser view of the HTML file is printed out. In PDF, Word 2007+ and RTF output, a page break is inserted at the specified locations.

Page Number

Click **Page | Number** to insert the current page number in the RTF, PDF, and Word 2007+outputs. The page number appears as a block (i.e. as a separate line) or as an inline (embedded in document text), depending on where in the document the page number has been inserted. For example, if the page number is inserted within a paragraph element, then the page number appears inline within the paragraph. If, on the other hand, the page number is inserted, say, between two elements, then it appears on a separate line by itself.

Page Total

Click **Page | Total** to insert the total number of pages in the PDF output. The page total can be inserted anywhere in the document design, including in headers and footers. It is particularly useful when numbering pages. For example, the page total can be inserted in a header design as follows: Page: (page number) / (page total). This would produce output in the form: Page: 1/25.

New Column

The number of columns that a page in a given section must have is specified in the <u>page properties</u> of that section. In the output, text will fill the columns on a multi-column page one by one. Text can however be forced into a new column by inserting a column break (new column) in the design. To insert a new column in a document, place the cursor at the location in the design where the new section is to be added and click the **New Column** command, which is also available via the context menu.

New Document Section

A document is made up of one initial section and, optionally, additional sections. Each <u>section</u> has its own page properties. To insert a new section in a document, place the cursor at the location in the design where the new section is to be added and click the **New Document Section** command, which is also available via the context menu.

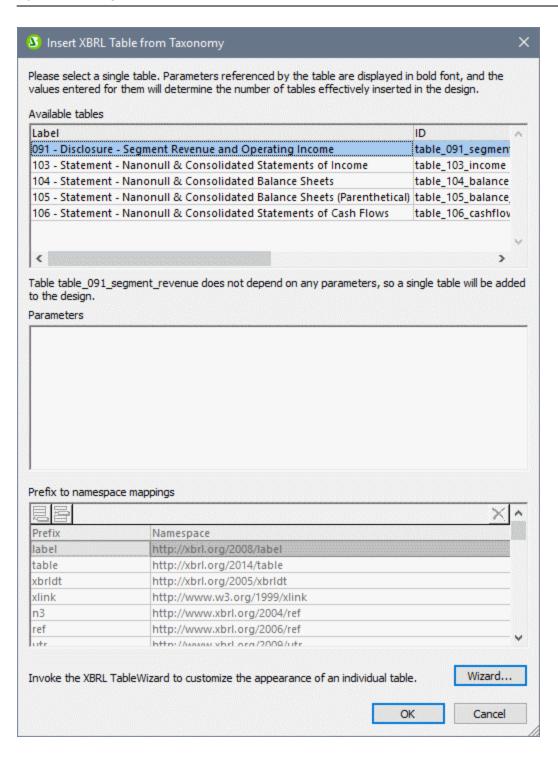

Deleting Page Breaks, Page Numbers, and Page Total

To delete page breaks, page numbers, and page total, select the placeholder and click **Delete**.

17.8.28 XBRL Table from Taxonomy

The **Insert XBRL Table from Taxonomy** command opens the Insert XBRL Table from Taxonomy dialog (*screenshot below*). To insert a table, select it from the list of available tables (in the first pane). If the selected table depends on parameters, these parameters are displayed in the dialog's second pane. The taxonomy's namespaces are displayed in the third pane.

Click **OK** to insert the table. If you want to customize the appearance of the selected table, click **Wizard**. This opens the XBRL Table Wizard which is described here 1941.

17.8.29 XBRL Element

The Insert XBRL Element command inserts any of the following XBRL elements as a template:

- Context: Creates an empty xbrli:context element template. The location where the template is inserted determines what context element is selected. The content of the template will have to be created.
- Periods: The three empty period templates match three period elements: period; startDate; and endDate. Note that startDate and endDate are children of the period element. There is no template for the instant element, which is also an allowed child of period; however, since instant can only occur as an only child of period, the built-in XSLT templates will select the instant template automatically if templates are applied (xsl:apply-template) to the period template (with the contents placeholder, for example).
- *Identifier:* Creates an empty template for the identifier element.
- *Unit:* Creates an empty template to match the unit element. You can create a global template for xbrli:measure, and use this locally within the Unit template to actually generate the monetary unit.
- Footnote: Creates a template that matches the footnote element. Footnotes have two parts: a reference and the actual footnote text.

For more information, see the section XBRL Templates (762).

17.8.30 User-Defined Item

Mousing over the **Insert | User-Defined Item** command causes a sub-menu to roll out that contains commands to insert a <u>User-Defined Element</u> or a <u>User-Defined XML Text Block</u>. How to use these two components is described in the section <u>SPS File: Content | User-Defined Elements, XML Text Blocks</u> 146.

17.9 Enclose With Menu

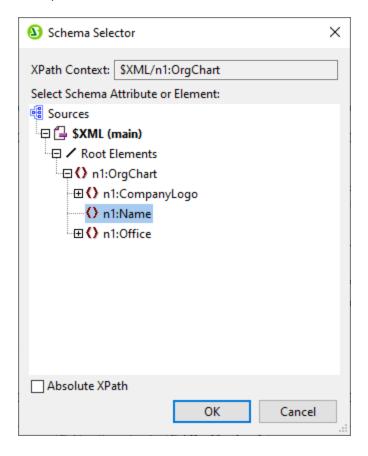

The **Enclose with** menu provides commands enabling you to enclose a selection in the design with a variety of design components. Some of these commands are available as <u>toolbar icons</u> that enable you to insert the component in the design (equivalent commands are available in the <u>Insert menu</u> (937)). Additionally, **Enclose with** menu commands are also available via **context menus** which appear when, in the SPS design, you right-click a selection. In the menus and context menus, commands that are not available at that location in the SPS are disabled.

Note: Since the **Enclose with** commands are used for constructing the SPS, they are available in Design View only.

17.9.1 Template

The **Enclose with | Template** command encloses the selected design component or text with a template for the schema tree node you select. Do this as follows.

- 1. Select the design component or text you wish to enclose with a template.
- 2. Click the **Enclose with | Template** command. This pops up the Schema Selector dialog (*screenshot below*).

- 3. The XPath Context field contains the context node of the selection and will be the context node of the template when it is created. Select the node for which you wish to create the template. In the screenshot above the n1: Name node is selected as the node for which the template is being created.
- 4. Click **OK** to finish.

A template for the selected node will be created around the selection.

17.9.2 **User-Defined Template**

The Enclose with | User-Defined Template command encloses the selection with a template for a node the user specifies in an XPath expression. Insert a user-defined template as follows.

- 1. Select the component in the design that you wish to enclose with a user-defined template.
- 2. Click the Enclose with | User-Defined Template command. This pops up the Edit XPath Expression 917 dialog.
- 3. Enter the XPath expression to select the node you want. There are a few points to note in this connection: (i) The XPath expression will be evaluated in the context of the node within which the userdefined template is being created; (ii) The XPath expression can select any node anywhere in the document as well as in another XML document.
- 4. After you have entered the XPath expression, click **OK** to finish.

A user-defined template for the targeted node will be created around the selection.

For more information, see the section, SPS File: Structure | Templates and Design Fragments | User-Defined Templates 349.

17.9.3 **Variable Template**

The **Enclose with I Variable Template** command encloses the selection with a template for a variable defined in the SPS design.

- 1. Select the component in the design that you wish to enclose with a variable template.
- 2. Click the Enclose with | Variable Template command. This pops up the Enclose with Variable Template dialog 352.
- 3. From the list in the dialog, select the variable for which you wish to create the template.
- 4. Click **OK** to finish.

A variable template will be created around the selection.

For more information, see the section, SPS File: Structure | Templates and Design Fragments | Variable Templates 352

17.9.4 Paragraph, Special Paragraph

The **Paragraph** command inserts an HTML paragraph element around the selected component. A component is considered selected for this purpose when the entire node is selected (by clicking either of its tags) or when static text is selected. If the cursor is placed within static text, the paragraph element is inserted (start and end tags) at this point. A paragraph can also be inserted by using the **Insert Paragraph** icon in the Insert Design Elements toolbar.

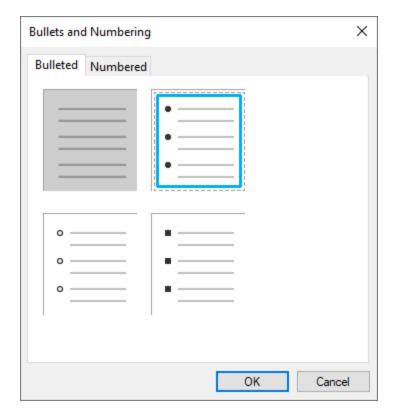

The **Special Paragraph** command allows you to assign a predefined format to the selected node. The available predefined formats can also be selected from the combo box in the toolbar.

Each paragraph type has particular formatting features that can be used to advantage. Note that the pre format type enables carriage returns to be output as such instead of them being normalized to whitespace.

17.9.5 Bullets and Numbering

The **Enclose with | Bullets and Numbering** command creates a static list and list items around the selection. If the selection contains a CR-LF, carriage-return and/or linefeed (inserted by pressing the **Enter** key), then separate list items are created for each text fragment separated by a CR-LF.

When this command is selected, the Bullets and Numbering dialog (screenshot below) pops up.

Select the list item marker you want and click **OK**. A list is created. The number of list items in the list corresponds to the number of CR-LFs (carriage-returns and/or linefeeds) in the selection. You can add more list items to the list by pressing Enter.

Note: You can obtain the same results by selecting static content and then clicking the Bulleted List or Numbered List icons in the <u>Insert Design Elements toolbar</u> ⁹⁴⁰.

Bookmarks and Hyperlinks 17.9.6

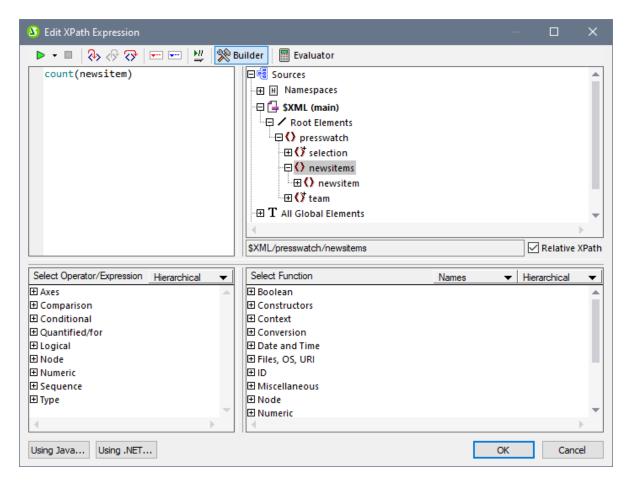

The Enclose with | Bookmark and Enclose With | Hyperlink commands are enabled when some text or component in the SPS design is selected. These commands enable a bookmark and hyperlink, respectively, to be created around the selection. For more information about how bookmarks and hyperlinks work and how to create them, see the section Advanced Features | Table of Contents, Referencing, Bookmarks 440.

17.9.7 Condition, Output-Based Condition

The Condition command enables you to insert a condition at the cursor point or around the selection. A condition consists of one or more branches, with each branch containing a specific set of processing rules. In this way, different sets of processing rules can be specified for different branches. For example, if the content of a node is the string Stop, the branch can test this, and specify that the contents of the node be colored red; a second branch can test whether the contents of the node is the string Go, and, if yes, color the contents of the node green; a third branch can specify that if the contents of the node is neither the string Stop nor the string Go, the contents of the node should be colored black.

To insert a condition, do the following:

- 1. Place the cursor at the desired location in the design or select the component around which the condition is to be inserted.
- 2. Select the menu command Insert | Condition or right-click and select the context menu command Insert | Condition.
- 3. In the Edit XPath Expression dialog 1917 that pops up (screenshot below), enter the XPath expression.

The context node for the expression being built is highlighted in the schema tree in the pane at extreme left. You can enter the XPath expression directly in the text box, or you can double click an item (in any of the three panes) to insert that item. Nodes inserted from the schema tree in the left-hand pane are inserted relative to the context node (if the *Relative XPath* check box is checked) or as an absolute expression starting from the document node (if the *Relative XPath* check box is unchecked).

4. Click **OK** to finish inserting the condition. The condition is created with one branch, the test for which is the XPath expression you entered.

Insert Output-Based Condition

This command inserts an output based-condition at the cursor location or around the selected component. Each branch of the condition represents a single output (Authentic View, RTF, PDF, Word 2007, Text or HTML). To determine which branch represents which output, mouseover the branch tag or check the XPath expression of the selected branch (in the Properties sidebar, in the Condition Branch entry, click the Edit button 333). If the output-based condition was created at a cursor insertion point, all branches will be empty and content will have to be inserted for each branch. If the output-based condition was created around a component, each branch will contain that component. For more details about output-based conditions, see Output-Based Conditions 335. You can edit, move, and delete output-based conditions in the same way you would with a standard condition.

Editing the XPath expressions of branches

To edit the XPath expression of a branch, select the branch in Design View. Then, in the Properties sidebar,

select condition branch | when. Click the Edit button if for the XPath item. This pops up the Edit XPath Expression dialog (screenshot above), in which you can edit the expression. Click OK when done.

Adding branches, changing the order of branches, and deleting branches

To add new branches, change the order of branches, and delete branches, right-click the required branch and select the relevant item from the context menu.

17.9.8 **Disabled**

The Disabled command encloses selected content (including design components) with a Disabled component (see screenshot below).

Content inside a Disabled component is ignored in the output. So you can enclose content that you want to ignore with a Disabled component.

When you want to reinstate disabled content, simply remove the Disabled tags from around the content. To do this, select the Disabled component, right-click, and select Remove Tag Only.

17.9.9 **TOC Bookmarks and TOC Levels**

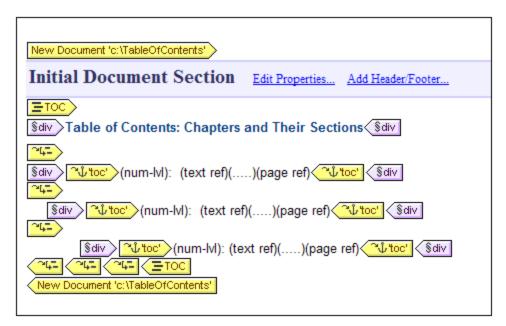

When a component in the design is selected, it can be enclosed with one or more relevant Table of Contents (TOC) components. The list of TOC commands is as follows. For the details of how to use them click on the respective links, which will take you to the section on how to use that particular TOC component.

- TOC Bookmark 420
- TOC Bookmark (Wizard) 416
- Level 417
- Level Reference 425

Note: These commands are also available as commands in a context menu, depending on where you right click in the design.

17.9.10 New Document

The **Enclose With New Document** command encloses the current selection with a New Document template (*screenshot below*).

The New Document template contains an Initial Document Section that contains the design selection that was highlighted when the **Enclose With New Document** command was selected. In the screenshot above, the TOC design component was selected and enclosed with a New Document template. Content can now be entered in the Initial Document Section. If desired, additional Document Sections can be appended to the Initial Document Section via the **Insert | Insert Page / Column / Document Section** command.

A New Document template creates a new document in the output. As a result, the output will consist of multiple output-documents.

For a detailed description of how to work with multiple output-documents, see the section, <u>Multiple Document</u> Output ³⁵².

17.9.11 User-Defined Element

The **Enclose with | User-Defined Element** command creates a <u>User-Defined Element</u> around the selection in the design. How to use user-defined elements is described in the section <u>SPS File: Content | User-Defined Elements</u>.

17.10 Table Menu

The **Table** menu provides commands enabling you to insert a static or dynamic table and to change the structure and properties of static and dynamic tables. You can edit table structure by appending, inserting, deleting, joining, and splitting rows and columns. Properties of the table as well as of individual columns, rows, and cells are defined using CSS styles 150 and HTML properties for tables and its sub-components 150.

The Table commands are available in the **Table** menu (*see list below*) and as icons in the <u>Table toolbar</u> The availability of various table commands depends on the current cursor position. A table can be inserted at any location in the SPS by clicking the <u>Insert Table</u> command. To edit the table structure, place the cursor in the appropriate cell, column, or row, and select the required editing command. To edit a formatting property, place the cursor in the appropriate cell, column, row, or table, and, in the <u>Styles sidebar</u> and/or <u>Properties sidebar</u> define the required property for that table component.

The following commands are available in the Table menu:

- Insert Table, Delete Table 1031
- Add Table Headers, Footers 1032
- Append/Insert Row/Column 1032
- Delete Row, Column 1033
- Join Cell Left, Right, Below, Above 1033
- Split Cell Horizontally, Vertically
 1033
- View Cell Bounds, Table Markup 1034
- <u>Table Properties</u> 1034
- Vertical Alignment of Cell Content 1035

Headers and footers

When you create a dynamic table, you can specify whether you wish to include headers and/or footers. (Footers are allowed only when the table grows top–down.) You can create a header and footer in a static table by manually inserting a top and bottom row, respectively. The structures of headers and footers in both static and dynamic tables can be modified by splitting and joining cells.

Navigating in tables

Use the Tab and arrow keys to navigate the table cells.

Adding cell content

Any type of SPS component can be inserted as the content of a cell. The component should be formatted using the standard formatting tools.

17.10.1 Insert Table, Delete Table

The **Insert Table** command inserts an empty table in the design tab. Selecting this command opens a dialog box in which you select whether you wish to create a static or dynamic table.

 If you choose to create a static table, a dialog prompts you for the size of the table (in terms of its rows and columns). • If you choose to create a dynamic, the XPath Selector dialog pops up, in which you can select the node that is to be created as a dynamic table. On clicking **OK**, the Create Dynamic Table dialog pops up, in which you can select the child nodes you wish to display as the fields of each table item. For details, see <u>Creating dynamic tables</u> 153.

You can change the structure of a table subsequently by appending, inserting, and deleting rows and/or columns.

The **Delete Table** command deletes the static or dynamic table in which the cursor is.

17.10.2 Add Table Headers, Footers

Table headers can appear as a header row (above the table body) or as a header column (to the left of the table body, though markup-wise a header column might be placed inside the table body). Similarly, table footers can appear as a footer row (below the table body) or as a footer column (to the right of the table body, though markup-wise a footer might be placed inside the table body).

Note: In the HTML output since table headers are enclosed in th elements, they appear bold (because the bold formatting is inherent in the th element).

The Add Table Header and Add Table Footer commands add table headers and footers as columns and rows, as follows:

Add Table Header Column: Adds a header column to the left of the table body.

Add Table Footer Column: Adds a footer column to the right of the table body.

Add Table Header Row: Adds a header row above the table body.

Add Table Footer Row: Adds a footer row below the table body.

17.10.3 Append/Insert Row/Column

The **Append Row** command appends a row to the static or dynamic table in which the cursor is.

The **Insert Row** command inserts a row above the row in which the cursor is. This command applies to both static and dynamic tables.

The **Append Column** command appends a column to the static or dynamic table in which the cursor is.

The **Insert Column** command inserts a column to the left of the column in which the cursor is. This command applies to both static and dynamic tables.

17.10.4 Delete Row, Column

The **Delete Row** command deletes the row in which the cursor is. This command applies to both static and dynamic tables.

The **Delete Column** command deletes the column in which the cursor is. This command applies to both static and dynamic tables.

17.10.5 Join Cell Left, Right, Below, Above

The **Join Cell Left** command joins the cell in which the cursor is to the adjacent cell on the left. The contents of both cells are concatenated in the new cell. All property values of the cell to the left are passed to the new cell. This command applies to both static and dynamic tables.

The **Join Cell Right** command joins the cell in which the cursor is to the cell on the right. The contents of both cells are concatenated in the new cell. All property values of the cell to the left are passed to the new cell. This command applies to both static and dynamic tables.

The **Join Cell Below** command joins the cell in which the cursor is to the cell below. The contents of both cells are concatenated in the new cell. All property values of the cell on the top are passed to the new cell. This command applies to both static and dynamic tables.

The **Join Cell Above** command joins the cell in which the cursor is to the cell above. The contents of both cells are concatenated in the new cell. All property values of the cell on top are passed to the new cell. This command applies to both static and dynamic tables.

17.10.6 Split Cell Horizontally, Vertically

The **Split Cell Horizontally** command creates a new cell to the right of the cell in which the cursor is. The contents of the original cell stay in the original cell. All properties of the original cell are passed to the new cell. This command applies to both static and dynamic tables.

The **Split Cell Vertically** command creates a new cell below the cell in which the cursor is. The contents of the original cell remain in the upper cell. All properties of the original cell are passed to the new cell. This command applies to both static and dynamic tables.

17.10.7 View Cell Bounds, Table Markup

The **View Cell Bounds** and **View Table Markup** commands display the boundaries of cells and table column and row markup, respectively. With these two options switched on, you can better understand the structure of the table. Switched off, however, you can visualize the table more accurately.

The **View Cell Bounds** command toggles the display of table boundaries (borders) on and off for tables that have a table border value of 0.

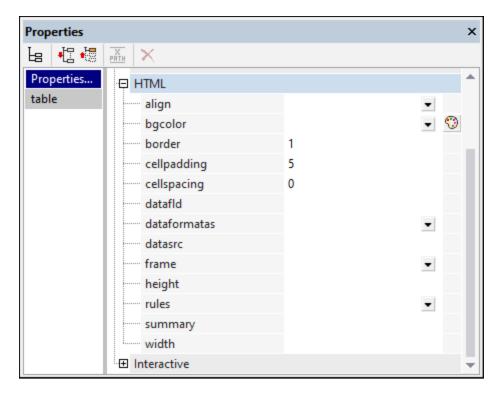

The **View Table Markup** command toggles the display of the blue column and row markers on and off.

17.10.8 Table Properties

The **Table Properties** command is enabled when the cursor is placed inside a <u>static or dynamic table</u> (149). Clicking the command, pops up the Properties sidebar, with the *Table* component selected (*screenshot below*).

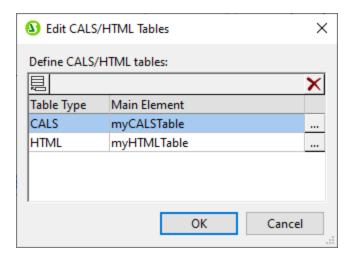

You can now edit the properties of the table. Click **OK** when done.

Edit CALS/HTML Tables 17.10.9

If the underlying schema of the SPS has an element with a sub-structure that follows the CALS table model or HTML table model, then you can automatically generate this XML element as a table in the outputs. You essentially need to specify which SPS schema element corresponds to which CALS or HTML table element. The table markup in the output formats is then derived directly from the XML document.

The Edit CALS/HTML Tables command pops up the Edit CALS/HTML Tables dialog (screenshot below). In the dialog, select the SPS schema element name that corresponds to a CALS or HTML table element. You can specify basic table formatting styles in the dialog and can add styles subsequently in the design.

For details about CALS/HTML tables, see the section Tables 149.

17.10.10 Vertical Alignment of Cell Content

Commands to set the vertical alignment of cell content are available as icons in the Table toolbar. Place the cursor anywhere in the cell, and click the required icon.

- \blacksquare **Vertically Align Top** vertically aligns cell content with the top of the cell.
- ₩ Vertically Align Middle vertically aligns cell content with the middle of the cell.
- \blacksquare Vertically Align Bottom vertically aligns cell content with the bottom of the cell.

17.11 Authentic Menu

The Authentic menu contains commands that enable you to:

- Customize aspects of the Authentic View of an XML document that will be displayed using the SPS.
- Edit documents in the Authentic View preview of StyleVision.

The commands in the Authentic menu are listed below:

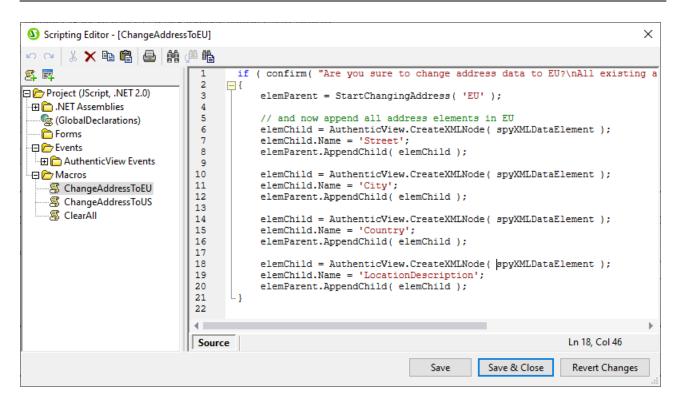

- Edit Authentic Scripts 1036
- Custom Toolbar Buttons 1037
- Check Macro References 1040
- Auto-Add Date Picker 1041
- Auto-Add DB Controls

 1041
- Reload, Validate XML 1041
- Select New Row with XML Data for Editing 1042
- XML Signature 1043
- Define XML Entities 1044
- Markup Commands 1045
- (Dynamic Table) Row Commands 1046

Each of these commands is described in detail in the sub-sections of this section.

17.11.1 Edit Authentic Scripts

The Edit Authentic Scripts command pops up StyleVision's Scripting Editor (screenshot below), in which you can create Forms, Event, and Macros for use in Authentic View.

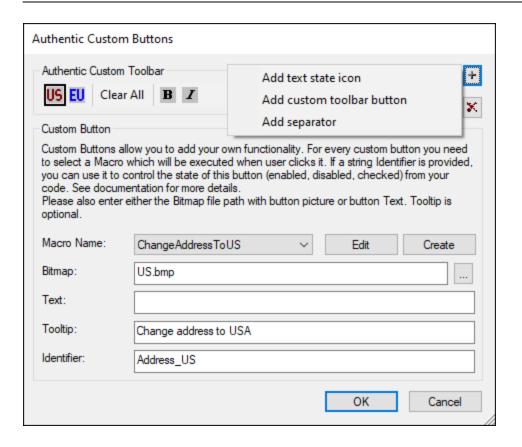

For an overview of how scripts can be used in Authentic View, see the section, <u>Scripting for Authentic</u> 1881. For a description of how the Scripting Editor works, see the section, <u>Scripting</u> 1082 in the <u>Programmers'</u> Reference 1083.

17.11.2 Custom Toolbar Buttons

Clicking the **Custom Toolbar Buttons** command pops up the Authentic Custom Buttons dialog (*screenshot below*), in which you can design a customized Authentic toolbar. After the Authentic toolbar has been saved with an SPS, the toolbar will appear in the Authentic View of Enterprise and Professional editions of Altova products whenever an XML file associated with this SPS is edited in Authentic View.

Note: Altova products that have an Authentic View window are: the Enterprise and Professional editions of XMLSpy, and StyleVision and the Enterprise edition of Authentic Desktop and Authentic Browser.

Adding a button

To add a button or separator to the Authentic toolbar, click the **Add** button at the top right of the dialog. This pops up a menu in which you can select what you wish to add: (i) a text state icon, (ii) a custom button to execute a macro, or (iii) a separator line in the toolbar to separate groups of buttons. Text state icons and custom buttons are described in detail below.

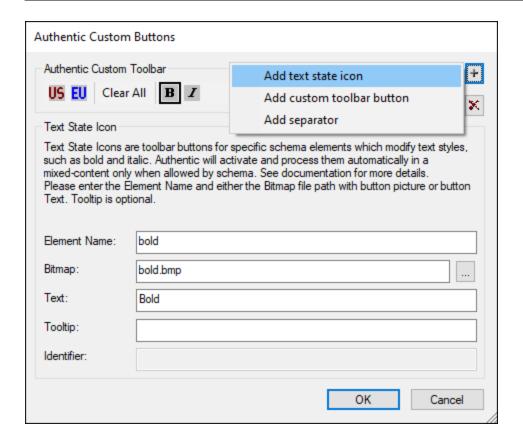

Moving a button and deleting a button

To move a button or separator to another location in the toolbar, select it and drag it to the new position. To delete a button or separator, select it and click the **Delete** button at the top right of the dialog.

Text state icons

A text state icon defines an icon for a global element. When the Authentic View user selects text in the Authentic View document and clicks a text state icon, then the element that the icon defines is inserted around the selected text. Text state icons are intended for elements that provide inline formatting, such as bold and italic formatting.

To add a text state icon to the Authentic toolbar, click the **Add** button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select **Add Text State Icon**. Enter the name of the XML element for which the text state icon is being created, then browse for a bitmap image file for the button or enter a text for the button. You can optionally enter a tooltip as a guide for the Authentic View user when he or she mouses over the text state icon. Click **OK** to add the button to the Authentic toolbar.

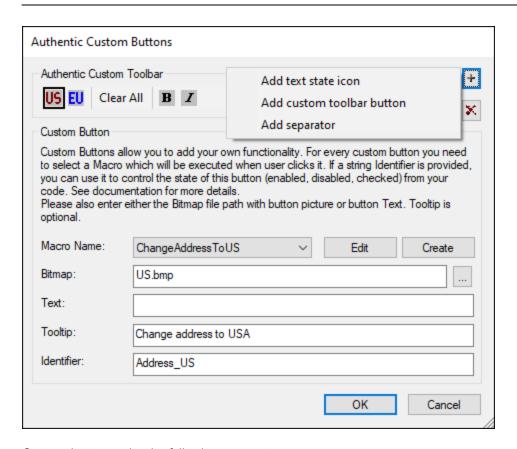

The screenshot above shows the text state icon for the <code>bold</code> element selected. This text state icon uses an image named <code>bold.bmp</code>. Text for the button can be entered as a fallback. For the text state icon defined in the screenshot above, if the image cannot be found, then the text <code>Bold</code> will be used instead of the button.

Custom buttons

When an Authentic View user clicks a custom button in the Authentic toolbar, a macro is executed. In the SPS design you can create a custom button and specify what macro it will trigger.

To add a custom button to the Authentic toolbar, click the **Add** button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select **Add Custom Toolbar Button**.

Custom buttons take the following parameters:

- The location of an image for the button (in the Bitmap field) or text for the button (in the Text field).
- In the Macro Name combo box select a macro from the dropdown list. The macros listed here are those that have been saved with the SPS. When you click the **New** button, the <u>Scripting Editor</u> of StyleVision opens in its own window, enabling you to quickly and easily create a macro and save it with the SPS. Clicking the **Edit** button opens the selected macro for editing in the <u>Scripting Editor</u> (1034).
- You can optionally enter a tooltip as a guide for the Authentic View user when he or she mouses over the custom button.
- In the Identifier field enter a text string that will be used as the identifier of the custom button. This identifier can then be used in scripting code.

The screenshot above shows custom button for the <code>ChangeAddressToUs</code> macro. This custom button uses an image named <code>Us.bmp</code>. Text for the button can be entered as a fallback. A tooltip has been entered and the custom button has the identifier <code>Address_Us</code>. These examples are from the file <code>ToolbarButtons.sps</code> is in the <code>Authentic\Scripting</code> folder of the <code>Examples</code> project in the Project window.

17.11.3 Check Macro References

The **Check Macro References** command checks that references from toolbar buttons and scripts to macros are correct. If any incorrect reference is found an error message is displayed.

17.11.4 Auto-Add Date Picker

This is a toggle command that switches the Auto-Add Date Picker feature on and off. When the Auto-Add Date Picker feature is ON, any xs:date or xs:dateTime datatype element that is created as contents or as an input field will have the Date Picker automatically inserted within the element tags and after the contents placeholder or input field.

17.11.5 **Auto-Add DB Controls**

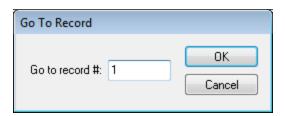

This is a toggle command that switches the Auto-Add DB Controls feature on and off.

When the Auto-Add DB Controls is on, then, whenever a DB table element is dropped into the design, the DB Controls panel (shown below) is inserted immediately before the Row child element of that DB table element.

The DB Controls panel enables the Authentic View user to navigate the rows of the DB table in Authentic View. The first (leftmost) button navigates to the first record; the second button navigates to the previous record; the third button is the Goto button; it pops up a dialog (screenshot below) that prompts you for the number of the record to which you wish to go; the fourth button navigates to the next record; and the fifth button navigates to the last record.

When the Auto-Add DB Controls toggle is turned off, the DB Controls panel is not inserted when a DB table is dropped into the Design document.

Note: You can manually insert navigation buttons by placing the cursor anywhere between the start and end tags of the DB table and selecting the required option from the Insert | DB Controls submenu. Note that in this submenu the DB Controls panel can be inserted as the four navigation buttons or as the four navigation buttons plus the button that calls the Goto Record dialog.

Reload Authentic View, Validate XML 17.11.6

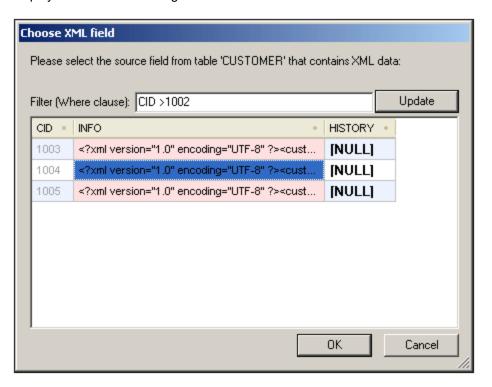

The **Reload** command reloads the Authentic XML data file. This can be useful if the file has been modified outside StyleVision, especially by another user working from another machine.

The **Validate XML** (**F8**) command checks the validity of the XML file against the associated schema. Whether StyleVision's XSD 1.0 or XSD 1.1 validator is used can be specified in the <u>Properties dialog</u>. Any additional validation requirement that you have entered for individual nodes (Properties sidebar: Additional validation in the *Authentic* group of properties) is also checked. The result of the validation check is displayed in a pop-up message box.

17.11.7 Select New Row with XML Data for Editing

The **Select New Row with XML Data for Editing** command enables you to select a new row from the relevant table in an XML DB, such as IBM DB2. This row appears in Authentic View, can be edited there, and then saved back to the DB.

When an XML DB is used as the XML data source, the XML data that is displayed in Authentic View is the XML document contained in one of the cells of the XML data column. The **Select New Row with XML Data for Editing** command enables you to select an XML document from another cell (or row) of that XML column. Selecting the **Select New Row...** command pops up the Choose XML Field dialog (*screenshot below*), which displays the table containing the XML column.

You can enter a filter for this table. The filter should be an SQL WHERE clause (just the condition, without the WHERE keyword, for example: CID>1002). Click **Update** to refresh the dialog. In the screenshot above, you can see the result of a filtered view. Next, select the cell containing the required XML document and click **OK**. The XML document in the selected cell (row) is loaded into Authentic View.

17.11.8 XML Signature

The **XML Signature** command is available in Authentic View when the associated SPS has <u>XML Signatures</u> enabled on the XML Signature command is also available as the XML Signature toolbar icon in the Authentic toolbar.

Verification and own certificate/password

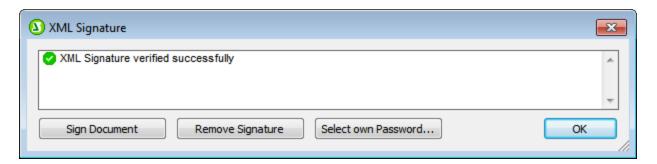

Clicking the **XML Signature** command starts the signature verification process. If no signature is present in the document, a message to that effect is displayed in the XML Signature dialog (see screenshot below), and the dialog will have a button that enables the Authentic View user to sign the document.

If the **Select Own Certificate** or **Select Own Password** button is present in this dialog, it means that the Authentic View has been given the option of selecting an own certificate/password. (Whether a certificate or password is to be chosen has been decided by the SPS designer at the time the signature was configured. The signature will be either certificate-based or password-based.) Clicking either of these buttons, if present in the dialog, enables the Authentic View user to browse for a certificate or to enter a password. The Authentic View user's selection is stored in memory and is valid for the current session only. If, after selecting a certificate or password, the document or application is closed, the certificate/password setting reverts to the setting originally saved with the SPS.

Verification and authentication information

If the verification process is run on a signed document, two general situations are possible. First: If the authentication information is available (in the signature or the SPS), then the verification process is executed directly and the result is displayed (*screenshot below*).

Authentication information is either the signing certificate's key information or the signing password. The SPS designer can specify, in the XML Signature Settings (503), that the certificate's key information be saved in the

signature, or that the password be saved in the SPS. In either of these cases, the authentication is available. Consequently the verification process will be run directly, without requiring any input from the Authentic View user.

The second possible general situation occurs when authentication information is not available in the signature (password not saved) or SPS file (certificate's key information not saved). In this situation, the Authentic View user will be asked to supply the authentication information: a password (see screenshot below) or the location of a certificate.

17.11.9 Define XML Entities

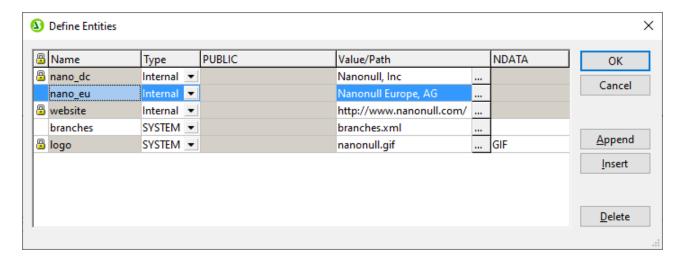

The **Define XML Entities** command is available only in Authentic View. With the **Define Entities** command in Authentic View, you can define entities that you want to add to your **XML document**. After an entity has been defined, it can be inserted in the XML document by right-clicking at the location where you wish to insert the entity, and, from the context menu that pops up, selecting **Insert Entity**, and then the name of the entity to be inserted.

An entity that you define with this command can be any of three types:

- Internal parsed entity. The value of the entity is a text string that usually occurs frequently in the document. Using an entity ensures that all occurrences are expanded to the value defined here.
- External parsed entity. This is an external XML file that will replace each occurrence of the entity. The value of the entity is the URI of the external XML file.
- External unparsed entity. This is an external resource that will be called when the entity is processed. The value of the entity is the URI of the external resource.

Clicking the command, pops up the Define Entities dialog (screenshot below).

For a description of how to use this dialog, see <u>Define Entities</u> on the Authentic View documentation.

17.11.10 View Markup

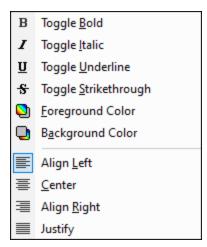

The **View Markup** command has a submenu with options to control markup in the Authentic XML document. With the four markup commands (*screenshot below*), you can select between the Hide Markup and the various Show Markup modes.

The markup refers to how the various node tags are displayed in Authentic View. These are mutually exclusive options, and one option must be selected at any given time. With Hide Markup selected node tags are not displayed. Small Markup shows opening and closing tags without node names. Large Markup shows opening and closing node tags with their respective node names. Mixed Markup refers to the markup specified in the Authentic Node Properties of individual nodes. Since the default markup property for individual nodes is Hide Markup, no markup (either small or large) will be displayed—unless you have specified (as a node property small or large markup for some node/s.

17.11.11 RichEdit

The **RichEdit** command pops out a submenu containing the RichEdit markup commands (*screenshot below*). The menu commands in this submenu are enabled only in Authentic View and when the cursor is placed inside an element that has been created as a RichEdit component.

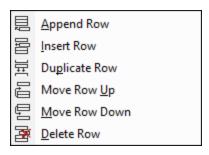

The text-styling properties of the RichEdit menu will be applied to the selected text when a RichEdit command is clicked. The Authentic View user can specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of the selected text.

For more information about the RichEdit feature in context, see <u>Text-Styling Flexibility in Authentic</u> ⁴⁸³.

17.11.12 (Dynamic Table) Row Commands

The **(Dynamic Table) Row commands** are enabled in Authentic View when the cursor is placed inside the row of a dynamic table. They enable you to manipulate the rows of a dynamic table. You can append, insert, duplicate, and delete rows, and you can move the selected row up and down relative to the other rows of the table. Since a row in a dynamic table represents a fixed data structure, the Authentic View user will be manipulating units of a data structure in the context of the data structure represented by the dynamic table.

A row is selected by placing the cursor inside it. An empty row can then be inserted (before) or appended (after) the selected row. A row can be duplicated, in the sense that a copy of the row plus its content is created after the selected. A row can also be moved up or down relative to adjacent rows.

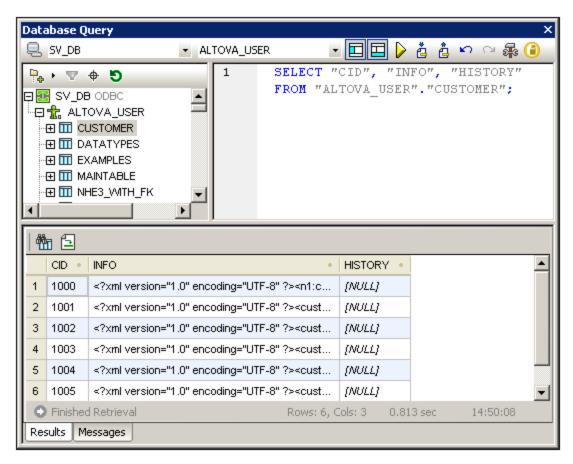

17.12 Database Menu

The **Database** menu contains commands to query the connected database and to edit and clear the filters applied to the connected database.

- Query <u>Database</u> 1047 starts up the <u>Connect to Database</u> 633 process and opens the Database Query window
- Edit DB Filter, Clear DB Filter (048), to access the Edit DB Filters dialog and clear DB Filters, respectively.

17.12.1 Query Database

The **Query Database** command pops up the <u>Database Query window</u> (screenshot below), via which you can connect to a database and query it. How to use the Database Query window is explained in the section <u>Query Database</u>.

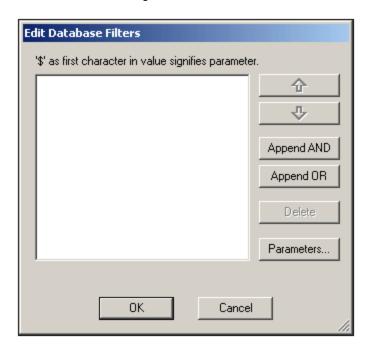

The Database Query window is toggled on and off by clicking the Query Database command.

17.12.2 Edit DB Filter, Clear DB Filter

The **Edit DB Filter** command allows you to create and edit a filter for a database table (a DB Filter). A DB Filter determines what data from the selected database table is imported and displayed. A DB Filter consists of one or more criteria. When you specify criteria, you use an expression, which is a combination of operators (= or >) and values (text or numbers). Additionally, criteria can be joined by the logical operators **AND** or **OR**.

To create or edit a DB Filter, do the following:

- 1. Select the top-level data table element for which you wish to create or edit a DB Filter. Do this by clicking either the element tag in Design View or the element name in the schema tree.
- 2. Select **Database** | **Edit DB Filter** or click the toolbar icon for the command. This pops up the Edit Database Filters dialog.

- 3. To add criteria use the **Append AND** and **Append OR** buttons. To move a criterion up or down, use the arrow buttons. To delete a criterion, use the Delete button.
- 4. Specify the criteria for the DB Filter. Each criterion consists of three parts: Field Name + Operator + Value. The options for Field Names and Operators are available in combo boxes. The value of the expression must be keyed in, and may be a parameter (indicated by a preceding \$ character).

Clear DB Filter command

The Clear DB Filter command deletes the filter after asking for and receiving a confirmation from you.

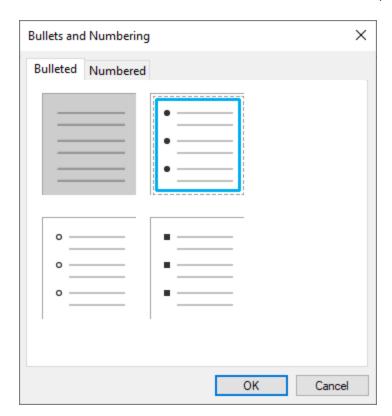

17.13 **Properties Menu**

The Properties menu contains commands that enable you to insert lists and define datatype formats for the input formatting 455 feature. The description of the commands is organized into the following sub-sections:

- Bullets and Numbering 1049 command, to insert lists.
- Predefined Format Strings (049) command, to define numeric datatype formats for a given SPS.

Edit Bullets and Numbering 17.13.1

The Edit Bullets and Numbering command enables you to insert a list at the cursor location. Clicking the command pops up the Bullets and Numbering dialog (screenshot below), in which you can select the list style; in the case of a numbered list, the initial number can also be specified.

Predefined Value Formatting Strings 17.13.2

Any (content) placeholder, input field, or Auto-Calculation which is of a numeric, date, time, dateTime or duration datatype can be assigned a custom format with the Value Formatting 455 dialog. In the Value Formatting dialog, you can either create a format directly or select from a drop-down list of predefined formats.

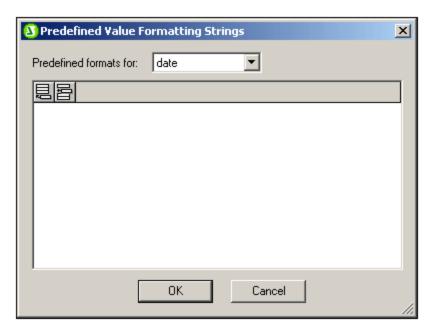

The predefined formats that are available in the dropdown list are of two types:

- Predefined formats that have been delivered with StyleVision, and
- Predefined formats that the user creates with the Predefined Value Formatting Strings command (this command). When a user creates predefined value formats, these are created for the currently open SPS file—not for the entire application. After the user creates predefined value formats, the SPS file must be saved in order for the formats to be available when the file is next opened.

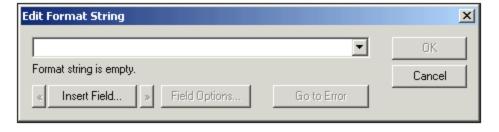

Creating a predefined value formatting string

A predefined value format string is specific to a datatype. To create a predefined value formatting string, do the following:

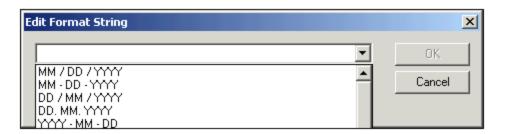

1. Click **Properties | Predefined Value Formatting Strings**. The following dialog appears:

2. Select a datatype from the drop-down list in the combo box, and then click the **Append** or **Insert** icon as required. This pops up the Edit Format String dialog:

If you click the down arrow of the combo box, a drop-down list with the StyleVision-supplied predefined formats for that datatype is displayed (shown in the screenshot below).

You can either select a format from the list and modify it, or you can enter a format directly into the input field. The syntax for defining a format is explained in the section, Value Formatting 455. If you need help with the syntax, use the **Insert Field** and **Field Options** buttons.

3. After you have defined a format, click **OK** and save the SPS file. The formatting string is added to the list of predefined formats for that datatype, and it will appear as an option in the Value Formatting dialog (of the current SPS file) when the selected element is of the corresponding datatype.

Note the following points:

- You can add as many custom format strings for different datatypes as you want.
- The sequential order of format strings in the Predefined Format Strings dialog determines the order in which these format strings appear in the Value Formatting dialog. The customized format strings appear above the supplied predefined formats.
- To edit a custom format string, double-click the entry in the Predefined Format Strings dialog.
- To delete a custom format string, select it, and click the **Delete** icon in the Predefined Value Formatting Strings dialog.

17.14 Tools Menu

The **Tools** menu contains the spell-check command and commands that enable you to customize StyleVision. Among other options, you can customize the toolbar, and specify spell-checking and FO processor options.

The description of the Tools menu commands is organized into the following sub-sections:

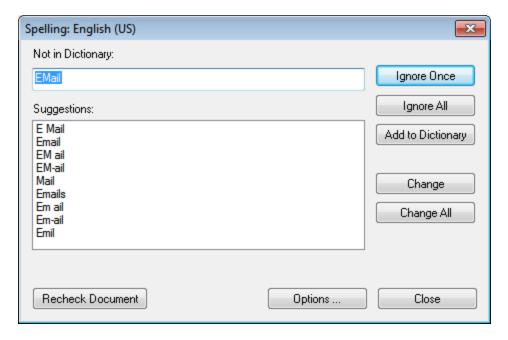

- Spelling 1052
- Spelling Options 1053
- Global Resources 1056
- Active Configuration 1057
- XBRL Taxonomy Manager 1058
- XML Schema Manager
 XML Schema Manager
- Customize 1058
- Options 1063

17.14.1 Spelling

The **Spelling** command runs a spelling check on the SPS (in Design View) or the document in Authentic View, depending on which is active. You can use what language to use from the spellchecker's built-in language dictionaries (*see note below*).

Note: The selection of built-in dictionaries that ship with Altova software does not constitute any language preferences by Altova, but is largely based on the availability of dictionaries that permit redistribution with commercial software, such as the MPL, LGPL, or BSD licenses. Many other open-source dictionaries exist, but are distributed under more restrictive licenses, such as the GPL license. Many of these dictionaries are available as part of a separate installer located at http://www.altova.com/dictionaries. It is your choice as to whether you can agree to the terms of the license applicable to the dictionary and whether the dictionary is appropriate for your use with the software on your computer.

On clicking this command, the dialog shown below appears. Words that are not present in the selected dictionary are displayed, in document order and one at a time, in the Not in Dictionary field of the dialog and highlighted in the Design Document.

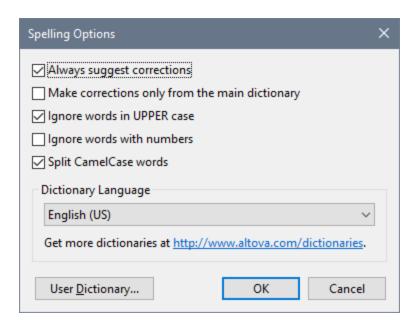

You can then select an entry from the list in the Suggestions pane and click **Change** or **Change All** to change the highlighted instance of this spelling or all its instances, respectively. (Double-clicking a word in the Suggestions list causes it to replace the unknown word.) Alternatively, you can ignore *this instance* of the unknown word (**Ignore Once**); or ignore *all instances* of this unknown word (**Ignore All**); or add this unknown word to the user dictionary (**Add to Dictionary**). Adding the unknown word to the dictionary causes the spell-checker to treat the word as correct and to pass on to the next word not found in the dictionary. You can recheck the document from the beginning (**Recheck Document**) or close the dialog (**Close**) at any time.

The **Options** button opens the <u>Spelling Options</u> dialog, in which you can specify options for the spelling check.

17.14.2 Spelling Options

The **Spelling options** command opens a dialog box (shown below) in which you specify options for the spelling check.

Always suggest corrections:

Activating this option causes suggestions (from both the language dictionary and the user dictionary) to be displayed in the Suggestions list box. Disabling this option causes no suggestions to be shown.

Make corrections only from main dictionary:

Activating this option causes only the language dictionary (main dictionary) to be used. The user dictionary is not scanned for suggestions. It also disables the **User Dictionary** button, preventing any editing of the user dictionary.

Ignore words in UPPER case:

Activating this option causes all upper case words to be ignored.

Ignore words with numbers:

Activating this option causes all words containing numbers to be ignored.

Split CamelCase words

CamelCase words are words that have capitalization within the word. For example the word "CamelCase" has the "C" of "Case" capitalized, and is therefore said to be CamelCased. Since CamelCased words are rarely found in dictionaries, the spellchecker would flag them as errors. To avoid this, the *Split CamelCase words* option splits CamelCased words into their capitalized components and checks each component individually. This option is checked by default.

Dictionary Language

Use this combo box to select the dictionary language for the spellchecker. The default selection is US English. Other language dictionaries are available for download free of charge from the <u>Altova website</u>.

Adding dictionaries for the spellchecker

For each dictionary language there are two Hunspell dictionary files that work together: a .aff file and .dic file. All language dictionaries are installed in a Lexicons folder at the following location: C:

\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons.

Within the Lexicons folder, different language dictionaries are each stored in a different folder: <language name>\<dictionary files>. For example, files for the two English-language dictionaries (English (British) and English (US)) will be stored as below:

```
 \begin{tabular}{l} $\tt C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (British) \english (British)
```

- C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (British)
 \en GB.dic
- C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (US)\en_US.aff
 C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (US)\en US.dic

In the Spelling Options dialog, the dropdown list of the *Dictionary Language* combo box displays the language dictionaries. These dictionaries are those available in the <code>Lexicons</code> folder and have the same names as the language subfolders in the <code>Lexicons</code> folder. For example, in the case of the English-language dictionaries shown above, the dictionaries would appear in the Dictionary Language combo box as: *English* (*British*) and *English* (*US*).

All installed dictionaries are shared by the different users of the machine and the different major versions of Altova products (whether 32-bit or 64-bit).

You can add dictionaries for the spellchecker in two ways, neither of which require that the files be registered with the system:

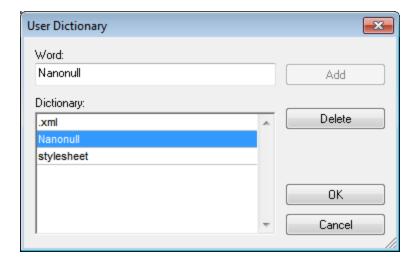

- By adding Hunspell dictionaries into a new subfolder of the Lexicons folder. Hunspell dictionaries can be downloaded, for example, from https://wiki.openoffice.org/wiki/Dictionaries or https://extensions.services.openoffice.org/en/dictionaries. (Note that OpenOffice uses the zipped OXT format. So change the extension to .zip and unzip the .aff and .dic file to the language folders in the Lexicons folder. Also note that Hunspell dictionaries are based on Myspell dictionaries. So Myspell dictionaries can also be used.)
- By using the <u>Altova dictionary installer</u>, which installs a package of multiple language dictionaries by default to the correct location on your machine. The installer can be downloaded via the link in the Dictionary language pane of the Spelling Options dialog (see screenshot below). Installation of the dictionaries must be done with administrator rights, otherwise installation will fail with an error.

Note: It is your choice as to whether you agree to the terms of the license applicable to the dictionary and whether the dictionary is appropriate for your use with the software on your computer.

Working with the user dictionary

Each user has one user dictionary, in which user-allowed words can be stored. During a spellcheck, spellings are checked against a word list comprising the words in the language dictionary and the user dictionary. You can add words to and delete words from the user dictionary via the User Dictionary dialog (*screenshot below*). This dialog is accessed by clicking the User Dictionary button in the Spelling Options dialog (*see second screenshot in this section*).

To add a word to the user dictionary, enter the word in the Word text box and click **Add**. The word will be added to the alphabetical list in the Dictionary pane. To delete a word from the dictionary, select the word in the Dictionary pane and click **Delete**. The word will be deleted from the Dictionary pane. When you have finished editing the User Dictionary dialog, click **OK** for the changes to be saved to the user dictionary.

Words may also be added to the User Dictionary during a spelling check. If an unknown word is encountered during a spelling check, then the <u>Spelling dialog</u> pops up prompting you for the action you wish to take. If you click the **Add to Dictionary** button, then the unknown word is added to the user dictionary.

The user dictionary is located at: C:\Users\<user>\Documents\Altova\SpellChecker\Lexicons\user.dic

17.14.3 Global Resources

The **Global Resources** command pops up the Altova Global Resources dialog (*screenshot below*), in which you can:

- Specify the Altova Global Resources XML File to use for global resources.
- Add file, folder, and database global resources (or aliases)
- Specify various configurations for each global resource (alias). Each configuration maps to a specific resource.

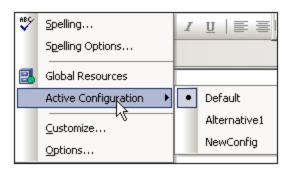

How to define global resources is described in detail in the section, <u>Defining Global Resources</u> ⁵⁴².

Note: The Altova Global Resources dialog can also be accessed via the <u>Global Resources toolbar</u> (View | Toolbars | Global Resources).

17.14.4 Active Configuration

Mousing over the **Active Configuration** menu item rolls out a submenu containing all the configurations defined in the currently active <u>Global Resources XML File</u> (screenshot below).

The currently active configuration is indicated with a bullet. In the screenshot above the currently active configuration is <code>Default</code>. To change the active configuration, select the configuration you wish to make active.

Note: The active configuration can also be selected via the Global Resources toolbar (View | Toolbars | Global Resources).

17.14.5 XBRL Taxonomy Manager

This command opens the Taxonomy Manager dialog, which enables you to manage your XBRL taxonomy packages.

To install an XBRL taxonomy, select the check box next to the taxonomy you want to install and click **Apply**. You can also uninstall taxonomies, upgrade taxonomies, check for new taxonomies, and generally manage all your taxonomies in one central location.

For more information, see <u>Taxonomy Manager</u> ⁷³⁷.

17.14.6 XML Schema Manager

This command opens the XML Schema Manager dialog, which enables you to manage your XML Schema packages.

To install an XML schema, select the check box next to the schema you want to install and click **Apply**. You can also uninstall schemas, upgrade schemas, check for new schemas, and generally manage all your schemas in one central location.

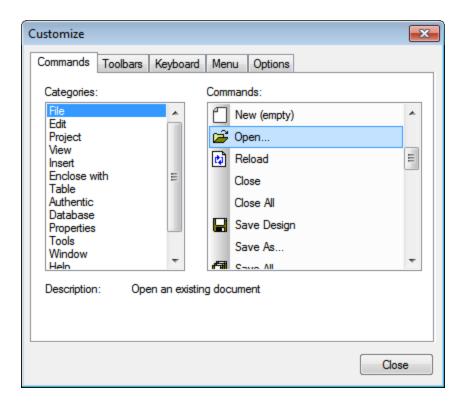

For more information, see Schema Manager 311.

17.14.7 **Customize**

The customize command lets you customize StyleVision to suit your personal needs.

Commands tab

The **Commands** tab of the Customize dialog allows you to place individual commands in the menu bar and the toolbar.

To add a command to the menu bar or toolbar, select the command in the Commands pane of the Commands tab, and drag it to the menu bar or toolbar. When the cursor is placed over a valid position an I-beam appears, and the command can be dropped at this location. If the location is invalid, a check mark appears. When you drop the command it is created as an icon if the command already has an associated icon; otherwise the command is created as text. After adding a command to the menu bar or toolbar, you can edit its appearance by right-clicking it and then selecting the required action.

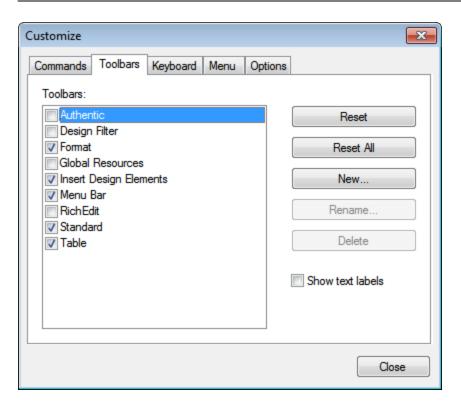

To delete a menu bar or toolbar item, with the Customize dialog open, right-click the item to be deleted, and select **Delete**.

Note:

- The customization described above applies to the application, and applies whether a document is open in StyleVision or not.
- To reset menus and toolbars to the state they were in when StyleVision was installed, go to the Toolbars tab and click the appropriate **Reset** button.

Toolbars tab

The **Toolbars** tab allows you to activate or deactivate specific toolbars, to show text labels for toolbar items, and to reset the menu bar and toolbars to their installation state.

The StyleVision interface displays a fixed menu bar and several optional toolbars (Authentic, Design Filter, Format, Standard, Table, and Table of Contents).

Each toolbar can be divided into groups of commands. Commands can be added to a toolbar via the Commands tab. A toolbar can be dragged from its docked position to any location on the screen. Double-clicking a toolbar's (maximized or minimized) title bar docks and undocks the toolbar.

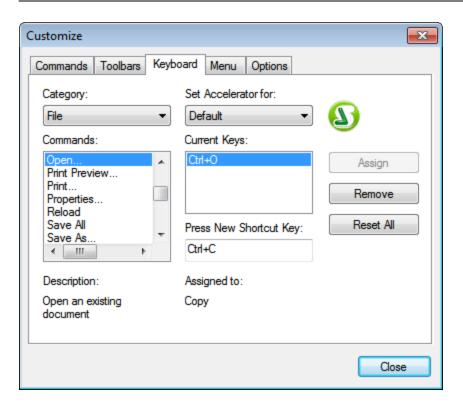

In the Toolbars tab of the Customize dialog, you can toggle a toolbar on and off by clicking in its checkbox. When a toolbar is selected (in the Toolbars tab), you can cause the text labels of that toolbar's items to be displayed by clicking the **Show text labels** check box. You can also reset a selected toolbar to the state it was in when StyleVision was installed by clicking the **Reset** button. You can reset all toolbars and the menu bar by clicking the **Reset All** button.

Note about Menu Bar

Commands can be added to, and items deleted from, the menu bar: see Commands above. To reset the menu bar to the state it was in when StyleVision was installed, select Menu Bar in the Toolbars tab of the Customize dialog, and click the **Reset** button. (Clicking the **Reset All** button will reset the toolbars as well.)

Keyboard tab

The **Keyboard** tab allows you to define (or change) keyboard shortcuts for any StyleVision command.

To assign a shortcut to a command

- 1. Select the category in which the command is by using the Category combo box.
- 2. Select the command you want to assign a shortcut to in the Commands list box.
- 3. Click in the Press New Shortcut Key input field, and press the shortcut keys that are to activate the command. The shortcut immediately appears in the Press New Shortcut Key input field. If this shortcut has already been assigned to a command, then that command is displayed below the input field. (For example, in the screenshot above, Ctrl+C has already been assigned to the Copy command and cannot be assigned to the Open File command.) To clear the New Shortcut Key input field, press any of the control keys, Ctrl, Alt, or Shift.
- 4. Click the **Assign** button to permanently assign the shortcut. The shortcut now appears in the Current Keys list box.

To de-assign (or delete) a shortcut

- 1. Select the command for which the shortcut is to be deleted.
- 2. Click the shortcut you want to delete in the Current Keys list box.
- 3. Click the **Remove** button (which has now become active).

To reset all keyboard assignments

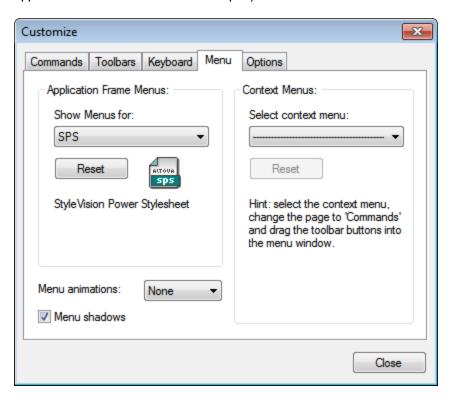

- 1. Click the **Reset All** button to go back to the original, installation-time shortcuts. A dialog box appears prompting you to confirm whether you want to reset all keyboard assignments.
- 2. Click **Yes** if you want to reset all keyboard assignments.

Set accelerator for

Currently no function is available.

Menu tab

The **Menu** tab allows you to customize the main menu bar as well as the context menus (right-click menus). There are two types of main menu bar: *Default* (which appears when no document is open), and *SPS* (which appears when an SPS document is open).

To customize a menu

- 1. Select the menu bar you want to customize (SPS menu in the screenshot above).
- 2. Click the **Commands** tab, and drag the commands to the menu bar of your choice.

To delete commands from a menu

- 1. In the Application Frame Menus pane, select either *Default* (which shows available menus when no document is open) or *SPS* (which shows available menus when one or more documents are open).
- 2. With the Customize dialog open, select (i) the menu you want to delete from the application's menu bar, or (ii) the command you want to delete from one of these menus.
- 3. Either (i) drag the menu from the menu bar or the menu command from the menu, or (ii) right-click the menu or menu command and select **Delete**.

To reset either of the menu bars

- 1. Select the menu entry you want to reset in the combo box of the Application Frame Menus pane.
- 2. Click the **Reset** button just below the menu name. A prompt appears asking if you are sure you want to reset the menu bar.

To customize a context menu (a right-click menu)

- 1. Select the context menu from the combo box.
- 2. Click the **Commands** tab and drag the commands to the context menu that is now open.

To delete commands from a context menu

- 1. Click right on the command or icon representing the command.
- 2. Select the **Delete** option from the popup menu or drag the command away from the context menu and drop it as soon as the check mark icon appears below the mouse pointer.

To reset a context menu

- 1. Select the context menu from the combo box, and
- 2. Click the **Reset** button just below the context menu name. A prompt appears asking if you are sure you want to reset the context menu.

To close a context menu window

- Click on the Close icon at the top right of the title bar, or
- Click the Close button of the Customize dialog box.

Menu animations

The menu animation option specifies the way a menu is displayed when a menu is clicked. Select an option from the drop-down list of menu animations.

Menu shadows

If you wish to have menus displayed with a shadow around it, select this option. All menus will then have a shadow

Options tab

The **Options** tab allows you to customize additional features of the toolbar.

Screen Tips for toolbar items will be displayed if the Show Screen Tips option is checked. The Screen Tips option has a sub-option for whether shortcuts (where available) are displayed in the Screen Tips or not.

17.14.8 Restore Toolbars and Windows

This command restores toolbars, windows, entry helpers and other GUI components to their default state. You will need to restart StyleVision for the changes to take effect.

17.14.9 **Options**

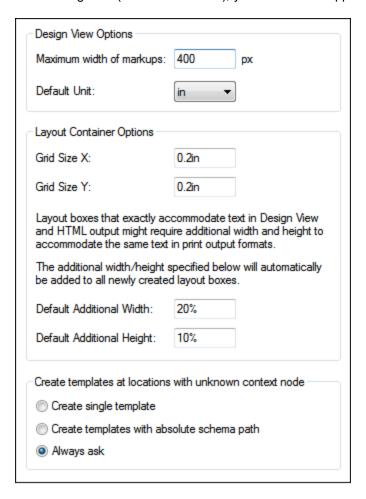

The **Options** command opens a dialog in which you specify settings for:

- The <u>properties of the following Design View components</u> markup tags, layout containers, and templates with no known context
- Select options for the previews 1065
- Sorting of attributes and elements in the Schema Tree View
 Sorting of attributes and elements in the Schema Tree View
- Actions to undertake when a file is double-clicked from within a project window
- The encoding of output documents 1066
- The <u>processing of the internally generated XSL-FO document (1057)</u>, which is required in order to enable the PDF Preview and the generation of PDF files in StyleVision
- The XBRL taxonomy packages that should be used for validations and transformations

- The conversion of SPS files to <u>MobileTogether Design files</u> ¹⁰⁷⁵
- Locating the <u>Java Virtual Machine</u> 1075
- <u>Selecting the default Help format</u> (Online Help or local PDF file) to open when the <u>Help</u> command (1078) is selected

Design options

In the Design tab (screenshot below), you can set the application-wide general options for designs.

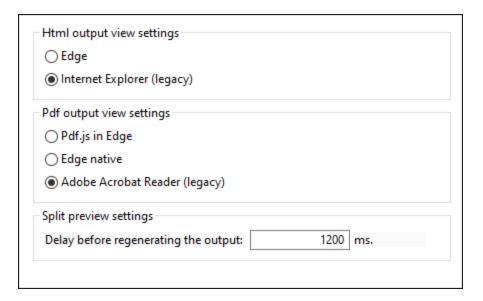

The following options can be set:

- Maximum width (in pixels) of markup tags. Enter the positive integer that is the required number of pixels.
- Grid size of layout containers in absolute length units. The specified lengths are the distances between two points on the respective grid axis.
- Default additional width and height of Layout Boxes. These additional lengths are added to all layout boxes in order to provide the extra length that is often required to accommodate the bigger text renditions of print formats. These values can be specified as percentage values or as absolute length units.
- The default behavior when a node-template is created at a location where the context node is not known. This option typically applies to User-Defined Templates in which the template has been created for items that cannot be placed in context in the schema source of the design. If a node is created

within such a user-defined template, then the node can be created with (i) only its name, or (ii) with the full path to it from the schema root. You can set one of these options as the default behavior, or, alternatively, ask to be prompted each time this situation arises. The default selection for this option is Always Ask.

Previews

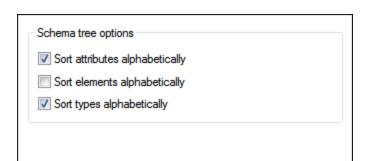

In the Previews tab (screenshot below), you can select options for the previews.

- HTML Output: Select whether to use Edge/Webview2 or Internet Explorer as the browser for HTML previews.
- PDF Output: Select which PDF reader to use for the PDF preview: (i) PDF.js (an open-source PDF viewer for browsers) in Edge; (ii) Edge native (the built-in PDF reader of Microsoft Edge); or (iii) Adobe Acrobat Reader.
- Split Preview settings: You can set a delay for the output previews that are generated on automatic refreshes. Automatic refreshes occur when the design is modified or data is revised in Authentic View. If you set, for example, a zero delay, then the output preview will be regenerated with a zero delay each time the design or Authentic data is modified. If the delay is a short period, then the output generation will be triggered at short intervals and therefore occur at high frequency. This might result not only in slow output-preview generation, but also to intermediate outputs, such as error messages that occur if a modification in progress leads to a temporarily invalid design or invalid data. On the other hand, a long delay could lead to a long wait for the output preview. Select an optimal value according to the size of your design and data. Note that the delay specified in this setting does not apply when you first switch to the split preview or when you run a manual refresh by clicking the Refresh button of the Output preview pane. In both these latter cases, the output is generated immediately.

Schema options

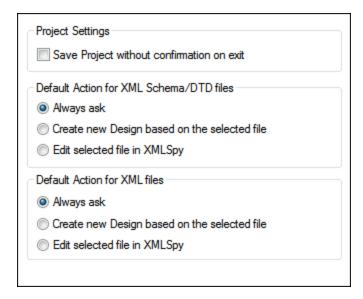

In the Schema tab, elements and attributes can be listed alphabetically in ascending order. To do this, check the respective check boxes in the Schema tab (screenshot below). By default, attributes are listed alphabetically and elements are listed in an order corresponding to the schema structure, as far as this is possible.

Project options

1066

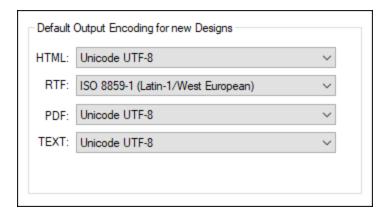

In the Project sidebar, when an XML file or XSD file is double-clicked, one of three actions is executed depending on the options set in the Project tab of the Options dialog (*screenshot below*): (i) Edit the file in XMLSpy; (ii) Create a new design based on the selected file; (iii) Ask the user which action to execute.

If the *Save Without Confirmation* setting is checked, then any changes to the project are automatically saved when the project or StyleVision is closed. Otherwise, you will be prompted to save any unsaved changes.

Default Encoding (of output files)

In the Default Encoding tab (*screenshot below*), you can set default encodings for the various outputs separately. The encoding specifies the codepoints sets for various character sets. The dropdown list of each combo box displays a list of encoding options. Select the encoding you require for each output type, and click **OK**. Every new SPS you create from this point on will set the respective output encodings as defined in this tab.

In the XSLT-for-HTML, the output encoding information is registered at the following locations:

- In the encoding attribute of the stylesheet's xsl:output element:

 <xsl:output version="1.0" encoding="UTF-8" indent="no" omit-xml-declaration="no"

 media-type="text/html" />
- In the charset attribute of the content-type meta element in the HTML header:

 <meta http-equiv="Content-Type" content="text/html; charset=UTF-8" />

In the XSLT-for-RTF, the output encoding information is registered in the <code>encoding</code> attribute of the stylesheet's <code>xsl:output element</code>:

```
<xsl:output version="1.0" encoding="ISO-8859-1" indent="no" method="text" omit-xml-
declaration="yes" media-type="text/rtf" />
```

In the XSLT-for-PDF, the output encoding information is registered in the encoding attribute of the stylesheet's xsl:output element:

```
<xsl:output version="1.0" encoding="UTF-8" indent="no" omit-xml-declaration="no" media-
type="text/html" />
```

Note: These settings are the default encodings, and will be used for new SPSs. You cannot change the encoding of the currently open SPS using this dialog. To change the encoding of the currently open SPS, use the <u>File | Properties</u> command.

XSL options

In the XSL options tab, you can specify a few parameters about the HTML and PDF outputs generated by StyleVision.

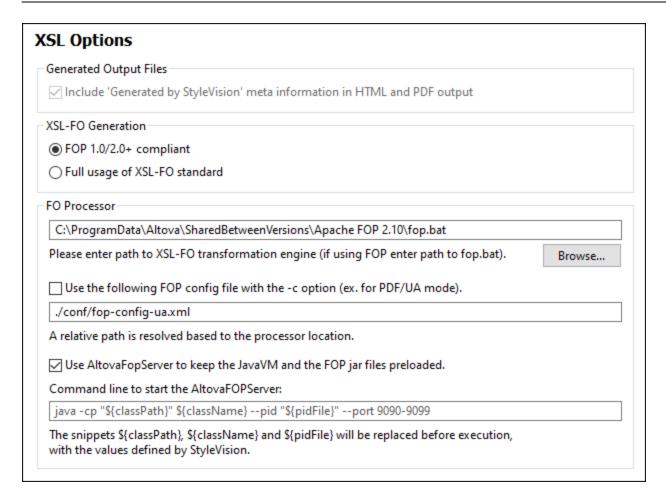

Disabling proprietary line

In the meta information of HTML and PDF output files, the line 'Generated by StyleVision' will be added by default. Purchased versions of StyleVision provide an option to disable the generation of this line.

About XSL-FO generation and PDF generation

PDF generation from an XML document is a two-step process:

- 1. The XML document is processed by the the currently active SPS or an XSLT document to generate an XSL-FO document.
- 2. The XSL-FO document is passed to an FO processor, which generates the PDF document. This is the PDF document that is displayed in the PDF Preview window.

XSL-FO Generation

In the XSL-FO Generation pane, you can specify what compliance level the generated XSL-FO document should have. Select the compliance level according to the FO processor you plan to use. If you are going to use Apache's FOP processor, select the first option (see screenshot above). In this case, the SPS will generate an XSL-FO document in which those XSL-FO features that are not supported by FOP are filtered out. If you plan to use an FO processor that is fully compliant, select the second option.

Depending on your selection, be aware of the possible outcomes, which are as follows:

- If you have selected FOP 1.0/2.x compliance and use FOP as your processor, then the PDF generation should work fine.
- If you have selected full usage of the XSL-FO standard and use FOP as your processor, then any formatting object or property in the XSL-FO document that is not supported by the current version of FOP will cause FOP to generate either a warning or an error. An error is fatal, and no PDF will be generated.
- If you use a processor other than FOP, the success of the transformation will depend upon the compliance level of the processor.

For standard use, we recommend:

- Installing FOP 2.10. If you notice any problems with FOP 2.10, the try either FOP 2.9, FOP 1.0 or FOP 0.93.
- Selecting FOP 1.0/2.x compliant in the Options dialog.

Note: The XSLT-for-FO that you generate with the **File | Save Generated Files | Save Generated XSL-FO File** command will have the compliance level you select in this dialog. Any error will be reported only when the XSL-FO document is processed by the FO processor.

Technical Note

StyleVision starts the FO processor at the path location you enter in the *FO Processor* pane of this dialog. It sends the following arguments to the executable:

```
%1 : -fo
%2 : filename.fo
%3 : -pdf
%4 : filename.pdf
```

These arguments are as used in the FOP command: FOP -fo filename.fo -pdf fileame.pdf. You can use these arguments to invoke any other FO processor if these four arguments suffice to make a successful call.

FO Processor

You can use any FO processor of your choice. Enter the path to the processor's executable in this pane. For details, see <u>Setting up StyleVision</u> 27.

You can specify a particular FOP config file to use when running FOP. (A configuration file would be useful, for example, if you want to generate PDFs in UA mode.) A default FOP config file for UA compatibility named fop-config-u.xml is stored in the conf folder of your Apache FOP installation folder. Note: When using the veraPDF validator for validating a PDF/UA document, you might get a validation error because the config file uses embedding-mode="subset" for its default font-embedding. To fix this error, open the config file and change the font's embedding-mode attribute to a value of full. Be aware, however, that full embedding would increase the size of the PDF noticeably.

You can use AltovaFOPServer to speed up transformations. The higher speed is obtained because AltovaFOPServer keeps the Java VM and FOP jar files loaded after the first transformation. The AltovaFOPServer is stopped when StyleVision is closed.

The command to start AltovaFOPServer at the command line has the following syntax:

```
java -cp "${classPath}" ${className} --pid "${pidFile}" --port 9090-9099
```

The classPath argument must contain the paths to the gson.jar and AltovaFOPServer.jar files.

An example command line to start AltovaFOPServer:

```
java -cp "C:\Program Files\Altova\Common2024\jar\gson\gson.jar;C:\Program
Files\Altova\Common2024\jar\AltovaFOPServer.jar" com.altova.stylevision.fopserver.Main
--pid "C:\Users\user\AppData\Local\Temp\AltovaFopServer.pid" --port 9090-9103,9999
```

StyleVision will by itself replace the argument snippets with the correct values, so you do not have to enter their values. If, however, you wish to use jar files that are at some specific locations, then you should replace the argument snippets with the actual paths to these locations.

Taxonomy packages

The Taxonomy Packages pane (i) provides access to <u>Taxonomy Manager</u> and (ii) enables you to add custom packages. Altova's XBRL Taxonomy Manager allows you to install, upgrade, and manage commonly used taxonomies. How to use it is described in the section <u>Taxonomy Manager</u> . The description below focuses exclusively on the installation of custom taxonomy packages.

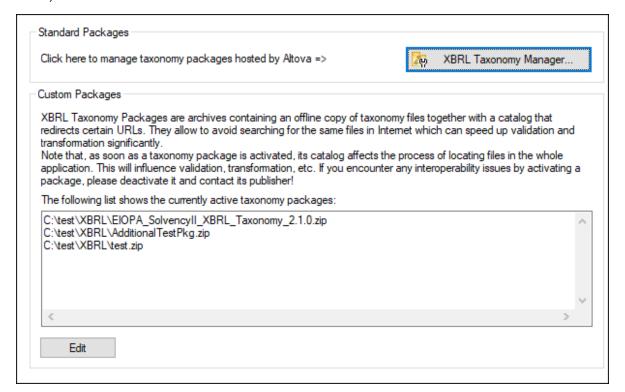

An XBRL Taxonomy Package is a zipped archive that contains an offline copy of a taxonomy. The package contains a catalog XML file that maps URIs to the taxonomy's file locations, and so makes the taxonomy available offline to applications. The rules that specify how taxonomy packages are to be structured and built are laid out in the Taxonomy Packages Recommendation of XBRL.org.

After you have downloaded a taxonomy package, you can set up StyleVision to automatically identify and use the entry point catalog file of the package. Do this by adding the package to the list of active taxonomy packages. The catalog files of active packages will then be used to locate resources for operations such as XBRL validation.

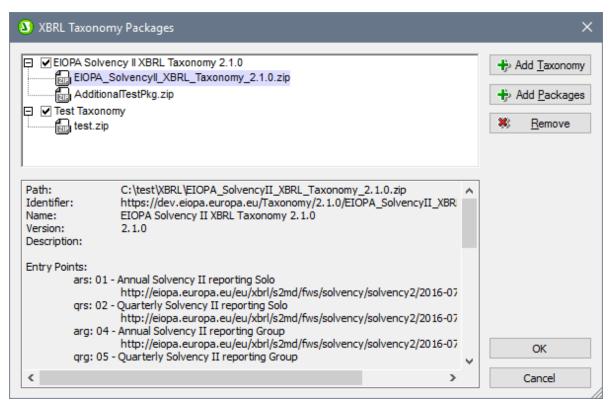

Note: A resource pointed to by an active package's catalog file will be used for all StyleVision operations that require that resource. If such a resource is different in some way than the resource that was previously used by StyleVision, then errors might result when operations are run. For more information, see the caution at the bottom of this topic.

To add a taxonomy package, do the following:

1. Select **Tools | Options | Taxonomy Packages** to display the Taxonomy Packages pane (*screenshot below*).

2. Click **Edit** (see screenshot above) to display the XBRL Taxonomy Packages dialog (screenshot below).

- 3. Click **Add Taxonomy**, then browse to the location of the taxonomy package, select it, and click **Open**. (You can also select multiple packages to add at one time.) The package will be added to the taxonomy package list in the dialog. The list is displayed as a tree of two levels. The first level indicates the taxonomy; the second level shows the packages of that taxonomy. The check box to the left of a taxonomy entry indicates whether that taxonomy is active or not. A newly added taxonomy will be active by default.
- 4. Click **OK** to finish. The newly added packages will be displayed in the Taxonomy Packages pane of the Options dialog (*first screenshot above*).

Note the following points:

- If you wish to add an additional package to a taxonomy, do this: Select the taxonomy in the XBRL Taxonomy Packages dialog (*screenshot above*), then add the additional package/s via the **Add Packages** button. The added package/s will be displayed at the second level of that taxonomy.
- When a taxonomy package is selected in the list in the upper pane of the XBRL Taxonomy Packages
 dialog, its details (including its offline location) are displayed in the dialog's lower pane (see screenshot
 above).
- To deactivate a taxonomy, uncheck its check box. If you deactivate a taxonomy, its catalog file/s will not be used. Deactivation is useful if, say, you wish to switch between two versions of a taxonomy.
- You can remove a package by selecting it and clicking Remove.
- The following Altova applications support Taxonomy Package Registration: XMLSpy, MapForce, and StyleVision. The taxonomy package list is common to all these applications. If you edit the list in one application, then the modified list will be displayed in the other applications as well. If you edit the package list in one application, and another application is open at the same time, then the other

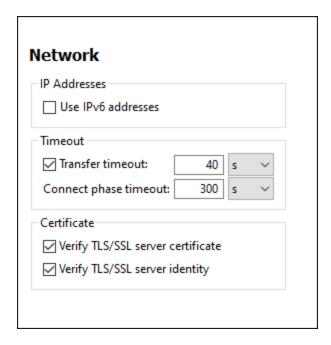

application will display an alert asking whether you wish to reload the package list to reflect the modification.

Caution: Package catalogs might redirect to incompatible resources

A resource pointed to by an active package's catalog file/s will be used for all StyleVision operations that require that resource. An example of such a resource would be XML Schema, which is used for both XML validation as well as XBRL validation. If the offline resource located by the package's catalog file is incompatible with your existing environment, then errors might result. In this case, deactivate the taxonomy package and contact the creators of the package with the error information.

Network options

The **Network** section (*screenshot below*) enables you to configure important network settings.

IP addresses

When host names resolve to more than one address in mixed IPv4/IPv6 networks, selecting this option causes the IPv6 addresses to be used. If the option is not selected in such environments and IPv4 addresses are available, then IPv4 addresses are used.

Timeout

- Transfer timeout: If this limit is reached for the transfer of any two consecutive data packages of a transfer (sent or received), then the entire transfer is aborted. Values can be specified in seconds [s] or milliseconds [ms], with the default being 40 seconds. If the option is not selected, then there is no time limit for aborting a transfer.
- Connection phase timeout: This is the time limit within which the connection has to be established, including the time taken for security handshakes. Values can be specified in seconds [s] or milliseconds [ms], with the default being 300 seconds. This timeout cannot be disabled.

Certificate

- Verify TLS/SSL server certificate: If selected, then the authenticity of the server's certificate is checked
 by verifying the chain of digital signatures until a trusted root certificate is reached. This option is
 enabled by default. If this option is not selected, then the communication is insecure, and attacks (for
 example, a man-in-the-middle attack) would not be detected. Note that this option does not verify that
 the certificate is actually for the server that is communicated with. To enable full security, both the
 certificate and the identity must be checked (see next option).
- Verify TLS/SSL server identity: If selected, then the server's certificate is verified to belong to the server
 we intend to communicate with. This is done by checking that the server name in the URL is the same
 as the name in the certificate. This option is enabled by default. If this option is not selected, then the
 server's identify is not checked. Note that this option does not enable verification of the server's
 certificate. To enable full security, both the certificate as well as the identity must be checked (see
 previous option).

Network Proxy options

The *Network Proxy* section enables you to configure custom proxy settings. These settings affect how the application connects to the Internet (for XML validation purposes, for example). By default, the application uses the system's proxy settings, so you should not need to change the proxy settings in most cases. If necessary, however, you can set an alternative network proxy by selecting, in the *Proxy Configuration* combo box, either *Automatic* or *Manual* to configure the settings accordingly.

Note: The network proxy settings are shared among all Altova MissionKit applications. So, if you change the settings in one application, all MissionKit applications will be affected.

<u>Use system proxy settings</u>

Uses the Internet Explorer (IE) settings configurable via the system proxy settings. It also queries the settings configured with netsh.exe winhttp.

Automatic proxy configuration

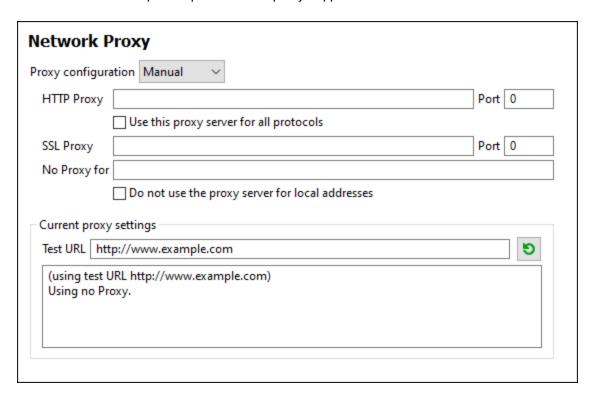

The following options are provided:

 Auto-detect settings: Looks up a WPAD script (http://wpad.Localdomain/wpad.dat) via DHCP or DNS, and uses this script for proxy setup.

- Script URL: Specify an HTTP URL to a proxy-auto-configuration (.pac) script that is to be used for proxy setup.
- Reload: Resets and reloads the current auto-proxy-configuration. This action requires Windows 8 or newer, and may need up to 30s to take effect.

Manual proxy configuration

Manually specify the fully qualified host name and port for the proxies of the respective protocols. A supported scheme may be included in the host name (for example: http://hostname). It is not required that the scheme is the same as the respective protocol if the proxy supports the scheme.

The following options are provided:

- HTTP Proxy: Uses the specified host name and port for the HTTP protocol. If Use this proxy server for all protocols is selected, then the specified HTTP proxy is used for all protocols.
- SSL Proxy: Uses the specified host name and port for the SSL protocol.
- No Proxy for: A semi-colon (;) separated list of fully qualified host names, domain names, or IP addresses for hosts that should be used without a proxy. IP addresses may not be truncated and IPv6 addresses have to be enclosed by square brackets (for example:

 [2606:2800:220:1:248:1893:25c8:1946]
 Domain names must start with a leading dot (for example: .example.com).
- Do not use the proxy server for local addresses: If checked, adds <local> to the No Proxy for list. If this option is selected, then the following will not use the proxy: (i) 127.0.0.1, (ii) [::1], (iii) all host names not containing a dot character (.).

Note: If a proxy server has been set and you want to deploy a transformation to <u>Altova FlowForce Server</u>, you must select the option *Do not use the proxy server for local addresses*.

Current proxy settings

Provides a verbose log of the proxy detection. It can be refreshed with the **Refresh** button to the right of the *Test URL* field (for example, when changing the test URL, or when the proxy settings have been changed).

• Test URL: A test URL can be used to see which proxy is used for that specific URL. No I/O is done with this URL. This field must not be empty if proxy-auto-configuration is used (either through Use system proxy settings or Authomatic proxy configuration).

MobileTogether Design

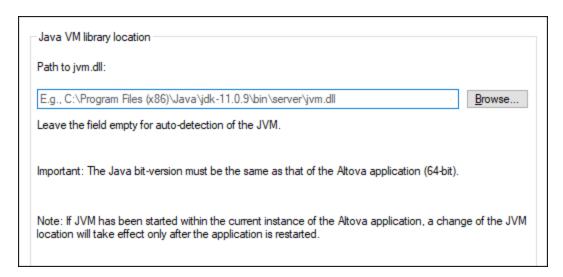

The options listed below are available for the conversion of SPS files to MobileTogether Design (MTD) files. (These conversions are done via the **Export as MobileTogether Design File** (985) command.)

- Static text and paragraph-level text that contain inline formatting (for example a paragraph element that contains a bold or italic element) is by default converted into a single MTD label, where the text will have the formatting of the block-level text. You can however set an option to split this kind of text (block-level text with inline formatting) into multiple MTD labels, where each label has the formatting that corresponds to the original text fragment.
- If the SPS has a condition with branches, then the conversion to MTD will, by default, convert all branches of the condition and will position them in sequence one below the other in the MTD document. You can optionally choose to suppress the conversion of the condition (and all its branches).

Java options

In the Java section (see screenshot below), you can optionally enter the path to a Java VM (Virtual Machine) on your file system. Note that adding a custom Java VM path is not always necessary. By default, StyleVision attempts to detect the Java VM path automatically by reading (in this order) the Windows registry and the JAVA_HOME environment variable. The custom path added in this dialog box will take priority over any other Java VM path detected automatically.

You may need to add a custom Java VM path, for example, if you are using a Java virtual machine which does not have an installer and does not create registry entries (e.g., Oracle's OpenJDK). You might also want to set this path if you need to override, for whatever reason, any Java VM path detected automatically by StyleVision.

Note the following:

- The Java VM path is shared between Altova desktop (not server) applications. Consequently, if you change it in one application, it will automatically apply to all other Altova applications.
- The path must point to the jvm.dll file from the \bin\server or \bin\client directory, relative to the directory where the JDK was installed.
- The StyleVision platform (32-bit, 64-bit) must be the same as that of the JDK.
- After changing the Java VM path, you may need to restart StyleVision for the new settings to take effect.

Changing the Java VM path affects the following areas:

- JDBC connectivity
- Java extension functions for XSLT/XPath
- Barcode support

Help

StyleVision provides Help (the user manual) in two formats:

- Online Help, in HTML format, which is available at the Altova website. In order to access the Online Help you will need Internet access.
- A Help file in PDF format, which is installed on your machine when you install StyleVision. It is named StyleVision.pdf and is located in the application folder (in the Program Files folder). If you do not have Internet access, you can always open this locally saved Help fie.

The Help option (*screenshot below*) enables you to select which of the two formats is opened when you click the **Help (F1)** command in the **Help** menu.

Help

Use <u>Altova Online Help</u>

O Use help file saved locally on your disk

You can change this option at any time for the new selection to take effect. The links in this section (see screenshot above) open the respective Help format.

17.15 Window Menu

The Window menu has commands to specify how StyleVision windows should be displayed in the GUI (cascaded, tiled, or maximized). To maximize a window, click the maximize button of that window.

Additionally, all currently open document windows are listed in this menu by document name, with the active window being checked. To make another window active, click the name of the window you wish to make active.

Windows dialog

At the bottom of the list of open windows is an entry for the Windows dialog. Clicking this entry opens the Windows dialog, which displays a list of all open windows and provides commands that can be applied to the selected window/s. (A window is selected by clicking on its name.)

Warning: To exit the Windows dialog, click OK; do not click the Close Window(s) button. The Close Window(s) button closes the window/s currently selected in the Windows dialog.

17.16 Help Menu

The **Help** menu contains commands to access the onscreen help manual for StyleVision, commands to provide information about StyleVision, and links to support pages on the Altova web site. The Help menu also contains the Registration dialog which lets you enter your license key-code once you have purchased the product.

The description of the **Help** menu commands is organized into the following sub-sections:

- Help 1078
- Activation, Order Form, Registration, Updates 1078
- Other Commands 1081

17.16.1 Help

The **Help (F1)** command opens the application's Help documentation (its user manual). By default, the Online Help in HTML format at the Altova website will be opened.

If you do not have Internet access or do not want, for some other reason, to access the Online Help, you can use the locally stored version of the user manual. The local version is a PDF file named styleVision.pdf that is stored in the application folder (in the Program Files folder).

If you want to change the default format to open (Online Help or local PDF), do this in the Help section of the Options dialog (menu command **Tools | Options**).

17.16.2 Activation, Order Form, Registration, Updates

Software Activation

License your product

After you download your Altova product software, you can license—or activate—it using either a free evaluation key or a purchased permanent license key.

- Free evaluation license. When you first start the software after downloading and installing it, the Software Activation dialog will pop up. In it is a button to request a free evaluation license. Click it to get your license. When you click this button, your machine-ID will be hashed and sent to Altova via HTTPS. The license information will be sent back to the machine via an HTTP response. If the license is created successfully, a dialog to this effect will appear in your Altova application. On clicking OK in this dialog, the software will be activated for a period of 30 days on this particular machine.
- **Permanent license key.** The **Software Activation** dialog allows you to purchase a permanent license key. Clicking this button takes you to Altova's online shop, where you can purchase a permanent license key for your product. Your license will be sent to you by e-mail in the form of a license file, which contains your license-data.

There are three types of permanent license: installed, concurrent user, and named user. An

installed license unlocks the software on a single computer. If you buy an installed license for *N* computers, then the license allows use of the software on up to *N* computers. A concurrent-user license for *N* concurrent users allows *N* users to run the software concurrently. (The software may be installed on 10N computers.) A named-user license authorizes a specific user to use the software on up to 5 different computers. To activate your software, click **Upload a New License**, and, in the dialog that appears, enter the path to the license file, and click **OK**.

Note: For multi-user licenses, each user will be prompted to enter his or her own name.

Your license email and the different ways to license (activate) your Altova product

The license email that you receive from Altova will contain your license file as an attachment.

The license file has a .altova_licenses file extension.

To activate your Altova product, you can do one of the following:

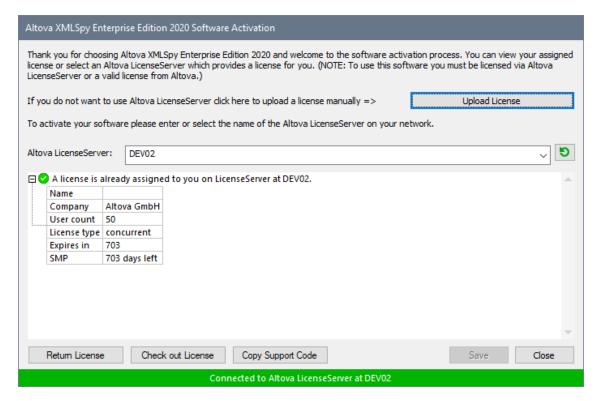

- Save the license file (.altova_licenses) to a suitable location, double-click the
 license file, enter any requested details in the dialog that appears, and finish by
 clicking Apply Keys.
- Save the license file (.altova_licenses) to a suitable location. In your Altova product, select the menu command Help | Software Activation, and then Upload a New License. Browse for or enter the path to the license file, and click OK.
- Save the license file (.altova_licenses) to any suitable location, and upload it from this location to the license pool of your <u>Altova LicenseServer</u>. You can then either: (i) acquire the license from your Altova product via the product's Software Activation dialog (see below) or (ii) assign the license to the product from Altova LicenseServer. For more information about licensing via LicenseServer, read the rest of this topic.

You can access the **Software Activation** dialog (*screenshot below*) at any time by clicking the **HeIp** | **Software Activation** command.

Activate your software

You can activate the software by registering the license in the Software Activation dialog or by licensing via Altova LicenseServer (see details below).

- Registering the license in the Software Activation dialog. In the dialog, click Upload a New
 License and browse for the license file. Click OK to confirm the path to the license file and to
 confirm any data you entered (your name in the case of multi-user licenses). Finish by clicking
 Save.
- Licensing via Altova LicenseServer on your network: To acquire a license via an Altova LicenseServer on your network, click **Use Altova LicenseServer**, located at the bottom of the **Software Activation** dialog. Select the machine on which the LicenseServer you want to use has been installed. Note that the auto-discovery of License Servers works by means of a broadcast sent out on the LAN. As these broadcasts are limited to a subnet, License Server must be on the same subnet as the client machine for auto-discovery to work. If auto-discovery does not work, then type in the name of the server. The Altova LicenseServer must have a license for your Altova product in its license pool. If a license is available in the LicenseServer pool, this is indicated in the **Software Activation** dialog (see screenshot below showing the dialog in Altova XMLSpy). Click **Save** to acquire the license.

After a machine-specific (aka installed) license has been acquired from LicenseServer, it cannot be returned to LicenseServer for a period of seven days. After that time, you can return the machine license to LicenseServer (click **Return License**) so that this license can be acquired from LicenseServer by another client. (A LicenseServer administrator, however, can unassign an acquired license at any time via the administrator's Web UI of LicenseServer.) Note that the returning of licenses applies only to machine-specific licenses, not to concurrent licenses.

Check out license

You can check out a license from the license pool for a period of up to 30 days so that the license is stored on the product machine. This enables you to work offline, which is useful, for example, if you wish to work in an environment where there is no access to your Altova LicenseServer (such as when your Altova product is installed on a laptop and you are traveling). While the license is checked out, LicenseServer displays the license as being in use, and the license cannot be used by any other machine. The license automatically reverts to the checked-in state when the checkout period ends. Alternatively, a checked-out license can be checked in at any time via the **Check in** button of the **Software Activation** dialog.

To check out a license, do the following: (i) In the **Software Activation** dialog, click **Check out License** (see screenshot above); (ii) In the **License Check-out** dialog that appears, select the check-out period you want and click **Check out**. The license will be checked out. After checking out a license, two things happen: (i) The **Software Activation** dialog will display the check-out information, including the time when the check-out period ends; (ii) The **Check out License** button in the dialog changes to a **Check In** button. You can check the license in again at any time by clicking **Check In**. Because the license automatically reverts to the checked-in status after the check-out period elapses, make sure that the check-out period you select adequately covers the period during which you will be working offline.

If the license being checked out is a Installed User license or Concurrent User license, then the license is checked out to the machine and is available to the user who checked out the license. If the license being checked out is a Named User license, then the license is checked out to the Windows account of the named user. License check-out will work for virtual machines, but not for virtual desktop (in a VDI). Note that, when a Named User license is checked out, the data to identify that license check-out is stored in the user's profile. For license check-out to work, the user's profile must be stored on the local machine that will be used for offline work. If the user's profile is stored at a non-local location (such as a file-share), then the checkout will be reported as invalid when the user tries to start the Altova application.

License check-ins must be to the same major version of the Altova product from which the license was checked out. So make sure to check in a license before you upgrade your Altova product to the next major version.

Note: For license check-outs to be possible, the check-out functionality must be enabled on LicenseServer. If this functionality has not been enabled, you will get an error message to this effect when you try to check out. In this event, contact your LicenseServer administrator.

Copy Support Code

Click Copy Support Code to copy license details to the clipboard. This is the data that you will need to provide when requesting support via the online support form.

Altova LicenseServer provides IT administrators with a real-time overview of all Altova licenses on a network, together with the details of each license as well as client assignments and client usage of licenses. The advantage of using LicenseServer therefore lies in administrative features it offers for largevolume Altova license management. Altova LicenseServer is available free of cost from the Altova website. For more information about Altova LicenseServer and licensing via Altova LicenseServer, see the Altova LicenseServer documentation.

Order Form

When you are ready to order a licensed version of the software product, you can use either the **Purchase** a Permanent License Key button in the Software Activation dialog (see previous section) or the Order Form command to proceed to the secure Altova Online Shop.

Registration

Opens the Altova Product Registration page in a tab of your browser. Registering your Altova software will help ensure that you are always kept up to date with the latest product information.

Check for Updates

Checks with the Altova server whether a newer version than yours is currently available and displays a message accordingly.

Other Commands 17.16.3

Support Center

A link to the Altova Support Center on the Internet. The Support Center provides FAQs, discussion forums

where problems are discussed, and access to Altova's technical support staff.

■ Download Components and Free Tools

A link to Altova's Component Download Center on the Internet. From here you can download a variety of companion software to use with Altova products. Such software ranges from XSLT and XSL-FO processors to Application Server Platforms. The software available at the Component Download Center is typically free of charge.

■ StyleVision on the Internet

A link to the <u>Altova website</u> on the Internet. You can learn more about StyleVision, related technologies and products on the <u>Altova website</u>.

■ About StyleVision

Displays the splash window and version number of your product. If you are using the 64-bit version of StyleVision, this is indicated with the suffix (x64) after the application name. There is no suffix for the 32-bit version.

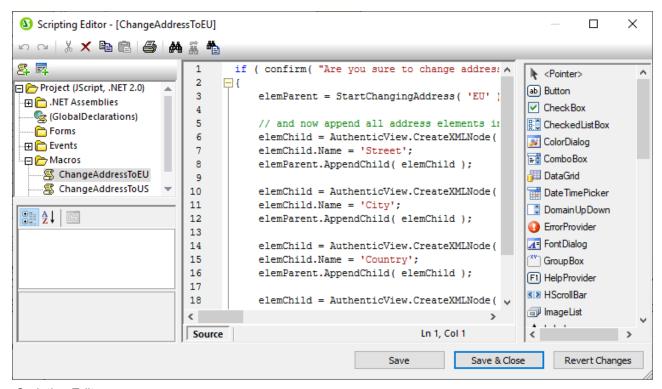

18 Programmers' Reference

StyleVision is an Automation Server. That is, it is an application that exposes programmable objects to other applications (called Automation Clients). As a result, an Automation Client can directly access the objects and functionality that the Automation Server makes available. This is beneficial to an Automation Client because it can make use of the functionality of StyleVision. For example, an Automation Client can generate an XSLT file from an SPS via StyleVision. Developers can therefore improve their applications by using the ready-made functionality of StyleVision.

The programmable objects of StyleVision are made available to Automation Clients via the **StyleVision API**, which is a COM API. A complete description of all available objects are provided in <u>its documentation</u>.

18.1 Scripting Editor

Scripting Editor is a development environment built into StyleVision from where you can customize the functionality of the Authentic View with the help of JScript or VBScript scripts. For example, you can add a new toolbar button that performs a custom task such as text formatting, or you can have StyleVision display a notification message box each time when an action is taken in the Authentic View. To make this possible, you create scripting projects—files with .asprj extension (Altova Scripting Project).

Scripting Editor

Scripting projects are portable; you can create them as part of the .sps (StyleVision Power Stylesheet) file. An Altova application that consumes the .sps file will be able to execute the macros inside the project—this can be not only StyleVision, but also XMLSpy or Authentic Desktop.

Scripting Editor requires .NET Framework 2.0 or later to be installed before StyleVision is installed.

18.1.1 Creating a Scripting Project

All scripts and scripting information created in the Scripting Editor are stored in Altova Scripting Projects (.asprj files). A scripting project may contain macros, application event handlers, and forms (which can have their own event handlers). In addition, you can add global variables and functions to a "Global Declarations" script—this makes such variables and functions accessible across the entire project. To start a new project:

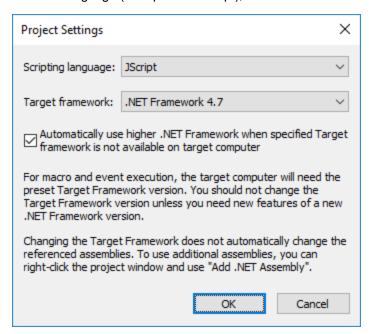

1. Create or open the .sps file that the scripting project should be part of.

- 2. Do one of the following:
 - On the Authentic menu, click Authentic Scripts.
 - Click the **Design** tab at the base of the main window, and then select **Authentic Script**.

Each .sps file can have a single scripting project assigned to it. To open an existing scripting project associated with an .sps file, follow the same instructions as above. This opens the Scripting Editor window. As you edit the scripting project, you can temporarily save changes in memory, by clicking the **Save** button at the base of Scripting Editor . To save the scripting project to disk, first click **Save & Close** in Scripting Editor, and then save the .sps file.

The languages supported for use in a scripting project are JScript and VBScript (not to be confused with Visual Basic, which is not supported). These scripting engines are available by default on Windows and have no special requirements to run. You can select a scripting language as follows:

- 1. Right-click the **Project** item in the upper-left pane, and select **Project settings** from the context menu.
- 2. Select a language (JScript or VBScript), and click **OK**.

From the Project settings dialog box above, you can also change the target .NET Framework version. This is typically necessary if your scripting project requires features available in a newer .NET Framework version. Note that any clients using your scripting project will need to have the same .NET Framework version installed (or a later compatible version).

By default, a scripting project references several .NET assemblies, like <code>System.Data</code>, <code>System.Windows.Forms</code>, and others. If necessary, you can import additional .NET assemblies, including assemblies from .NET Global Assembly Cache (GAC) or custom .dll files. You can import assemblies as follows:

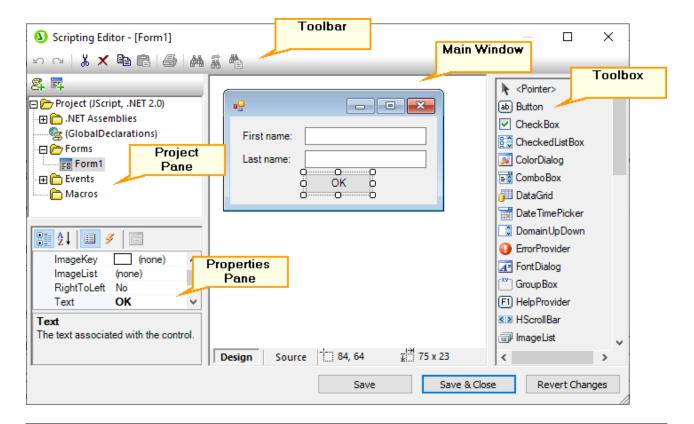

- 1. Statically, by adding them manually to the project. Right-click **Project** in the top-left pane, and select **Add .NET Assembly** from the context menu.
- 2. Dynamically, at runtime, by calling the CLR. LoadAssembly command from the code.

The next sections focus on the parts that your scripting project may need: global declarations, macros, forms, and events. For further information about scripting and examples of scripting projects, see <u>Authentic Scripting</u> 831.

18.1.1.1 Overview of the Environment

The Scripting Editor consists of the following parts:

- Toolbar
- Project pane
- Properties pane
- Main window
- Toolbox

The scripting project is saved when you save the .sps file of which the scripting project is part of. The **Save** button illustrated above creates only a temporary in-memory copy.

Toolbar

The toolbar includes the **Undo (Ctrl+Z)** and **Redo (Ctrl+Y)** commands and editor commands (**Copy**, **Cut**, **Delete**, **Paste**). When editing source code, the **Find** and **Replace** commands are additionally available, as well as the **Print** command.

Project pane

The project pane helps you view and manage the structure of the project. A scripting project consists of several components that can work together and may be created in any order:

- A "Global Declarations" script. As the name suggests, this script stores information available globally across the project. You can declare in this script any variables or functions that you need to be available in all forms, event handler scripts, and macros.
- Forms. Forms are typically necessary to collect user input, or provide some informative dialog boxes. A form is invoked by a call to it either within a function (in the Global Declarations script) or directly in a macro.
- Events. The "Events" folder displays StyleVision application events provided by the COM API. To write a script that will be executed when an event occurs, double-click any event, and then type the handling code in the editor. The application events should not be confused with form events; the latter are handled at form level, as further detailed below.
- Macros. A macro is a script that can be invoked either on demand from a context menu or be executed
 automatically when StyleVision starts. Macros do not have parameters or return values. A macro can
 access all variables and functions declared in the Global Declarations script and it can also display
 forms.

Right-click any of the components to see the available context menu commands and their shortcuts. Double-click any file (such as a form or a script) to open it in the main window.

The toolbar buttons provide the following quick commands:

New macro Adds a new macro to the project, in the **Macros** directory.

New form

Adds a new form to the project, in the **Forms** directory.

Properties pane

The Properties pane is very similar to the one in Visual Studio. It displays the following:

- Form properties, when a form is selected
- Object properties, when an object in a form is selected
- Form events, when a form is selected
- Object events, when an object in a form is selected

To switch between the properties and events of the selected component, click the **Properties** or **Events** to buttons, respectively.

The **Categorized** and **Alphabetical** icons display the properties or events either organized by category or organized in ascending alphabetical order.

When a property or event is selected, a short description of it is displayed at the bottom of the Properties pane.

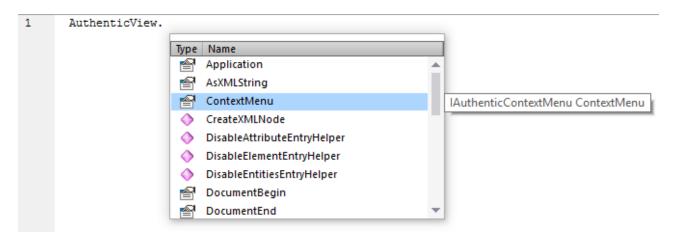

Main window

The main window is the working area where you can enter source code or modify the design of the form. When editing forms, you can work in two tabs: the **Design** tab and the **Source** tab. The **Design** tab shows the layout of the form, while the **Source** tab contains the source code such as handler methods for the form events.

The source code editor provides code editing aids such as syntax coloring, source code folding, highlighting of starting and ending braces, zooming, autocompletion suggestions, bookmarks.

Autocompletion suggestions

JScript and VBScript are untyped languages, so autocompletion is limited to COM API names and StyleVision built-in <u>commands</u> . The full method or property signature is shown next to the autocompletion entry helper.

Placing the mouse over a known method or property displays its signature (and documentation if available), for example:

The auto-completion entry helper is normally shown automatically during editing, but it can also be obtained on demand by pressing **Ctrl+Space**.

Book mark s

- To set or remove a bookmark, click inside a line, and then press Ctrl+F2
- To navigate to the next bookmark, press F2
- To navigate to the previous bookmark, press **Shift+F2**
- To delete all bookmarks, press Ctrl+Shift+F2

Zooming in/out

 To zoom in or out, hold the Ctrl key pressed and then press the "+" or "-" keys or rotate the mouse wheel.

Text view settings

To trigger text settings, right-click inside the editor, and select **Text View Settings** from the context menu.

Font settings

To change the font, right-click inside the editor, and select **Text View Font** from the context menu.

Toolbox

The Toolbox contains all the objects that are available for designing forms, such as buttons, text boxes, combo boxes, and so on.

To add a Toolbox item to a form:

- 1. Create or open a form and make sure that the **Design** tab is selected.
- 2. Click the Toolbox object (for example, **Button**), and then click at the location in the form where you wish to insert it. Alternatively, drag the object directly onto the form.

Some objects such as Timer are not added to the Form but are created in a tray at the bottom of the main window. You can select the object in the tray and set properties and event handlers for the object from the Properties pane. For an example of handling tray components from the code, see Handling form events [19].

You can also add registered ActiveX controls to the form. To do this, right-click the Toolbox area and select Add ActiveX Control from the context menu.

18.1.1.2 Global Declarations

The "Global Declarations" script is present by default in any scripting project; you do not need to create it explicitly. Any variables or functions that you add to this script are considered global across the entire project. Consequently, you can refer to such variables and functions from any of the project's macros and events. The following is an example of a global declarations script that imports the System, Windows, Forms namespace into the project. To achieve that, the code below invokes the CLR. Import command built into Scripting Editor.

```
// import System.Windows.Forms namespace for all macros, forms and events:
CLR.Import( "System.Windows.Forms" );
```

Note: Every time a macro is executed or an event handler is called, the global declarations are re-initialized.

18.1.1.3 Macros

Macros are scripts that contain JScript (or VBScript, depending on your project's language) statements, such as variable declarations and functions.

If your projects should use macros, you can add them as follows: right-click inside the Project pane, select Add Macro from the context menu, and then enter the macro's code in the main form. The code of a macro could be as simple as an alert, for example:

```
alert("Hello, I'm a macro!");
```

More advanced macros can contain variables and local functions. Macros can also contain code that invokes forms from the project. The listing below illustrates an example of a macro that shows a form. It is assumed that this form has already been created in the "Forms" folder and has the name "SampleForm", see also Forms 1091

```
// display a form
ShowForm( "SampleForm" );
```

In the code listing above, ShowForm is a command built into Scripting Editor. For reference to other similar commands that you can use to work with forms and .NET objects, see the <u>Built-in Commands</u>.

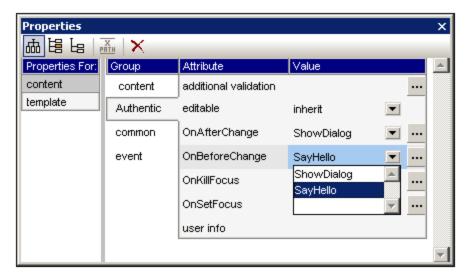

Only one macro can be run at a time. After a macro (or event) is executed, the script is closed and global variables lose their values.

To run a macro directly in Script Editor, click **Run Macro** . To debug a macro using the Visual Studio debugger, click **Debug Macro** .

Running macros

To run a macro, you need to first bind the macro to an Authentic event. The macro will run when that Authentic event is triggered. For example, say you wish to run a macro before editing text in Authentic. You must go about this as follows:

- 1. In Design View, select the editable content for which the macro is to be set.
- 2. In the Properties sidebar (*screenshot below*), select the *Authentic* group of properties of the relevant design component.

- 3. Select the Authentic event that will trigger the macro and open the dropdown list of this event's *Value* combo box. All the macros defined in the Scripting Project of the SPS will be listed. Select the macro you wish to associate with this function.
- 4. In Authentic View, when any Authentic event that has a macro assigned to it is triggered, then the macro will be executed.

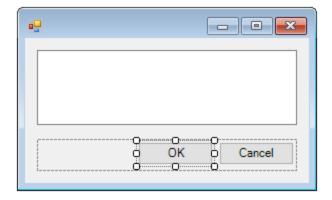

See the section, <u>Authentic Scripting >> Macros</u> (884), for a detailed description of how to use macros in a StyleVision design document.

18.1.1.4 Forms

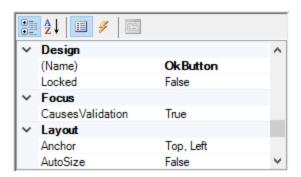

Forms are particularly useful if you need to collect input data from users or display data to users. A form can contain miscellaneous controls to facilitate this, such as buttons, check boxes, combo boxes, and so on.

To add a form, right-click inside the Project pane, and then select **Add Form** from the context menu. To add a control to a form, drag it from the Toolbox available to the right side of Scripting Editor and drop it onto the form.

You can change the position and size of the controls directly on the form, by using the handles that appear when you click any control, for example:

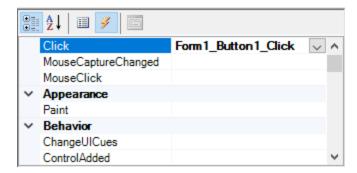

All form controls have properties that you can easily adjust in the Properties pane. To do this, first select the control on the form, and then edit the required properties in the Properties pane.

Handling form events

Each form control also exposes various events to which your scripting project can bind. For example, you might want to invoke some StyleVision COM API method whenever a button is clicked. To create a function that binds to a form event, do the following:

- 1. In the Properties pane, click **Events** [₹].
- 2. In the **Action** column, double-click the event where you need the method (for example, in the image below, the handled event is "Click").

You can also add handler methods by double-clicking a control on the form. For example, double-clicking a button in the form design generates a handler method for the "Click" event of that button.

Once the body of the handler method is generated, you can type code that handles this event, for example:

```
//Occurs when the component is clicked.
function MyForm_ButtonClick( objSender, e_EventArgs )
{
   alert("A button was clicked");
}
```

To display a work-in-progress form detached from the Scripting Editor, right-click the form in the Project window, and select **Test Form** from the context menu. Note that the **Test Form** command just displays the form; the form's events (such as button clicks) are still disabled. To have the form react to events, call it from a macro, for example:

```
// Instantiate and display a form
ShowForm( "SampleForm" );
```

Accessing form controls

You can access any components on a form from your code by using field access syntax. For example, suppose there is a form designed as follows:

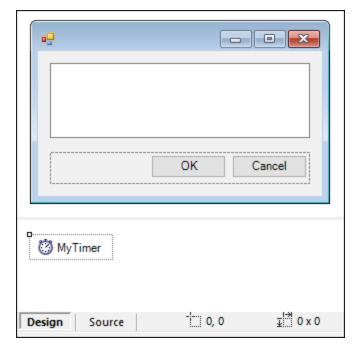

```
// MyForm
// ButtonPanel
// OkButton
// CancelButton
// TextEditor
// AxMediaPlayer1
// TrayComponents
// MyTimer
```

The code below shows how to instantiate the form, access some of its controls using field access syntax, and then display the form:

```
// Instantiate the form
var objForm = CreateForm("MyForm");
```

```
// Disable the OK button
objForm.ButtonPanel.OkButton.Enabled = false;
// Change the text of TextEditor
objForm.TextEditor.Text = "Hello";
// Show the form
objForm.ShowDialog();
```

When you add certain controls such as timers to the form, they are not displayed on the form; instead, they are shown as tray components at the base of the form design, for example:

To access controls from the tray, use the GetTrayComponent method on the form object, and supply the name of the control as argument. In this example, to get a reference to MyTimer and enable it, use the following code:

```
var objTimer = objForm.GetTrayComponent("MyTimer");
objTimer.Enabled = true;
```

For ActiveX Controls, you can access the underlying COM object via the OCX property:

```
var ocx = lastform.AxMediaPlayer1.OCX; // get underlying COM object
ocx.enableContextMenu = true;
ocx.URL = "mms://apasf.apa.at/fm4_live_worldwide";
```

18.1.1.5 Events

Your scripting project may optionally include scripts that handle events in the Authentic View, such as cutting, copying, or pasting text, or opening a context menu. These events are provided by the StyleVision COM API,

and you can find them in the "Events" folder of your scripting project. Note that these events are StyleVision-specific, as opposed to form events.

To create an event handler script, right-click an event, and select **Open** from the context menu (or double-click the event). The event handler script is displayed in the main window, where you can start editing it. For example, the event handler illustrated below calls a function when a toolbar button is executed. The function definition is in the <u>Global Declarations</u> (1039) script, so it is available to the event handler script.

```
Scripting Editor - [On_AuthenticToolbarButtonExecuted]
//event fired when a toolbar button action was executed
       OII_AUTHERITICUEFOFEFASTE
                                      2
                                            function On_AuthenticToolbarButtonExecuted( varBtnIdentifier )

4 On AuthenticBeforeSave

     4
                                               // After whatever command user has executed -
                                      5
                                               // make sure to update toolbar button states

On_AuthenticDragOver

                                               UpdateOwnToolbarButtonStates();
                                      6
     On_AuthenticKeyboardEvent
                                      7

§ On_AuthenticLoad

                                      8

On_AuthenticMouseEvent

     G On AuthenticToolbarButtonClicked
     On_AuthenticToolbarButtonExecuted
     On AuthenticUserAddedXMLNode
```

The name of the event handler function must not be changed; otherwise, the event handler script will not be called.

You can optionally define local variables and helper functions within event handler scripts, for example:

```
var local;

function On_AuthenticLoad( )
{
   local = "OnAuthenticLoad";
   Helper();
}

function Helper()
{
   alert("I'm a helper function for " + local);
}
```

18.1.1.6 JScript Programming Tips

Below are a few JScript programming tips that you may find useful while developing a scripting project in StyleVision Scripting Editor.

Out parameters

Out parameters from methods of the NET Framework require special variables in JScript. For example:

```
var dictionary =
CLR.Create("System.Collections.Generic.Dictionary<System.String,System.String>");
dictionary.Add("1", "A");
dictionary.Add("2", "B");
// use JScript method to access out-parameters
var strOut = new Array(1);
if ( dictionary.TryGetValue("1", strOut) ) // TryGetValue will set the out parameter
  alert( strOut[0] ); // use out parameter
```

Integer arguments

.NET Methods that require integer arguments should not be called directly with JScript number objects which are floating point values. For example, instead of:

```
var objCustomColor = CLR.Static("System.Drawing.Color").FromArgb(128,128,128);
```

use:

```
var objCustomColor =
CLR.Static("System.Drawing.Color").FromArgb(Math.floor(128), Math.floor(128), Math.floor(128)
8));
```

Iterating .NET collections

To iterate .NET collections, the JScript Enumerator as well as the .NET iterator technologies can be used, for example:

```
// iterate using the JScript iterator
var itr = new Enumerator( coll );
for ( ; !itr.atEnd(); itr.moveNext() )
 alert( itr.item() );
// iterate using the .NET iterator
var itrNET = coll.GetEnumerator();
while( itrNET.MoveNext() )
  alert( itrNET.Current );
```

.NET templates

.NET templates can be instantiated as shown below:

```
var coll = CLR.Create( "System.Collections.Generic.List<System.String>" );
```

or

```
CLR.Import( "System" );
CLR.Import( "System.Collections.Generic" );
```

```
var dictionary = CLR.Create( "Dictionary<String, Dictionary<String, String>>" );
```

.NET enumeration values

.NET enumeration values are accessed as shown below:

```
var enumValStretch = CLR.Static( "System.Windows.Forms.ImageLayout" ).Stretch;
```

Enumeration literals

The enumeration literals from the StyleVision API can be accessed as shown below (there is no need to know their numerical value).

```
objExportXMIFileDlg.XMIType = eXMI21ForUML23;
```

18.1.2 Built-in Commands

This section provides reference to all the commands you can use in the StyleVision Scripting Editor.

- <u>alert</u> 1096
- confirm 1097
- CLR.Create 1098
- CLR.Import 1098
- CLR.LoadAssembly 1099
- CLR.ShowImports 1100
- <u>CLR.ShowLoadedAssemblies</u> 1100
- CLR.Static 1101
- <u>CreateForm</u> 1102
- doevents 1103
- <u>lastform</u> 1103
- prompt 1104
- ShowForm 1104
- watchdoq 1105

18.1.2.1 alert

Displays a message box that shows a given message and the "OK" button. To proceed, the user will have to click "OK".

Signature

For JScript, the signature is:

```
alert(strMessage : String) -> void
```

For VBScript, the signature is:

```
MsgBox(strMessage : String) -> void
```

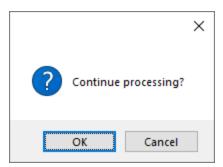

Example

The following JScript code displays a message box with the text "Hello World".

```
alert("Hello World");
```

18.1.2.2 confirm

Opens a dialog box that shows a given message, a confirmation button, and a cancel button. The user will have to click either "OK" or "Cancel" to proceed. Returns a Boolean that represents the user's answer. If the user clicked "OK", the function returns **true**; if the user clicked "Cancel", the function returns **false**.

Signature

```
confirm(strMessage : String) -> result : Boolean
```

Example (JScript)

```
if ( confirm( "Continue processing?" ) == false )
  alert("You have cancelled this action");
```

Example (VBScript)

```
If ( confirm( "Continue processing?" ) = false ) Then
   MsgBox("You have cancelled this action")
End If
```

18.1.2.3 CLR.Create

Creates a new .NET object instance of the type name supplied as argument. If more than one argument is passed, the successive arguments are interpreted as the arguments for the constructor of the .NET object. The return value is a reference to the created .NET object

Signature

```
CLR.Create(strTypeNameCLR : String, constructor arguments ... ) -> object
```

Example

The following JScript code illustrates how to create instances of various .NET classes.

```
// Create an ArrayList
var objArray = CLR.Create("System.Collections.ArrayList");
// Create a ListViewItem
var newItem = CLR.Create( "System.Windows.Forms.ListViewItem", "NewItemText" );
// Create a List<string>
var coll = CLR.Create( "System.Collections.Generic.List<System.String>" );
// Import required namespaces and create a Dictionary object
CLR.Import( "System" );
CLR.Import( "System.Collections.Generic" );
var dictionary = CLR.Create( "Dictionary< String, Dictionary< String, String > >" );
```

18.1.2.4 CLR.Import

Imports a namespace. This is the scripting equivalent of C# using and VB.Net imports keyword. Calling CLR.Import makes it possible to leave out the namespace part in subsequent calls like CLR.Create() and CLR.Static().

Note: Importing a namespace does not add or load the corresponding assembly to the scripting project. You can add assemblies to the scripting project dynamically (at runtime) in the source code by calling CLR.LoadAssembly 1099.

Signature

```
CLR.Import(strNamespaceCLR : String) -> void
```

Example

Instead of having to use fully qualified namespaces like:

```
if ( ShowForm( "FormName" ) == CLR.Static( "System.Windows.Forms.DialogResult" ).OK )
   var sName = lastform.textboxFirstName.Text + " " + lastform.textboxLastName.Text;
   CLR.Static( "System.Windows.Forms.MessageBox" ).Show( "Hello " + sName );
```

One can import namespaces first and subsequently use the short form:

```
CLR.Import( "System.Windows.Forms" );
if ( ShowForm( "FormName" ) == CLR.Static( "DialogResult" ).OK )
   var sName = lastform.textboxFirstName.Text + " " + lastform.textboxLastName.Text;
   CLR.Static( "MessageBox" ).Show( "Hello " + sName );
```

18.1.2.5 CLR.LoadAssembly

Loads the .NET assembly with the given long assembly name or file path. Returns Boolean true if the assembly could be loaded; false otherwise.

Signature

```
CLR.LoadAssembly(strAssemblyNameCLR : String, showLoadErrors : Boolean) -> result :
Boolean
```

Example

The following JScript code attempts to set the clipboard text by loading the required assembly dynamically.

```
// set clipboard text (if possible)
// System.Windows.Clipboard is part of the PresentationCore assembly, so load this
assembly first:
if (CLR.LoadAssembly("PresentationCore, Version=3.0.0.0, Culture=neutral,
PublicKeyToken=31bf3856ad364e35", true ) )
```

```
var clipboard = CLR.Static( "System.Windows.Clipboard" );
if ( clipboard != null )
    clipboard.SetText( "HelloClipboard" );
}
```

18.1.2.6 CLR.ShowImports

Opens a message box that shows the currently imported namespaces. The user will have to click "OK" to proceed.

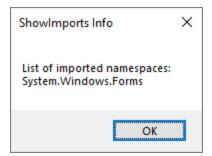

Signature

```
CLR.ShowImports() -> void
```

Example

The following JScript code first imports a namespace, and then displays the list of imported namespaces:

```
CLR.Import( "System.Windows.Forms");
CLR.ShowImports();
```

18.1.2.7 CLR.ShowLoadedAssemblies

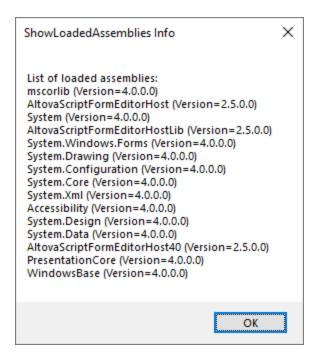

Opens a message box that shows the currently loaded assemblies. The user will have to click "OK" to proceed.

Signature

```
CLR.ShowLoadedAssemblies() -> void
```

Example

```
CLR.ShowLoadedAssemblies();
```

18.1.2.8 CLR.Static

Returns a reference to a static .NET object. You can use this function to get access to .NET types that have no instances and contain only static members.

Signature

```
CLR.Static(strTypeNameCLR : String) -> object
```

Example (JScript)

```
// Get the value of a .NET Enum into a variable
var enumValStretch = CLR.Static( "System.Windows.Forms.ImageLayout" ).Stretch

// Set the value of the Windows clipboard
var clipboard = CLR.Static( "System.Windows.Clipboard" );
clipboard.SetText( "HelloClipboard" );

// Check the buttons pressed by the user on a dialog box
if ( ShowForm( "FormName" ) == CLR.Static( "System.Windows.Forms.DialogResult" ).OK )
    alert( "ok" );
else
    alert( "cancel" );
```

18.1.2.9 CreateForm

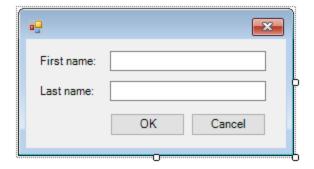

Instantiates the Form object identified by the name supplied as argument. The form must exist in the "Forms" folder of the scripting project. Returns the form object (System.Windows.Forms.Form) corresponding to the given name, or null if no form with such name exists.

Signature

```
CreateForm (strFormName : String) -> System.Windows.Forms.Form | null
```

Example

Let's assume that a form called "FormName" exists in the scripting project.

The following JScript code instantiates the form with some default values and displays it to the user.

```
var myForm = CreateForm( "FormName" );
if ( myForm != null )
{
   myForm.textboxFirstName.Text = "Daniela";
   myForm.textboxLastName.Text = "Heidegger";
   var dialogResult = myForm.ShowDialog();
}
```

The dialogResult can subsequently be evaluated as follows:

```
if ( dialogResult == CLR.Static( "System.Windows.Forms.DialogResult" ).OK )
    alert( "ok" );
else
    alert( "cancel" );
```

Note: The code above will work only if the **DialogResult** property of the "OK" and "Cancel" buttons is set correctly from the Properties pane (for example, it must be **OK** for the "OK" button).

18.1.2.10 doevents

Processes all Windows messages currently in the message queue.

Signature

```
doevents() -> void
```

Example (JScript)

```
for ( i=0; i < nLongLastingProcess; ++i )
{
    // do long lasting process

    doevents(); // process Windows messages; give UI a chance to update
}</pre>
```

18.1.2.11 lastform

This is a global field that returns a reference to the last form object that was created via CreateForm() or ShowForm().

Signature

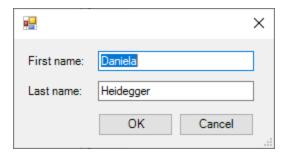

```
lastform -> formObj : System.Windows.Forms.Form
```

Example

The following JScript code shows the form "FormName" as a dialog box.

```
CreateForm( "FormName" );
if ( lastform != null )
{
    lastform.textboxFirstName.Text = "Daniela";
    lastform.textboxLastName.Text = "Heidegger";
    var dialogResult = lastform.ShowDialog();
}
```

The values of both textbox controls are initialized with the help of lastform.

18.1.2.12 prompt

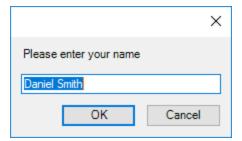

Opens a dialog box that shows a message and a textbox control with a default answer. This can be used to let the user input a simple string value. The return value is a string that contains the textbox value or null if the user selected "Cancel".

Signature

```
prompt(strMessage : String, strDefault : String) -> val : String
```

Example

```
var name = prompt( "Please enter your name", "Daniel Smith" );
if ( name != null )
   alert( "Hello " + name + "!" );
```

18.1.2.13 ShowForm

Instantiates a new form object from the given form name and immediately shows it as dialog box. The return value is an integer that represents the generated <code>DialogResult</code> (System.Windows.Forms.DialogResult). For the list of possible values, refer to the documentation of the <code>DialogResult</code> Enum (https://docs.microsoft.com/en-us/dotnet/api/system.windows.forms.dialogresult?view=netframework-4.8).

Signature

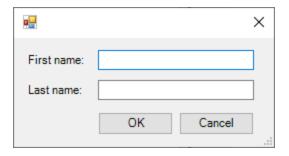

```
ShowForm(strFormName : String) -> result : Integer
```

Example

The following JScript code

```
var dialogResult = ShowForm( "FormName" );
```

Shows the form "FormName" as a dialog box:

The DialogResult can subsequently be evaluated, for example:

```
if ( dialogResult == CLR.Static( "System.Windows.Forms.DialogResult" ).OK )
    alert( "ok" );
else
    alert( "cancel" );
```

Note: The code above will work only if the **DialogResult** property of the "OK" and "Cancel" buttons is set correctly from the Properties pane (for example, it must be **OK** for the "OK" button).

18.1.2.14 watchdog

Long running CPU-intensive scripts may ask the user if the script should be terminated. The watchdog() method is used to disable or enable this behavior. By default, the watchdog is enabled.

Calling watchdog (true) can also be used to reset the watchdog. This can be useful before executing long running CPU-intensive tasks to ensure they have the maximum allowed script processing quota.

Signature

```
watchdog(bEnable : boolean) -> void
```

Example

1106

```
watchdog( false ); // disable watchdog - we know the next statement is CPU intensive but
it will terminate for sure
doCPUIntensiveScript();
watchdog( true ); // re-enable watchdog
```

18.2 **COM API**

The COM-based API of StyleVision enables other applications to use the functionality of StyleVision. As a result, it is possible to automate a wide range of StyleVision tasks. StyleVision and the StyleVision API follow the common specifications for automation servers set out by Microsoft. It is possible to access the methods and properties of the StyleVision API from common development environments, such as those using C#, C++, VisualBasic, and Delphi, and with scripting languages like JScript and VBScript.

StyleVision API documentation

The StyleVision API documentation can be accessed here: https://www.altova.com/manual/en/api/stylevisionapi/index.html.

18.3 ActiveX Integration

The StyleVision user interface and the functionality described in this section can be integrated into custom applications that can consume ActiveX controls. ActiveX technology enables a wide variety of languages to be used for integration, such as C++, C#, and VB.NET. All components are full OLE Controls. Integration into Java is provided through wrapper classes.

To integrate the ActiveX controls into your custom code, the StyleVision Integration Package must be installed (see https://www.altova.com/components/download). Ensure that you install StyleVision first, and then the StyleVision Integration Package. Other prerequisites apply, depending on language and platform (see Perequisites (103).

You can flexibly choose between two different levels of integration: application level and document level.

Integration at application level means embedding the complete interface of StyleVision (including its menus, toolbars, panes, etc) as an ActiveX control into your custom application. For example, in the most simple scenario, your custom application could consist of only one form that embeds the StyleVision graphical user interface. This approach is easier to implement than integration at document level but may not be suitable if you need flexibility to configure the StyleVision graphical user interface according to your custom requirements.

Integration at document level means embedding StyleVision into your own application piece-by-piece. This includes implementing not only the main StyleVision control but also the main document editor window, and, optionally, any additional windows. This approach provides greater flexibility to configure the GUI, but requires advanced interaction with ActiveX controls in your language of choice.

The sections Integration at the Application Level and Integration at Document Level describe the key steps at these respective levels. The ActiveX Integration Examples section provides examples in C# and Java. Looking through these examples will help you to make the right decisions quickly. The Object Reference section describes all COM objects that can be used for integration, together with their properties and methods.

For information about using StyleVision as a Visual Studio plug-in, see StyleVision in Visual Studio 902.

18.3.1 Prerequisites

To integrate the StyleVision ActiveX control into a custom application, the following must be installed on your computer:

- StyleVision
- The StyleVision Integration Package, available for download at https://www.altova.com/components/download

To integrate the 64-bit ActiveX control, install the 64-bit versions of StyleVision and StyleVision Integration Package. For applications developed under Microsoft .NET platform with Visual Studio, both the 32-bit and 64-bit versions of StyleVision and StyleVision Integration Package must be installed, as explained below.

Microsoft .NET (C#, VB.NET) with Visual Studio

To integrate the StyleVision ActiveX control into a 32-bit application developed under Microsoft .NET, the following must be installed on your computer:

- Microsoft .NET Framework 4.0 or later
- Visual Studio 2012/2013/2015/2017/2019/2022
- StyleVision 32-bit and StyleVision Integration Package 32-bit
- The ActiveX controls must be added to the Visual Studio toolbox (see Adding the ActiveX Controls to the Toolbox 1109).

If you want to integrate the 64-bit ActiveX control, the following prerequisites apply in addition to the ones above:

- StyleVision 32-bit and StyleVision Integration Package 32-bit must still be installed (this is required to provide the 32-bit ActiveX control to the Visual Studio designer, since Visual Studio runs on 32-bit)
- StyleVision 64-bit and StyleVision Integration Package 64-bit must be installed (provides the actual 64bit ActiveX control to your custom application at runtime)
- In Visual Studio, create a 64-bit build configuration and build your application using this configuration. For an example, see Running the Sample C# Solution 1116.

Java

To integrate the StyleVision ActiveX control into Java application using the Eclipse development environment, the following must be installed on your computer:

- Java Runtime Environment (JRE) or Java Development Kit (JDK) 7 or later
- **Eclipse**
- StyleVision and StyleVision Integration Package

Note: To run the 64-bit version of the StyleVision ActiveX control, use a 64-bit version of Eclipse, as well as the 64-bit version of StyleVision and the StyleVision Integration Package.

StyleVision integration and deployment on client computers

If you create a .NET application and intend to distribute it to other clients, you will need to install the following on the client computer(s):

- StyleVision
- The StyleVision Integration Package
- The custom integration code or application.

18.3.2 Adding the ActiveX Controls to the Toolbox

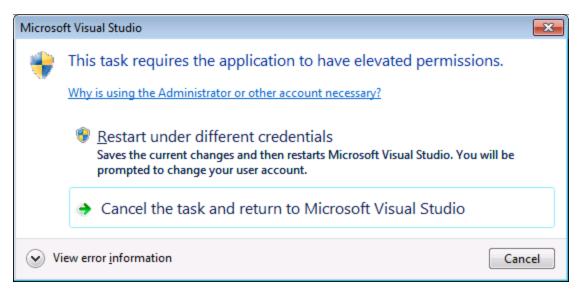

To use the StyleVision ActiveX controls in an application developed with Visual Studio, the controls must first be added to the Visual Studio Toolbox, as follows:

1. On the **Tools** menu of Visual Studio, click **Choose Toolbox Items**.

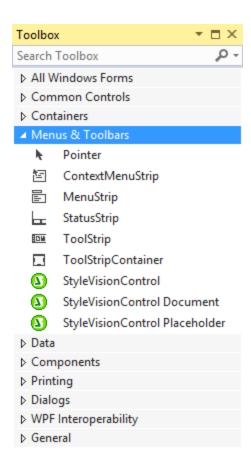

2. On the **COM Components** tab, select the check boxes next to the StyleVisionControl, StyleVisionControl Document, and StyleVisionControl Placeholder.

In case the controls above are not available, follow the steps below:

- 1. On the **COM Components** tab, click **Browse**, and select the **StyleVisionControl.ocx** file from the StyleVision installation folder. Remember that the StyleVision Integration Package must be installed; otherwise, this file is not available, see <u>Prerequisites</u> 1108.
- 2. If prompted to restart Visual Studio with elevated permissions, click **Restart under different credentials**.

If the steps above were successful, the StyleVision ActiveX controls become available in the Visual Studio Toolbox.

Note: For an application-level integration, only the StyleVisionControl ActiveX control is used (see Integration at Application Level (1911). The StyleVisionControl Document and StyleVisionControl Placeholder controls are used for document-level integration (see Integration at Document Level 1113).

18.3.3 Integration at Application Level

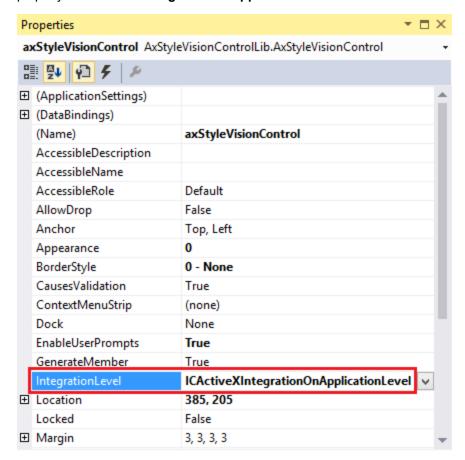

Integration at application level allows you to embed the complete interface of StyleVision into a window of your application. With this type of integration, you get the whole user interface of StyleVision, including all menus, toolbars, the status bar, document windows, and helper windows. Customization of the application's user interface is restricted to what StyleVision provides. This includes rearrangement and resizing of helper windows and customization of menus and toolbars.

The only ActiveX control you need to integrate is StyleVisionControl 147. Do not instantiate or access StyleVisionControlDocument or StyleVisionControlPlaceHolder ActiveX controls when integrating at application-level.

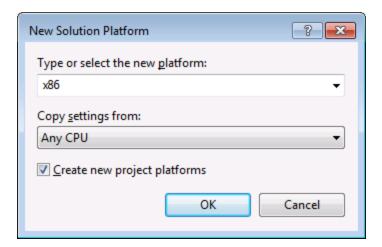

If you have any initialization to do or if you want to automate some behaviour of StyleVision, use the properties, methods, and events described for StyleVisionControl Consider using StyleVisionControl.Application 148 for more complex access to StyleVision functionality.

In C# or VB.NET with Visual Studio, the steps to create a basic, one-form application which integrates the StyleVision ActiveX controls at application level are as follows:

- 1. Check that all prerequisites are met (see Prerequisites 108).
- 2. Create a new Visual Studio Windows Forms project with a new empty form.
- 3. If you have not done that already, add the ActiveX controls to the toolbox (see <u>Adding the ActiveX</u> Controls to the Toolbox (100)).
- 4. Drag the **StyleVisionControl** from the toolbox onto your new form.
- 5. Select the **StyleVisionControl** on the form, and, in the Properties window, set the **IntegrationLevel** property to **ICActiveXIntegrationOnApplicationLevel**.

- 6. Create a build platform configuration that matches the platform under which you want to build (x86, x64). Here is how you can create the build configuration:
 - a. Right-click the solution in Visual Studio, and select Configuration Manager.
 - b. Under **Active solution platform**, select **New...** and then select the x86 or x64 configuration (in this example, **x86**).

You are now ready to build and run the solution in Visual Studio. Remember to build using the configuration that matches your target platform (x86, x64).

18.3.4 Integration at Document Level

Compared to integration at application level, integration at document level is a more complex, yet more flexible way to embed StyleVision functionality into your application by means of ActiveX controls. With this approach, your code can access selectively the following parts of the StyleVision user interface:

- Document editing window
- Project window
- Design Overview window
- Schema Tree window
- Design Tree window
- Styles window
- Style Repository window
- Properties window
- Messages window

As mentioned in Integration at Application Level (1111), for an ActiveX integration at application level, only one control is required, namely the StyleVisionControl. However, for an ActiveX integration at document level, StyleVision functionality is provided by the following ActiveX controls:

- StyleVisionControl 1147
- StyleVisionControl Document 1154
- StyleVisionControl Placeholder 1161

These controls are supplied by the StyleVisionControl.ocx file available in the application installation folder of StyleVision. When you develop the ActiveX integration with Visual Studio, you will need to add these controls to the Visual Studio toolbox (see Adding the ActiveX Controls to the Toolbox (109)).

The basic steps to integrate the ActiveX controls at document level into your application are as follows:

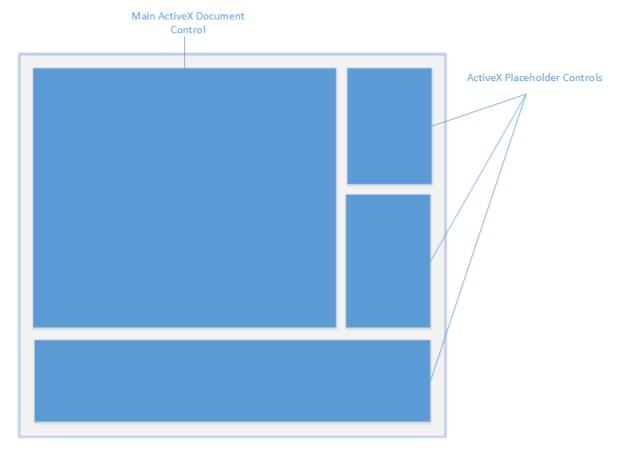

1. First, instantiate StyleVisionControl in your application. Instantiating this control is mandatory; it enables support for the StyleVisionControl Document and StyleVisionControl Placeholder controls mentioned above. It is important to set the IntegrationLevel property to ICActiveXIntegrationOnDocumentLevel (or "1"). To hide the control from the user, set its Visible property to False. Note that, when integrating at document level, do not use the Open method of the StyleVisionControl; this might lead to unexpected results. Use the corresponding open methods of StyleVisionControl Document and StyleVisionControl PlaceHolder instead.

- 2. Create at least one instance of StyleVisionControl Document in your application. This control supplies the document editing window of StyleVision to your application and can be instantiated multiple times if necessary. Use the method Open to load any existing file. To access document-related functionality, use the Path and Save or methods and properties accessible via the property Document. Note that the control does not support a read-only mode. The value of the property ReadOnly is ignored.
- 3. Optionally, add to your application the StyleVisionControl Placeholder control for each additional window (other than the document window) that must be available to your application. Instances of StyleVisionControl PlaceHolder allow you to selectively embed additional windows of StyleVision into your application. The window kind (for example, Project window) is defined by the property PlaceholderWindowID. Therefore, to set the window kind, set the property PlaceholderWindowID. For valid window identifiers, see StyleVisionControlPlaceholderWindow Use only one StyleVisionControl PlaceHolder for each window identifier.

For placeholder controls that select the StyleVision project window, additional methods are available. Use OpenProject to load a StyleVision project. Use the property Project and the methods and properties from the StyleVision automation interface to perform any other project related operations.

For example, in C# or VB.NET with Visual Studio, the steps to create a basic, one-form application which integrates the StyleVision ActiveX controls at document level could be similar to those listed below. Note that your application may be more complex if necessary; however, the instructions below are important to understand the minimum requirements for an ActiveX integration at document level.

- 1. Create a new Visual Studio Windows Forms project with a new empty form.
- 2. If you have not done that already, add the ActiveX controls to the toolbox (see Adding the ActiveX Controls to the Toolbox Controls to the Toolbox
- 3. Drag the <u>StyleVisionControl</u> from the toolbox onto your new form.
- 4. Set the IntegrationLevel property of the StyleVisionControl to ICActiveXIntegrationOnDocumentLevel, and the Visible property to False. You can do this either from code or from the Properties window.
- 5. Drag the <u>StyleVisionControl Document</u> from the toolbox onto the form. This control provides the main document window of StyleVision to your application, so you may need to resize it to a reasonable size for a document.
- 6. Optionally, add one or more <u>StyleVisionControl Placeholder</u> controls to the form (one for each additional window type that your application needs, for example, the Project window). You will typically want to place such additional placeholder controls either below or to the right or left of the main document control, for example:

- 7. Set the PlaceholderWindowlD property of each StyleVisionControl Placeholder control to a valid window identifier. For the list of valid values, see <u>StyleVisionControlPlaceholderWindow</u> indow identifier.
- 8. Add commands to your application (at minimum, you will need to open, save and close documents), as shown below.

Querying StyleVision Commands

When you integrate at document level, no StyleVision menu or toolbar is available to your application. Instead, you can retrieve the required commands, view their status, and execute them programmatically, as follows:

- To retrieve all available commands, use the CommandsList property of the StyleVisionControl.
- To retrieve commands organized according to their menu structure, use the MainMenu property.
- To retrieve commands organized by the toolbar in which they appear, use the Toolbars property.
- To send commands to StyleVision, use the Exec 1151 method.
- To query if a command is currently enabled or disabled, use the Query Status (152) method.

This enables you to flexibly integrate StyleVision commands into your application's menus and toolbars.

Your installation of StyleVision also provides you with command label images used within StyleVision. See the folder <ApplicationFolder>\Examples\ActiveX\Images of your StyleVision installation for icons in GIF format. The file names correspond to the command names as they are listed in the <u>Command Reference</u> section.

General considerations

To automate the behaviour of StyleVision, use the properties, methods, and events described for the StyleVisionControl (1147), StyleVisionControl Document (1154), and StyleVisionControl Placeholder (1161).

For more complex access to StyleVision functionality, consider using the following properties:

- StyleVisionControl.Application 1148
- StyleVisionControlDocument.Document
- StyleVisionControlPlaceHolder.Project 1162

These properties give you access to the StyleVision automation interface (StyleVisionAPI)

Note: To open a document, always use StyleVisionControlDocument.New on the appropriate document control. To open a project, always use StyleVisionControlPlaceHolder.OpenProject on a placeholder control embedding a StyleVision project window.

For examples that show how to instantiate and access the necessary controls in different programming environments, see ActiveX Integration Examples (116).

18.3.5 ActiveX Integration Examples

This section contains examples of StyleVision document-level integration using different container environments and programming languages. Source code for all examples is available in the folder ApplicationFolder>\Examples\ActiveX of your StyleVision installation.

18.3.5.1 C#

A basic ActiveX integration example solution for C# and Visual Studio is available in the folder <applicationFolder>\Examples\activeX\c#. Before you compile the source code and run the sample, make sure that all prerequisites are met (see Running the Sample C# Solution (1116)).

18.3.5.1.1 Running the Sample C# Solution

The sample Visual Studio solution available in the folder **<ApplicationFolder>\Examples\ActiveX\C#** illustrates how to consume the StyleVision ActiveX controls. Before attempting to build and run this solution, note the following steps:

Step 1: Check the prerequisites

Visual Studio 2010 or later is required to open the sample solution. For the complete list of prerequisites, see Prerequisites 1103.

Step 2: Copy the sample to a directory where you have write permissions

To avoid running Visual Studio as an Administrator, copy the source code to a directory where you have write permissions, instead of running it from the default location.

Step 3: Check and set all required control properties

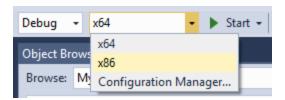

The sample application contains one instance of <u>StyleVisionControlDocument</u> and several instances of StyleVisionControlPlaceHolder 100 controls. Double-check that the following properties of these controls are set as shown in the table below:

Control name	Property	Property value
axStyleVisionControl	IntegrationLevel	ICActiveXIntegrationOnDocumentLe vel
axStyleVisionControlHelperWndSchemaSour ce	PlaceholderWindowlD	2
axStyleVisionControlHelperWndStyleReposit ory	PlaceholderWindowlD	4
axStyleVisionControlHelperWndContextStyle	PlaceholderWindowlD	6
axStyleVisionControlHelperWndContextPrope rties	PlaceholderWindowlD	5
axStyleVisionControlHelperWndProject	PlaceholderWindowlD	0
axStyleVisionControlHelperWndDesignOvervi ew	PlaceholderWindowlD	1
axStyleVisionControlHelperWndDesignTree	PlaceholderWindowlD	3

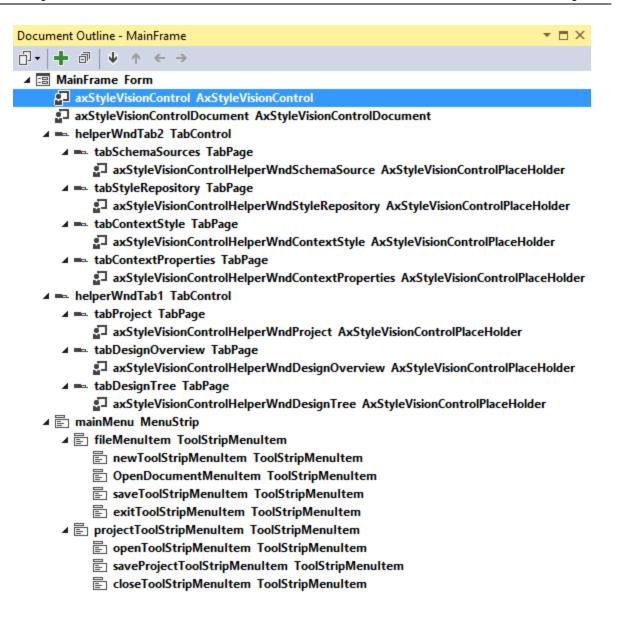

Here is how you can view or set the properties of an ActiveX control:

1. Open the **MDIMain.cs** form in the designer window.

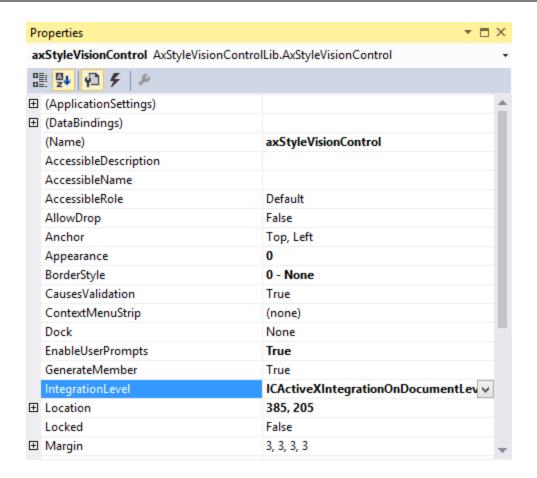

Note: On 64-bit Windows, it may be necessary to change the build configuration of the Visual Studio solution to "x86" before opening the designer window. If you need to build the sample as a 64-bit application, see Prerequisites 1108

2. Open the **Document Outline** window of Visual Studio (On the **View** menu, click **Other Windows** | Document Outline).

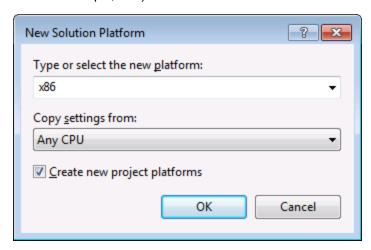

Click an ActiveX control in the **Document Outline** window, and edit its required property in the **Properties** window, for example:

Step 4: Set the build platform

- Create a build platform configuration that matches the platform under which you want to build (x86, x64). Here is how you can create the build configuration:
 - a. Right-click the solution in Visual Studio, and select Configuration Manager.
 - b. Under Active solution platform, select New... and then select the x86 or x64 configuration (in this example, x86).

You are now ready to build and run the solution in Visual Studio. Remember to build using the configuration that matches your target platform (x86, x64); otherwise, runtime errors might occur.

18.3.5.2 Java

StyleVision ActiveX components can be accessed from Java code. Java integration is provided by the libraries listed below. These libraries are available in the folder ApplicationFolderLexamples \JavaAPI of your StyleVision installation, after you have installed both StyleVision and the StyleVision Integration Package (see also Prerequisites (see

- AltovaAutomation.dll: a JNI wrapper for Altova automation servers (in case of the 32-bit installation of StyleVision)
- AltovaAutomation_x64.dll: a JNI wrapper for Altova automation servers (in case of the 64-bit installation of StyleVision)
- AltovaAutomation.jar: Java classes to access Altova automation servers
- StyleVisionActiveX.jar: Java classes that wrap the StyleVision ActiveX interface
- StyleVisionActiveX_JavaDoc.zip: a Javadoc file containing help documentation for the Java interface

Note: In order to use the Java ActiveX integration, the .dll and .jar files must be included in the Java class search path.

Example Java project

An example Java project is supplied with your product installation. You can test the Java project and modify and use it as you like. For more details, see Example Java Project [122].

Rules for mapping the ActiveX Control names to Java

For the documentation of ActiveX controls, see <u>Object Reference</u> Note that the object naming conventions are slightly different in Java compared to other languages. Namely, the rules for mapping between the ActiveX controls and the Java wrapper are as follows:

Classes and class names

For every component of the StyleVision ActiveX interface a Java class exists with the name of the component.

Method names

Method names on the Java interface are the same as used on the COM interfaces but start with a small letter to conform to Java naming conventions. To access COM properties, Java methods that prefix the property name with get and set can be used. If a property does not support write-access, no setter method is available. Example: For the IntegrationLevel property of the StyleVisionControl, the Java methods getIntegrationLevel and setIntegrationLevel are available.

Enumerations

For every enumeration defined in the ActiveX interface, a Java enumeration is defined with the same name and values.

Events and event handlers

For every interface in the automation interface that supports events, a Java interface with the same name plus 'Event' is available. To simplify the overloading of single events, a Java class with default implementations for all events is provided. The name of this Java class is the name of the event interface plus 'DefaultHandler'. For example:

StyleVisionControl: Java class to access the application StyleVisionControlEvents: Events interface for the StyleVisionControl StyleVisionControlEventsDefaultHandler: Default handler for StyleVisionControlEvents

Exceptions to mapping rules

There are some exceptions to the rules listed above. These are listed below:

Interface	Java name
StyleVisionControlDocument, method New	newDocument
AuthenticView, method Goto	gotoElement
AuthenticRange, method Goto	gotoElement
AuthenticRange, method Clone	cloneRange

This section

This section shows how some basic StyleVision ActiveX functionality can be accessed from Java code. It is organized into the following sub-sections:

- Example Java Project 1121
- Creating the ActiveX Controls (1123)
- Loading Data in the Controls 1124
- Basic Event Handling 1124
- Menus 1125
- UI Update Event Handling
- Creating a StyleVision Node Tree 1128

18.3.5.2.1 **Example Java Project**

The StyleVision installation package contains an example Java project, located in the ActiveX Examples folder of the application folder: <applicationFolder>\Examples\ActiveX\Java\.

The Java example shows how to integrate the StyleVisionControl in a common desktop application created with Java. You can test it directly from the command line using the batch file BuildAndRun.bat, or you can compile and run the example project from within Eclipse. See below for instructions on how to use these procedures.

File list

The Java examples folder contains all the files required to run the example project. These files are listed below:

.classpath	Eclipse project helper file
------------	-----------------------------

.project	Eclipse project file
AltovaAutomation.dll	Java-COM bridge: DLL part (for the 32-bit installation)
AltovaAutomation_x64.dll	Java-COM bridge: DLL part (for the 64-bit installation)
AltovaAutomation.jar	Java-COM bridge: Java library part
BuildAndRun.bat	Batch file to compile and run example code from the command line prompt. Expects folder where Java Virtual Machine resides as parameter.
StyleVisionActiveX.jar	Java classes of the StyleVision ActiveX control
StyleVisionActiveX_JavaDoc.zip	Javadoc file containing help documentation for the Java API
StyleVisionContainer.java	Java example source code
StyleVisionContainerEventHandler.java	Java example source code
StyleVisionDialog.java	Java example source code

What the example does

The example places one StyleVision document editor window, the StyleVision project window, the StyleVision schema tree window and the StyleVision design overview window in an AWT frame window. It reads out the main menu defined for StyleVision and creates an AWT menu with the same structure. You can use this menu or the project window to open and work with files in the document editor.

You can modify the example in any way you like.

The following specific features are described in code listings:

- <u>Creating the ActiveX Controls</u> Starts StyleVision, which is registered as an automation server, or activates StyleVision if it is already running.
- Loading Data in the Controls 122: Locates one of the example documents installed with StyleVision and opens it.
- <u>Basic Event Handling</u> Changes the view of all open documents to Text View. The code also shows how to <u>iterate</u> through open documents.
- Menus 1125: Validates the active document and shows the result in a message box. The code shows how to use output parameters.
- <u>UI Update Event Handling</u> Shows how to handle StyleVision events.
- <u>Creating a StyleVision Node Tree</u> (1128): Shows how to create a StyleVision node tree and prepare it for modal activation.

Updating the path to the Examples folder

Before running the provided sample, you may need to edit the **StyleVisionContainer.java** file. Namely, check that the following path refers to the actual folder where the StyleVision example files are stored on your operating system:

// Locate samples installed with the product.

```
final String strExamplesFolder = System.getenv( "USERPROFILE" ) + "\\Documents\\Altova\
\StyleVision2025\\StyleVisionExamples\\";
```

Running the example from the command line

To run the example from the command line:

- 1. Check that all prerequisites are met (see Prerequisites (108)).
- 2. Open a command prompt window, change the current directory to the sample Java project folder, and type:

```
buildAndRun.bat "<Path-to-the-Java-bin-folder>"
```

3. Press **Enter**.

The Java source in StyleVisionContainer.java will be compiled and then executed.

Compiling and running the example in Eclipse

To import the sample Java project into Eclipse:

- 1. Check that all prerequisites are met (see Prerequisites (108)).
- 2. On the **File** menu, click **Import**.
- Select Existing Projects into Workspace, and browse for the Eclipse project file located at <ApplicationFolder>\Examples\ActiveX\Java\. Since you may not have write-access in this folder, it is recommended to select the Copy projects into workspace check box on the Import dialog box.

To run the example application, right-click the project in Package Explorer and select the command Run as I Java Application.

Help for Java API classes is available through comments in code as well as the Javadoc view of Eclipse. To enable the Javadoc view in Eclipse, select the menu command Window | Show View | JavaDoc.

18.3.5.2.2 Creating the ActiveX Controls

The code listing below show how ActiveX controls can be created. The constructors will create the Java wrapper objects. Adding these Canvas-derived objects to a panel or to a frame will trigger the creation of the wrapped ActiveX object.

```
01
02
   * StyleVision manager control - always needed
03
0.4
  05
06
07
   * StyleVisionDocument editing control
0.8
```

```
09
    public static StyleVisionControlDocument
                                                   styleVisionDocument = null;
10
     /**
11
     * Tool windows - StyleVision place-holder controls
12
13
14
    private static StyleVisionControlPlaceHolder
                                                     styleVisionProjectToolWindow = null;
15
    private static StyleVisionControlPlaceHolder
                                                     styleVisionDesignToolWindow = null;
16
    private static StyleVisionControlPlaceHolder
                                                    styleVisionSchemaTreeToolWindow = null;
17
18
    // Create the StyleVision ActiveX controls. First should be StyleVisionControl
     // determining that we want to place document controls and place-holder
19
     // controls individually. It gives us full control over the menu, as well.
20
        styleVisionControl = new StyleVisionControl(
        ICActiveXIntegrationLevel.ICActiveXIntegrationOnDocumentLevel.getValue() );
21
22
        styleVisionDocument = new StyleVisionControlDocument();
23
        frame.add( styleVisionDocument, BorderLayout.CENTER );
24
25
26
    // Create a project window and open the sample project in it
27
        styleVisionProjectToolWindow = new StyleVisionPlaceHolder(
        {\tt StyleVisionControlPlaceholderWindow.StyleVisionControlProjectWindowToolWnd.getValue}
());
28
        styleVisionProjectToolWindow.setPreferredSize( new Dimension( 200, 200 ) );
```

18.3.5.2.3 Loading Data in the Controls

The code listing below show how data can be loaded in the ActiveX controls.

18.3.5.2.4 Basic Event Handling

The code listing below shows how basic events can be handled. When calling the StyleVisionControl's open method, or when trying to open a file via the menu or Project tree, the onOpenedOrFocused event is sent to the attached event handler. The basic handling for this event is opening the file by calling the StyleVisionDocumentControl's open method.

```
// Open the PXF file when button is pressed
btnOpenPxf.addActionListener( new ActionListener() {
    public void actionPerformed(ActionEvent e) {
        try {
            styleVisionControl.open( strExamplesFolder + "OrgChart.pxf" );
        } catch (AutomationException e1) {
            e1.printStackTrace();
        }
}
```

```
08
             }
09
           }
10
         } );
11
          public void onOpenedOrFocused( String i strFileName, boolean
i bOpenWithThisControl, boolean i bFileAlreadyOpened ) throws AutomationException
12
       // Handle the New/Open events coming from the Project tree or from the menus
13
14
       if ( !i bFileAlreadyOpened )
1.5
16
         // This is basically an SDI interface, so open the file in the already existing
document control
17
        try {
18
           StyleVisionContainer.initStyleVisionDocument();
19
           StyleVisionContainer.styleVisionDocument.open( i strFileName );
20
         } catch (Exception e) {
21
           e.printStackTrace();
22
23
       }
24
```

18.3.5.2.5 Menus

The code listing below shows how menu items can be created. Each StyleVisionCommand object gets a corresponding MenuItem object, with the ActionCommand set to the ID of the command. The actions generated by all menu items are handled by the same function, which can perform specific handlings (like reinterpreting the closing mechanism) or can delegate the execution to the StyleVisionControl object by calling its exec method. The menuMap object that is filled during menu creation is used later (see section Ul Update Event Handling (1127).

```
01
02
         // Load the file menu when the button is pressed
0.3
         btnMenu.addActionListener( new ActionListener() {
0.4
           public void actionPerformed(ActionEvent e) {
0.5
             try {
06
               // Create the menubar that will be attached to the frame
07
               MenuBar mb = new MenuBar();
0.8
               // Load the main menu's first item - the File menu
09
               StyleVisionCommand xmlSpyMenu =
styleVisionControl.getMainMenu().getSubCommands().getItem(0);
10
               // Create Java menu items from the Commands objects
11
               Menu fileMenu = new Menu();
12
               handlerObject.fillMenu( fileMenu, xmlSpyMenu.getSubCommands() );
13
               fileMenu.setLabel( xmlSpyMenu.getLabel().replace( "&", "" ) );
14
               mb.add(fileMenu);
15
               frame.setMenuBar( mb );
16
               frame.validate();
17
             } catch (AutomationException e1) {
18
               el.printStackTrace();
19
             }
20
             // Disable the button when the action has been performed
21
             ((AbstractButton) e.getSource()).setEnabled( false );
22
```

```
23
        } ) ;
24
     * Populates a menu with the commands and submenus contained in a StyleVisionCommands
25
object
26
      */
27
    public void fillMenu (Menu newMenu, StyleVisionCommands styleVisionMenu) throws
AutomationException
28
29
       // For each command/submenu in the xmlSpyMenu
       for ( int i = 0 ; i < styleVisionMenu.getCount() ; ++i )</pre>
30
31
32
         StyleVisionCommand styleVisionCommand = styleVisionMenu.getItem( i );
33
         if ( styleVisionCommand.getIsSeparator() )
34
           newMenu.addSeparator();
3.5
         else
36
37
           StyleVisionCommands subCommands = styleVisionCommand.getSubCommands();
38
           // Is it a command (leaf), or a submenu?
39
           if ( subCommands.isNull() || subCommands.getCount() == 0 )
40
41
             // Command -> add it to the menu, set its ActionCommand to its ID and store it
in the menuMap
42

18.3.5.2.6 **UI Update Event Handling**

The code listing below shows how a UI-Update event handler can be created.

```
/**
01
02
     * Call-back from the StyleVisionControl.
03
     * Called to enable/disable commands
04
05
   @Override
06 public void onUpdateCmdUI() throws AutomationException
07
08
     // A command should be enabled if the result of queryStatus contains the Supported
(1) and Enabled (2) flags
09
       for ( java.util.Map.Entry<Integer, MenuItem> pair : menuMap.entrySet() )
pair.getValue().setEnabled( StyleVisionContainer.styleVisionControl.queryStatus( pair.getKe
y() > 2 );
11 }
12
    /**
13
14
     * Call-back from the StyleVisionControl.
    * Usually called while enabling/disabling commands due to UI updates
15
16
17
    @Override
    public boolean onIsActiveEditor( String i strFilePath ) throws AutomationException
18
19
20
      try {
        return
StyleVisionContainer.styleVisionDocument.getDocument().getFullName().equalsIgnoreCase( i st
rFilePath );
22
     } catch ( Exception e ) {
23
        return false;
24
     }
25 }
```

18.3.5.2.7 Listing the Properties of a StyleVision Document

The listing below shows the properties of a StyleVision document (schemas, parameters, etc) can be loaded as nodes in a tree.

```

```

18.3.6 Command Reference

This section lists the names and identifiers of all menu commands that are available within StyleVision. Every sub-section lists the commands from the corresponding top-level menu of StyleVision. The command tables are organized as follows:

- The "Menu Item" column shows the command's menu text as it appears in StyleVision, to make it easier for you to identify the functionality behind the command.
- The "Command Name" column specifies the string that can be used to get an icon with the same name from **ActiveX\Images** folder of the StyleVision installation directory.
- The "ID" column shows the numeric identifier of the column that must be supplied as argument to methods which execute or query this command.

To execute a command, use the StyleVisionControlDocument.Exec methods. To query the status of a command, use the StyleVisionControl.QueryStatus or StyleVisionControlDocument.QueryStatus methods.

Depending on the edition of StyleVision you have installed, some of these commands might not be supported.

18.3.6.1 "File" Menu

The "File" menu has the following commands:

Menu item	Command name	ID
New from XML Schema/DTD/XML	IDC_FILE_NEW_FROM_SCHEMA	37579

18.3.7 **Object Reference**

Objects:

StyleVisionCommand 1144 StyleVisionCommands 1146 StyleVisionControl 1147 StyleVisionControlDocument 1154 <u>StyleVisionControlPlaceHolder</u>¹¹⁶¹

To give access to standard StyleVision functionality, objects of the **StyleVision automation interface** can be accessed as well. See <u>StyleVisionControl.Application</u> (1148), <u>StyleVisionControlDocument</u> (156) and StyleVisionControlPlaceHolder.Project for more information.

18.3.7.1 StyleVisionCommand

Properties:

Description:

A command object can be one of the following: an executable command, a command container (for example, a menu, submenu, or toolbar), or a menu separator. To determine what kind of information is stored in the current Command object, query its ID, IsSeparator, and SubCommands properties, as follows.

The Command object is	When
An executable command	 ID is greater than zero IsSeparator is false SubCommands is empty
A command container	 ID is zero IsSeparator is false SubCommands contains a collection of Command objects.
Separator	ID is zeroIsSeparator is true

18.3.7.1.1 Accelerator

Property: Accelerator as string

Description:

Returns the accelerator key defined for the command. If the command has no accelerator key assigned, this property returns the empty string. The string representation of the accelerator key has the following format:

[ALT+][CTRL+][SHIFT+]key

Where ${\tt key}$ is converted using the Windows Platform SDK function ${\tt GetKeyNameText}.$

18.3.7.1.2 ID

Property: ID as long

Description:

This property gets the unique identifier of the command. A command's ID is required to execute the command (using <u>Exec</u> 155) or query its status (using <u>QueryStatus</u> 1552). If the command is a container for other commands (for example, a top-level menu), or a separator, the ID is 0.

18.3.7.1.3 IsSeparator

Property: IsSeparator as boolean

Description:

The property returns true if the command object is a menu separator; false otherwise. See also Command (1144).

18.3.7.1.4 Label

Property: Label as string

Description:

This property gets the text of the command as it is displayed in the graphical user interface of StyleVision. If the command is a separator, "Label" is an empty string. This property may also return an empty string for some toolbar commands that do not have any GUI text associated with them.

18.3.7.1.5 Name

Property: Name as string

Description:

This property gets the unique name of the command. This value can be used to get the icon file of the command, where it is available. The available icon files can be found in the folder <ApplicationFolder>\Examples\ActiveX\Images of your StyleVision installation.

18.3.7.1.6 StatusText

Property: Label as string

Description:

The status text is the text shown in the status bar of StyleVision when the command is selected. It applies only to command objects that are not separators or containers of other commands; otherwise, the property is an empty string.

18.3.7.1.7 SubCommands

Property: SubCommands as Commands 1146

Description:

The SubCommands property gets the collection of Command objects that are sub-commands of the current command. The property is applicable only to commands that are containers for other commands (menus, submenus, or toolbars). Such container commands have the ID set to 0, and the IsSeparator property set to false.

18.3.7.1.8 ToolTip

Property: ToolTip as string

Description:

This property gets the text that is shown as a tool-tip for each command. If the command does not have a tooltip text, the property returns an empty string.

18.3.7.2 StyleVisionCommands

Properties:

Count 1146

Item 1146

Description:

Collection of <u>command</u> objects to get access to command labels and IDs of the StyleVisionControl. Those commands can be executed with the Exec method and their status can be queried with <u>QueryStatus</u> to get access to command labels and IDs of the StyleVisionControl. Those commands can be executed with the <u>Exec</u> method and their status can be queried with <u>QueryStatus</u> to get access to command labels and IDs of the StyleVisionControl. Those commands can be executed with the <u>Exec</u> method and their status can be queried with <u>QueryStatus</u> to get access to command labels and IDs of the StyleVisionControl.

18.3.7.2.1 Count

Property: Count as long

Description:

Number of Command objects on this level of the collection.

18.3.7.2.2 Item

Property: Item (n as long) as Command (1144)

Description:

Gets the command with the index ${\tt n}$ in this collection. Index is 1-based.

18.3.7.3 StyleVisionControl

Properties:

IntegrationLevel
Appearance
1148
Application
BorderStyle
CommandsList
EnableUserPrompts
MainMenu
Toolbars
1149
1149
1149
1149

Methods:

Open 1151 Exec 1151 QueryStatus 1152

Events:

OnUpdateCmdUI 154
OnOpenedOrFocused 1153
OnCloseEditingWindow 1152
OnFileChangedAlert 1153
OnDocumentOpened 1153
OnValidationWindowUpdated 1154

This object is a complete ActiveX control and should only be visible if the StyleVision library is used in the Application Level mode.

18.3.7.3.1 Properties

The following properties are defined:

IntegrationLevel
EnableUserPrompts
Appearance
BorderStyle

Command related properties:

CommandsList MainMenu Toolbars 1149

Access to StyleVisionAPI:

Application 1148

18.3.7.3.1.1 Appearance

Property: Appearance as short

Dispatch Id: -520

Description:

1148

A value not equal to 0 displays a client edge around the control. Default value is 0.

18.3.7.3.1.2 Application

Property: Application as Application

Dispatch Id: 1

Description:

The Application property gives access to the Application object of the complete StyleVision automation server API. The property is read-only.

18.3.7.3.1.3 BorderStyle

Property: BorderStyle as short

Dispatch Id: -504

Description:

A value of 1 displays the control with a thin border. Default value is 0.

18.3.7.3.1.4 CommandsList

Property: CommandList as Commands (read-only)

Dispatch Id: 1004

Description:

This property returns a flat list of all commands defined available with StyleVisionControl. To get commands organized according to their menu structure, use MainMenu 149. To get toolbar commands, use Toolbars 150.

```
public void GetAllStyleVisionCommands()
{
    // Get all commands from the StyleVision ActiveX control assigned to the current form
    StyleVisionControlLib.StyleVisionCommands =
```

```
this.axStyleVisionControl1.CommandList;
   // Iterate through all commands
    for (int i = 0; i < commands.Count; i++)</pre>
      // Get each command by index and output it to the console
      StyleVisionControlLib.StyleVisionCommand cmd =
axStyleVisionControl1.CommandList[i];
      Console.WriteLine("\{0\} \{1\} \{2\}", cmd.ID, cmd.Name, cmd.Label.Replace("\&", ""));
```

C# example

18.3.7.3.1.5 EnableUserPrompts

Property: EnableUserPrompts as boolean

Dispatch Id: 1006

Description:

Setting this property to false, disables user prompts in the control. The default value is true.

18.3.7.3.1.6 IntegrationLevel

Property: IntegrationLevel as ICActiveXIntegrationLevel 1164

Dispatch Id: 1000

Description:

The IntegrationLevel property determines the operation mode of the control. See also Integration at Application Level and Integration at Document Level for more information.

Note: It is important to set this property immediately after the creation of the StyleVisionControl object.

18.3.7.3.1.7 MainMenu

Property: MainMenu as Command (read-only)

Dispatch Id: 1003

Description:

This property provides information about the structure and commands available in the StyleVisionControl main menu, as a Command object. The Command object contains all available submenus of StyleVision (for example "File", "Edit", "View" etc.). To access the submenu objects, use the SubCommands property of the MainMenu property. Each submenu is also a Command object. For each submenu, you can then further iterate through their SubCommands property in order to get their corresponding child commands and separators (this technique may be used, for example, to create the application menu programmatically). Note that some menu commands act as containers ("parents") for other menu commands, in which case they also have a SubCommands property. To get the structure of all menu commands programmatically, you will need a recursive function.

```
public void GetStyleVisionMenus()
{
    // Get the main menu from the StyleVision ActiveX control assigned to the current
form
    StyleVisionControlLib.StyleVisionCommand mainMenu =
    this.axStyleVisionControll.MainMenu;

    // Loop through entries of the main menu (e.g. File, Edit, etc.)
    for (int i = 0; i < mainMenu.SubCommands.Count; i++)
    {
        StyleVisionControlLib.StyleVisionCommand menu = mainMenu.SubCommands[i];
        Console.WriteLine("{0} menu has {1} children items (including separators)",
        menu.Label.Replace("&", ""), menu.SubCommands.Count);
    }
}</pre>
```

C# example

18.3.7.3.1.8 Toolbars

Property: Toolbars as Commands (read-only)

Dispatch Id: 1005

Description:

This property provides information about the structure of StyleVisionControl toolbars, as a Command object. The Command object contains all available toolbars of StyleVision. To access the toolbars, use the SubCommands property of the Toolbars property. Each toolbar is also a Command object. For each toolbar, you can then further iterate through their SubCommands property in order to get their commands (this technique may be used, for example, to create the application's toolbars programmatically).

```
public void GetStyleVisionToolbars()
{
    // Get the application toolbars from the StyleVision ActiveX control assigned to the current form
    StyleVisionControlLib.StyleVisionCommands toolbars = this.axStyleVisionControl1.Toolbars;

// Iterate through all toolbars
for (int i = 0; i < toolbars.Count; i++)
{
    StyleVisionControlLib.StyleVisionCommand toolbar = toolbars[i];
    Console.WriteLine();
    Console.WriteLine("The toolbar \"{0}\" has the following commands:",</pre>
```

```
toolbar.Label);
      // Iterate through all commands of this toolbar
      for (int j = 0; j < toolbar.SubCommands.Count; j++)</pre>
         StyleVisionControlLib.StyleVisionCommand cmd = toolbar.SubCommands[j];
         // Output only command objects that are not separators
         if (!cmd.IsSeparator)
            Console.WriteLine("{0}, {1}, {2}", cmd.ID, cmd.Name, cmd.Label.Replace("&",
""));
```

C# example

18.3.7.3.2 Methods

The following methods are defined:

18.3.7.3.2.1 Exec

Method: Exec (nCmdID as long) as boolean

Dispatch Id: 6

Description:

This method calls the StyleVision command with the ID ncmdID. If the command can be executed, the method returns true. To get a list of all available commands, use CommandsList 1140. To retrieve the status of any command, use QueryStatus 1152.

18.3.7.3.2.2 Open

Method: Open (strFilePath as string) as boolean

Dispatch Id: 5

Description:

The result of the method depends on the extension passed in the argument strFilePath. If the file extension is .sps, a new document is opened. If the file extension is .svp, the corresponding project is opened. If a

different file extension is passed into the method, the control tries to load the file as a new component into the active document.

Do not use this method to load documents or projects when using the control in document-level integration mode. Instead, use StyleVisionControlDocument.Open and StyleVisionControlPlaceHolder.OpenProject (162).

18.3.7.3.2.3 QueryStatus

Method: QueryStatus (nCmdID as long) as long

Dispatch Id: 7

Description:

QueryStatus returns the enabled/disabled and checked/unchecked status of the command specified by nCmdID. The status is returned as a bit mask.

Bit	Value	Name	Meaning
0	1	Supported	Set if the command is supported.
1	2	Enabled	Set if the command is enabled (can be executed).
2	4	Checked	Set if the command is checked.

This means that if <code>QueryStatus</code> returns 0 the command ID is not recognized as a valid StyleVision command. If <code>QueryStatus</code> returns a value of 1 or 5, the command is disabled.

18.3.7.3.3 Events

The StyleVisionControl ActiveX control provides the following connection point events:

OnUpdateCmdUI
OnOpenedOrFocused
OnCloseEditingWindow
OnFileChangedAlert
OnDocumentOpened
OnValidationWindowUpdated

18.3.7.3.3.1 OnCloseEditingWindow

Event: OnCloseEditingWindow (i_strFilePath as String) as boolean

Dispatch Id: 1002

Description:

This event is triggered when StyleVision needs to close an already open document. As an answer to this event, clients should close the editor window associated with *i_strFilePath*. Returning *true* from this event indicates

that the client has closed the document. Clients can return false if no specific handling is required and StyleVisionControl should try to close the editor and destroy the associated document control.

18.3.7.3.3.2 **OnDocumentOpened**

Event: OnDocumentOpened (objDocument as Document)

Dispatch Id: 1

Description:

This event is triggered whenever a document is opened. The argument obj Document is a Document object from the StyleVision automation interface and can be used to query for more details about the document, or perform additional operations. When integrating on document-level, it is often better to use the event StyleVisionControlDocument.OnDocumentOpened instead.

18.3.7.3.3.3 OnFileChangedAlert

Event: OnFileChangedAlert (i strFilePath as String) as bool

Dispatch Id: 1001

Description:

This event is triggered when a file loaded with StyleVisionControl is changed on the hard disk by another application. Clients should return true, if they handled the event, or false, if StyleVision should handle it in its customary way, i.e. prompting the user for reload.

18.3.7.3.3.4 OnLicenseProblem

Event: OnLicenseProblem (i strLicenseProblemText as String)

Dispatch Id: 1005

Description:

This event is triggered when StyleVisionControl detects that no valid license is available for this control. In case of restricted user licenses this can happen some time after the control has been initialized. Integrators should use this event to disable access to this control's functionality. After returning from this event, the control will block access to its functionality (e.g. show empty windows in its controls and return errors on requests).

18.3.7.3.3.5 OnOpenedOrFocused

Event: OnOpenedOrFocused (i strFilePath as String, i bOpenWithThisControl as bool)

Dispatch Id: 1000

Description:

When integrating at application level, this event informs clients that a document has been opened, or made active by StyleVision.

When integrating at document level, this event instructs the client to open the file i_strFilePath in a document window. If the file is already open, the corresponding document window should be made the active window.

if i_bOpenWithThisControl is true, the document must be opened with StyleVisionControl, since internal access is required. Otherwise, the file can be opened with different editors.

18.3.7.3.3.6 OnToolWindowUpdated

Event: OnToolWindowUpdated(pToolWnd as long)

Dispatch Id: 1006

Description:

This event is triggered when the tool window is updated.

18.3.7.3.3.7 OnUpdateCmdUI

Event: OnUpdateCmdUI()

Dispatch Id: 1003

Description:

Called frequently to give integrators a good opportunity to check status of StyleVision commands using StyleVisionControl.QueryStatus (1152). Do not perform long operations in this callback.

18.3.7.3.3.8 OnValidationWindowUpdated

Event: OnValidationWindowUpdated()

Dispatch Id: 3

Description:

This event is triggered whenever the validation output window is updated with new information.

18.3.7.4 StyleVisionControlDocument

Properties: Appearance

Methods:

Exec 1157 New 1157 <u>Open</u> 1158 QueryStatus 1158 Reload 1158 Save 1158 SaveAs 1159

Events:

OnDocumentOpened 1160 OnDocumentClosed 1159 OnModifiedFlagChanged 1160 OnFileChangedAlert 1160 OnActivate 1159

If the StyleVisionControl is integrated in the Document Level mode each document is displayed in an own object of type StyleVisionControlDocument. The StyleVisionControlDocument contains only one document at the time but can be reused to display different files one after another.

This object is a complete ActiveX control.

18.3.7.4.1 **Properties**

The following properties are defined:

ReadOnly 1157 IsModified 1156 Path 1156 Appearance 1155 BorderStyle 1156

Access to StyleVisionAPI: Document 1156

18.3.7.4.1.1 Appearance

Property: Appearance as short

Dispatch Id: -520

Description:

A value not equal to 0 displays a client edge around the document control. Default value is 0.

ActiveX Integration

18.3.7.4.1.2 BorderStyle

Property: BorderStyle as short

Dispatch Id: -504

Description:

A value of 1 displays the control with a thin border. Default value is 0.

18.3.7.4.1.3 Document

Property: Document as Document

Dispatch Id: 1

Description:

The Document property gives access to the Document object of the StyleVision automation server API. This interface provides additional functionality which can be used with the document loaded in the control. The property is read-only.

18.3.7.4.1.4 IsModified

Property: IsModified as boolean (read-only)

Dispatch Id: 1006

Description:

IsModified is *true* if the document content has changed since the last open, reload or save operation. It is *false*, otherwise.

18.3.7.4.1.5 Path

Property: Path as string

Dispatch Id: 1005

Description:

Sets or gets the full path name of the document loaded into the control.

18.3.7.4.1.6 ReadOnly

Property: ReadOnly as boolean

Dispatch Id: 1007

Description:

Using this property you can turn on and off the read-only mode of the document. If ReadOnly is true it is not possible to do any modifications.

18.3.7.4.2 Methods

The following methods are defined:

Document handling:

New 1157 Open 1158 Reload 1158 Save 1158 SaveAs 1159

Command Handling:

Exec 1157 QueryStatus 1158

18.3.7.4.2.1 Exec

Method: Exec (nCmdID as long) as boolean

Dispatch Id: 8

Description:

Exec calls the StyleVision command with the ID ncmdID. If the command can be executed, the method returns true. This method should be called only if there is currently an active document available in the application.

To get commands organized according to their menu structure, use the MainMenu 149 property of StyleVisionControl. To get toolbar commands, use the Toolbars property of the StyleVisionControl.

18.3.7.4.2.2 New

Method: New () as boolean

Dispatch Id: 1000

Description:

This method initializes a new document inside the control.

18.3.7.4.2.3 Open

Method: Open (strFileName as string) as boolean

Dispatch Id: 1001

Description:

Open loads the file strFileName as the new document into the control.

18.3.7.4.2.4 QueryStatus

Method: QueryStatus (nCmdID as long) as long

Dispatch Id: 9

Description:

QueryStatus returns the enabled/disabled and checked/unchecked status of the command specified by nCmdID. The status is returned as a bit mask.

Bit	Value	Name	Meaning
0	1	Supported	Set if the command is supported.
1	2	Enabled	Set if the command is enabled (can be executed).
2	4	Checked	Set if the command is checked

This means that if <code>QueryStatus</code> returns 0 the command ID is not recognized as a valid StyleVision command. If <code>QueryStatus</code> returns a value of 1 or 5 the command is disabled. The client should call the <code>QueryStatus</code> method of the document control if there is currently an active document available in the application.

18.3.7.4.2.5 Reload

Method: Reload() as boolean

Dispatch Id: 1002

Description:

Reload updates the document content from the file system.

18.3.7.4.2.6 Save

Method: Save() as boolean

Dispatch Id: 1003

Description:

Save saves the current document at the location Path 1150.

18.3.7.4.2.7 SaveAs

Method: SaveAs (strFileName as string) as boolean

Dispatch Id: 1004

Description:

SaveAs sets Path to strFileName and then saves the document to this location.

18.3.7.4.3 Events

The StyleVisionControlDocument ActiveX control provides following connection point events:

OnDocumentOpened 1160 OnDocumentClosed 1159 OnModifiedFlagChanged 1160 OnFileChangedAlert OnActivate 1159 OnSetEditorTitle 1161

18.3.7.4.3.1 OnActivate

Event: OnActivate ()

Dispatch Id: 1005

Description:

This event is triggered when the document control is activated, has the focus, and is ready for user input.

18.3.7.4.3.2 OnDocumentClosed

Event: OnDocumentClosed (objDocument as Document)

Dispatch Id: 1001

Description:

This event is triggered whenever the document loaded into this control is closed. The argument obj Document is a Document object from the StyleVision automation interface and should be used with care.

18.3.7.4.3.3 OnDocumentOpened

Event: OnDocumentOpened (objDocument as Document)

Dispatch Id: 1000

Description:

This event is triggered whenever a document is opened in this control. The argument <code>objDocument</code> is a <code>Document</code> object from the StyleVision automation interface, and can be used to query for more details about the document, or perform additional operations.

18.3.7.4.3.4 OnDocumentSaveAs

Event: OnContextDocumentSaveAs (i strFileName as String)

Dispatch Id: 1007

Description:

This event is triggered when this document gets internally saved under a new name.

18.3.7.4.3.5 OnFileChangedAlert

Event: OnFileChangedAlert () as bool

Dispatch Id: 1003

Description:

This event is triggered when the file loaded into this document control is changed on the hard disk by another application. Clients should return true, if they handled the event, or false, if StyleVision should handle it in its customary way, i.e. prompting the user for reload.

18.3.7.4.3.6 OnModifiedFlagChanged

Event: OnModifiedFlagChanged (i_blsModified as boolean)

Dispatch Id: 1002

Description:

This event gets triggered whenever the document changes between modified and unmodified state. The parameter *i_blsModifed* is *true* if the document contents differs from the original content, and *false*, otherwise.

18.3.7.4.3.7 OnSetEditorTitle

Event: OnSetEditorTitle ()

Dispatch Id: 1006

Description:

This event is being raised when the contained document is being internally renamed.

18.3.7.5 StyleVisionControlPlaceHolder

Properties available for all kinds of placeholder windows:

PlaceholderWindowID 1162

Properties for project placeholder window:

Project 1162

Methods for project placeholder window:

OpenProject 116 CloseProject 1163

The StyleVisionControlPlaceHolder control is used to show the additional StyleVision windows like Overview, Library or Project window. It is used like any other ActiveX control and can be placed anywhere in the client application.

18.3.7.5.1 **Properties**

The following properties are defined:

PlaceholderWindowID 1162

Access to StyleVisionAPI:

Project 1162

18.3.7.5.1.1 Label

Property: Label as String (read-only)

Dispatch Id: 1001

Description:

This property gives access to the title of the placeholder. The property is read-only.

18.3.7.5.1.2 PlaceholderWindowD

Property: PlaceholderWindowID as StyleVisionControlPlaceholderWindow 1164

Dispatch Id: 1

Description:

This property specifies which StyleVision window should be displayed in the client area of the control. The PlaceholderWindowID can be set at any time to any valid value of the StyleVisionControlPlaceholderWindow enumeration. The control changes its state immediately and shows the new StyleVision window.

18.3.7.5.1.3 **Project**

Property: Project as Project (read-only)

Dispatch Id: 2

Description:

The Project property gives access to the Project object of the StyleVision automation server API. This interface provides additional functionality which can be used with the project loaded into the control. The property will return a valid project interface only if the placeholder window has PlaceholderWindowID (162) with a value of StyleVisionXProjectWindow (=3). The property is read-only.

18.3.7.5.2 Methods

The following method is defined:

OpenProject 1162 CloseProject 1163

18.3.7.5.2.1 OpenProject

Method: OpenProject (strFileName as string) as boolean

Dispatch Id: 3

Description:

OpenProject loads the file strFileName as the new project into the control. The method will fail if the placeholder window has a PlaceholderWindowID (=3).

18.3.7.5.2.2 CloseProject

Method: CloseProject ()

Dispatch Id: 4

Description:

CloseProject closes the project loaded by the control. The method will fail if the placeholder window has a PlaceholderWindowID different to StyleVisionXProjectWindow (=3).

18.3.7.5.3 **Events**

The StyleVisionControlPlaceholder ActiveX control provides following connection point events:

OnModifiedFlagChanged 1163

18.3.7.5.3.1 **OnModifiedFlagChanged**

Event: OnModifiedFlagChanged (i bIsModified as boolean)

Dispatch Id: 1

Description:

This event gets triggered only for placeholder controls with a PlaceholderWindowID 1162 of StyleVisionXProjectWindow (=3). The event is fired whenever the project content changes between modified and unmodified state. The parameter i blsModifed is true if the project contents differs from the original content, and false, otherwise.

18.3.7.5.3.2 OnSetLabel

Event: OnSetLabel(i_strNewLabel as string)

Dispatch Id: 1000

Description:

Raised when the title of the placeholder window is changed.

18.3.7.6 Enumerations

The following enumerations are defined:

ICActiveXIntegrationLevel 1164 StyleVisionControlPlaceholderWindow 1164

18.3.7.6.1 ICActiveXIntegrationLevel

Possible values for the IntegrationLevel 149 property of the StyleVisionControl.

```
ICActiveXIntegrationOnApplicationLevel = 0
ICActiveXIntegrationOnDocumentLevel = 1
```

18.3.7.6.2 StyleVisionControlPlaceholderWindow

This enumeration contains the list of the supported additional StyleVision windows.

```
StyleVisionControlNoToolWnd = -1
StyleVisionControlProjectWnd = 0
StyleVisionControlDesignOverviewWnd = 1
StyleVisionControlSchemaSourcesWnd = 2
StyleVisionControlDesignTreeWnd = 3
StyleVisionControlStyleRepositoryWnd = 4
StyleVisionControlContextPropertiesWnd = 5
StyleVisionControlContextStylesWnd = 6
StyleVisionControlMessageWnd = 7
StyleVisionControlDBQueryWnd = 8
```

Appendices 1165

19 Appendices

These appendices contain (i) information about the XSLT Engines used in StyleVision; (ii) information about the conversion of DB datatypes to XML Schema datatypes; (iii) technical information about StyleVision; and (iv) licensing information for StyleVision. Each appendix contains the sub-sections listed below:

XSLT Engine Information 1166

Provides implementation-specific information about the Altova XSLT Engines, which are used by StyleVision to generate output.

- Altova XSLT 1.0 Engine
- Altova XSLT 2.0 Engine
- Altova XSLT 3.0 Engine
- XSLT and XPath/XQuery Functions

DatatypesDB2XSD 1284

When DB fields are converted to XML nodes, the DB datatypes are converted to XML Schema datatypes. This appendix lists the mappings for the following source DBs.

- MS Access
- MS SQL Server
- MySQL
- Oracle
- ODBC
- ADO
- Sybase

Technical Data 1290

Provides technical information about StyleVision.

- OS and memory requirements
- Altova XML Parser
- Altova XSLT and XQuery Engines
- Unicode support
- Internet usage

License Information 1292

Contains information about the way StyleVision is distributed and about its licensing.

- Electronic software distribution
- License metering
- Copyright
- End User License Agreement

19.1 XSLT and XQuery Engine Information

The XSLT and XQuery engines of StyleVision follow the W3C specifications closely and are therefore stricter than previous Altova engines—such as those in previous versions of XMLSpy. As a result, minor errors that were ignored by previous engines are now flagged as errors by StyleVision.

For example:

- It is a type error (err:XPTY0018) if the result of a path operator contains both nodes and non-nodes.
- It is a type error (err:XPTY0019) if E1 in a path expression E1/E2 does not evaluate to a sequence of nodes.

If you encounter this kind of error, modify either the XSLT/XQuery document or the instance document as appropriate.

This section describes implementation-specific features of the engines, organized by specification:

- XSLT 1.0 1166
- XSLT 2.0 1166
- XSLT 3.0 1168
- XQuery 1.0 1169
- XQuery 3.1 1172

19.1.1 XSLT 1.0

The XSLT 1.0 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XSLT 1.0 Recommendation of 16 November 1999 and XPath 1.0 Recommendation of 16 November 1999. Note the following information about the implementation.

Notes about the implementation

When the method attribute of xsl:output is set to HTML, or if HTML output is selected by default, then special characters in the XML or XSLT file are inserted in the HTML document as HTML character references in the output. For instance, the character U+00A0 (the hexadecimal character reference for a non-breaking space) is inserted in the HTML code either as a character reference (or) or as an entity reference, .

19.1.2 XSLT 2.0

This section:

- Engine conformance 1167
- Backward compatibility 1167
- Namespaces 1167
- Schema awareness 1167
- Implementation-specific behavior 1168

Conformance

The XSLT 2.0 engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XSLT 2.0 Recommendation of 23 January 2007 and XPath 2.0 Recommendation of 14 December 2010.

Backwards Compatibility

The XSLT 2.0 engine is backwards compatible. Typically, the backwards compatibility of the XSLT 2.0 engine comes into play when using the XSLT 2.0 engine to process an XSLT 1.0 stylesheet or instruction. Note that there could be differences in the outputs produced by the XSLT 1.0 Engine and the backwards-compatible XSLT 2.0 engine.

Namespaces

Your XSLT 2.0 stylesheet should declare the following namespaces in order for you to be able to use the type constructors and functions available in XSLT 2.0. The prefixes given below are conventionally used; you could use alternative prefixes if you wish.

Namespace Name	Prefix	Namespace URI	
XML Schema types	xs:	http://www.w3.org/2001/XMLSchema	
XPath 2.0 functions	fn:	http://www.w3.org/2005/xpath-functions	

Typically, these namespaces will be declared on the xsl:stylesheet or xsl:transform element, as shown in the following listing:

```
<xsl:stvlesheet version="2.0"</pre>
   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:fn="http://www.w3.org/2005/xpath-functions"
</msl:stylesheet>
```

The following points should be noted:

- The XSLT 2.0 engine uses the XPath 2.0 and XQuery 1.0 Functions namespace (listed in the table above) as its default functions namespace. So you can use XPath 2.0 and XSLT 2.0 functions in your stylesheet without any prefix. If you declare the XPath 2.0 Functions namespace in your stylesheet with a prefix, then you can additionally use the prefix assigned in the declaration.
- When using type constructors and types from the XML Schema namespace, the prefix used in the namespace declaration must be used when calling the type constructor (for example, xs:date).
- Some XPath 2.0 functions have the same name as XML Schema datatypes. For example, for the XPath functions fn:string and fn:boolean there exist XML Schema datatypes with the same local names: xs:string and xs:boolean. So if you were to use the XPath expression string('Hello'), the expression evaluates as fn:string('Hello')—not as xs:string('Hello').

Schema-awareness

The XSLT 2.0 engine is schema-aware. So you can use user-defined schema types and the xsl:validate instruction.

Implementation-specific behavior

Given below is a description of how the XSLT 2.0 engine handles implementation-specific aspects of certain XSLT 2.0 functions.

xsl:result-document

Additionally supported encodings are (the Altova-specific): x-base16tobinary and x-base64tobinary.

function-available

The function tests for the availability of in-scope functions (XSLT, XPath, and extension functions).

unparsed-text

The href argument accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the file:// protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64. Example: xs:base64Binary(unparsed-text('chart.png', 'x-binarytobase64')).

unparsed-text-available

The href argument accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the file:// protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64.

Note: The following encoding values, which were implemented in earlier versions of RaptorXML's predecessor product, AltovaXML, are now deprecated: base16tobinary, base64tobinary, binarytobase16 and binarytobase64.

19.1.3 XSLT 3.0

The XSLT 3.0 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XSLT 3.0 Recommendation of 8 June 2017 and XPath 3.1 Recommendation of 21 March 2017.

The XSLT 3.0 engine has the <u>same implementation-specific characteristics as the XSLT 2.0 engine</u> Additionally, it includes support for a number of new XSLT 3.0 features: XPath/XQuery 3.1 functions and operators, and the <u>XPath 3.1 specification</u>.

Note: The optional <u>streaming feature</u> is not supported currently. The entire document will be loaded into memory regardless of the value of the <u>streamable</u> attribute. If enough memory is available, then: (i) the entire document will be processed—without streaming, (ii) <u>guaranteed-streamable constructs</u> will be processed correctly, as if the execution used streaming, and (iii) streaming errors will not be detected. In 64-bit apps, non-streaming execution should not be a problem. If memory does turn out to be an issue, a solution would be to add more memory to the system.

Namespaces

Your XSLT 3.0 stylesheet should declare the following namespaces in order for you to be able to use all the type constructors and functions available in XSLT 3.0. The prefixes given below are conventionally used; you could use alternative prefixes if you wish.

Namespace Name Prefix	Namespace URI
-----------------------	---------------

XML Schema types	xs:	http://www.w3.org/2001/XMLSchema
XPath/XQuery 3.1 functions	fn:	http://www.w3.org/2005/xpath-functions
Math functions	math:	http://www.w3.org/2005/xpath-functions/math
Map functions	map:	http://www.w3.org/2005/xpath-functions/map
Array functions	array:	http://www.w3.org/2005/xpath-functions/array
XQuery, XSLT, and XPath Error Codes	err:	http://www.w3.org/2005/xpath-functions/xqt-errors
Serialization functions	output	http://www.w3.org/2010/xslt-xquery-serialization

Typically, these namespaces will be declared on the xsl:stylesheet or xsl:transform element, as shown in the following listing:

```
<xsl:stylesheet version="3.0"</pre>
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:fn="http://www.w3.org/2005/xpath-functions"
</xsl:stylesheet>
```

The following points should be noted:

- The XSLT 3.0 engine uses the XPath and XQuery Functions and Operators 3.1 namespace (listed in the table above) as its default functions namespace. So you can use the functions of this namespace in your stylesheet without any prefix. If you declare the Functions namespace in your stylesheet with a prefix, then you can additionally use the prefix assigned in the declaration.
- When using type constructors and types from the XML Schema namespace, the prefix used in the namespace declaration must be used when calling the type constructor (for example, xs:date).
- Some XPath/XQuery functions have the same name as XML Schema datatypes. For example, for the XPath functions fn:string and fn:boolean there exist XML Schema datatypes with the same local names: xs:string and xs:boolean. So if you were to use the XPath expression string('Hello'), the expression evaluates as fn:string('Hello')—not as xs:string('Hello').

19.1.4 XQuery 1.0

This section:

- Engine conformance 1170
- Schema awareness 1170
- Encoding 1170
- Namespaces 1167
- XML source and validation 1171
- Static and dynamic type checking
- Library modules 1171
- External functions 1171

- Collations (177)
- Precision of numeric data 1172
- XQuery instructions support 1172
- Implementation-specific behavior 1172

Conformance

The XQuery 1.0 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XQuery 1.0 Recommendation of 14 December 2010. The XQuery standard gives implementations discretion about how to implement many features. Given below is a list explaining how the XQuery 1.0 Engine implements these features.

Schema awareness

The XQuery 1.0 Engine is **schema-aware**.

Encoding

The UTF-8 and UTF-16 character encodings are supported.

Namespaces

The following namespace URIs and their associated bindings are pre-defined.

Namespace Name	Prefix	Namespace URI	
XML Schema types	xs:	http://www.w3.org/2001/XMLSchema	
Schema instance	xsi:	http://www.w3.org/2001/XMLSchema-instance	
Built-in functions	fn:	http://www.w3.org/2005/xpath-functions	
Local functions	local:	http://www.w3.org/2005/xquery-local-functions	

The following points should be noted:

- The XQuery 1.0 Engine recognizes the prefixes listed above as being bound to the corresponding namespaces.
- Since the built-in functions namespace listed above (see fn:) is the default functions namespace in XQuery, the fn: prefix does not need to be used when built-in functions are invoked (for example, string("Hello") will call the fn:string function). However, the prefix fn: can be used to call a built-in function without having to declare the namespace in the query prolog (for example: fn:string("Hello")).
- You can change the default functions namespace by declaring the default function namespace expression in the query prolog.
- When using types from the XML Schema namespace, the prefix xs: may be used without having to explicitly declare the namespaces and bind these prefixes to them in the query prolog. (Example: xs:date and xs:yearMonthDuration.) If you wish to use some other prefix for the XML Schema namespace, this must be explicitly declared in the query prolog. (Example: declare namespace alt = "http://www.w3.org/2001/XMLSchema"; alt:date("2004-10-04").)
- Note that the untypedAtomic, dayTimeDuration, and yearMonthDuration datatypes have been moved, with the CRs of 23 January 2007, from the XPath Datatypes namespace to the XML Schema namespace, so: xs:yearMonthDuration.

If namespaces for functions, type constructors, node tests, etc are wrongly assigned, an error is reported. Note, however, that some functions have the same name as schema datatypes, e.g. fn:string and fn:boolean. (Both xs:string and xs:boolean are defined.) The namespace prefix determines whether the function or type constructor is used.

XML source document and validation

XML documents used in executing an XQuery document with the XQuery 1.0 Engine must be well-formed. However, they do not need to be valid according to an XML Schema. If the file is not valid, the invalid file is loaded without schema information. If the XML file is associated with an external schema and is valid according to it, then post-schema validation information is generated for the XML data and will be used for query evaluation.

Static and dynamic type checking

The static analysis phase checks aspects of the query such as syntax, whether external references (e.g. for modules) exist, whether invoked functions and variables are defined, and so on. If an error is detected in the static analysis phase, it is reported and the execution is stopped.

Dynamic type checking is carried out at run-time, when the query is actually executed. If a type is incompatible with the requirement of an operation, an error is reported. For example, the expression xs:string("1") + 1 returns an error because the addition operation cannot be carried out on an operand of type xs:string.

Library Modules

Library modules store functions and variables so they can be reused. The XQuery 1.0 Engine supports modules that are stored in a single external XQuery file. Such a module file must contain a module declaration in its prolog, which associates a target namespace. Here is an example module:

```
module namespace libns="urn:module-library";
declare variable $libns:company := "Altova";
declare function libns:webaddress() { "http://www.altova.com" };
```

All functions and variables declared in the module belong to the namespace associated with the module. The module is used by importing it into an XQuery file with the import module statement in the query prolog. The import module statement only imports functions and variables declared directly in the library module file. As follows:

```
import module namespace modlib = "urn:module-library" at "modulefilename.xq";
          ($modlib:company = "Altova")
then
           modlib:webaddress()
           error("No match found.")
else
```

External functions

External functions are not supported, i.e. in those expressions using the external keyword, as in:

```
declare function hoo($param as xs:integer) as xs:string external;
```

Collations

The default collation is the Unicode-codepoint collation, which compares strings on the basis of their Unicode codepoint. Other supported collations are the ICU collations listed here 177. To use a specific collation, supply its URI as given in the list of supported collations 42. Any string comparisons, including for the fn:max and fn:min functions, will be made according to the specified collation. If the collation option is not specified, the default Unicode-codepoint collation is used.

Precision of numeric types

- The xs:integer datatype is arbitrary-precision, i.e. it can represent any number of digits.
- The xs:decimal datatype has a limit of 20 digits after the decimal point.
- The xs:float and xs:double datatypes have limited-precision of 15 digits.

XQuery Instructions Support

The Pragma instruction is not supported. If encountered, it is ignored and the fallback expression is evaluated.

Implementation-specific behavior

Given below is a description of how the XQuery and XQuery Update 1.0 engines handle implementation-specific aspects of certain functions.

unparsed-text

The href argument accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the file:// protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64. Example: xs:base64Binary(unparsed-text('chart.png', 'xbinarytobase64')).

unparsed-text-available

The href argument accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the file:// protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64.

Note: The following encoding values, which were implemented in earlier versions of RaptorXML's predecessor product, AltovaXML, are now deprecated: base16tobinary, base64tobinary, binarytobase16 and binarytobase64.

19.1.5 XQuery 3.1

The XQuery 3.1 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XQuery 3.1 Recommendation of 21 March 2017 and includes support for XPath and XQuery Functions 3.1. The XQuery 3.1 specification is a superset of the 3.0 specification. The XQuery 3.1 engine therefore supports XQuery 3.0 features.

Namespaces

Your XQuery 3.1 document should declare the following namespaces in order for you to be able to use all the type constructors and functions available in XQuery 3.1. The prefixes given below are conventionally used; you could use alternative prefixes if you wish.

Namespace Name Prefix	Namespace URI
-----------------------	---------------

XML Schema types	xs:	http://www.w3.org/2001/XMLSchema
XPath/XQuery 3.1 fn: http://www.w3.org/2005/xpath-functions		http://www.w3.org/2005/xpath-functions
Math functions	math:	http://www.w3.org/2005/xpath-functions/math
Map functions	map:	http://www.w3.org/2005/xpath-functions/map
Array functions	array:	http://www.w3.org/2005/xpath-functions/array
XQuery, XSLT, and XPath Error Codes	err:	http://www.w3.org/2005/xpath-functions/xqt-errors
Serialization functions	output	http://www.w3.org/2010/xslt-xquery-serialization

The following points should be noted:

- The XQuery 3.1 Engine recognizes the prefixes listed above as being bound to the corresponding namespaces.
- Since the built-in functions namespace listed above (see fn:) is the default functions namespace in XQuery, the fn: prefix does not need to be used when built-in functions are invoked (for example, string ("Hello") will call the fn:string function). However, the prefix fn: can be used to call a builtin function without having to declare the namespace in the guery prolog (for example: fn:string("Hello")).
- You can change the default functions namespace by declaring the default function namespace expression in the query prolog.
- When using types from the XML Schema namespace, the prefix xs: may be used without having to explicitly declare the namespaces and bind these prefixes to them in the query prolog. (Example: xs:date and xs:yearMonthDuration.) If you wish to use some other prefix for the XML Schema namespace, this must be explicitly declared in the query prolog. (Example: declare namespace alt = "http://www.w3.org/2001/XMLSchema"; alt:date("2004-10-04").)

If namespaces for functions, type constructors, node tests, etc are wrongly assigned, an error is reported. Note, however, that some functions have the same name as schema datatypes, e.g. fn:string and fn:boolean. (Both xs:string and xs:boolean are defined.) The namespace prefix determines whether the function or type constructor is used.

Implementation-specific behavior

Implementation-specific characteristics are the same as for XQuery 1.0 (199).

Additionally, the Altova-specific encoding x-base64tobinary can be used to create a binary result document, such as an image.

19.2 XSLT and XPath/XQuery Functions

This section lists Altova extension functions and other extension functions that can be used in XPath and/or XQuery expressions. Altova extension functions can be used with Altova's XSLT and XQuery engines, and provide functionality additional to that available in the function libraries defined in the W3C standards.

This section describes XPath/XQuery extension functions that have been created by Altova to provide additional operations, as well as other extension functions (256). These extension functions (1175) can be computed by Altova's XSLT and XQuery engines according to the rules described in this section. For information about the regular XPath/XQuery functions, see Altova's XPath/XQuery Function Reference.

General points

The following general points should be noted:

- Functions from the core function libraries defined in the W3C specifications can be called without a prefix. That's because the Altova XSLT and XQuery engines read non-prefixed functions as belonging to the namespace http://www.w3.org/2005/xpath-functions, which is the default functions namespace specified in the XPath/XQuery functions specifications. If this namespace is explicitly declared in an XSLT or XQuery document, the prefix used in the namespace declaration can also optionally be used on function names.
- In general, if a function expects a sequence of one item as an argument, and a sequence of more than one item is submitted, then an error is returned.
- All string comparisons are done using the Unicode codepoint collation.
- Results that are QNames are serialized in the form [prefix:]localname.

Precision of xs:decimal

The precision refers to the number of digits in the number, and a minimum of 18 digits is required by the specification. For division operations that produce a result of type xs:decimal, the precision is 19 digits after the decimal point with no rounding.

Implicit timezone

When two date, time, or dateTime values need to be compared, the timezones of the values being compared need to be known. When the timezone is not explicitly given in such a value, the implicit timezone is used. The implicit timezone is taken from the system clock, and its value can be checked with the implicittimezone() function.

Collations

The default collation is the Unicode codepoint collation, which compares strings on the basis of their Unicode codepoint. The engine uses the Unicode Collation Algorithm. Other supported collations are the ICU collations listed below; to use one of these, supply its URI as given in the table below. Any string comparisons, including for the max and minions functions, will be made according to the specified collation. If the collation option is not specified, the default Unicode-codepoint collation is used.

Namespace axis

The namespace axis is deprecated in XPath 2.0. Use of the namespace axis is, however, supported. To access namespace information with XPath 2.0 mechanisms, use the in-scope-prefixes(), namespaceuri() and namespace-uri-for-prefix() functions.

19.2.1 **Altova Extension Functions**

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

Functions defined in the W3C's XPath/XQuery Functions specifications can be used in: (i) XPath expressions in an XSLT context, and (ii) in XQuery expressions in an XQuery document. In this documentation we indicate the functions that can be used in the former context (XPath in XSLT) with an xp symbol and call them XPath functions; those functions that can be used in the latter (XQuery) context are indicated with an 🚾 symbol; they work as XQuery functions. The W3C's XSLT specifications—not XPath/XQuery Functions specifications—also

define functions that can be used in XPath expressions in XSLT documents. These functions are marked with an XSLT symbol and are called XSLT functions. The XPath/XQuery and XSLT versions in which a function can be used are indicated in the description of the function (see symbols below). Functions from the XPath/XQuery and XSLT function libraries are listed without a prefix. Extension functions from other libraries, such as Altova extension functions, are listed with a prefix.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

Usage of Altova extension functions

In order to use Altova extension functions, you must declare the Altova extension functions namespace (*first highlight in code listing below*) and then use the extension functions so that they are resolved as belonging to this namespace (*see second highlight*). The example below uses the Altova extension function named age.

XSLT functions 1177

XSLT functions can only be used in XPath expressions in an XSLT context (similarly to XSLT 2.0's $\operatorname{current-group}()$ or $\operatorname{key}()$ functions). These functions are not intended for, and will not work in, a non-XSLT context (for instance, in an XQuery context). Note that XSLT functions for XBRL can be used only with editions of Altova products that have XBRL support.

XPath/XQuery functions

XPath/XQuery functions can be used both in XPath expressions in XSLT contexts as well as in XQuery expressions:

- Date/Time 1180
- Geolocation 1197
- Image-related 1208
- Numeric 1213
- <u>S</u>chema 1215
- <u>Sequen</u>ce 1234

- String 1242
- Miscellaneous 1249

Chart functions (Enterprise and Server Editions only)

Altova extension functions for charts 1251 are supported only in the Enterprise and Server Editions of Altova products and enable charts to be generated from XML data.

Barcode functions

Altova's barcode extension functions enable barcodes to be generated and placed in output generated via XSLT stylesheets.

19.2.1.1 XSLT Functions

XSLT extension functions can be used in XPath expressions in an XSLT context. They will not work in a non-XSLT context (for instance, in an XQuery context).

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xsltextensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

General functions

distinct-nodes [altova:]

altova:distinct-nodes(node()*) as node()* XSLT1 XSLT2 XSLT3 Takes a set of one or more nodes as its input and returns the same set minus nodes with duplicate values. The comparison is done using the XPath/XQuery function fn:deep-equal.

- Examples
 - altova:distinct-nodes (country) returns all child country nodes less those having duplicate values.
- evaluate [altova:]

altova:evaluate(XPathExpression as xs:string[, ValueOf\$p1, ... ValueOf\$pN]) XSLT1 XSLT2

Takes an XPath expression, passed as a string, as its mandatory argument. It returns the output of the evaluated expression. For example: altova:evaluate('//Name[1]') returns the contents of the first Name element in the document. Note that the expression //Name[1] is passed as a string by enclosing it in single quotes.

The altova:evaluate function can optionally take additional arguments. These arguments are the values of in-scope variables that have the names p1, p2, p3... pN. Note the following points about usage: (i) The variables must be defined with names of the form pX, where X is an integer; (ii) the altova:evaluate function's arguments (see signature above), from the second argument onwards, provide the values of the variables, with the sequence of the arguments corresponding to the numerically ordered sequence of variables: p1 to pN: The second argument will be the value of the variable p1, the third argument that of the variable p2, and so on; (iii) The variable values must be of type item*.

■ Example

```
<xsl:variable name="xpath" select="'$p3, $p2, $p1'" />
<xsl:value-of select="altova:evaluate($xpath, 10, 20, 'hi')" />
outputs "hi 20 10"
```

In the listing above, notice the following:

- The second argument of the altova:evaluate expression is the value assigned to the variable \$p1, the third argument that assigned to the variable \$p2, and so on.
- Notice that the fourth argument of the function is a string value, indicated by its being enclosed in quotes.
- The select attribute of the xs:variable element supplies the XPath expression. Since this expression must be of type xs:string, it is enclosed in single quotes.

■ Examples to further illustrate the use of variables

```
• <xsl:variable name="xpath" select="'$p1'" />
    <xsl:value-of select="altova:evaluate($xpath, //Name[1])" />
    Outputs value of the first Name element.
```

The altova:evaluate() extension function is useful in situations where an XPath expression in the XSLT stylesheet contains one or more parts that must be evaluated dynamically. For example, consider a situation in which a user enters his request for the sorting criterion and this criterion is stored in the attribute UserReq/@sortkey_ In the stylesheet, you could then have the expression: <xsl:sort select="altova:evaluate(../UserReq/@sortkey)" order="ascending"/>. The altova:evaluate() function reads the sortkey attribute of the UserReq child element of the parent of the context node. Say the value of the sortkey attribute is Price, then Price is returned by the altova:evaluate() function and becomes the value of the select attribute: <xsl:sort select="Price" order="ascending"/>. If this sort instruction occurs within the context of an element called Order, then the Order elements will be sorted according to the values of their Price children. Alternatively, if the value of @sortkey were, say, Date, then the Order elements would be sorted according to the values of their Date children. So the sort criterion for Order is selected from the sortkey attribute at runtime. This could not have been achieved with an expression like: <xsl:sort select="../UserReq/@sortkey" order="ascending"/>. In the case shown above, the sort criterion would be the sortkey attribute itself, not Price or Date (or any other

current content of sortkey).

Note: The static context includes namespaces, types, and functions—but not variables—from the calling environment. The base URI and default namespace are inherited.

■ More examples

- Static variables: <xs1:value-of select="\$i3, \$i2, \$i1" /> Outputs the values of three variables.
- Dynamic XPath expression with dynamic variables:

```
<xsl:variable name="xpath" select="'$p3, $p2, $p1'" />
<xsl:value-of select="altova:evaluate($xpath, 10, 20, 30)" />
Outputs "30 20 10"
```

• Dynamic XPath expression with no dynamic variable:

```
<xsl:variable name="xpath" select="'$p3, $p2, $p1'" />
<xsl:value-of select="altova:evaluate($xpath)" />
Outputs error: No variable defined for $p3.
```

encode-for-rtf [altova:]

```
altova:encode-for-rtf(input as xs:string, preserveallwhitespace as xs:boolean,
preservenewlines as xs:boolean) as xs:string XSLT2 XSLT3
```

Converts the input string into code for RTF. Whitespace and new lines will be preserved according to the boolean value specified for their respective arguments.

[Top 177]

XBRL functions

Altova XBRL functions can be used only with editions of Altova products that have XBRL support.

xbrl-footnotes [altova:]

```
altova:xbrl-footnotes(node()) as node() * XSLT2 XSLT3
```

Takes a node as its input argument and returns the set of XBRL footnote nodes referenced by the input node.

xbrl-labels [altova:]

```
altova:xbrl-labels(xs:QName, xs:string) as node()* XSLT2 XSLT3
```

Takes two input arguments: a node name and the taxonomy file location containing the node. The function returns the XBRL label nodes associated with the input node.

19.2.1.2 XPath/XQuery Functions: Date and Time

Altova's date/time extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data held as XML Schema's various date and time datatypes. The functions in this section can be used with Altova's **XPath 3.0** and **XQuery 3.0** engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

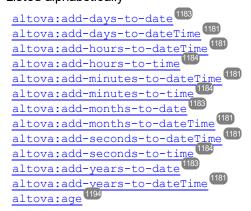

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the **Altova extension functions namespace**, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

Grouped by functionality

- Add a duration to xs:dateTime and return xs:dateTime
- Add a duration to xs:date and return xs:date
- Add a duration to xs:time and return xs:time
- Format and retrieve durations 1184
- Remove timezone from functions that generate current date/time
- Return days, hours, minutes, and seconds from durations
- Return weekday as integer from date 1188
- Return week number as integer from date 1188
- Build date, time, or duration type from lexical components of each type
- Construct date, dateTime, or time type from string input input
- Age-related functions 1194
- Epoch time (Unix time) functions (1195)

[Top 1180]

Add a duration to xs:dateTime xp3.1 xq3.1

These functions add a duration to xs:dateTime and return xs:dateTime. The xs:dateTime type has a format of CCYY-MM-DDThh:mm:ss.sss. This is a concatenation of the xs:date and xs:time formats separated by the letter T. A timezone suffix (+01:00, for example) is optional.

add-years-to-dateTime [altova:]

```
altova:add-years-to-dateTime (DateTime as xs:dateTime, Years as xs:integer) as
xs:dateTime XP3.1 XQ3.1
```

Adds a duration in years to an xs:dateTime (see examples below). The second argument is the number of years to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

Examples

- altova:add-years-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10) returns 2024-
- altova:add-years-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -4) returns 2010-01-15T14:00:00
- add-months-to-dateTime [altova:]

```
altova:add-months-to-dateTime (DateTime as xs:dateTime, Months as xs:integer) as
xs:dateTime XP3.1 XQ3.1
```

Adds a duration in months to an xs:dateTime (see examples below). The second argument is the number of months to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

■ Examples

- altova:add-months-to-dateTime (xs:dateTime("2014-01-15T14:00:00"), 10) returns 2014-11-15T14:00:00
- altova:add-months-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -2) returns 2013-11-15T14:00:00

add-days-to-dateTime [altova:]

```
altova:add-days-to-dateTime (DateTime as xs:dateTime, Days as xs:integer) as xs:dateTime XP3.1 XQ3.1
```

Adds a duration in days to an xs:dateTime (see examples below). The second argument is the number of days to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

Examples

- altova:add-days-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10) returns 2014-01-25T14:00:00
- altova:add-days-to-dateTime (xs:dateTime("2014-01-15T14:00:00"), -8) returns 2014-01-07T14:00:00

add-hours-to-dateTime [altova:]

```
altova:add-hours-to-dateTime (DateTime as xs:dateTime, Hours as xs:integer) as
xs:dateTime XP3.1 XQ3.1
```

Adds a duration in hours to an xs:dateTime (see examples below). The second argument is the number of hours to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

■ Examples

- altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T13:00:00"), 10) returns 2014-01-15T23:00:00
- altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T13:00:00"), -8) returns 2014-01-15T05:00:00

add-minutes-to-dateTime [altova:]

```
altova:add-minutes-to-dateTime (DateTime as xs:dateTime, Minutes as xs:integer) as
xs:dateTime XP3.1 XQ3.1
```

Adds a duration in minutes to an xs:dateTime (see examples below). The second argument is the number of minutes to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

■ Examples

- altova:add-minutes-to-dateTime(xs:dateTime("2014-01-15T14:10:00"), 45) returns 2014-01-15T14:55:00
- altova:add-minutes-to-dateTime(xs:dateTime("2014-01-15T14:10:00"), -5) returns 2014-01-15T14:05:00

add-seconds-to-dateTime [altova:]

```
altova:add-seconds-to-dateTime (DateTime as xs:dateTime, Seconds as xs:integer) as
xs:dateTime XP3.1 XQ3.1
```

Adds a duration in seconds to an xs:dateTime (see examples below). The second argument is the number of seconds to be added to the xs:dateTime supplied as the first argument. The result is of type xs:dateTime.

Examples

- altova:add-seconds-to-dateTime (xs:dateTime ("2014-01-15T14:00:10"), 20) returns 2014-01-15T14:00:30
- altova:add-seconds-to-dateTime (xs:dateTime("2014-01-15T14:00:10"), -5) returns 2014-01-15T14:00:05

Add a duration to xs:date xp3.1 xq3.1

These functions add a duration to xs:date and return xs:date. The xs:date type has a format of CCYY-MM-DD.

add-years-to-date [altova:]

altova:add-years-to-date(Date as xs:date, Years as xs:integer) as xs:date XP3.1 XQ3.1 Adds a duration in years to a date. The second argument is the number of years to be added to the xs:date supplied as the first argument. The result is of type xs:date.

■ Examples

- altova:add-years-to-date(xs:date("2014-01-15"), 10) returns 2024-01-15
- altova:add-years-to-date(xs:date("2014-01-15"), -4) returns 2010-01-15
- add-months-to-date [altova:]

altova:add-months-to-date (Date as xs:date, Months as xs:integer) as xs:date XP3.1 XQ3.1 Adds a duration in months to a date. The second argument is the number of months to be added to the xs:date supplied as the first argument. The result is of type xs:date.

■ Examples

- altova:add-months-to-date(xs:date("2014-01-15"), 10) returns 2014-11-15
- altova:add-months-to-date(xs:date("2014-01-15"), -2) returns 2013-11-15
- add-days-to-date [altova:]

altova:add-days-to-date(Date as xs:date, Days as xs:integer) as xs:date XP3.1 XQ3.1 Adds a duration in days to a date. The second argument is the number of days to be added to the xs:date supplied as the first argument. The result is of type xs:date.

Examples

- altova:add-days-to-date(xs:date("2014-01-15"), 10) returns 2014-01-25
- altova:add-days-to-date(xs:date("2014-01-15"), -8) returns 2014-01-07

[<u>Top</u>¹¹⁸⁰]

Format and retrieve durations xp3.1 xo3.1

These functions parse an input xs:duration or xs:string and return, respectively, an xs:string or xs:duration.

format-duration [altova:]

altova:format-duration(Duration as xs:duration, Picture as xs:string) as xs:string XP3.1
XO3.1

Formats a duration, which is submitted as the first argument, according to a picture string submitted as the second argument. The output is a text string formatted according to the picture string.

- Examples
 - altova:format-duration(xs:duration("P2DT2H53M11.7S"), "Days:[D01] Hours:[H01] Minutes:[m01] Seconds:[s01] Fractions:[f0]") returns "Days:02 Hours:02 Minutes:53 Seconds:11 Fractions:7"
 - altova:format-duration(xs:duration("P3M2DT2H53M11.7S"), "Months:[M01] Days:[D01] Hours:[H01] Minutes:[m01]") returns "Months:03 Days:02 Hours:02 Minutes:53"
- parse-duration [altova:]

altova:parse-duration(InputString as xs:string, Picture as xs:string) as xs:duration

Takes a patterned string as the first argument, and a picture string as the second argument. The input string is parsed on the basis of the picture string, and an xs:duration is returned.

- Examples
 - altova:parse-duration("Days:02 Hours:02 Minutes:53 Seconds:11 Fractions:7"),
 "Days:[D01] Hours:[H01] Minutes:[m01] Seconds:[s01] Fractions:[f0]") returns
 "P2DT2H53M11.7S"
 - altova:parse-duration("Months:03 Days:02 Hours:02 Minutes:53 Seconds:11 Fractions:7", "Months:[M01] Days:[D01] Hours:[H01] Minutes:[m01]") returns "P3M2DT2H53M"

Add a duration to xs:time xp3.1 xo3.1

These functions add a duration to xs:time and return xs:time. The xs:time type has a lexical form of hh:mm:ss.sss. An optional time zone may be suffixed. The letter z indicates Coordinated Universal Time (UTC). All other time zones are represented by their difference from UTC in the format +hh:mm, or -hh:mm. If no time zone value is present, it is considered unknown; it is not assumed to be UTC.

add-hours-to-time [altova:]

altova:add-hours-to-time(Time as xs:time, Hours as xs:integer) as xs:time XP3.1 XQ3.1

Adds a duration in hours to a time. The second argument is the number of hours to be added to the xs:time supplied as the first argument. The result is of type xs:time.

Examples

- altova:add-hours-to-time(xs:time("11:00:00"), 10) returns 21:00:00
- altova:add-hours-to-time(xs:time("11:00:00"), -7) returns 04:00:00

add-minutes-to-time [altova:]

altova:add-minutes-to-time (Time as xs:time, Minutes as xs:integer) as xs:time XP3.1 XQ3.1 Adds a duration in minutes to a time. The second argument is the number of minutes to be added to the xs:time supplied as the first argument. The result is of type xs:time.

Examples

- altova:add-minutes-to-time(xs:time("14:10:00"), 45) returns 14:55:00
- altova:add-minutes-to-time(xs:time("14:10:00"), -5) returns 14:05:00

add-seconds-to-time [altova:]

altova:add-seconds-to-time (Time as xs:time, Minutes as xs:integer) as xs:time XP3.1 XQ3.1 Adds a duration in seconds to a time. The second argument is the number of seconds to be added to the xs:time supplied as the first argument. The result is of type xs:time. The Seconds component can be in the range of 0 to 59.999.

Examples

- altova:add-seconds-to-time(xs:time("14:00:00"), 20) returns 14:00:20
- altova:add-seconds-to-time(xs:time("14:00:00"), 20.895) returns 14:00:20.895

Remove the timezone part from date/time datatypes xp3.1 xq3.1

These functions remove the timezone from the current xs:dateTime, xs:date, or xs:time values, respectively. Note that the difference between xs:dateTime and xs:dateTimeStamp is that in the case of the latter the timezone part is required (while it is optional in the case of the former). So the format of an xs:dateTimeStamp value is: CCYY-MM-DDThh:mm:ss.sss±hh:mm. or CCYY-MM-DDThh:mm:ss.sssz. If the date and time is read from the system clock as xs:dateTimeStamp, the current-dateTime-no-TZ() function can be used to remove the timezone if so required.

current-date-no-TZ [altova:]

```
altova:current-date-no-TZ() as xs:date XP3.1 XQ3.1
```

This function takes no argument. It removes the timezone part of current-date() (which is the current date according to the system clock) and returns an xs:date value.

Examples

If the current date is 2014-01-15+01:00:

• altova:current-date-no-TZ() returns 2014-01-15

current-dateTime-no-TZ [altova:]

```
altova:current-dateTime-no-TZ() as xs:dateTime XP3.1 XQ3.1
```

This function takes no argument. It removes the timezone part of current-dateTime() (which is the current date-and-time according to the system clock) and returns an xs:dateTime value.

Examples

If the current dateTime is 2014-01-15T14:00:00+01:00:

- altova:current-dateTime-no-TZ() returns 2014-01-15T14:00:00
- current-time-no-TZ [altova:]

```
altova:current-time-no-TZ() as xs:time XP3.1 XQ3.1
```

This function takes no argument. It removes the timezone part of current-time() (which is the current time according to the system clock) and returns an xs:time value.

■ Examples

If the current time is 14:00:00+01:00:

- altova:current-time-no-TZ() returns 14:00:00
- date-no-TZ [altova:]

```
altova:date-no-TZ(InputDate as xs:date) as xs:date XP3.1 XQ3.1
```

This function takes an xs:date argument, removes the timezone part from it, and returns an xs:date value. Note that the date is not modified.

- Examples
 - altova:date-no-TZ(xs:date("2014-01-15+01:00")) returns 2014-01-15
- dateTime-no-TZ [altova:]

altova:dateTime-no-TZ(InputDateTime as xs:dateTime) as xs:dateTime XP3.1 XQ3.1 This function takes an xs:dateTime argument, removes the timezone part from it, and returns an xs:dateTime value. Note that neither the date nor the time is modified.

- Examples
 - altova:dateTime-no-TZ(xs:date("2014-01-15T14:00:00+01:00")) returns 2014-01-15T14:00:00
- time-no-TZ [altova:]

```
altova:time-no-TZ(InputTime as xs:time) as xs:time XP3.1 XQ3.1
```

This function takes an xs:time argument, removes the timezone part from it, and returns an xs:time value. Note that the time is not modified.

■ Examples

• altova:time-no-TZ(xs:time("14:00:00+01:00")) returns 14:00:00

[Top 1180]

Return the number of days, hours, minutes, seconds from durations xp3.1 xq3.1

These functions return the number of days in a month, and the number of hours, minutes, and seconds, respectively, from durations.

days-in-month [altova:]

altova:days-in-month (Year as xs:integer, Month as xs:integer) as xs:integer XP3.1 XQ3.1 Returns the number of days in the specified month. The month is specified by means of the Year and Month arguments.

- Examples
 - altova:days-in-month(2018, 10) returns 31
 - altova:days-in-month(2018, 2) returns 28
 - altova:days-in-month(2020, 2) returns 29
- hours-from-dayTimeDuration-accumulated

altova: hours-from-dayTimeDuration-accumulated (DayAndTime as xs:duration) as xs:integer

Returns the total number of hours in the duration submitted by the DayAndTime argument (which is of type xs:duration). The hours in the Day and Time components are added together to give a result that is an integer. A new hour is counted only for a full 60 minutes. Negative durations result in a negative hour value.

- Examples
 - altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5D")) returns 120, Which is the total number of hours in 5 days.
 - altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H")) returns 122, which is the total number of hours in 5 days plus 2 hours.
 - altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H60M")) returns 123, which is the total number of hours in 5 days plus 2 hours and 60 mins.
 - altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H119M")) returns 123, which is the total number of hours in 5 days plus 2 hours and 119 mins.
 - altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H120M")) returns 124, which is the total number of hours in 5 days plus 2 hours and 120 mins.
 - altova:hours-from-dayTimeDuration-accumulated(xs:duration("-P5DT2H")) returns -122
- minutes-from-dayTimeDuration-accumulated

```
altova:minutes-from-dayTimeDuration-accumulated (DayAndTime as xs:duration) as
xs:integer XP3.1 XQ3.1
```

Returns the total number of minutes in the duration submitted by the DayAndTime argument (which is of type xs:duration). The minutes in the Day and Time components are added together to give a result that is an integer. Negative durations result in a negative minute value.

■ Examples

- altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT60M")) returns 60
- altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT1H")) returns 60, which is the total number of minutes in 1 hour.
- altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT1H40M")) returns 100
- altova:minutes-from-dayTimeDuration-accumulated(xs:duration("P1D")) returns 1440, which is the total number of minutes in 1 day.
- altova:minutes-from-dayTimeDuration-accumulated(xs:duration("-P1DT60M")) returns 1500
- seconds-from-dayTimeDuration-accumulated

```
altova:seconds-from-dayTimeDuration-accumulated(DayAndTime as xs:duration) as xs:integer XP3.1 XQ3.1
```

Returns the total number of seconds in the duration submitted by the <code>DayAndTime</code> argument (which is of type <code>xs:duration</code>). The seconds in the <code>Day</code> and <code>Time</code> components are added together to give a result that is an integer. Negative durations result in a negative seconds value.

■ Examples

- altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT1M")) returns 60, which is the total number of seconds in 1 minute.
- altova: seconds-from-dayTimeDuration-accumulated (xs:duration("PT1H")) returns 3600, which is the total number of seconds in 1 hour.
- altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT1H2M")) returns 3720
- altova:seconds-from-dayTimeDuration-accumulated(xs:duration("P1D")) returns 86400, which is the total number of seconds in 1 day.
- altova:seconds-from-dayTimeDuration-accumulated(xs:duration("-P1DT1M")) returns 86460

Return the weekday from xs:dateTime or xs:date xp3.1 xq3.1

These functions return the weekday (as an integer) from xs:dateTime or xs:date. The days of the week are numbered (using the American format) from 1 to 7, with Sunday=1. In the European format, the week starts with Monday (=1). The American format, where Sunday=1, can be set by using the integer 0 where an integer is accepted to indicate the format.

weekday-from-dateTime [altova:]

altova:weekday-from-dateTime (DateTime as xs:dateTime) as xs:integer XP3.1 XQ3.1 Takes a date-with-time as its single argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with sunday=1. If the European format is required (where monday=1), use the other signature of this function (see next signature below).

■ Examples

• altova:weekday-from-dateTime (xs:dateTime("2014-02-03T09:00:00")) returns 2, which would indicate a Monday.

```
altova:weekday-from-dateTime(DateTime as xs:dateTime, Format as xs:integer) as
xs:integer XP3.1 XQ3.1
```

Takes a date-with-time as its first argument and returns the day of the week of this date as an integer. If

the second (integer) argument is 0, then the weekdays are numbered 1 to 7 starting with Sunday=1. If the second argument is an integer other than 0, then Monday=1. If there is no second argument, the function is read as having the other signature of this function (see previous signature).

■ Examples

- altova:weekday-from-dateTime (xs:dateTime("2014-02-03T09:00:00"), 1) returns 1, Which would indicate a Monday
- altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00"), 4) returns 1, which would indicate a Monday
- altova:weekday-from-dateTime (xs:dateTime("2014-02-03T09:00:00"), 0) returns 2, which would indicate a Monday.
- weekday-from-date [altova:]

altova:weekday-from-date(Date as xs:date) as xs:integer XP3.1 XQ3.1 Takes a date as its single argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with Sunday=1. If the European format is required (where Monday=1), use the other signature of this function (see next signature below).

■ Examples

• altova: weekday-from-date (xs:date("2014-02-03+01:00")) returns 2, which would indicate a Monday.

altova:weekday-from-date(Date as xs:date, Format as xs:integer) as xs:integer XP3.1 XQ3.1 Takes a date as its first argument and returns the day of the week of this date as an integer. If the second (Format) argument is 0, then the weekdays are numbered 1 to 7 starting with Sunday=1. If the second argument is an integer other than 0, then Monday=1. If there is no second argument, the function is read as having the other signature of this function (see previous signature).

■ Examples

- altova:weekday-from-date (xs:date("2014-02-03"), 1) returns 1, which would indicate a
- altova: weekday-from-date (xs:date("2014-02-03"), 4) returns 1, which would indicate a Monday
- altova:weekday-from-date(xs:date("2014-02-03"), 0) returns 2, which would indicate a Monday.

Return the week number from xs:dateTime or xs:date xp2 xq1 xp3.1 xq3.1

These functions return the week number (as an integer) from xs:dateTime or xs:date. Week-numbering is available in the US, ISO/European, and Islamic calendar formats. Week-numbering is different in these calendar formats because the week is considered to start on different days (on Sunday in the US format, Monday in the ISO/European format, and Saturday in the Islamic format).

weeknumber-from-date [altova:]

altova:weeknumber-from-date(Date as xs:date, Calendar as xs:integer) as xs:integer XP2 XQ1 XP3.1 XQ3.1

Returns the week number of the submitted Date argument as an integer. The second argument (Calendar) specifies the calendar system to follow.

Supported calendar values are:

- 0 = US calendar (week starts Sunday)
- 1 = ISO standard, European calendar (week starts Monday)
- 2 = Islamic calendar (week starts Saturday)

Default is o.

■ Examples

```
    altova:weeknumber-from-date(xs:date("2014-03-23"), 0) returns 13
    altova:weeknumber-from-date(xs:date("2014-03-23"), 1) returns 12
    altova:weeknumber-from-date(xs:date("2014-03-23"), 2) returns 13
    altova:weeknumber-from-date(xs:date("2014-03-23") ) returns 13
```

The day of the date in the examples above (2014-03-23) is Sunday. So the US and Islamic calendars are one week ahead of the European calendar on this day.

weeknumber-from-dateTime [altova:]

```
altova:weeknumber-from-dateTime (DateTime as xs:dateTime, Calendar as xs:integer) as
xs:integer XP2 XQ1 XP3.1 XQ3.1
```

Returns the week number of the submitted DateTime argument as an integer. The second argument (Calendar) specifies the calendar system to follow.

Supported calendar values are:

- 0 = US calendar (week starts Sunday)
- 1 = ISO standard, European calendar (week starts Monday)
- 2 = Islamic calendar (week starts Saturday)

Default is o.

■ Examples

```
    altova:weeknumber-from-dateTime (xs:dateTime("2014-03-23T00:00:00"), 0) returns 13
    altova:weeknumber-from-dateTime (xs:dateTime("2014-03-23T00:00:00"), 1) returns 12
    altova:weeknumber-from-dateTime (xs:dateTime("2014-03-23T00:00:00"), 2) returns 13
    altova:weeknumber-from-dateTime (xs:dateTime("2014-03-23T00:00:00")) returns 13
```

The day of the dateTime in the examples above (2014-03-23T00:00:00) is Sunday. So the US and Islamic calendars are one week ahead of the European calendar on this day.

[Top 1180]

Build date, time, and duration datatypes from their lexical components xp3.1 xq3.1

The functions take the lexical components of the xs:date, xs:time, or xs:duration datatype as input arguments and combine them to build the respective datatype.

build-date [altova:]

```
altova:build-date(Year as xs:integer, Month as xs:integer, Date as xs:integer) as
xs:date XP3.1 XQ3.1
```

The first, second, and third arguments are, respectively, the year, month, and date. They are combined to build a value of xs:date type. The values of the integers must be within the correct range of that particular date part. For example, the second argument (for the month part) should not be greater than 12.

- Examples
 - altova:build-date(2014, 2, 03) returns 2014-02-03
- build-time [altova:]

```
altova:build-time (Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer) as
xs:time XP3.1 XQ3.1
```

The first, second, and third arguments are, respectively, the hour (0 to 23), minutes (0 to 59), and seconds (0 to 59) values. They are combined to build a value of xs:time type. The values of the integers must be within the correct range of that particular time part. For example, the second (Minutes) argument should not be greater than 59. To add a timezone part to the value, use the other signature of this function (see next signature).

- Examples
 - altova:build-time(23, 4, 57) returns 23:04:57

```
altova:build-time (Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer,
TimeZone as xs:string) as xs:time XP3.1 XQ3.1
```

The first, second, and third arguments are, respectively, the hour (0 to 23), minutes (0 to 59), and seconds (0 to 59) values. The fourth argument is a string that provides the timezone part of the value. The four arguments are combined to build a value of xs:time type. The values of the integers must be within the correct range of that particular time part. For example, the second (Minutes) argument should not be greater than 59.

- Examples
 - altova:build-time(23, 4, 57, '+1') returns 23:04:57+01:00
- build-duration [altova:]

```
altova:build-duration(Years as xs:integer, Months as xs:integer) as
xs:yearMonthDuration XP3.1 XQ3.1
```

Takes two arguments to build a value of type xs: yearMonthDuration. The first argument provides the Years part of the duration value, while the second argument provides the Months part. If the second (Months) argument is greater than or equal to 12, then the integer is divided by 12; the quotient is added to the first argument to provide the Years part of the duration value while the remainder (of the division) provides the Months part. To build a duration of type xs:dayTimeDuration., see the next signature.

■ Examples

- altova:build-duration(2, 10) returns P2Y10M
- altova:build-duration(14, 27) returns P16Y3M
- altova:build-duration(2, 24) returns P4Y

altova:build-duration(Days as xs:integer, Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer) as xs:dayTimeDuration XP3.1 XQ3.1

Takes four arguments and combines them to build a value of type xs:dayTimeDuration. The first argument provides the Days part of the duration value, the second, third, and fourth arguments provide, respectively, the Hours, Minutes, and Seconds parts of the duration value. Each of the three Time arguments is converted to an equivalent value in terms of the next higher unit and the result is used for calculation of the total duration value. For example, 72 seconds is converted to 1M+12S (1 minute and 12 seconds), and this value is used for calculation of the total duration value. To build a duration of type xs:yearMonthDuration., see the previous signature.

■ Examples

- altova:build-duration(2, 10, 3, 56) returns P2DT10H3M56S
- altova:build-duration(1, 0, 100, 0) returns P1DT1H40M
- altova:build-duration(1, 0, 0, 3600) returns P1DT1H

[<u>Top</u>¹¹⁸⁰]

Construct date, dateTime, and time datatypes from string input xp2 xq1 xp3.1 xq3.1

These functions take strings as arguments and construct xs:date, xs:dateTime, or xs:time datatypes. The string is analyzed for components of the datatype based on a submitted pattern argument.

parse-date [altova:]

altova:parse-date(Date as xs:string, DatePattern as xs:string) as xs:date XP2 XQ1 XP3.1

Returns the input string Date as an xs:date value. The second argument DatePattern specifies the pattern (sequence of components) of the input string. DatePattern is described with the component specifiers listed below and with component separators that can be any character. See the examples below.

- D Date
- M Month
- Y Year

The pattern in DatePattern must match the pattern in Date. Since the output is of type xs:date, the output will always have the lexical format YYYY-MM-DD.

Examples

- altova:parse-date(xs:string("09-12-2014"), "[D]-[M]-[Y]") returns 2014-12-09
- altova:parse-date(xs:string("09-12-2014"), "[M]-[D]-[Y]") returns 2014-09-12
- altova:parse-date("06/03/2014", "[M]/[D]/[Y]") returns 2014-06-03
- altova:parse-date("06 03 2014", "[M] [D] [Y]") returns 2014-06-03
- altova:parse-date("6 3 2014", "[M] [D] [Y]") returns 2014-06-03

parse-dateTime [altova:]

```
altova:parse-dateTime(DateTime as xs:string, DateTimePattern as xs:string) as
xs:dateTime XP2 XQ1 XP3.1 XQ3.1
```

Returns the input string DateTime as an xs:dateTime value. The second argument DateTimePattern specifies the pattern (sequence of components) of the input string. DateTimePattern is described with the component specifiers listed below and with component separators that can be any character. See the examples below.

D	Date
М	Month
Y	Year
н	Hour
m	minutes
s	seconds

The pattern in DateTimePattern must match the pattern in DateTime. Since the output is of type xs:dateTime, the output will always have the lexical format YYYY-MM-DDTHH:mm:ss.

■ Examples

```
• altova:parse-dateTime(xs:string("09-12-2014 13:56:24"), "[M]-[D]-[Y] [H]:[M]:
  [s]") returns 2014-09-12T13:56:24
```

```
• altova:parse-dateTime("time=13:56:24; date=09-12-2014", "time=[H]:[m]:[s];
  date=[D]-[M]-[Y]") returns 2014-12-09T13:56:24
```

parse-time [altova:]

altova:parse-time (Time as xs:string, TimePattern as xs:string) as xs:time XP2 XQ1 XP3.1 XO3.1

Returns the input string Time as an xs:time value. The second argument TimePattern specifies the pattern (sequence of components) of the input string. TimePattern is described with the component specifiers listed below and with component separators that can be any character. See the examples below.

н Hour minutes seconds

The pattern in TimePattern must match the pattern in Time. Since the output is of type xs:time, the output will always have the lexical format HH:mm:ss.

■ Examples

```
• altova:parse-time(xs:string("13:56:24"), "[H]:[m]:[s]") returns 13:56:24
• altova:parse-time("13-56-24", "[H]-[m]") returns 13:56:00
• altova:parse-time("time=13h56m24s", "time=[H]h[m]m[s]s") returns 13:56:24
• altova:parse-time("time=24s56m13h", "time=[s]s[m]m[H]h") returns 13:56:24
```

[Top 1180]

Age-related functions xp3.1 xq3.1

These functions return the age as calculated (i) between one input argument date and the current date, or (ii) between two input argument dates. The altova:age function returns the age in terms of years, the altova:age-details function returns the age as a sequence of three integers giving the years, months, and days of the age.

age [altova:]

```
altova:age(StartDate as xs:date) as xs:integer XP3.1 XQ3.1
```

Returns an integer that is the age *in years* of some object, counting from a start-date submitted as the argument and ending with the current date (taken from the system clock). If the input argument is a date anything greater than or equal to one year in the future, the return value will be negative.

■ Examples

If the current date is 2014-01-15:

```
    altova:age (xs:date("2013-01-15")) returns 1
    altova:age (xs:date("2013-01-16")) returns 0
    altova:age (xs:date("2015-01-15")) returns -1
    altova:age (xs:date("2015-01-14")) returns 0
```

altova:age(StartDate as xs:date, EndDate as xs:date) as xs:integer XP3.1 XQ3.1

Returns an integer that is the age *in years* of some object, counting from a start-date that is submitted as the first argument up to an end-date that is the second argument. The return value will be negative if the first argument is one year or more later than the second argument.

■ Examples

If the current date is 2014-01-15:

```
    altova:age (xs:date("2000-01-15"), xs:date("2010-01-15")) returns 10
    altova:age (xs:date("2000-01-15"), current-date()) returns 14 if the current date is 2014-01-15
```

• altova:age(xs:date("2014-01-15"), xs:date("2010-01-15")) returns -4

age-details [altova:]

```
altova:age-details(InputDate as xs:date) as (xs:integer) * XP3.1 XQ3.1
```

Returns three integers that are, respectively, the years, months, and days between the date that is submitted as the argument and the current date (taken from the system clock). The sum of the returned years+months+days together gives the total time difference between the two dates (the input date and the current date). The input date may have a value earlier or later than the current date, but whether the input date is earlier or later is not indicated by the sign of the return values; the return values are always positive.

■ Examples

If the current date is 2014-01-15:

```
    altova:age-details (xs:date("2014-01-16")) returns (0 0 1)
    altova:age-details (xs:date("2014-01-14")) returns (0 0 1)
    altova:age-details (xs:date("2013-01-16")) returns (1 0 1)
```

• altova:age-details(current-date()) returns (0 0 0)

altova:age-details(Date-1 as xs:date, Date-2 as xs:date) as (xs:integer) * XP3.1 XQ3.1 Returns three integers that are, respectively, the years, months, and days between the two argument dates. The sum of the returned years+months+days together gives the total time difference between the two input dates; it does not matter whether the earlier or later of the two dates is submitted as the first argument. The return values do not indicate whether the input date occurs earlier or later than the current date. Return values are always positive.

■ Examples

```
• altova:age-details(xs:date("2014-01-16"), xs:date("2014-01-15")) returns (0 0 1)
• altova:age-details(xs:date("2014-01-15"), xs:date("2014-01-16")) returns (0 0 1)
```

[Top 1180]

Epoch time (Unix time) functions xp3.1 xQ3.1

Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. Altova's Epoch time extension functions convert xs:dateTime values to Epoch time values and vice versa.

dateTime-from-epoch [altova:]

altova:dateTime-from-epoch(Epoch as xs:decimal as xs:dateTime XP3.1 XQ3.1 Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. The dateTime-from-epoch function returns the xs:dateTime equivalent of an Epoch time, adjusts it for the local timezone, and includes the timezone information in the result.

The function takes an xs:decimal argument and returns an xs:dateTime value that includes a TZ (timezone) part. The result is obtained by calculating the UTC dateTime equivalet of the Epoch time, and adding to it the local timezone (taken from the system clock). For example, if the function is executed on a machine that has been set to be in a timezone of +01:00 (relative to UTC), then after the UTC dateTime equivalent has been calculated, one hour will be added to the result. The timezone information, which is an optional lexical part of the xs:dateTime result, is also reported in the dateTime result. Compare this result with that of dateTime-from-epoch-no-TZ, and also see the function epoch-from-dateTime.

■ Examples

The examples below assume a local timezone of UTC +01:00. Consequently, the UTC dateTime equivalent of the submitted Epoch time will be incremented by one hour. The timezone is reported in the result.

```
• altova:dateTime-from-epoch(34) returns 1970-01-01T01:00:34+01:00
• altova:dateTime-from-epoch(62) returns 1970-01-01T01:01:02+01:00
```

dateTime-from-epoch-no-TZ [altova:]

altova:dateTime-from-epoch-no-TZ(Epoch as xs:decimal as xs:dateTime XP3.1 XQ3.1

Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. The dateTime-from-epoch-no-TZ function returns the xs:dateTime equivalent of an Epoch time, adjusts it for the local timezone, but does not include the timezone information in the result.

The function takes an xs:decimal argument and returns an xs:dateTime value that does not includes a TZ (timeZone) part. The result is obtained by calculating the UTC dateTime equivalet of the Epoch time, and adding to it the local timeZone (taken from the system clock). For example, if the function is executed on a machine that has been set to be in a timeZone of +01:00 (relative to UTC), then after the UTC dateTime equivalent has been calculated, one hour will be added to the result. The timeZone information, which is an optional lexical part of the xs:dateTime result, is not reported in the dateTime result. Compare this result with that of dateTime-from-epoch, and also see the function epoch-from-dateTime.

■ Examples

The examples below assume a local timezone of UTC +01:00. Consequently, the UTC dateTime equivalent of the submitted Epoch time will be incremented by one hour. The timezone is not reported in the result.

```
• altova:dateTime-from-epoch(34) returns 1970-01-01T01:00:34
```

• altova:dateTime-from-epoch(62) returns 1970-01-01T01:01:02

epoch-from-dateTime [altova:]

altova:epoch-from-dateTime(dateTimeValue as xs:dateTime) as xs:decimal XP3.1 XQ3.1 Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. The epoch-from-dateTime function returns the Epoch time equivalent of the xs:dateTime that is submitted as the argument of the function. Note that you might have to explicitly construct the xs:dateTime value. The submitted xs:dateTime value may or may not contain the optional Tz (timezone) part.

Whether the timezone part is submitted as part of the argument or not, the local timezone offset (taken from the system clock) is subtracted from the submitted <code>dateTimeValue</code> argument. This produces the equivalent UTC time, from which the equivalent Epoch time is calculated. For example, if the function is executed on a machine that has been set to be in a timezone of +01:00 (relative to UTC), then one hour is subtracted from the submitted <code>dateTimeValue</code> before the Epoch value is calculated. Also see the function <code>dateTime-from-epoch</code>.

■ Examples

The examples below assume a local timezone of UTC +01:00. Consequently, one hour will be subtracted from the submitted dateTime before the Epoch time is calculated.

```
• altova:epoch-from-dateTime(xs:dateTime("1970-01-01T01:00:34+01:00")) returns 34
• altova:epoch-from-dateTime(xs:dateTime("1970-01-01T01:00:34")) returns 34
```

• altova:epoch-from-dateTime(xs:dateTime("2021-04-01T11:22:33")) returns 1617272553

19.2.1.3 XPath/XQuery Functions: Geolocation

The following geolocation XPath/XQuery extension functions are supported in the current version of StyleVision and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xsltextensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

format-geolocation [altova:]

```
altova: format-geolocation (Latitude as xs:decimal, Longitude as xs:decimal,
GeolocationOutputStringFormat as xs:integer) as xs:string XP3.1 XQ3.1
```

Takes the latitude and longitude as the first two arguments, and outputs the geolocation as a string. The third argument, GeolocationOutputStringFormat, is the format of the geolocation output string; it uses integer values from 1 to 4 to identify the output string format (see 'Geolocation output string formats' below). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: The image-exif-data to supply the input strings.

■ Examples

```
• altova:format-geolocation(33.33, -22.22, 4) returns the xs:string "33.33 -22.22"
• altova:format-geolocation (33.33, -22.22, 2) returns the xs:string "33.33N 22.22W"
• altova:format-geolocation(-33.33, 22.22, 2) returns the xs:string "33.33S 22.22E"
• altova: format-geolocation (33.33, -22.22, 1) returns the xs: string "33°19'48.00"S 22°
 13'12.00"E"
```

■ Geolocation output string formats:

The supplied latitude and longitude is formatted in one of the output formats given below. The desired format is identified by its integer ID (1 to 4). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

```
1
Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)
```

```
D°M'S.SS"N/S D°M'S.SS"E/W

<u>Example</u>: 33°55'11.11"N 22°44'66.66"W
```

```
Decimal degrees, with suffixed orientation (N/S, E/W)
D.DDN/S D.DDE/W
Example: 33.33N 22.22W
```

```
Degrees, minutes, decimal seconds, with prefixed sign (+/-); plus sign for (n/E) is optional +/-D°M's.ss" +/-D°M's.ss"

Example: 33°55'11.11" -22°44'66.66"
```

```
Decimal degrees, with prefixed sign (+/-); plus sign for (N/E) is optional +/-D.DD +/-D.DD

Example: 33.33 -22.22
```

■ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

GPSLatitude	GPSLatitudeRe f	GPSLongitude	GPSLongitudeRe f	Geolocation
33 51 21.91	s	151 13 11.73		33°51'21.91" <mark>\$</mark> 151° 13'11.73" E

parse-geolocation [altova:]

altova:parse-geolocation(GeolocationInputString as xs:string) as xs:decimal+ XP3.1 XQ3.1 Parses the supplied GeolocationInputString argument and returns the geolocation's latitude and longitude (in that order) as a sequence two xs:decimal items. The formats in which the geolocation input string can be supplied are listed below.

Note: The <u>image-exif-data</u> 1208 function and the Exif metadata's <u>@Geolocation</u> 2008 attribute can be used to supply the geolocation input string (see example below).

■ Examples

• altova:parse-geolocation("33.33 -22.22") returns the sequence of two xs:decimals (33.33, 22.22)

- altova:parse-geolocation ("48°51'29.6""N 24°17'40.2""") returns the sequence of two xs:decimals (48.858222222222, 24.2945)
- altova:parse-geolocation (48°51' 29.6"N 24°17' 40.2"') returns the sequence of two xs:decimals (48.858222222222, 24.2945)
- altova:parse-geolocation(image-exifdata (//MyImages/Image20141130.01) /@Geolocation) returns a sequence of two xs:decimals

■ Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to s). Longitude values range from +180 to -180 (E to W).

Note: If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minutevalues and second-values. In such cases, the guotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (") while unit indicators that are escaped are highlighted in blue ("").

- Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W) D°M'S.SS"N/S D°M'S.SS"W/E Example: 33°55'11.11"N 22°44'55.25"W
- Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional

```
+/-D°M'S.SS" +/-D°M'S.SS"
Example: 33°55'11.11" -22°44'55.25"
```

Degrees, decimal minutes, with suffixed orientation (N/S, E/W) D°M.MM'N/S D°M.MM'W/E Example: 33°55.55'N 22°44.44'W

Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional +/-D°M.MM' +/-D°M.MM' Example: +33°55.55' -22°44.44'

Decimal degrees, with suffixed orientation (N/S, E/W) D.DDN/S D.DDW/E Example: 33.33N 22.22W

Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional +/-D.DD +/-D.DD Example: 33.33 -22.22

Examples of format-combinations:

```
33.33N -22°44'55.25"
33.33 22°44'55.25"W
33.33 22.45
```

■ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

GPSLatitude	GPSLatitudeRe f	GPSLongitude	GPSLongitudeRe f	Geolocation
33 51 21.93	S	151 13 11.73		33°51'21.91"S 151° 13'11.73"E

geolocation-distance-km [altova:]

```
altova:geolocation-distance-km(GeolocationInputString-1 as xs:string, GeolocationInputString-2 as xs:string) as xs:decimal XP3.1 XQ3.1 Calculates the distance between two geolocations in kilometers. The formats in which the geolocation input string can be supplied are listed below. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).
```

Note: The <u>image-exif-data</u> function and the Exif metadata's <u>@Geolocation</u> attribute can be used to supply geolocation input strings.

■ Examples

```
• altova:geolocation-distance-km("33.33 -22.22", "48°51'29.6""N 24°17'40.2""") returns the xs:decimal 4183.08132372392
```

■ Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (") while unit indicators that are escaped are highlighted in blue ("").

- Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)
 D°M'S.SS"N/S D°M'S.SS"W/E
 Example: 33°55'11.11"N 22°44'55.25"W
- Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional +/-D°M'S.SS" +/-D°M'S.SS"
 Example: 33°55'11.11" -22°44'55.25"

Degrees, decimal minutes, with suffixed orientation (N/S, E/W) D°M.MM'N/S D°M.MM'W/E

Example: 33°55.55'N 22°44.44'W

Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (n/E) is optional $+/-D^{\circ}M.MM' +/-D^{\circ}M.MM'$ Example: +33°55.55' -22°44.44'

Decimal degrees, with suffixed orientation (N/S, E/W)

Example: 33.33N 22.22W

D.DDN/S D.DDW/E

Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional +/-D.DD +/-D.DD Example: 33.33 -22.22

Examples of format-combinations:

33.33N -22°44'55.25" 33.33 22°44'55.25"W 33.33 22.45

■ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

GPSLatitud	e GPSLatitudeRe f	GPSLongitude	GPSLongitudeRe f	Geolocation
33 51 21.9	1 S	151 13 11.73		33°51'21.91" <mark>\$</mark> 151° 13'11.73" E

▼ geolocation-distance-mi [altova:]

altova:geolocation-distance-mi(GeolocationInputString-1 as xs:string, GeolocationInputString-2 as xs:string) as xs:decimal XP3.1 XQ3.1

Calculates the distance between two geolocations in miles. The formats in which a geolocation input string can be supplied are listed below. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: The image-exif-data to function and the Exif metadata's @Geolocation attribute can be used to supply geolocation input strings.

■ Examples

• altova: qeolocation-distance-mi("33.33 -22.22", "48°51'29.6""N 24°17'40.2""") returns the xs:decimal 2599.40652340653

□ Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (") while unit indicators that are escaped are highlighted in blue ("").

Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)
 D°M'S.SS"N/S D°M'S.SS"W/E
 Example: 33°55'11.11"N 22°44'55.25"W

Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional

```
+/-D°M'S.SS" +/-D°M'S.SS"

<u>Example</u>: 33°55'11.11" -22°44'55.25"
```

Degrees, decimal minutes, with suffixed orientation (N/S, E/W)
 D°M.MM'N/S D°M.MM'W/E
 Example: 33°55.55'N 22°44.44'W

• Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional +/-D°M.MM' +/-D°M.MM'

Example: +33°55.55' −22°44.44'

Decimal degrees, with suffixed orientation (N/S, E/W)
 D.DDN/S D.DDW/E
 Example: 33.33N 22.22W

• Decimal degrees, with prefixed sign (+/-); the plus sign for (Ŋ/S E/W) is optional +/-D.DD +/-D.DD

Example: 33.33 -22.22

Examples of format-combinations:

```
33.33N -22°44'55.25"
33.33 22°44'55.25"W
33.33 22.45
```

■ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

GPSLatitude GPSLatitudeRe	GPSLongitude	GPSLongitudeRe	Geolocation
---------------------------	--------------	----------------	-------------

	f		f	
33 51 21.91	S	151 13 11.73	E	33°51'21.91" <mark>\$</mark> 151°
				13'11.73"E

geolocations-bounding-rectangle [altova:]

```
altova: geolocations -bounding-rectangle (Geolocations as xs: sequence,
GeolocationOutputStringFormat as xs:integer) as xs:string XP3.1 XQ3.1
```

Takes a sequence of strings as its first argument; each string in the sequence is a geolocation. The function returns a sequence of two strings which are, respectively, the top-left and bottom-right geolocation coordinates of a bounding rectangle that is optimally sized to enclose all the geolocations submitted in the first argument. The formats in which a geolocation input string can be supplied are listed below (see 'Geolocation input string formats'). Latitude values range from +90 to -90 (N to s). Longitude values range from +180 to -180 (E to W).

The function's second argument specifies the format of the two geolocation strings in the output sequence. The argument takes an integer value from 1 to 4, where each value identifies a different geolocation string format (see 'Geolocation output string formats' below).

Note: The image-exif-data to supply the input strings.

■ Examples

- altova:geolocations-bounding-rectangle(("48.2143531 16.3707266", "51.50939 -0.11832"), 1) returns the sequence ("51°30'33.804"N 0°7'5.952"W", "48°12'51.67116"N 16°22'14.61576"E")
- altova:geolocations-bounding-rectangle(("48.2143531 16.3707266", "51.50939 -0.11832", "42.5584577 -70.8893334"), 4) returns the sequence ("51.50939 -70.8893334", "42.5584577 16.3707266")

■ Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minutevalues and second-values. In such cases, the guotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, guotes used to delimit the input string are highlighted in yellow (") while unit indicators that are escaped are highlighted in blue ("").

Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W) D°M'S.SS"N/S D°M'S.SS"W/E Example: 33°55'11.11"N 22°44'55.25"W

Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional

```
.
+/-D°M'S.SS" +/-D°M'S.SS"
Example: 33°55'11.11" -22°44'55.25"
```

• Degrees, decimal minutes, with suffixed orientation (N/S, E/W)

```
D°M.MM'N/S D°M.MM'W/E

<u>Example</u>: 33°55.55'N 22°44.44'W
```

• Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional +/-D°M.MM' +/-D°M.MM'

```
Example: +33°55.55' -22°44.44'
```

Decimal degrees, with suffixed orientation (N/S, E/W)

```
D.DDN/S D.DDW/E

Example: 33.33N 22.22W
```

• Decimal degrees, with prefixed sign (+/-); the plus sign for (n/s E/w) is optional

```
+/-D.DD +/-D.DD

<u>Example</u>: 33.33 -22.22
```

Examples of format-combinations:

```
33.33N -22°44'55.25"
33.33 22°44'55.25"W
33.33 22.45
```

■ Geolocation output string formats:

The supplied latitude and longitude is formatted in one of the output formats given below. The desired format is identified by its integer ID (1 to 4). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

```
Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)
D°M'S.SS"N/S D°M'S.SS"E/W

Example: 33°55'11.11"N 22°44'66.66"W
```

```
Decimal degrees, with suffixed orientation (N/S, E/W)
D.DDN/S D.DDE/W
Example: 33.33N 22.22W
```

```
Degrees, minutes, decimal seconds, with prefixed sign (+/-); plus sign for (N/E) is optional +/-D°M's.ss" +/-D°M's.ss"

Example: 33°55'11.11" -22°44'66.66"
```

```
Decimal degrees, with prefixed sign (+/-); plus sign for (n/E) is optional
+/-D.DD +/-D.DD
Example: 33.33 -22.22
```

□ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

GPSLatitude	GPSLatitudeRe f	GPSLongitude	GPSLongitudeRe f	Geolocation
33 51 21.91	S	151 13 11.73		33°51'21.91" <mark>\$</mark> 151° 13'11.73" E

geolocation-within-polygon [altova:]

```
altova:geolocation-within-polygon(Geolocation as xs:string, ((PolygonPoint as
xs:string)+)) as xs:boolean XP3.1 XQ3.1
```

Determines whether Geologation (the first argument) is within the polygonal area described by the PolygonPoint arguments. If the PolygonPoint arguments do not form a closed figure (formed when the first point and the last point are the same), then the first point is implicitly added as the last point in order to close the figure. All the arguments (Geolocation and PolygonPoint+) are given by geolocation input strings (formats listed below). If the Geolocation argument is within the polygonal area, then the function returns true(); otherwise it returns false(). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: The image-exif-data function and the Exif metadata's @Geolocation attribute can be used to supply geolocation input strings.

Examples

- altova:qeolocation-within-polygon("33 -22", ("58 -32", "-78 -55", "48 24", "58 -32")) returns true()
- altova: qeolocation-within-polygon ("33 -22", ("58 -32", "-78 -55", "48 24")) returns
- altova:geolocation-within-polygon("33 -22", ("58 -32", "-78 -55", "48°51'29.6""N 24°17'40.2"")) returns true()

■ Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minutevalues and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (") while unit indicators that are escaped are highlighted in blue ("").

Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)
 D°M'S.SS"N/S D°M'S.SS"W/E
 Example: 33°55'11.11"N 22°44'55.25"W

Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional

```
+/-D°M'S.SS" +/-D°M'S.SS"

<u>Example</u>: 33°55'11.11" -22°44'55.25"
```

• Degrees, decimal minutes, with suffixed orientation (N/S, E/W)

D°M.MM'N/S D°M.MM'W/E <u>Example</u>: 33°55.55'N 22°44.44'W

• Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional +/-D°M.MM' +/-D°M.MM' Example: +33°55.55' −22°44.44'

Decimal degrees, with suffixed orientation (N/S, E/W)
 D.DDN/S D.DDW/E
 Example: 33.33N 22.22W

• Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional +/-D.DD +/-D.DD Example: 33.33 -22.22

Examples of format-combinations:

```
33.33N -22°44'55.25"
33.33 22°44'55.25"W
33.33 22.45
```

■ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

GPSLatitude	GPSLatitudeRe f	GPSLongitude	GPSLongitudeRe f	Geolocation
33 51 21.91	S	151 13 11.73		33°51'21.91"S 151° 13'11.73"E

geolocation-within-rectangle [altova:]

```
altova: geolocation-within-rectangle (Geolocation as xs:string, RectCorner-1 as
xs:string, RectCorner-2 as xs:string) as xs:boolean XP3.1 XQ3.1
Determines whether Geologation (the first argument) is within the rectangle defined by the second and
third arguments, RectCorner-1 and RectCorner-2, which specify opposite corners of the rectangle. All
the arguments (Geolocation, RectCorner-1 and RectCorner-2) are given by geolocation input strings
(formats listed below). If the Geolocation argument is within the rectangle, then the function returns
true(); otherwise it returns false(). Latitude values range from +90 to -90 (N to s). Longitude values
range from +180 to -180 (E to W).
```

Note: The image-exif-data 1208 function and the Exif metadata's @Geolocation 1208 attribute can be used to supply geolocation input strings.

■ Examples

- altova:geolocation-within-rectangle("33 -22", "58 -32", "-48 24") returns true() • altova: qeolocation-within-rectangle ("33 -22", "58 -32", "48 24") returns false()
- altova:geolocation-within-rectangle("33 -22", "58 -32", "48°51'29.6""S 24° 17'40.2"") returns true()

■ Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minutevalues and second-values. In such cases, the guotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (") while unit indicators that are escaped are highlighted in blue ("").

- Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W) D°M'S.SS"N/S D°M'S.SS"W/E Example: 33°55'11.11"N 22°44'55.25"W
- Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is

```
+/-D°M'S.SS" +/-D°M'S.SS"
Example: 33°55'11.11" -22°44'55.25"
```

- Degrees, decimal minutes, with suffixed orientation (N/S, E/W) D°M.MM'N/S D°M.MM'W/E Example: 33°55.55'N 22°44.44'W
- Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional +/-D°M.MM' +/-D°M.MM' Example: +33°55.55' -22°44.44'

Decimal degrees, with suffixed orientation (N/S, E/W)
 D.DDN/S
 D.DDW/E

Example: 33.33N 22.22W

• Decimal degrees, with prefixed sign (+/−); the plus sign for (n/s E/w) is optional

+/-D.DD +/-D.DD <u>Example</u>: 33.33 -22.22

Examples of format-combinations:

33.33N -22°44'55.25" 33.33 22°44'55.25"W

33.33 22.45

■ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

GPSLatitude	GPSLatitudeRe f	GPSLongitude	GPSLongitudeRe f	Geolocation
33 51 21.91	s	151 13 11.73		33°51'21.91" <mark>\$</mark> 151° 13'11.73" E

[<u>Top</u>¹¹⁹⁷]

19.2.1.4 XPath/XQuery Functions: Image-Related

The following image-related XPath/XQuery extension functions are supported in the current version of StyleVision and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the **Altova extension functions namespace**, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3

XQuery functions (used in XQuery expressions in XQuery): XQ1 XQ3.1

suggested-image-file-extension [altova:]

altova:suggested-image-file-extension(Base64String as string) as string? XP3.1 XQ3.1 Takes the Base64 encoding of an image file as its argument and returns the file extension of the image as recorded in the Base64-encoding of the image. The returned value is a suggestion based on the image type information available in the encoding. If this information is not available, then an empty string is returned. This function is useful if you wish to save a Base64 image as a file and wish to dynamically retrieve an appropriate file extension.

■ Examples

- altova:suggested-image-file-extension(/MyImages/MobilePhone/Image20141130.01) returns 'jpg'
- altova:suggested-image-file-extension (\$XML1/Staff/Person/@photo) returns ''

In the examples above, the nodes supplied as the argument of the function are assumed to contain a Base64-encoded image. The first example retrieves jpg as the file's type and extension. In the second example, the submitted Base64 encoding does not provide usable file extension information.

image-exif-data [altova:]

altova:image-exif-data(Base64BinaryString as string) as element? XP3.1 XQ3.1 Takes a Base64-encoded JPEG image as its argument and returns an element called Exif that contains the Exif metadata of the image. The Exif metadata is created as attribute-value pairs of the Exif element. The attribute names are the Exif data tags found in the Base64 encoding. The list of Exif-specification tags is given below. If a vendor-specific tag is present in the Exif data, this tag and its value will also be returned as an attribute-value pair. Additional to the standard Exif metadata tags (see list below), Altova-specific attribute-value pairs are also generated. These Altova Exif attributes are listed below.

■ Examples

- To access any one attribute, use the function like this: image-exif-data(//MyImages/Image20141130.01)/@GPSLatitude image-exif-data(//MyImages/Image20141130.01)/@Geolocation
- To access all the attributes, use the function like this: image-exif-data(//MyImages/Image20141130.01)/@*
- To access the names of all the attributes, use the following expression: for \$i in image-exif-data(//MyImages/Image20141130.01)/@* return name(\$i) This is useful to find out the names of the attributes returned by the function.

■ Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, With units added (see table below).

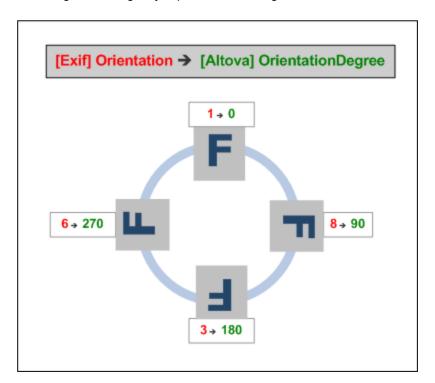

GP	SLatitude	GPSLatitudeRe	GPSLongitude	GPSLongitudeRe	Geolocation
----	-----------	---------------	--------------	----------------	-------------

	f		f	
33 51 21.91	S	151 13 11.73	E	33°51'21.91" <mark>\$</mark> 151°
				13'11.73"E

■ Altova Exif Attribute: OrientationDegree

The Altova XPath/XQuery Engine generates the custom attribute OrientationDegree from the Exif metadata tag Orientation.

OrientationDegree translates the standard Exif tag Orientation from an integer value (1, 8, 3, or 6) to the respective degree values of each (0, 90, 180, 270), as shown in the figure below. Note that there are no translations of the Orientation values of 2, 4, 5, 7. (These orientations are obtained by flipping image 1 across its vertical center axis to get the image with a value of 2, and then rotating this image in 90-degree jumps clockwise to get the values of 7, 4, and 5, respectively).

19.2.1.5 XPath/XQuery Functions: Numeric

Altova's numeric extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova's XPath 3.0 and **XQuery 3.0** engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xsltextensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

Auto-numbering functions

generate-auto-number [altova:]

altova:generate-auto-number(ID as xs:string, StartsWith as xs:double, Increment as xs:double, ResetOnChange as xs:string) as xs:integer XP1 XP2 XQ1 XP3.1 XQ3.1 Generates a number each time the function is called. The first number, which is generated the first time the function is called, is specified by the StartsWith argument. Each subsequent call to the function generates a new number, this number being incremented over the previously generated number by the value specified in the Increment argument. In effect, the altova: generate-auto-number function creates a counter having a name specified by the ID argument, with this counter being incremented each time the function is called. If the value of the ResetonChange argument changes from that of the previous function call, then the value of the number to be generated is reset to the StartsWith value. Auto-numbering can also be reset by using the altova: reset-auto-number function.

■ Examples

• altova:generate-auto-number("ChapterNumber", 1, 1, "SomeString") will return one number each time the function is called, starting with 1, and incrementing by 1 with each call to the function. As long as the fourth argument remains "SomeString" in each subsequent call, the incrementing will continue. When the value of the fourth argument changes, the counter (called ChapterNumber) will reset to 1. The value of ChapterNumber can also be reset by a call to the

altova:reset-auto-number function, like this: altova:reset-auto-number("ChapterNumber").

reset-auto-number [altova:]

```
altova:reset-auto-number(ID as xs:string) XP1 XP2 XQ1 XP3.1 XQ3.1

This function resets the number of the auto-numbering counter named in the ID argument. The number is reset to the number specified by the StartsWith argument of the altova:generate-auto-number function that created the counter named in the ID argument.
```

- Examples
 - altova:reset-auto-number("ChapterNumber") resets the number of the auto-numbering counter named ChapterNumber that was created by the altova:generate-auto-number function. The number is reset to the value of the StartsWith argument of the altova:generate-auto-number function that created ChapterNumber.

Numeric functions

hex-string-to-integer [altova:]

altova:hex-string-to-integer (HexString as xs:string) as xs:integer XP3.1 XQ3.1 Takes a string argument that is the Base-16 equivalent of an integer in the decimal system (Base-10), and returns the decimal integer.

■ Examples

```
altova:hex-string-to-integer('1') returns 1
altova:hex-string-to-integer('9') returns 9
altova:hex-string-to-integer('A') returns 10
altova:hex-string-to-integer('B') returns 11
altova:hex-string-to-integer('F') returns 15
altova:hex-string-to-integer('G') returns an error
altova:hex-string-to-integer('10') returns 16
altova:hex-string-to-integer('01') returns 1
altova:hex-string-to-integer('20') returns 32
altova:hex-string-to-integer('21') returns 33
altova:hex-string-to-integer('5A') returns 90
altova:hex-string-to-integer('USA') returns an error
```

integer-to-hex-string [altova:]

altova:integer-to-hex-string (Integer as xs:integer) as xs:string XP3.1 XQ3.1 Takes an integer argument and returns its Base-16 equivalent as a string.

■ Examples

```
    altova:integer-to-hex-string(1) returns '1'
    altova:integer-to-hex-string(9) returns '9'
    altova:integer-to-hex-string(10) returns 'A'
    altova:integer-to-hex-string(11) returns 'B'
```

```
• altova:integer-to-hex-string(15) returns 'F'
• altova:integer-to-hex-string(16) returns '10'
• altova:integer-to-hex-string(32) returns '20'
• altova:integer-to-hex-string(33) returns '21'
• altova:integer-to-hex-string(90) returns '5A'
```

19.2.1.6 XPath/XQuery Functions: Schema

The Altova extension functions listed below return schema information. Given below are descriptions of the functions, together with (i) examples and (ii) a listing of schema components and their respective properties. They can be used with Altova's XPath 3.0 and XQuery 3.0 engines and are available in XPath/XQuery contexts.

Schema information from schema documents

The function altova: schema has two arguments: one with zero arguments and the other with two arguments. The zero-argument function returns the whole schema. You can then, from this starting point, navigate into the schema to locate the schema components you want. The two-argument function returns a specific component kind that is identified by its QName. In both cases, the return value is a function. To navigate into the returned component, you must select a property of that specific component. If the property is a non-atomic item (that is, if it is a component), then you can navigate further by selecting a property of this component. If the selected property is an atomic item, then the value of the item is returned and you cannot navigate any further.

Note: In XPath expressions, the schema must be imported into the processing environment (for example, into XSLT) with the xslt:import-schema instruction. In XQuery expressions, the schema must be explicitly imported using a schema import.

Schema information from XML nodes

The function altova: type submits the node of an XML document and returns the node's type information from the PSVI.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xsltextensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3

XQuery functions (used in XQuery expressions in XQuery): xQ1 xQ3.1

Schema (zero arguments)

```
altova:schema() as (function(xs:string) as item()*)? XP3.1 XQ3.1

Returns the schema component as a whole. You can navigate further into the schema component by selecting one of the schema component's properties.
```

- If this property is a component, you can navigate another step deeper by selecting one of this component's properties. This step can be repeated to navigate further into the schema.
- If the component is an atomic value, the atomic value is returned and you cannot navigate any deeper.

The properties of the schema component are:

```
"type definitions"

"attribute declarations"

"element declarations"

"attribute group definitions"

"model group definitions"

"notation declarations"

"identity-constraint definitions"
```

The properties of all other component kinds (besides schema) are listed below.

Note: In XQuery expressions, the schema must be explicitly imported. In XPath expressions, the schema must have been imported into the processing environment, for example, into XSLT with the **xslt:import** instruction.

■ Examples

```
• import schema "" at "C:\Test\ExpReport.xsd"; for $typedef in altova:schema()
  ("type definitions")
  return $typedef ("name") returns the names of all simple types or complex types in the schema
```

• import schema "" at "C:\Test\ExpReport.xsd";
altova:schema() ("type definitions")[1]("name") returns the name of the first of all simple
types or complex types in the schema

Components and their properties

Assertion

Property name	Property type	Property value
kind	string	"Assertion"
test	XPath Property Record	

Attribute Declaration

Property name	Property type	Property value
kind	string	"Attribute Declaration"
name	string	Local name of the attribute
target namespace	string	Namespace URI of the attribute
type definition	Simple Type or Complex Type	
scope	A function with properties ("class":"Scope", "variety": "global" or "local", "parent": the containing Complex Type or Attribute Group)	
value constraint	If present, a function with properties ("class": "Value Constraint", "variety": "fixed" or "default", "value": atomic value, "lexical form": string. Note that the "value" property is not available for namespace-sensitive types	
inheritable	boolean	

■ Attribute Group Declaration

Property name	Property type	Property value
kind	string	"Attribute Group Definition"
name	string	Local name of the attribute group
target namespace	string	Namespace URI of the attribute group
attribute uses	Sequence of (Attribute Use)	
attribute wildcard	Optional Attribute Wildcard	

■ Attribute Use

Property name	Property type	Property value
kind	string	"Attribute Use"
required	boolean	true if the attribute is required, false if optional
value constraint	See Attribute Declaration	
inheritable	boolean	

Attribute Wildcard

Property name	Property type	Property value
kind	string	"Wildcard"
namespace constraint	function with properties ("class": "Namespace Constraint", "variety":	

	"any" "enumeration" "not", "namespaces": sequence of xs:anyURI, "disallowed names": list containing QNames and/or the strings "defined" and "definedSiblings"	
process contents	string ("strict" "lax" "skip")	

■ Complex Type

Property name	Property type	Property value
kind	string	"Complex Type"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
base type definition	Complex Type Definition	
final	Sequence of strings ("restriction" "extension")	
context	Empty sequence (not implemented)	
derivation method	string ("restriction" "extension")	
abstract	boolean	
attribute uses	Sequence of Attribute Use	
attribute wildcard	Optional Attribute Wildcard	
content type	function with properties: ("class":"Content Type", "variety":string ("element- only" "empty" "mixed" "simple"), particle: optional Particle, "open content": function with properties ("class":"Open Content", "mode": string ("interleave" "suffix"), "wildcard": Wildcard), "simple type definition": Simple Type)	
prohibited substitutions	Sequence of strings ("restriction" "extension")	
assertions	Sequence of Assertion	

■ Element Declaration

Property name	Property type	Property value
kind	string	"Complex Type"
name	•	Local name of the type (empty if anonymous)

target namespace	string	Namespace URI of the type (empty if anonymous)
type definition	Simple Type or Complex Type	
type table	function with properties ("class":"Type Table", "alternatives": sequence of Type Alternative, "default type definition": Simple Type or Complex Type)	
scope	function with properties ("class":"Scope", "variety": ("global" "local"), "parent": optional Complex Type)	
value constraint	see Attribute Declaration	
nillable	boolean	
identity-constraint definitions	Sequence of Identity Constraint	
substitution group affiliations	Sequence of Element Declaration	
substitution group exclusions	Sequence of strings ("restriction" "extension")	
disallowed substitutions	Sequence of strings ("restriction" "extension" "substitution")	
abstract	boolean	

■ Element Wildcard

Property name	Property type	Property value
kind	string	"Wildcard"
namespace constraint	function with properties ("class": "Namespace Constraint", "variety": "any" "enumeration" "not", "namespaces": sequence of xs:anyURI, "disallowed names": list containing QNames and/or the strings "defined" and "definedSiblings"	
process contents	string ("strict" "lax" "skip")	

■ Facet

Property name	Property type	Property value
kind	string	The name of the facet, for example "minLength" or "enumeration"
value	depends on facet	The value of the facet
fixed	boolean	

typed-value	For the enumeration facet only, array(xs:anyAtomicType*)	An array containing the enumeration values, each of which may in general be a sequence of atomic values. (Note: for the enumeration facet, the "value" property is a sequence of strings,
		regardless of the actual type)

■ Identity Constraint

Property name	Property type	Property value
kind	string	"Identity-Constraint Definition"
name	string	Local name of the constraint
target namespace	string	Namespace URI of the constraint
identity-constraint category	string ("key" "unique" "keyRef")	
selector	XPath Property Record	
fields	Sequence of XPath Property Record	
referenced key	(For keyRef only): Identity Constraint	The corresponding key constraint

■ Model Group

Property name	Property type	Property value
kind	string	"Model Group"
compositor	string ("sequence" "choice" "all")	
particles	Sequence of Particle	

■ Model Group Definition

Property name	Property type	Property value
kind	string	"Model Group Definition"
name	string	Local name of the model group
target namespace	string	Namespace URI of the model group
model group	Model Group	

Notation

Property name	Property type	Property value
kind	string	"Notation Declaration"
name	string	Local name of the notation
target namespace	string	Namespace URI of the notation

system identifier	anyURI	
public identifier	string	

■ Particle

Property name	Property type	Property value
kind	string	"Particle"
min occurs	integer	
max occurs	integer, or string("unbounded")	
term	Element Declaration, Element Wildcard, or ModelGroup	

■ Simple Type

Property name	Property type	Property value
kind	string	"Simple Type Definition"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
final	Sequence of string("restriction" "extension" "list" "unio n")	
context	containing component	
base type definition	Simple Type	
facets	Sequence of Facet	
fundamental facets	Empty sequence (not implemented)	
variety	string ("atomic" "list" "union")	
primitive type definition	Simple Type	
item type definition	(for list types only) Simple Type	
member type definitions	(for union types only) Sequence of Simple Type	

■ Type Alternative

Property name	Property type	Property value
kind	string	"Type Alternative"
test	XPath Property Record	
type definition	Simple Type or Complex Type	

XPath Property Record

Property name	Property type	Property value
namespace bindings	Sequence of functions with properties ("prefix": string, "namespace": anyURI)	
default namespace	anyURI	
base URI	anyURI	The static base URI of the XPath expression
expression	string	The XPath expression as a string

Schema (two arguments)

```
altova:schema(ComponentKind as xs:string, Name as xs:QName) as (function(xs:string) as item()*)? XP3.1 XQ3.1
```

Returns the component kind that is specified in the first argument which has a name that is the same as the name supplied in the second argument. You can navigate further by selecting one of the component's properties.

- If this property is a component, you can navigate another step deeper by selecting one of this component's properties. This step can be repeated to navigate further into the schema.
- If the component is an atomic value, the atomic value is returned and you cannot navigate any deeper.

Note: In XQuery expressions, the schema must be explicitly imported. In XPath expressions, the schema must have been imported into the processing environment, for example, into XSLT with the xslt:import instruction.

■ Examples

```
• import schema "" at "C:\Test\ExpReport.xsd";

altova:schema("element declaration", xs:QName("OrgChart"))("type definition")

("content type")("particles")[3]!.("term")("kind")
```

returns the kind property of the term of the third particles component. This particles component is a descendant of the element declaration having a <code>QName</code> of <code>OrgChart</code>

```
• import schema "" at "C:\Test\ExpReport.xsd";

let $typedef := altova:schema("type definition", xs:QName("emailType"))

for $facet in $typedef ("facets")

return [$facet ("kind"), $facet("value")]

returns, for each facet of each emailType component, an array containing that facet's kind and value
```

Components and their properties

Assertion

Property name	Property type	Property value
kind	string	"Assertion"

test	XPath Property Record	
------	-----------------------	--

■ Attribute Declaration

Property name	Property type	Property value
kind	string	"Attribute Declaration"
name	string	Local name of the attribute
target namespace	string	Namespace URI of the attribute
type definition	Simple Type or Complex Type	
scope	A function with properties ("class":"Scope", "variety": "global" or "local", "parent": the containing Complex Type or Attribute Group)	
value constraint	If present, a function with properties ("class": "Value Constraint", "variety": "fixed" or "default", "value": atomic value, "lexical form": string. Note that the "value" property is not available for namespace-sensitive types	
inheritable	boolean	

■ Attribute Group Declaration

Property name	Property type	Property value
kind	string	"Attribute Group Definition"
name	string	Local name of the attribute group
target namespace	string	Namespace URI of the attribute group
attribute uses	Sequence of (Attribute Use)	
attribute wildcard	Optional Attribute Wildcard	

■ Attribute Use

Property name	Property type	Property value
kind	string	"Attribute Use"
required	boolean	true if the attribute is required, false if optional
value constraint	See Attribute Declaration	
inheritable	boolean	

■ Attribute Wildcard

kind	string	"Wildcard"
namespace constraint	function with properties ("class": "Namespace Constraint", "variety": "any" "enumeration" "not", "namespaces": sequence of xs:anyURI, "disallowed names": list containing QNames and/or the strings "defined" and "definedSiblings"	
process contents	string ("strict" "lax" "skip")	

■ Complex Type

Property name	Property type	Property value
kind	string	"Complex Type"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
base type definition	Complex Type Definition	
final	Sequence of strings ("restriction" "extension")	
context	Empty sequence (not implemented)	
derivation method	string ("restriction" "extension")	
abstract	boolean	
attribute uses	Sequence of Attribute Use	
attribute wildcard	Optional Attribute Wildcard	
content type	function with properties: ("class":"Content Type", "variety":string ("element- only" "empty" "mixed" "simple"), particle: optional Particle, "open content": function with properties ("class":"Open Content", "mode": string ("interleave" "suffix"), "wildcard": Wildcard), "simple type definition": Simple Type)	
prohibited substitutions	Sequence of strings ("restriction" "extension")	
assertions	Sequence of Assertion	

■ Element Declaration

Property name	Property type	Property value
---------------	---------------	----------------

kind	string	"Complex Type"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
type definition	Simple Type or Complex Type	
type table	function with properties ("class":"Type Table", "alternatives": sequence of Type Alternative, "default type definition": Simple Type or Complex Type)	
scope	function with properties ("class":"Scope", "variety": ("global" "local"), "parent": optional Complex Type)	
value constraint	see Attribute Declaration	
nillable	boolean	
identity-constraint definitions	Sequence of Identity Constraint	
substitution group affiliations	Sequence of Element Declaration	
substitution group exclusions	Sequence of strings ("restriction" "extension")	
disallowed substitutions	Sequence of strings ("restriction" "extension" "substitution")	
abstract	boolean	

■ Element Wildcard

Property name	Property type	Property value
kind	string	"Wildcard"
namespace constraint	function with properties ("class": "Namespace Constraint", "variety": "any" "enumeration" "not", "namespaces": sequence of xs:anyURI, "disallowed names": list containing QNames and/or the strings "defined" and "definedSiblings"	
process contents	string ("strict" "lax" "skip")	

■ Facet

P	roperty name	Property type	Property value
ki	ind	string	The name of the facet, for example "minLength" or

		"enumeration"
value	depends on facet	The value of the facet
fixed	boolean	
typed-value	For the enumeration facet only, array(xs:anyAtomicType*)	An array containing the enumeration values, each of which may in general be a sequence of atomic values. (Note: for the enumeration facet, the "value" property is a sequence of strings, regardless of the actual type)

■ Identity Constraint

Property name	Property type	Property value
kind	string	"Identity-Constraint Definition"
name	string	Local name of the constraint
target namespace	string	Namespace URI of the constraint
identity-constraint category	string ("key" "unique" "keyRef")	
selector	XPath Property Record	
fields	Sequence of XPath Property Record	
referenced key	(For keyRef only): Identity Constraint	The corresponding key constraint

■ Model Group

Property name	Property type	Property value
kind	string	"Model Group"
compositor	string ("sequence" "choice" "all")	
particles	Sequence of Particle	

■ Model Group Definition

Property name	Property type	Property value
kind	string	"Model Group Definition"
name	string	Local name of the model group
target namespace	string	Namespace URI of the model group
model group	Model Group	

■ Notation

kind	string	"Notation Declaration"
name	string	Local name of the notation
target namespace	string	Namespace URI of the notation
system identifier	anyURI	
public identifier	string	

■ Particle

Property name	Property type	Property value
kind	string	"Particle"
min occurs	integer	
max occurs	integer, or string("unbounded")	
term	Element Declaration, Element Wildcard, or ModelGroup	

■ Simple Type

Property name	Property type	Property value
kind	string	"Simple Type Definition"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
final	Sequence of string("restriction" "extension" "list" "unio n")	
context	containing component	
base type definition	Simple Type	
facets	Sequence of Facet	
fundamental facets	Empty sequence (not implemented)	
variety	string ("atomic" "list" "union")	
primitive type definition	Simple Type	
item type definition	(for list types only) Simple Type	
member type definitions	(for union types only) Sequence of Simple Type	

■ Type Alternative

Property name	Property type	Property value
kind	string	"Type Alternative"

test	XPath Property Record	
type definition	Simple Type or Complex Type	

XPath Property Record

Property name	Property type	Property value
namespace bindings	Sequence of functions with properties ("prefix": string, "namespace": anyURI)	
default namespace	anyURI	
base URI	anyURI	The static base URI of the XPath expression
expression	string	The XPath expression as a string

Type

altova:type (Node as item?) as (function(xs:string) as item()*)? XP3.1 XQ3.1 The function altova:type submits an element or attribute node of an XML document and returns the node's type information from the PSVI.

Note: The XML document must have a schema declaration so that the schema can be referenced.

■ Examples

```
    for $element in //Email
    let $type := altova:type($element)
    return $type
    returns a function that contains the Email node's type information
```

```
• for $element in //Email
  let $type := altova:type($element)
  return $type ("kind")
```

takes the Email node's type component (Simple Type or Complex Type) and returns the value of the component's kind property

The "props" parameter returns the properties of the selected component. For example:

```
• for $element in //Email
  let $type := altova:type($element)
  return ($type ("kind"), $type ("_props"))
```

takes the Email node's type component (Simple Type or Complex Type) and returns (i) the value of the component's kind property, and then (ii) the properties of that component.

Components and their properties

Assertion

Property name Property ty	Property value
---------------------------	----------------

kind	string	"Assertion"
test	XPath Property Record	

■ Attribute Declaration

Property name	Property type	Property value
kind	string	"Attribute Declaration"
name	string	Local name of the attribute
target namespace	string	Namespace URI of the attribute
type definition	Simple Type or Complex Type	
scope	A function with properties ("class":"Scope", "variety": "global" or "local", "parent": the containing Complex Type or Attribute Group)	
value constraint	If present, a function with properties ("class": "Value Constraint", "variety": "fixed" or "default", "value": atomic value, "lexical form": string. Note that the "value" property is not available for namespace-sensitive types	
inheritable	boolean	

■ Attribute Group Declaration

Property name	Property type	Property value
kind	string	"Attribute Group Definition"
name	string	Local name of the attribute group
target namespace	string	Namespace URI of the attribute group
attribute uses	Sequence of (Attribute Use)	
attribute wildcard	Optional Attribute Wildcard	

■ Attribute Use

Property name	Property type	Property value
kind	string	"Attribute Use"
required	boolean	true if the attribute is required, false if optional
value constraint	See Attribute Declaration	
inheritable	boolean	

Attribute Wildcard

Property name	Property type	Property value
kind	string	"Wildcard"
namespace constraint	function with properties ("class": "Namespace Constraint", "variety": "any" "enumeration" "not", "namespaces": sequence of xs:anyURI, "disallowed names": list containing QNames and/or the strings "defined" and "definedSiblings"	
process contents	string ("strict" "lax" "skip")	

■ Complex Type

Property name	Property type	Property value
kind	string	"Complex Type"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
base type definition	Complex Type Definition	
final	Sequence of strings ("restriction" "extension")	
context	Empty sequence (not implemented)	
derivation method	string ("restriction" "extension")	
abstract	boolean	
attribute uses	Sequence of Attribute Use	
attribute wildcard	Optional Attribute Wildcard	
content type	function with properties: ("class":"Content Type", "variety":string ("element- only" "empty" "mixed" "simple"), particle: optional Particle, "open content": function with properties ("class":"Open Content", "mode": string ("interleave" "suffix"), "wildcard": Wildcard), "simple type definition": Simple Type)	
prohibited substitutions	Sequence of strings ("restriction" "extension")	
assertions	Sequence of Assertion	

■ Element Declaration

kind	string	"Complex Type"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
type definition	Simple Type or Complex Type	
type table	function with properties ("class":"Type Table", "alternatives": sequence of Type Alternative, "default type definition": Simple Type or Complex Type)	
scope	function with properties ("class":"Scope", "variety": ("global" "local"), "parent": optional Complex Type)	
value constraint	see Attribute Declaration	
nillable	boolean	
identity-constraint definitions	Sequence of Identity Constraint	
substitution group affiliations	Sequence of Element Declaration	
substitution group exclusions	Sequence of strings ("restriction" "extension")	
disallowed substitutions	Sequence of strings ("restriction" "extension" "substitution")	
abstract	boolean	

■ Element Wildcard

Property name	Property type	Property value
kind	string	"Wildcard"
namespace constraint	function with properties ("class": "Namespace Constraint", "variety": "any" "enumeration" "not", "namespaces": sequence of xs:anyURI, "disallowed names": list containing QNames and/or the strings "defined" and "definedSiblings"	
process contents	string ("strict" "lax" "skip")	

■ Facet

Property name	Property type	Property value
kind	string	The name of the facet, for example "minLength" or

		"enumeration"
value	depends on facet	The value of the facet
fixed	boolean	
typed-value	For the enumeration facet only, array(xs:anyAtomicType*)	An array containing the enumeration values, each of which may in general be a sequence of atomic values. (Note: for the enumeration facet, the "value" property is a sequence of strings, regardless of the actual type)

■ Identity Constraint

Property name	Property type	Property value
kind	string	"Identity-Constraint Definition"
name	string	Local name of the constraint
target namespace	string	Namespace URI of the constraint
identity-constraint category	string ("key" "unique" "keyRef")	
selector	XPath Property Record	
fields	Sequence of XPath Property Record	
referenced key	(For keyRef only): Identity Constraint	The corresponding key constraint

■ Model Group

Property name	Property type	Property value
kind	string	"Model Group"
compositor	string ("sequence" "choice" "all")	
particles	Sequence of Particle	

■ Model Group Definition

Property name	Property type	Property value
kind	string	"Model Group Definition"
name	string	Local name of the model group
target namespace	string	Namespace URI of the model group
model group	Model Group	

■ Notation

Property name	Property type	Property value

kind	string	"Notation Declaration"
name	string	Local name of the notation
target namespace	string	Namespace URI of the notation
system identifier	anyURI	
public identifier	string	

■ Particle

Property name	Property type	Property value
kind	string	"Particle"
min occurs	integer	
max occurs	integer, or string("unbounded")	
term	Element Declaration, Element Wildcard, or ModelGroup	

■ Simple Type

Property name	Property type	Property value
kind	string	"Simple Type Definition"
name	string	Local name of the type (empty if anonymous)
target namespace	string	Namespace URI of the type (empty if anonymous)
final	Sequence of string("restriction" "extension" "list" "unio n")	
context	containing component	
base type definition	Simple Type	
facets	Sequence of Facet	
fundamental facets	Empty sequence (not implemented)	
variety	string ("atomic" "list" "union")	
primitive type definition	Simple Type	
item type definition	(for list types only) Simple Type	
member type definitions	(for union types only) Sequence of Simple Type	

■ Type Alternative

Property name	Property type	Property value
kind	string	"Type Alternative"

test	XPath Property Record	
type definition	Simple Type or Complex Type	

XPath Property Record

Property name	Property type	Property value
namespace bindings	Sequence of functions with properties ("prefix": string, "namespace": anyURI)	
default namespace	anyURI	
base URI	anyURI	The static base URI of the XPath expression
expression	string	The XPath expression as a string

19.2.1.7 XPath/XQuery Functions: Sequence

Altova's sequence extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova's **XPath 3.0** and **XQuery 3.0** engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the **Altova extension functions namespace**, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

attributes [altova:]

altova:attributes (AttributeName as xs:string) as attribute() * XP3.1 XQ3.1 Returns all attributes that have a local name which is the same as the name supplied in the input argument, AttributeName. The search is case-sensitive and conducted along the attribute:: axis. This means that the context node must be the parent element node.

Examples

• altova:attributes("MyAttribute") returns MyAttribute()*

```
altova:attributes(AttributeName as xs:string, SearchOptions as xs:string) as
attribute() * XP3.1 XQ3.1
```

Returns all attributes that have a local name which is the same as the name supplied in the input argument. AttributeName. The search is case-sensitive and conducted along the attribute:: axis. The context node must be the parent element node. The second argument is a string containing option flags. Available flags are:

- r = switches to a regular-expression search; AttributeName must then be a regular-expression search string;
- f = If this option is specified, then AttributeName provides a full match; otherwise AttributeName need only partially match an attribute name to return that attribute. For example: if f is not specified, then MyAtt will return MyAttribute;
- i = switches to a case-insensitive search;
- p = includes the namespace prefix in the search; AttributeName should then contain the namespace prefix, for example: altova:MyAttribute.

The flags can be written in any order. Invalid flags will generate errors. One or more flags can be omitted. The empty string is allowed, and will produce the same effect as the function having only one argument (previous signature). However, an empty sequence is not allowed as the second argument.

■ Examples

- altova:attributes("MyAttribute", "rfip") returns MyAttribute()*
- altova:attributes("MyAttribute", "pri") returns MyAttribute()*
- altova:attributes("MyAtt", "rip") returns MyAttribute()*
- altova:attributes("MyAttributes", "rfip") returns no match
- altova:attributes("MyAttribute", "") returns MyAttribute()*
- altova:attributes ("MyAttribute", "Rip") returns an unrecognized-flag error.
- altova:attributes("MyAttribute",) returns a missing-second-argument error.

elements [altova:]

altova:elements(ElementName as xs:string) as element()* XP3.1 XQ3.1

Returns all elements that have a local name which is the same as the name supplied in the input argument, ElementName. The search is case-sensitive and conducted along the child:: axis. The context node must be the parent node of the element/s being searched for.

Examples

• altova:elements("MyElement") returns MyElement()*

```
altova:elements(ElementName as xs:string, SearchOptions as xs:string) as element()*
XP3.1 XO3.1
```

Returns all elements that have a local name which is the same as the name supplied in the input argument, ElementName. The search is case-sensitive and conducted along the child:: axis. The context node must be the parent node of the element/s being searched for. The second argument is a string containing option flags. Available flags are:

- r = switches to a regular-expression search; ElementName must then be a regular-expression search
- f = If this option is specified, then ElementName provides a full match; otherwise ElementName need only partially match an element name to return that element. For example: if f is not specified, then MyElem will return MyElement;
- i = switches to a case-insensitive search:
- p = includes the namespace prefix in the search; ElementName should then contain the namespace prefix,

for example: altova:MyElement.

The flags can be written in any order. Invalid flags will generate errors. One or more flags can be omitted. The empty string is allowed, and will produce the same effect as the function having only one argument (previous signature). However, an empty sequence is not allowed.

■ Examples

```
    altova:elements("MyElement", "rip") returns MyElement()*
    altova:elements("MyElement", "pri") returns MyElement()*
    altova:elements("MyElement", "") returns MyElement()*
    altova:elements("MyElem", "rip") returns MyElement()*
    altova:elements("MyElements", "rfip") returns no match
    altova:elements("MyElement", "Rip") returns an unrecognized-flag error.
    altova:elements("MyElement", ) returns a missing-second-argument error.
```

find-first [altova:]

```
altova:find-first((Sequence as item()*), (Condition( Sequence-Item as xs:boolean)) as
item()? XP3.1 XQ3.1
```

This function takes two arguments. The first argument is a sequence of one or more items of any datatype. The second argument, <code>Condition</code>, is a reference to an XPath function that takes one argument (has an arity of 1) and returns a boolean. Each item of <code>sequence</code> is submitted, in turn, to the function referenced in <code>Condition</code>. (Remember: This function takes a single argument.) The first <code>sequence</code> item that causes the function in <code>Condition</code> to evaluate to <code>true()</code> is returned as the result of <code>altova:find-first</code>, and the iteration stops.

■ Examples

• altova:find-first (5 to 10, function(\$a) {\$a mod 2 = 0}) returns xs:integer 6
The condition argument references the XPath 3.0 inline function, function(), which declares an inline function named \$a\$ and then defines it. Each item in the sequence argument of altova:find-first is passed, in turn, to \$a\$ as its input value. The input value is tested on the condition in the function definition (\$a mod 2 = 0). The first input value to satisfy this condition is returned as the result of altova:find-first (in this case 6).

```
• altova:find-first((1 to 10), (function($a) {$a+3=7})) returns xs:integer 4
```

Further examples

If the file C:\Temp\Customers.xml exists:

```
• altova:find-first( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1) ) returns xs:string C:\Temp\Customers.xml
```

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html exists:

```
• altova:find-first(("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1)) returns xs:string http://www.altova.com/index.html
```

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html also

does not exist:

• altova:find-first(("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1)) returns no result

Notes about the examples given above

- The XPath 3.0 function, doc-available, takes a single string argument, which is used as a URI, and returns true if a document node is found at the submitted URI. (The document at the submitted URI must therefore be an XML document.)
- The doc-available function can be used for condition, the second argument of altova: findfirst, because it takes only one argument (arity=1), because it takes an item() as input (a string which is used as a URI), and returns a boolean value.
- Notice that the doc-available function is only referenced, not called. The #1 suffix that is attached to it indicates a function with an arity of 1. In its entirety doc-available#1 simply means: Use the doc-availabe() function that has arity=1, passing to it as its single argument, in turn, each of the items in the first sequence. As a result, each of the two strings will be passed to doc-available(), which uses the string as a URI and tests whether a document node exists at the URI. If one does, the doc-available () evaluates to true () and that string is returned as the result of the altova:find-first function. Note about the doc-available() function: Relative paths are resolved relative to the the current base URI, which is by default the URI of the XML document from which the function is loaded.

find-first-combination [altova:]

```
altova:find-first-combination((Seq-01 as item()*), (Seq-02 as item()*),
(Condition (Seq-01-Item, Seq-02-Item as xs:boolean)) as item()* XP3.1 XQ3.1
This function takes three arguments:
```

- The first two arguments, seq-01 and seq-02, are sequences of one or more items of any
- The third argument, condition, is a reference to an XPath function that takes two arguments (has an arity of 2) and returns a boolean.

The items of seq-01 and seq-02 are passed in ordered pairs (one item from each sequence making up a pair) as the arguments of the function in Condition. The pairs are ordered as follows.

```
Ιf
    Seq-01 = X1, X2, X3 \dots Xn
And Seq-02 = Y1, Y2, Y3 ... Yn
Then (X1 Y1), (X1 Y2), (X1 Y3) ... (X1 Yn), (X2 Y1), (X2 Y2) ... (Xn Yn)
```

The first ordered pair that causes the condition function to evaluate to true () is returned as the result of altova:find-first-combination. Note that: (i) If the Condition function iterates through the submitted argument pairs and does not once evaluate to true(), then altova:find-first-combination returns No results; (ii) The result of altova:find-first-combination will always be a pair of items (of any datatype) or no item at all.

■ Examples

• altova:find-first-combination(11 to 20, 21 to 30, function(\$a, \$b) {\$a+\$b = 32}) returns the sequence of xs:integers (11, 21)

- altova:find-first-combination(11 to 20, 21 to 30, function(\$a, \$b) {\$a+\$b = 33}) returns the sequence of xs:integers (11, 22)
- altova:find-first-combination(11 to 20, 21 to 30, function(\$a, \$b) {\$a+\$b = 34}) returns the sequence of xs:integers (11, 23)

find-first-pair [altova:]

```
altova:find-first-pair((Seq-01 as item()*), (Seq-02 as item()*), (Condition( Seq-01-Item, Seq-02-Item as xs:boolean)) as item()* XP3.1 XQ3.1 This function takes three arguments:
```

- The first two arguments, seq-01 and seq-02, are sequences of one or more items of any datatype.
- The third argument, condition, is a reference to an XPath function that takes two arguments (has an arity of 2) and returns a boolean.

The items of seq-01 and seq-02 are passed in ordered pairs as the arguments of the function in Condition. The pairs are ordered as follows.

```
If Seq-01 = X1, X2, X3 ... Xn
And Seq-02 = Y1, Y2, Y3 ... Yn
Then (X1 \ Y1), (X2 \ Y2), (X3 \ Y3) ... (Xn \ Yn)
```

The first ordered pair that causes the Condition function to evaluate to true() is returned as the result of altova:find-first-pair. Note that: (i) If the Condition function iterates through the submitted argument pairs and does not once evaluate to true(), then altova:find-first-pair returns No results; (ii) The result of altova:find-first-pair will always be a pair of items (of any datatype) or no item at all.

■ Examples

- altova:find-first-pair(11 to 20, 21 to 30, function(\$a, \$b) {\$a+\$b = 32}) returns the sequence of xs:integers (11, 21)
- altova:find-first-pair(11 to 20, 21 to 30, function(\$a, \$b) {\$a+\$b = 33}) returns
 No results

Notice from the two examples above that the ordering of the pairs is: $(11, 21) (12, 22) (13, 23) \dots (20, 30)$. This is why the second example returns *No results* (because no ordered pair gives a sum of 33).

▼ find-first-pair-pos [altova:]

```
altova:find-first-pair-pos((Seq-01 as item()*), (Seq-02 as item()*), (Condition( Seq-01-Item, Seq-02-Item as xs:boolean)) as xs:integer XP3.1 XQ3.1

This function takes three arguments:
```

- The first two arguments, seq-01 and seq-02, are sequences of one or more items of any datatype.
- The third argument, condition, is a reference to an XPath function that takes two arguments (has an arity of 2) and returns a boolean.

The items of seq-01 and seq-02 are passed in ordered pairs as the arguments of the function in condition. The pairs are ordered as follows.

```
Seq-01 = X1, X2, X3 \dots Xn
And Seq-02 = Y1, Y2, Y3 ... Yn
Then (X1 Y1), (X2 Y2), (X3 Y3) ... (Xn Yn)
```

The index position of the first ordered pair that causes the condition function to evaluate to true() is returned as the result of altova:find-first-pair-pos. Note that if the Condition function iterates through the submitted argument pairs and does not once evaluate to true(), then altova:find-firstpair-pos returns No results.

Examples

- altova:find-first-pair-pos(11 to 20, 21 to 30, function(\$a, \$b) {\$a+\$b = 32})
- altova:find-first-pair-pos(11 to 20, 21 to 30, function(\$a, \$b) {\$a+\$b = 33}) returns No results

Notice from the two examples above that the ordering of the pairs is: (11, 21) (12, 22) (13, 23) ... (20, 30). In the first example, the first pair causes the condition function to evaluate to true (), and so its index position in the sequence, 1, is returned. The second example returns No results because no pair gives a sum of 33.

find-first-pos [altova:]

```
altova:find-first-pos((Sequence as item()*), (Condition( Sequence-Item as xs:boolean))
as xs:integer XP3.1 XQ3.1
```

This function takes two arguments. The first argument is a sequence of one or more items of any datatype. The second argument, condition, is a reference to an XPath function that takes one argument (has an arity of 1) and returns a boolean. Each item of sequence is submitted, in turn, to the function referenced in Condition. (Remember: This function takes a single argument.) The first sequence item that causes the function in condition to evaluate to true () has its index position in sequence returned as the result of altova: find-first-pos, and the iteration stops.

Examples

• altova:find-first-pos(5 to 10, function(\$a) {\$a mod 2 = 0}) returns xs:integer 2 The condition argument references the XPath 3.0 inline function, function(), which declares an inline function named \$a and then defines it. Each item in the sequence argument of altova:findfirst-pos is passed, in turn, to \$a as its input value. The input value is tested on the condition in the function definition ($\$a \mod 2 = 0$). The index position in the sequence of the first input value to satisfy this condition is returned as the result of altova:find-first-pos (in this case 2, since 6, the first value (in the sequence) to satisfy the condition, is at index position 2 in the sequence).

```
• altova:find-first-pos((2 to 10), (function($a) {$a+3=7})) returns xs:integer 3
```

Further examples

If the file C:\Temp\Customers.xml exists:

• altova:find-first-pos(("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1)) returns 1

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html exists:

```
• altova:find-first-pos( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1) ) returns 2
```

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html also does not exist:

```
• altova:find-first-pos( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1) ) returns no result
```

Notes about the examples given above

- The XPath 3.0 function, doc-available, takes a single string argument, which is used as a URI, and returns true if a document node is found at the submitted URI. (The document at the submitted URI must therefore be an XML document.)
- The doc-available function can be used for condition, the second argument of altova:find-first-pos, because it takes only one argument (arity=1), because it takes an item() as input (a string which is used as a URI), and returns a boolean value.
- Notice that the doc-available function is only referenced, not called. The #1 suffix that is attached to it indicates a function with an arity of 1. In its entirety doc-available#1 simply means: Use the doc-availabe() function that has arity=1, passing to it as its single argument, in turn, each of the items in the first sequence. As a result, each of the two strings will be passed to doc-available(), which uses the string as a URI and tests whether a document node exists at the URI. If one does, the doc-available() function evaluates to true() and the index position of that string in the sequence is returned as the result of the altova:find-first-pos function. Note about the doc-available() function: Relative paths are resolved relative to the the current base URI, which is by default the URI of the XML document from which the function is loaded.
- for-each-attribute-pair [altova:]

```
altova:for-each-attribute-pair(Seq1 as element()?, Seq2 as element()?, Function as
function()) as item()* XP3.1 XQ3.1
```

The first two arguments identify two elements, the attributes of which are used to build attribute pairs, where one attribute of a pair is obtained from the first element and the other attribute is obtained from the second element. Attribute pairs are selected on the basis of having the same name, and the pairs are ordered alphabetically (on their names) into a set. If, for one attribute no corresponding attribute on the other element exists, then the pair is "disjoint", meaning that it consists of one member only. The function item (third argument Function) is applied separately to each pair in the sequence of pairs (joint and disjoint), resulting in an output that is a sequence of items.

■ Examples

• altova:for-each-attribute-pair(/Example/Test-A, /Example/Test-B, function(\$a, \$b) {\$a+b}) returns ...

```
(2, 4, 6) if
<Test-A att1="1" att2="2" att3="3" />
<Test-B att1="1" att2="2" att3="3" />
(2, 4, 6) if
<Test-A att2="2" att1="1" att3="3" />
<Test-B att3="3" att2="2" att1="1" />
(2, 6) if
<Test-A att4="4" att1="1" att3="3" />
<Test-B att3="3" att2="2" att1="1" />
```

<u>Note</u>: The result (2, 6) is obtained by way of the following action: (1+1, ()+2, 3+3, 4+()). If one of the operands is the empty sequence, as in the case of items 2 and 4, then the result of the addition is an empty sequence.

• altova:for-each-attribute-pair(/Example/Test-A, /Example/Test-B, concat#2) returns

```
(11, 22, 33) if
<Test-A att1="1" att2="2" att3="3" />
<Test-B att1="1" att2="2" att3="3" />
(11, 2, 33, 4) if
<Test-A att4="4" att1="1" att3="3" />
<Test-B att3="3" att2="2" att1="1" />
```

for-each-combination [altova:]

```
altova:for-each-combination(FirstSequence as item()*, SecondSequence as item()*,
Function($i,$j){$i \mid | $j} ) as item()* XP3.1 XQ3.1
```

The items of the two sequences in the first two arguments are combined so that each item of the first sequence is combined, in order, once with each item of the second sequence. The function given as the third argument is applied to each combination in the resulting sequence, resulting in an output that is a sequence of items (see example).

Examples

```
• altova:for-each-combination( ('a', 'b', 'c'), ('1', '2', '3'), function($i, $j)
  {$i || $j} ) returns ('a1', 'a2', 'a3', 'b1', 'b2', 'b3', 'c1', 'c2', 'c3')
```

for-each-matching-attribute-pair [altova:]

```
altova:for-each-matching-attribute-pair(Seq1 as element()?, Seq2 as element()?,
Function as function()) as item()* XP3.1 XQ3.1
```

The first two arguments identify two elements, the attributes of which are used to build attribute pairs, where one attribute of a pair is obtained from the first element and the other attribute is obtained from the second element. Attribute pairs are selected on the basis of having the same name, and the pairs are ordered alphabetically (on their names) into a set. If, for one attribute no corresponding attribute on the other element exists, then no pair is built. The function item (third argument Function) is applied

separately to each pair in the sequence of pairs, resulting in an output that is a sequence of items.

■ Examples

```
• altova:for-each-matching-attribute-pair(/Example/Test-A, /Example/Test-B,
         function($a, $b) {$a+b}) returns ...
          (2, 4, 6) if
          <Test-A att1="1" att2="2" att3="3" />
          <Test-B att1="1" att2="2" att3="3" />
          (2, 4, 6) if
          <Test-A att2="2" att1="1" att3="3" />
          <Test-B att3="3" att2="2" att1="1" />
          (2, 6) if
          <Test-A att4="4" att1="1" att3="3" />
          <Test-B att3="3" att2="2" att3="1" />
      • altova:for-each-matching-attribute-pair(/Example/Test-A, /Example/Test-B,
         concat#2) returns ...
          (11, 22, 33) if
          <Test-A att1="1" att2="2" att3="3" />
          <Test-B att1="1" att2="2" att3="3" />
          (11, 33) if
          <Test-A att4="4" att1="1" att3="3" />
          <Test-B att3="3" att2="2" att1="1" />
substitute-empty [altova:]
   altova:substitute-empty(FirstSequence as item()*, SecondSequence as item()) as item()*
   If FirstSequence is empty, returns SecondSequence. If FirstSequence is not empty, returns
   FirstSequence.
```

■ Examples

- altova:substitute-empty((1,2,3), (4,5,6)) returns (1,2,3)
- altova:substitute-empty((), (4,5,6)) returns (4,5,6)

19.2.1.8 XPath/XQuery Functions: String

Altova's string extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova's **XPath 3.0** and **XQuery 3.0** engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xsltextensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

camel-case [altova:]

altova:camel-case(InputString as xs:string) as xs:string XP3.1 XQ3.1 Returns the input string Inputstring in CamelCase. The string is analyzed using the regular expression '\s' (which is a shortcut for the whitespace character). The first non-whitespace character after a whitespace or sequence of consecutive whitespaces is capitalized. The first character in the output string is capitalized.

■ Examples

- altova:camel-case("max") returns Max
- altova:camel-case("max max") returns Max Max
- altova:camel-case("file01.xml") returns File01.xml
- altova:camel-case("file01.xml file02.xml") returns File01.xml File02.xml
- altova:camel-case("file01.xml file02.xml") returns File01.xml
- altova:camel-case("file01.xml -file02.xml") returns File01.xml -file02.xml

```
altova:camel-case(InputString as xs:string, SplitChars as xs:string, IsRegex as
xs:boolean) as xs:string XP3.1 XQ3.1
```

Converts the input string Inputstring to camel case by using splitchars to determine the character/s that trigger the next capitalization. splitChars is used as a regular expression when isRegex = true(), or as plain characters when <code>IsReqex = false()</code>. The first character in the output string is capitalized.

Examples

- altova:camel-case("setname getname", "set|get", true()) returns setName getName
- altova:camel-case("altova\documents\testcases", "\", false()) returns Altova\Documents\Testcases

char [altova:]

```
altova:char(Position as xs:integer) as xs:string XP3.1 XQ3.1
```

Returns a string containing the character at the position specified by the Position argument, in the string obtained by converting the value of the context item to xs:string. The result string will be empty if no character exists at the index submitted by the Position argument.

■ Examples

If the context item is 1234ABCD:

- altova:char(2) returns 2
- altova:char(5) returns A
- altova: char (9) returns the empty string.
- altova:char(-2) returns the empty string.

altova:char(InputString as xs:string, Position as xs:integer) as xs:string XP3.1 XQ3.1 Returns a string containing the character at the position specified by the Position argument, in the string submitted as the InputString argument. The result string will be empty if no character exists at the index submitted by the Position argument.

Examples

- altova:char("2014-01-15", 5) returns -
- altova:char("USA", 1) returns U
- altova:char("USA", 10) returns the empty string.
- altova:char("USA", -2) returns the empty string.

create-hash-from-string[altova:]

```
altova:create-hash-from-string(InputString as xs:string) as xs:string XP2 XQ1 XP3.1 XQ3.1 altova:create-hash-from-string(InputString as xs:string, HashAlgo as xs:string) as xs:string XP2 XQ1 XP3.1 XQ3.1
```

Generates a hash string from InputString by using the hashing algorithm specified by the HashAlgo argument. The following hashing algorithms may be specified (in upper or lower case): MD5, SHA-1, SHA-224, SHA-256, SHA-384, SHA-512. If the second argument is not specified (see the first signature above), then the SHA-256 hashing algorithm is used.

Examples

- altova:create-hash-from-string('abc') returns a hash string generated by using the SHA-256 hashing algorithm.
- altova:create-hash-from-string('abc', 'md5') returns a hash string generated by using the MD5 hashing algorithm.
- altova:create-hash-from-string('abc', 'MD5') returns a hash string generated by using the MD5 hashing algorithm.

first-chars [altova:]

altova:first-chars(X-Number as xs:integer) as xs:string XP3.1 XQ3.1

Returns a string containing the first X-Number of characters of the string obtained by converting the value of the context item to xs:string.

■ Examples

If the context item is 1234ABCD:

```
• altova:first-chars(2) returns 12
```

• altova:first-chars(5) returns 1234A

• altova:first-chars(9) returns 1234ABCD

altova:first-chars(InputString as xs:string, X-Number as xs:integer) as xs:string XP3.1 XQ3.1

Returns a string containing the first X-Number of characters of the string submitted as the InputString argument.

■ Examples

- altova:first-chars("2014-01-15", 5) returns 2014-
- altova:first-chars("USA", 1) returns U

format-string [altova:]

altova:format-string(InputString as xs:string, FormatSequence as item()*) as xs:string XP3.1 XO3.1

The input string (first argument) contains positional parameters (%1, %2, etc). Each parameter is replaced by the string item that is located at the corresponding position in the format sequence (submitted as the second argument). So the first item in the format sequence replaces the positional parameter \$1, the second item replaces %2, and so on. The function returns this formatted string that contains the replacements. If no string exists for a positional parameter, then the positional parameter itself is returned. This happens when the index of a positional parameter is greater than the number of items in the format sequence.

Examples

- altova:format-string('Hello %1, %2, %3', ('Jane','John','Joe')) returns "Hello Jane, John, Joe"
- altova:format-string('Hello %1, %2, %3', ('Jane', 'John', 'Joe', 'Tom')) returns "Hello Jane, John, Joe"
- altova:format-string('Hello %1, %2, %4', ('Jane', 'John', 'Joe', 'Tom')) returns "Hello Jane, John, Tom"
- altova:format-string('Hello %1, %2, %4', ('Jane', 'John', 'Joe')) returns "Hello Jane, John, %4"

last-chars [altova:]

altova:last-chars(X-Number as xs:integer) as xs:string XP3.1 XQ3.1

Returns a string containing the last X-Number of characters of the string obtained by converting the value of the context item to xs:string.

Examples

If the context item is 1234ABCD:

- altova:last-chars(2) returns CD
- altova:last-chars(5) returns 4ABCD
- altova:last-chars(9) returns 1234ABCD

altova:last-chars(InputString as xs:string, X-Number as xs:integer) as xs:string XP3.1

Returns a string containing the last X-Number of characters of the string submitted as the InputString argument.

■ Examples

- altova:last-chars("2014-01-15", 5) returns 01-15
- altova:last-chars("USA", 10) returns USA

pad-string-left [altova:]

```
altova:pad-string-left(StringToPad as xs:string, StringLength as xs:integer,
PadCharacter as xs:string) as xs:string XP3.1 XQ3.1
```

The PadCharacter argument is a single character. It is padded to the left of the string to increase the number of characters in StringToPad so that this number equals the integer value of the StringLength argument. The StringLength argument can have any integer value (positive or negative), but padding will occur only if the value of StringLength is greater than the number of characters in StringToPad. If StringToPad. has more characters than the value of StringLength, then StringToPad is left unchanged.

■ Examples

- altova:pad-string-left('AP', 1, 'Z') returns 'AP'
 altova:pad-string-left('AP', 2, 'Z') returns 'AP'
 altova:pad-string-left('AP', 3, 'Z') returns 'ZAP'
 altova:pad-string-left('AP', 4, 'Z') returns 'ZZAP'
 altova:pad-string-left('AP', -3, 'Z') returns 'AP'
 altova:pad-string-left('AP', 3, 'YZ') returns a pad-character-too-long error
- pad-string-right [altova:]

```
altova:pad-string-right(StringToPad as xs:string, StringLength as xs:integer,
PadCharacter as xs:string) as xs:string XP3.1 XQ3.1
```

The PadCharacter argument is a single character. It is padded to the right of the string to increase the number of characters in StringToPad so that this number equals the integer value of the StringLength argument. The StringLength argument can have any integer value (positive or negative), but padding will occur only if the value of StringLength is greater than the number of characters in StringToPad. If StringToPad has more characters than the value of StringLength, then StringToPad is left unchanged.

Examples

```
altova:pad-string-right('AP', 1, 'Z') returns 'AP'
altova:pad-string-right('AP', 2, 'Z') returns 'AP'
altova:pad-string-right('AP', 3, 'Z') returns 'APZ'
altova:pad-string-right('AP', 4, 'Z') returns 'APZZ'
altova:pad-string-right('AP', -3, 'Z') returns 'AP'
altova:pad-string-right('AP', 3, 'YZ') returns a pad-character-too-long error
```

repeat-string [altova:]

```
altova:repeat-string(InputString as xs:string, Repeats as xs:integer) as xs:string XP2
XQ1 XP3.1 XQ3.1
```

Generates a string that is composed of the first InputString argument repeated Repeats number of times.

- Examples
 - altova:repeat-string("Altova #", 3) returns "Altova #Altova #Altova #Altova #
- substring-after-last [altova:]

```
altova:substring-after-last(MainString as xs:string, CheckString as xs:string) as
```

xs:string XP3.1 XQ3.1

If CheckString is found in MainString, then the substring that occurs after CheckString in MainString is returned. If CheckString is not found in MainString, then the empty string is returned. If CheckString is an empty string, then MainString is returned in its entirety. If there is more than one occurrence of CheckString in MainString, then the substring after the last occurrence of CheckString is returned.

Examples

```
• altova:substring-after-last('ABCDEFGH', 'B') returns 'CDEFGH'
• altova:substring-after-last('ABCDEFGH', 'BC') returns 'DEFGH'
• altova:substring-after-last('ABCDEFGH', 'BD') returns ''
• altova:substring-after-last('ABCDEFGH', 'Z') returns ''
• altova:substring-after-last('ABCDEFGH', '') returns 'ABCDEFGH'
• altova:substring-after-last('ABCD-ABCD', 'B') returns 'CD'
• altova:substring-after-last('ABCD-ABCD-ABCD', 'BCD') returns ''
```

substring-before-last [altova:]

```
altova:substring-before-last(MainString as xs:string, CheckString as xs:string) as
xs:string XP3.1 XQ3.1
```

If CheckString is found in MainString, then the substring that occurs before CheckString in MainString is returned. If CheckString is not found in MainString, or if CheckString is an empty string, then the empty string is returned. If there is more than one occurrence of CheckString in MainString, then the substring before the last occurrence of CheckString is returned.

■ Examples

```
• altova:substring-before-last('ABCDEFGH', 'B') returns 'A'
• altova:substring-before-last('ABCDEFGH', 'BC') returns 'A'
• altova:substring-before-last('ABCDEFGH', 'BD') returns ''
• altova:substring-before-last('ABCDEFGH', 'Z') returns ''
• altova:substring-before-last('ABCDEFGH', '') returns ''
• altova:substring-before-last('ABCD-ABCD', 'B') returns 'ABCD-A'
• altova:substring-before-last('ABCD-ABCD-ABCD', 'ABCD') returns 'ABCD-ABCD-'
```

substring-pos [altova:]

```
altova:substring-pos(StringToCheck as xs:string, StringToFind as xs:string) as
xs:integer XP3.1 XQ3.1
```

Returns the character position of the first occurrence of StringToFind in the string StringToCheck. The character position is returned as an integer. The first character of StringToCheck has the position 1. If StringToFind does not occur within StringToCheck, the integer 0 is returned. To check for the second or a later occurrence of StringToCheck, use the next signature of this function.

Examples

```
• altova: substring-pos('Altova', 'to') returns 3
• altova:substring-pos('Altova', 'tov') returns 3
• altova:substring-pos('Altova', 'tv') returns 0
• altova:substring-pos('AltovaAltova', 'to') returns 3
```

altova:substring-pos(StringToCheck as xs:string, StringToFind as xs:string, Integer as xs:integer) as xs:integer XP3.1 XQ3.1

Returns the character position of StringToFind in the string, StringToCheck. The search for StringToFind starts from the character position given by the Integer argument; the character substring before this position is not searched. The returned integer, however, is the position of the found string within the entire string, StringToCheck. This signature is useful for finding the second or a later position of a string that occurs multiple times with the StringToCheck. If StringToFind does not occur within StringToCheck, the integer 0 is returned.

■ Examples

```
    altova:substring-pos('Altova', 'to', 1) returns 3
    altova:substring-pos('Altova', 'to', 3) returns 3
    altova:substring-pos('Altova', 'to', 4) returns 0
    altova:substring-pos('Altova-Altova', 'to', 0) returns 3
    altova:substring-pos('Altova-Altova', 'to', 4) returns 10
```

trim-string [altova:]

altova:trim-string(InputString as xs:string) as xs:string XP3.1 XQ3.1 This function takes an xs:string argument, removes any leading and trailing whitespace, and returns a "trimmed" xs:string.

Examples

```
    altova:trim-string(" Hello World ") returns "Hello World"
    altova:trim-string("Hello World ") returns "Hello World"
    altova:trim-string(" Hello World") returns "Hello World"
    altova:trim-string("Hello World") returns "Hello World"
    altova:trim-string("Hello World") returns "Hello World"
```

trim-string-left [altova:]

altova:trim-string-left(InputString as xs:string) as xs:string XP3.1 XQ3.1 This function takes an xs:string argument, removes any leading whitespace, and returns a left-trimmed xs:string.

■ Examples

```
    altova:trim-string-left(" Hello World ") returns "Hello World "
    altova:trim-string-left("Hello World ") returns "Hello World "
    altova:trim-string-left(" Hello World") returns "Hello World"
    altova:trim-string-left("Hello World") returns "Hello World"
    altova:trim-string-left("Hello World") returns "Hello World"
```

trim-string-right [altova:]

altova:trim-string-right(InputString as xs:string) as xs:string XP3.1 XQ3.1

This function takes an xs:string argument, removes any trailing whitespace, and returns a right-trimmed xs:string.

■ Examples

```
    altova:trim-string-right(" Hello World ")) returns " Hello World"
    altova:trim-string-right("Hello World ")) returns "Hello World"
    altova:trim-string-right(" Hello World")) returns " Hello World"
```

```
• altova:trim-string-right("Hello World")) returns "Hello World"
```

19.2.1.9 XPath/XQuery Functions: Miscellaneous

The following general purpose XPath/XQuery extension functions are supported in the current version of StyleVision and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xsltextensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

XPath functions (used in XPath expressions in XSLT):	XP1 XP2 XP3.1
XSLT functions (used in XPath expressions in XSLT):	XSLT1 XSLT2 XSLT3
XQuery functions (used in XQuery expressions in XQuery):	XQ1 XQ3.1

decode-string [altova:]

```
altova:decode-string(Input as xs:base64Binary) as xs:string XP3.1 XQ3.1
altova:decode-string(Input as xs:base64Binary, Encoding as xs:string) as xs:string XP3.1
XQ3.1
```

Decodes the submitted base64Binary input to a string using the specified encoding. If no encoding is specified, then the UTF-8 encoding is used. The following encodings are supported: US-ASCII, ISO-8859-1, UTF-16, UTF-16LE, UTF-16BE, ISO-10646-UCS2, UTF-32, UTF-32LE, UTF-32BE, ISO-10646-UCS4

Examples

- altova:decode-string (\$XML1/MailData/Meta/b64B) returns the base64Binary input as a UTF-8 encoded string
- altova:decode-string (\$XML1/MailData/Meta/b64B, "UTF-8") returns the base64Binary input as a UTF-8-encoded string
- altova:decode-string(\$XML1/MailData/Meta/b64B, "ISO-8859-1") returns the base64Binary input as an ISO-8859-1-encoded string

encode-string [altova:]

[•] altova:trim-string-right("Hello World")) returns "Hello

altova:encode-string(InputString as xs:string) as xs:base64Binaryinteger XP3.1 XQ3.1 altova:encode-string(InputString as xs:string, Encoding as xs:string) as xs:base64Binaryinteger XP3.1 XQ3.1

Encodes the submitted string using, if one is given, the specified encoding. If no encoding is given, then the UTF-8 encoding is used. The encoded string is converted to base64Binary characters, and the converted base64Binary value is returned. Initially, UTF-8 encoding is supported, and support will be extended to the following encodings: US-ASCII, ISO-8859-1, UTF-16, UTF-16LE, UTF-16BE, ISO-10646-UCS2, UTF-32, UTF-32LE, UTF-32BE, ISO-10646-UCS4

■ Examples

- altova:encode-string("Altova") returns the base64Binary equivalent of the UTF-8 encoded string "Altova"
- altova:encode-string ("Altova", "UTF-8") returns the base64Binary equivalent of the UTF-8 encoded string "Altova"
- get-temp-folder [altova:]

```
altova:get-temp-folder() as xs:string XP2 XQ1 XP3.1 XQ3.1

This function takes no argument. It returns the path to the temporary folder of the current user.
```

- Examples
 - altova:get-temp-folder() would return, on a Windows machine, something like C: \UserName>\AppData\Local\Temp\ as an xs:string.
- generate-guid [altova:]

```
altova:generate-guid() as xs:string XP2 XQ1 XP3.1 XQ3.1 Generates a unique string GUID string.
```

- Examples
 - altova:generate-guid() returns (for example) 85F971DA-17F3-4E4E-994E-99137873ACCD
- high-res-timer [altova:]

```
altova:high-res-timer() as xs:double XP3.1 XQ3.1
```

Returns a system high-resolution timer value in seconds. A high-resolution timer, when present on a system, enables high precision time measurements when these are required (for example, in animations and for determining precise code-execution time). This function provides the resolution of the system's high-res timer.

- Examples
 - altova:high-res-timer() returns something like '1.16766146154566E6'
- parse-html [altova:]

```
altova:parse-html(HTMLText as xs:string) as node() XP3.1 XQ3.1
```

The HTMLText argument is a string that contains the text of an HTML document. The function creates an HTML tree from the string. The submitted string may or may not contain the HTML element. In either case, the root element of the tree is an element named HTML. It is best to make sure that the HTML code in the

submitted string is valid HTML.

- Examples
 - altova:parse-html("<html><head/><body><h1>Header</h1></body></html>") creates an HTML tree from the submitted string
- sleep[altova:]

altova:sleep (Millisecs as xs:integer) as empty-sequence() XP2 XQ1 XP3.1 XQ3.1 Suspends execution of the current operation for the number of milliseconds given by the Millisecs argument.

- Examples
 - altova:sleep (1000) suspends execution of the current operation for 1000 milliseconds.

19.2.1.10 Chart Functions

The chart functions listed below enable you to create, generate, and save charts as images. They are supported in the current version of your Altova product in the manner described below. However, note that in future versions of your product, support for one or more of these functions might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

Note: Chart functions are supported only in Altova's Server products and the Enterprise Editions of Altova products.

Note: Supported image formats for charts in server editions are jpg, png, and bmp. The best option is png because it is lossless and compressed. In Enterprise editions, the supported formats are jpg. png, bmp, and gif.

Functions for generating and saving charts

These functions take the chart object (obtained with the chart creation functions) and either generate an image or save an image to file

altova:generate-chart-image (\$chart, \$width, \$height, \$encoding) as atomic

where

- \$chart is the chart extension item obtained with the altova: create-chart function
- \$width and \$height must be specified with a length unit
- \$encoding may be x-binarytobase64 or x-binarytobase16

The function returns the chart image in the specified encoding.

altova:generate-chart-image (\$chart, \$width, \$height, \$encoding, \$imagetype) as atomic

where

- \$chart is the chart extension item obtained with the altova:create-chart function
- \$width and \$height must be specified with a length unit
- \$encoding may be x-binarytobase64 or x-binarytobase16
- \$imagetype may be one of the following image formats: png, gif, bmp, jpg, jpeg. Note that gif is not supported on server products. Also see note at top of page.

The function returns the chart image in the specified encoding and image format.

altova:save-chart-image (\$chart, \$filename, \$width, \$height) as empty() (Windows only)

where

- \$chart is the chart extension item obtained with the altova: create-chart function
- \$filename is the path to and name of the file to which the chart image is to be saved
- \$width and \$height must be specified with a length unit

The function saves the chart image to the file specified in \$filename. Alternatively to this function, you could also use the xsl:result-document function with encoding="x-base64tobinary", where the image-data content is obtained via either the generate-chart-image() function or chart() function.

altova:save-chart-image (\$chart, \$filename, \$width, \$height, \$imagetype) as empty()
(Windows only)

where

- \$chart is the chart extension item obtained with the altova: create-chart function
- \$filename is the path to and name of the file to which the chart image is to be saved
- \$width and \$height must be specified with a length unit
- \$imagetype may be one of the following image formats: png, gif, bmp, jpg, jpeg. Note that gif is not supported on server products. Also see note at top of page.

The function saves the chart image to the file specified in \$filename in the image format specified. Alternatively to this function, you could also use the xsl:result-document function with encoding="x-base64tobinary", where the image-data content is obtained via either the generate-chart-image() function or chart() function.

Functions for creating charts

The following functions are used to create charts.

altova:create-chart(\$chart-config, \$chart-data-series*) as chart extension item

where

• \$chart-config is the chart-config extension item obtained with the altova:create-chart-config function or via the altova:create-chart-config-from-xml function

where

• Schart-data-series is the chart-data-series extension item obtained with the altova; createchart-data-series function or altova: create-chart-data-series-from-rows function

The function returns a chart extension item, which is created from the data supplied via the arguments.

```
altova:chart($chart-config, $chart-data-series*) as chart extension item
```

- \$chart-config is the chart-config extension item. It is an unordered series of four key: value pairs, where the four keys are "width", "height", "title", and "kind". The values of width and height are integers and specify the width and height of the chart in pixels. The value of kind is one of: Pie, Pie3d, BarChart, BarChart3d, BarChart3dGrouped, LineChart, ValueLineChart, RoundGauge, BarGauge.
- \$chart-data-series is each an array of size 3, where each array defines a chart-data-series. Each array is composed of: (i) the name of the data series, (ii) the X-Axis values, (iii) the Y-Axis values. Multiple data series may be submitted; in the example below, for example, the two arrays respectively give data for monthly minimum and maximum temperatures.

The function returns an xs:base64Binary type item that contains the chart image. This image is created from the data supplied via the arguments of the function. Note that, since this function uses arrays and maps, it can be used only in XPath 3.1, XQuery 3.1, or XSLT 3.0.

```
Example: altova:chart( map{'width':800, 'height':600, "kind":"LineChart", "title":"Monthly
Temperatures"}, (['Min', $temps/Month, $temps/Month/@min], ['Max', $temps/Month,
$temps/Month/@max]) )
altova: create-chart-config ($type-name, $title) as chart-config extension item
```

where

- Stype-name specifies the type of chart to be created: Pie, Pie3d, BarChart, BarChart3d, BarChart3dGrouped, LineChart, ValueLineChart, RoundGauge, BarGauge
- \$title is the name of the chart

The function returns a chart-config extension item containing the configuration information of the chart.

```
altova:create-chart-config-from-xml($xml-struct) as chart-config extension item
```

\$xml-struct is the XML structure containing the configuration information of the chart

The function returns a chart-config extension item containing the configuration information of the chart. This information is supplied in an XML data fragment 1255.

```
altova:create-chart-data-series ($series-name?, $x-values*, $y-values*) as chart-data-series
extension item
```

where

where

- \$series-name specifies the name of the series
- \$x-values gives the list of X-Axis values
- \$y-values gives the list of Y-Axis values

The function returns a chart-data-series extension item containing the data for building the chart: that is, the names of the series and the Axes data.

altova:create-chart-data-row(x, y1, y2, y3, ...) as chart-data-x- N_y -row extension item

where

- x is the value of the X-Axis column of the chart data row
- yN are the values of the Y-Axis columns

The function returns a chart-data-x-Ny-row extension item, which contains the data for the X-Axis column and Y-Axis columns of a single series.

altova:create-chart-data-series-from-rows(\$series-names as xs:string*, \$row*) as chartdata-series extension item

where

- \$series-name is the name of the series to be created
- \$row is the chart-data-x-Ny-row extension item that is to be created as a series

The function returns a chart-data-series extension item, which contains the data for the X-Axis and Y-Axes of the series.

altova:create-chart-layer(\$chart-confiq, \$chart-data-series*) as chart-layer extension item

where

- \$chart-config is the chart-config extension item obtained with the altova:create-chart-config function or via the altova:create-chart-config-from-xml function
- \$chart-data-series is the chart-data-series extension item obtained with the altova:create-chart-data-series function or altova:create-chart-data-series-from-rows function

The function returns a chart-layer extension item, which contains chart-layer data.

altova:create-multi-layer-chart(\$chart-config, \$chart-data-series*, \$chart-layer*)

where

- \$chart-config is the chart-config extension item obtained with the altova:create-chart-config function or or via the altova:create-chart-config-from-xml function
- \$chart-data-series is the chart-data-series extension item obtained with the altova:create-chart-data-series function or altova:create-chart-data-series-from-rows function
- \$chart-layer is the chart-layer extension item obtained with the altova:create-chart-layer function

The function returns a multi-layer-chart item.

```
altova:create-multi-layer-chart($chart-config, $chart-data-series*, $chart-layer*,
xs:boolean $mergecategoryvalues)
```

where

- \$chart-config is the chart-config extension item obtained with the altova:create-chart-config function or or via the altova:create-chart-config-from-xml function
- \$chart-data-series is the chart-data-series extension item obtained with the altova:createchart-data-series function or altova: create-chart-data-series-from-rows function
- \$chart-layer is the chart-layer extension item obtained with the altova:create-chart-layer function
- \$mergecategoryvalues merges the values of multiple data series if true, does not merge if false

The function returns a multi-layer-chart item.

19.2.1.10.1 Chart Data XML Structure

Given below is the XML structure of chart data, how it might appear for the Altova extension functions for charts (25). This affects the appearance of the specific chart. Not all elements are used for all chart kinds, e.g. the <Pie> element is ignored for bar charts.

Note: Chart functions are supported only in the Enterprise and Server Editions of Altova products.

```
<chart-config>
       <General
       SettingsVersion="1" must be provided
       ChartKind="BarChart" Pie, Pie3d, BarChart, StackedBarChart, BarChart3d, BarChart3dGrouped,

19.2.1.10.2 Example: Chart Functions

The example XSLT document below shows how <u>Altova extension functions for charts</u> can be used. Given further below are an XML document and a screenshot of the output image generated when the XML document is processed with the XSLT document using the XSLT 2.0 or 3.0 Engine.

Note: Chart functions are supported only in the Enterprise and Server Editions of Altova products.

Note: For more information about how chart data tables are created, see the documentation of Altova's XMLSpy and StyleVision products.

XSLT document

This XSLT document (*listing below*) uses Altova chart extension functions to generate a pie chart. It can be used to process the XML document listed further below.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"</pre>
```

```
xmlns:altovaext="http://www.altova.com/xslt-extensions"
   exclude-result-prefixes="#all">
   <xsl:output version="4.0" method="html" indent="yes" encoding="UTF-8"/>
   <xsl:template match="/">
      <html>
          <head>
              <title>
                 <xsl:text>HTML Page with Embedded Chart</xsl:text>
              </title>
          </head>
          <body>
              <xsl:for-each select="/Data/Region[1]">
                 <xsl:variable name="extChartConfig" as="item() *">
                     <xsl:variable name="ext-chart-settings" as="item() *">
                        <chart-config>
                            <General
                               SettingsVersion="1"
                               ChartKind="Pie3d"
                               BKColor="#ffffff"
                               ShowBorder="1"
                               PlotBorderColor="#000000"
                               PlotBKColor="#ffffff"
                               Title="{@id}"
                               ShowLegend="1"
                               OutsideMargin="3.2%"
                               TitleToPlotMargin="3.%"
                               LegendToPlotMargin="6.%"
                               <TitleFont
                                   Color="#023d7d"
                                   Name="Tahoma"
                                   Bold="1"
                                   Italic="0"
                                   Underline="0"
                                   MinFontHeight="10.pt"
                                   Size="8.%" />
                            </General>
                        </chart-config>
                     </xsl:variable>
                     <xsl:sequence select="altovaext:create-chart-config-from-xml( $ext-</pre>
chart-settings )"/>
                 </xsl:variable>
                 <xsl:variable name="chartDataSeries" as="item() *">
                     <xsl:variable name="chartDataRows" as="item() *">
                        <xsl:for-each select="(Year)">
                            <xsl:sequence select="altovaext:create-chart-data-row( (@id),</pre>
( .) )"/>
                        </xsl:for-each>
                     </xsl:variable>
                     <xsl:variable name="chartDataSeriesNames" as="xs:string*"</pre>
select=" ( (" Series 1"), ' ' ) [1]"/>
                     <xsl:sequence</pre>
```

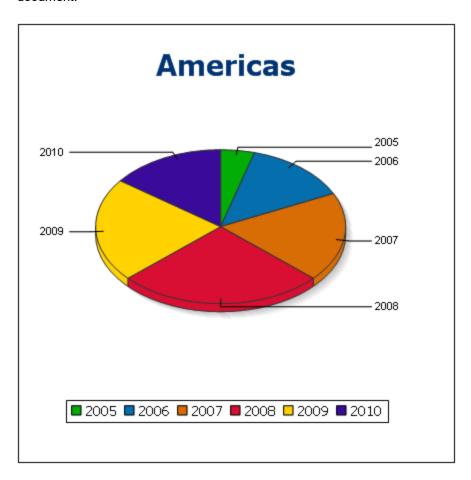

XML document

This XML document can be processed with the XSLT document above. Data in the XML document is used to generate the pie chart shown in the screenshot below.

```
<?xml version="1.0" encoding="UTF-8"?>
<Data xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"</pre>
     xsi:noNamespaceSchemaLocation="YearlySales.xsd">
   <ChartType>Pie Chart 2D</ChartType>
   <Region id="Americas">
      <Year id="2005">30000</year>
      <Year id="2006">90000</year>
      <Year id="2007">120000</year>
      <Year id="2008">180000</year>
      <Year id="2009">140000
      <Year id="2010">100000
   </Region>
   <Region id="Europe">
      <Year id="2005">50000</Year>
      <Year id="2006">60000</year>
      <Year id="2007">80000</year>
      <Year id="2008">100000</year>
      <Year id="2009">95000</year>
      <Year id="2010">80000</year>
   </Region>
   <Region id="Asia">
      <Year id="2005">10000</year>
      <Year id="2006">25000</year>
      <Year id="2007">70000</year>
      <Year id="2008">110000</year>
      <Year id="2009">125000</year>
      <Year id="2010">150000
   </Region>
</Data>
```

Output image

The pie chart show below is generated when the XML document listed above is processed with the XSLT document.

19.2.1.11 Barcode Functions

The XSLT Engine uses third-party Java libraries to create barcodes. Given below are the classes and the public methods used. The classes are packaged in AltovaBarcodeExtension.jar, which is located in the folder <ProgramFilesFolder>\Altova\Common2025\jar.

The Java libraries used are in sub-folders of the folder ProgramFilesFolder>\Altova\Common2025\jar:

- barcode4j\barcode4j.jar (Website: http://barcode4j.sourceforge.net/)
- zxing\core.jar (Website: http://code.google.com/p/zxing/)

The license files are also located in the respective folders.

Java virtual machine

In order to be able to use the barcode functions, a Java virtual machine must be available on your machine and it must match the bit version of the Altova application (32-bit or 64-bit). The path to the machine is found as noted below.

- If you are using an Altova desktop product, the Altova application attempts to detect the path to the Java virtual machine automatically, by reading (in this order): (i) the Windows registry, and (ii) the JAVA_HOME environment variable. You can also add a custom path in the Options dialog of the application; this entry will take priority over any other Java VM path detected automatically.
- If you are running an Altova server product on a Windows machine, the path to the Java virtual machine will be read first from the Windows registry; if this is not successful the JAVA_HOME environment variable will be used.
- If you are running an Altova server product on a Linux or macOS machine, then make sure that the JAVA_HOME environment variable is properly set and that the Java Virtual Machines library (on Windows, the jvm.dll file) can be located in either the \bin\server or \bin\client directory.

XSLT example to generate barcode

Given below is an XSLT example showing how barcode functions are used in an XSLT stylesheet.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"</pre>
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:fn="http://www.w3.org/2005/xpath-functions"
   xmlns:altova="http://www.altova.com"
   xmlns:altovaext="http://www.altova.com/xslt-extensions"
   xmlns:altovaext-barcode="java:com.altova.extensions.barcode.BarcodeWrapper"
   xmlns:altovaext-barcode-
property="java:com.altova.extensions.barcode.BarcodePropertyWrapper">
   <xsl:output method="html" encoding="UTF-8" indent="yes"/>
   <xsl:template match="/">
      <h+m1>
         <head><title/></head>
         <body>
            <img alt="barcode" src="data:image/png;base64"/>
         </body>
      </html>
      <xsl:result-document</pre>
         href="barcode.png"
         method="text" encoding="base64tobinary" >
         <xsl:variable name="barcodeObject"</pre>
            select="altovaext-barcode:newInstance('Code39',string('some value'),
            96,0, (altovaext-barcode-property:new( 'setModuleWidth', 25.4 div 96 *
2 ) ) "/>
         <xsl:value-of select="xs:base64Binary(xs:hexBinary(string(altovaext-</pre>
barcode:generateBarcodePngAsHexString($barcodeObject)) ))"/>
      </xsl:result-document>
   </xsl:template>
</xsl:stylesheet>
```

XQuery example to generate QR code

Given below is an XQuery example showing how barcode functions can be used to generate a QR code image.

```
declare variable $lines := unparsed-text-
lines('https://info.healthministry.gv.at/data/timeline-cases-provinces.csv', 'utf-8');
declare variable $main := map:merge(tokenize(head($lines), ';')!map{.:position()});
declare variable $data := map:merge(tail($lines)!array{tokenize(., ';')}!map{?($main?Name):
[?($main?Date), xs:integer(?($main?ConfirmedCasesProvinces)) - xs:integer(?($main?
Recovered))]}, map{'duplicates':'combine'});
declare variable $chart img := altovaext:chart(map{'width': 1900, 'height': 600}, map:for-
each($data, function($k, $v){[$k, $v?1!substring-before(., 'T'), $v?2][$k != 'Austria']}));
<img src="data:image/png;base64,{$chart img}"/>
(:$main, $data,:)
```

The com.altova.extensions.barcode package

The package, com.altova.extensions.barcode, is used to generate most of the barcode types.

The following classes are used:

```
public class BarcodeWrapper
  static BarcodeWrapper newInstance (String name, String msg, int dpi, int orientation,
BarcodePropertyWrapper[] arrProperties )
  double getHeightPlusQuiet()
  double getWidthPlusQuiet()
  org.w3c.dom.Document generateBarcodeSVG()
  byte[] generateBarcodePNG()
  String generateBarcodePngAsHexString()
```

public class BarcodePropertyWrapper Used to store the barcode properties that will be dynamically set later

```
BarcodePropertyWrapper( String methodName, String propertyValue )
BarcodePropertyWrapper( String methodName, Integer propertyValue )
BarcodePropertyWrapper( String methodName, Double propertyValue )
BarcodePropertyWrapper(String methodName, Boolean propertyValue)
BarcodePropertyWrapper(String methodName, Character propertyValue)
String getMethodName()
Object getPropertyValue()
```

public class AltovaBarcodeClassResolver Registers the class

com.altova.extensions.barcode.proxy.zxing.QRCodeBean for the qrcode bean, additionally to the classes registered by the org.krysalis.barcode4j.DefaultBarcodeClassResolver.

The com.altova.extensions.barcode.proxy.zxing package

The package, com.altova.extensions.barcode.proxy.zxing, is used to generate the QRCode barcode type.

The following classes are used:

class QRCodeBean

- Extends org.krysalis.barcode4j.impl.AbstractBarcodeBean
- Creates an AbstractBarcodeBean interface for com.google.zxing.qrcode.encoder

```
void generateBarcode(CanvasProvider canvasImp, String msg)
void setQRErrorCorrectionLevel(QRCodeErrorCorrectionLevel level)
BarcodeDimension calcDimensions(String msg)
double getVerticalQuietZone()
double getBarWidth()
```

class QRCodeErrorCorrectionLevel Error correction level for the QRCode

```
static QRCodeErrorCorrectionLevel byName(String name)
"L" = ~7% correction
"M" = ~15% correction
"H" = ~25% correction
"Q" = ~30% correction
```

19.2.2 Miscellaneous Extension Functions

There are several ready-made functions in programming languages such as Java and C# that are not available as XQuery/XPath functions or as XSLT functions. A good example would be the math functions available in Java, such as sin() and cos(). If these functions were available to the designers of XSLT stylesheets and XQuery queries, it would increase the application area of stylesheets and queries and greatly simplify the tasks of stylesheet creators. The XSLT and XQuery engines used in a number of Altova products support the use of extension functions in Java and NET and NET are well as MSXSL scripts for XSLT available extension functions and MSXSL scripts in your XSLT stylesheets. The available extension functions are organized into the following sections:

- Java Extension Functions
 .NET Extension Functions
- MSXSL Scripts for XSLT⁽¹²⁸¹⁾

The two main issues considered in the descriptions are: (i) how functions in the respective libraries are called; and (ii) what rules are followed for converting arguments in a function call to the required input format of the function, and what rules are followed for the return conversion (function result to XSLT/XQuery data object).

Requirements

For extension functions support, a Java Runtime Environment (for access to Java functions) and .NET Framework 2.0 (minimum, for access to .NET functions) must be installed on the machine running the XSLT transformation or XQuery execution, or must be accessible for the transformations.

19 2 2 1 Java Extension Functions

A Java extension function can be used within an XPath or XQuery expression to invoke a Java constructor or call a Java method (static or instance).

A field in a Java class is considered to be a method without any argument. A field can be static or instance. How to access fields is described in the respective sub-sections, static and instance.

This section is organized into the following sub-sections:

- Java: Constructors 1272
- Java: Static Methods and Static Fields 1272
- Java: Instance Methods and Instance Fields 1273
- Datatypes: XPath/XQuery to Java 1274
- Datatypes: Java to XPath/XQuery 1275

Note the following

- If you are using an Altova desktop product, the Altova application attempts to detect the path to the Java virtual machine automatically, by reading (in this order): (i) the Windows registry, and (ii) the JAVA HOME environment variable. You can also add a custom path in the Options dialog of the application; this entry will take priority over any other Java VM path detected automatically.
- If you are running an Altova server product on a Windows machine, the path to the Java virtual machine will be read first from the Windows registry; if this is not successful the JAVA HOME environment variable will be used.
- If you are running an Altova server product on a Linux or macOS machine, then make sure that the JAVA HOME environment variable is properly set and that the Java Virtual Machines library (on Windows, the jvm.dll file) can be located in either the \bin\server or \bin\client directory.

Form of the extension function

The extension function in the XPath/XQuery expression must have the form prefix:fname().

- The prefix: part identifies the extension function as a Java function. It does so by associating the extension function with an in-scope namespace declaration, the URI of which must begin with java: (see below for examples). The namespace declaration should identify a Java class, for example: xmlns:myns="java:java.lang.Math". However, it could also simply be: xmlns:myns="java" (without a colon), with the identification of the Java class being left to the fname() part of the extension function.
- The fname () part identifies the Java method being called, and supplies the arguments for the method (see below for examples). However, if the namespace URI identified by the prefix: part does not identify a Java class (see preceding point), then the Java class should be identified in the fname () part, before the class and separated from the class by a period (see the second XSLT example below).

Note: The class being called must be on the classpath of the machine.

XSLT example

Here are two examples of how a static method can be called. In the first example, the class name (java.lang.Math) is included in the namespace URI and, therefore, must not be in the fname() part. In the second example, the prefix: part supplies the prefix java: while the fname () part identifies the class as well as the method.

```
<xsl:value-of xmlns:jMath="java:java.lang.Math"</pre>
     select="jMath:cos(3.14)" />
<xsl:value-of xmlns:jmath="java"</pre>
     select="jmath:java.lang.Math.cos(3.14)" />
```

The method named in the extension function (cos() in the example above) must match the name of a public static method in the named Java class (java.lang.Math in the example above).

XQuery example

Here is an XQuery example similar to the XSLT example above:

```
<cosine xmlns:jMath="java:java.lang.Math">
   {jMath:cos(3.14)}
</cosine>
```

User-defined Java classes

If you have created your own Java classes, methods in these classes are called differently according to: (i) whether the classes are accessed via a JAR file or a class file, and (ii) whether these files (JAR or class) are located in the current directory (the same directory as the XSLT or XQuery document) or not. How to locate these files is described in the sections <u>User-Defined Class Files</u> and <u>User-Defined Jar Files</u>. Note that paths to class files not in the current directory and to all JAR files must be specified.

Note: If you wish to add a namespace to an XSLT stylesheet being generated from an SPS created in StyleVision, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based. Note that the following namespace declaration xmlns:java="java" is created automatically by default in every SPS created in StyleVision.

19.2.2.1.1 User-Defined Class Files

If access is via a class file, then there are four possibilities:

- The class file is in a package. The XSLT or XQuery file is in the same folder as the Java package. (See example below 2003).)
- The class file is not packaged. The XSLT or XQuery file is in the same folder as the class file. (See example below 200.)
- The class file is in a package. The XSLT or XQuery file is at some random location. (<u>See example below</u>)
- The class file is not packaged. The XSLT or XQuery file is at some random location. (<u>See example below</u> 1270.)

Consider the case where the class file is not packaged and is in the same folder as the XSLT or XQuery document. In this case, since all classes in the folder are found, the file location does not need to be specified. The syntax to identify a class is:

```
java:classname
```

where

java: indicates that a user-defined Java function is being called; (Java classes in the current directory will be loaded by default)

classname is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call.

Class file packaged, XSLT/XQuery file in same folder as Java package

The example below calls the getVehicleType() method of the Car class of the com.altova.extfunc package. The com.altova.extfunc package is in the folder JavaProject. The XSLT file is also in the folder JavaProject.

```
<xsl:stylesheet version="2.0"</pre>
       xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
       xmlns:xs="http://www.w3.org/2001/XMLSchema"
       xmlns:fn="http://www.w3.org/2005/xpath-functions"
       xmlns:car="java:com.altova.extfunc.Car" >
<xsl:output exclude-result-prefixes="fn car xsl fo xs"/>
<xsl:template match="/">
   <xsl:value-of select="car:getVehicleType()"/>
   </a>
</xsl:template>
</xsl:stylesheet>
```

Class file referenced, XSLT/XQuery file in same folder as class file

The example below calls the getVehicleType() method of the Car class. Let us say that: (i) the Car class file is in the following folder: JavaProject/com/altova/extfunc, and (ii) that this folder is the current folder in the example below. The XSLT file is also in the folder JavaProject/com/altova/extfunc.

```
<xsl:stylesheet version="2.0"</pre>
       xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
       xmlns:xs="http://www.w3.org/2001/XMLSchema"
       xmlns:fn="http://www.w3.org/2005/xpath-functions"
       xmlns:car="java:Car" >
<xsl:output exclude-result-prefixes="fn car xsl fo xs"/>
<xsl:template match="/">
   <a>>
   <xsl:value-of select="car:getVehicleType()"/>
   </a>
</xsl:template>
</xsl:stylesheet>
```

Class file packaged, XSLT/XQuery file at any location

The example below calls the getCarColor() method of the Car class of the com.altova.extfunc package. The com.altova.extfunc package is in the folder JavaProject. The XSLT file is at any location. In this case, the location of the package must be specified within the URI as a query string. The syntax is:

```
java:classname[?path=uri-of-package]
 where
```

java: indicates that a user-defined Java function is being called uri-of-package is the URI of the Java package classname is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call. The example below shows how to access a class file that is located in another directory than the current directory.

Class file referenced, XSLT/XQuery file at any location

The example below calls the <code>getCarColor()</code> method of the <code>Car</code> class. Let us say that the <code>Car</code> class file is in the folder <code>C:/JavaProject/com/altova/extfunc</code>, and the XSLT file is at any location. The location of the class file must then be specified within the namespace URI as a query string. The syntax is:

```
java:classname[?path=<uri-of-classfile>]
```

where

java: indicates that a user-defined Java function is being called uri-of-classfile is the URI of the folder containing the class file classname is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call. The example below shows how to access a class file that is located in another directory than the current directory.

```
<a><xsl:value-of select="car:getCarColor($myCar)"/></a>
</xsl:template>
</xsl:stylesheet>
```

Note: When a path is supplied via the extension function, the path is added to the ClassLoader.

19.2.2.1.2 User-Defined Jar Files

If access is via a JAR file, the URI of the JAR file must be specified using the following syntax:

```
xmlns:classNS="java:classname?path=jar:uri-of-jarfile!/"
```

The method is then called by using the prefix of the namespace URI that identifies the class: classNS:method()

In the above:

```
java: indicates that a Java function is being called
classname is the name of the user-defined class
? is the separator between the classname and the path
path=jar: indicates that a path to a JAR file is being given
uri-of-jarfile is the URI of the jar file
!/ is the end delimiter of the path
classNS:method() is the call to the method
```

Alternatively, the classname can be given with the method call. Here are two examples of the syntax:

```
xmlns:ns1="java:docx.layout.pages?path=jar:file:///c:/projects/docs/docx.jar!/"
ns1:main()
xmlns:ns2="java?path=jar:file:///c:/projects/docs/docx.jar!/"
ns2:docx.layout.pages.main()
```

Here is a complete XSLT example that uses a JAR file to call a Java extension function:

```
<xsl:stylesheet version="2.0"</pre>
      xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
      xmlns:xs="http://www.w3.org/2001/XMLSchema"
      xmlns:fn="http://www.w3.org/2005/xpath-functions"
      xmlns:car="java?path=jar:file:///C:/test/Car1.jar!/" >
<xsl:output exclude-result-prefixes="fn car xsl xs"/>
<xsl:template match="/">
      <xsl:variable name="myCar" select="car:Car1.new('red')" />
      <a><xsl:value-of select="car:Car1.getCarColor($myCar)"/></a>
</xsl:template>
<xsl:template match="car"/>
```

```
</xsl:stylesheet>
```

Note: When a path is supplied via the extension function, the path is added to the ClassLoader.

19.2.2.1.3 Java: Constructors

An extension function can be used to call a Java constructor. All constructors are called with the pseudo-function <code>new()</code>.

If the result of a Java constructor call can be <u>implicitly converted to XPath/XQuery datatypes</u> then the Java extension function will return a sequence that is an XPath/XQuery datatype. If the result of a Java constructor call cannot be converted to a suitable XPath/XQuery datatype, then the constructor creates a wrapped Java object with a type that is the name of the class returning that Java object. For example, if a constructor for the class <code>java.util.Date</code> is called (<code>java.util.Date.new()</code>), then an object having a type <code>java.util.Date</code> is returned. The lexical format of the returned object may not match the lexical format of an XPath datatype and the value would therefore need to be converted to the lexical format of the required XPath datatype.

There are two things that can be done with a Java object created by a constructor:

19.2.2.1.4 Java: Static Methods and Static Fields

A static method is called directly by its Java name and by supplying the arguments for the method. Static fields (methods that take no arguments), such as the constant-value fields \mathbb{E} and \mathbb{PI} , are accessed without specifying any argument.

XSLT examples

Here are some examples of how static methods and fields can be called:

Notice that the extension functions above have the form <code>prefix:fname()</code>. The prefix in all three cases is <code>jMath:</code>, which is associated with the namespace URI <code>java:java.lang.Math</code>. (The namespace URI must

begin with java:. In the examples above it is extended to contain the class name (java.lang.Math).) The fname () part of the extension functions must match the name of a public class (e.g. java.lang.Math) followed by the name of a public static method with its argument/s (such as cos (3.14)) or a public static field (such as PI()).

In the examples above, the class name has been included in the namespace URI. If it were not contained in the namespace URI, then it would have to be included in the fname() part of the extension function. For example:

```
<xsl:value-of xmlns:java="java:"</pre>
              select="java:java.lang.Math.cos(3.14)" />
```

XQuery example

A similar example in XQuery would be:

```
<cosine xmlns:jMath="java:java.lang.Math">
   { jMath: cos (3.14) }
</cosine>
```

19.2.2.1.5 Java: Instance Methods and Instance Fields

An instance method has a Java object passed to it as the first argument of the method call. Such a Java object typically would be created by using an extension function (for example a constructor call) or a stylesheet parameter/variable. An XSLT example of this kind would be:

```
<xsl:stylesheet version="1.0" exclude-result-prefixes="date"</pre>
 xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:date="java:java.util.Date"
  xmlns:jlang="java:java.lang">
  <xsl:param name="CurrentDate" select="date:new()"/>
  <xsl:template match="/">
      <enrollment institution-id="Altova School"</pre>
                date="{date:toString($CurrentDate)}"
                type="{jlang:Object.toString(jlang:Object.getClass( date:new() ))}">
      </enrollment>
  </xsl:template>
</xsl:stylesheet>
```

In the example above, the value of the node enrollment/@type is created as follows:

- 1. An object is created with a constructor for the class <code>java.util.Date</code> (with the date:new() constructor).
- 2. This Java object is passed as the argument of the <code>jlang.Object.getClass</code> method.
- 3. The object obtained by the getClass method is passed as the argument to the jlang.Object.toString method.

The result (the value of @type) will be a string having the value: java.util.Date.

An instance field is theoretically different from an instance method in that it is not a Java object per se that is passed as an argument to the instance field. Instead, a parameter or variable is passed as the argument. However, the parameter/variable may itself contain the value returned by a Java object. For example, the

parameter CurrentDate takes the value returned by a constructor for the class <code>java.util.Date</code>. This value is then passed as an argument to the instance method <code>date:toString</code> in order to supply the value of <code>/enrollment/@date</code>.

19.2.2.1.6 Datatypes: XPath/XQuery to Java

When a Java function is called from within an XPath/XQuery expression, the datatype of the function's arguments is important in determining which of multiple Java classes having the same name is called.

In Java, the following rules are followed:

- If there is more than one Java method with the same name, but each has a different number of arguments than the other/s, then the Java method that best matches the number of arguments in the function call is selected.
- The XPath/XQuery string, number, and boolean datatypes (see list below) are implicitly converted to a corresponding Java datatype. If the supplied XPath/XQuery type can be converted to more than one Java type (for example, xs:integer), then that Java type is selected which is declared for the selected method. For example, if the Java method being called is fx(decimal) and the supplied XPath/XQuery datatype is xs:integer, then xs:integer will be converted to Java's decimal datatype.

The table below lists the implicit conversions of XPath/XQuery string, number, and boolean types to Java datatypes.

xs:string	java.lang.String
xs:boolean	boolean (primitive), java.lang.Boolean
xs:integer	int, long, short, byte, float, double, and the wrapper classes of these, such as java.lang.Integer
xs:float	float (primitive), java.lang.Float, double (primitive)
xs:double	double (primitive), java.lang.Double
xs:decimal	float (primitive), java.lang.Float, double(primitive), java.lang.Double

Subtypes of the XML Schema datatypes listed above (and which are used in XPath and XQuery) will also be converted to the Java type/s corresponding to that subtype's ancestor type.

In some cases, it might not be possible to select the correct Java method based on the supplied information. For example, consider the following case.

- The supplied argument is an xs:untypedAtomic value of 10 and it is intended for the method mymethod(float).
- However, there is another method in the class which takes an argument of another datatype: mymethod(double).

- Since the method names are the same and the supplied type (xs:untypedAtomic) could be converted correctly to either float or double, it is possible that xs:untypedAtomic is converted to double instead of float.
- Consequently the method selected will not be the required method and might not produce the expected result. To work around this, you can create a user-defined method with a different name and use this method.

Types that are not covered in the list above (for example xs:date) will not be converted and will generate an error. However, note that in some cases, it might be possible to create the required Java type by using a Java constructor.

19.2.2.1.7 Datatypes: Java to XPath/XQuery

When a Java method returns a value, the datatype of the value is a string, numeric or boolean type, then it is converted to the corresponding XPath/XQuery type. For example, Java's java.lang.Boolean and boolean datatypes are converted to xsd:boolean.

One-dimensional arrays returned by functions are expanded to a sequence. Multi-dimensional arrays will not be converted, and should therefore be wrapped.

When a wrapped Java object or a datatype other than string, numeric or boolean is returned, you can ensure conversion to the required XPath/XQuery type by first using a Java method (e.g toString) to convert the Java object to a string. In XPath/XQuery, the string can be modified to fit the lexical representation of the required type and then converted to the required type (for example, by using the cast as expression).

19.2.2.2 .NET Extension Functions

If you are working on the .NET platform on a Windows machine, you can use extension functions written in any of the .NET languages (for example, C#), A .NET extension function can be used within an XPath or XQuery expression to invoke a constructor, property, or method (static or instance) within a .NET class.

A property of a .NET class is called using the syntax get PropertyName().

This section is organized into the following sub-sections:

- .NET: Constructors 1277
- .NET: Static Methods and Static Fields 1278
- .NET: Instance Methods and Instance Fields 1279
- Datatypes: XPath/XQuery to .NET [280]
- Datatypes: .NET to XPath/XQuery [28]

Form of the extension function

The extension function in the XPath/XQuery expression must have the form prefix:fname().

- The prefix: part is associated with a URI that identifies the .NET class being addressed.
- The fname () part identifies the constructor, property, or method (static or instance) within the .NET class, and supplies any argument/s, if required.

- - The URI must begin with clitype: (which identifies the function as being a .NET extension function).
 - The prefix:fname() form of the extension function can be used with system classes and with classes in a loaded assembly. However, if a class needs to be loaded, additional parameters containing the required information will have to be supplied.

Parameters

100

To load an assembly, the following parameters are used:

asm	The name of the assembly to be loaded.
ver	The version number (maximum of four integers separated by periods).
sn	The key token of the assembly's strong name (16 hex digits).
from	A URI that gives the location of the assembly (DLL) to be loaded. If the URI is relative, it is relative to the XSLT or XQuery document. If this parameter is present, any other parameter is ignored.
partialname	The partial name of the assembly. It is supplied to Assembly. LoadWith.PartialName(), which will attempt to load the assembly. If partialname is present, any other parameter is ignored.

The locale, for example, en-US. The default is neutral.

If the assembly is to be loaded from a DLL, use the from parameter and omit the sn parameter. If the assembly is to be loaded from the Global Assembly Cache (GAC), use the sn parameter and omit the from parameter.

A question mark must be inserted before the first parameter, and parameters must be separated by a semicolon. The parameter name gives its value with an equals sign (see example below).

Examples of namespace declarations

An example of a namespace declaration in XSLT that identifies the system class System. Environment:

```
xmlns:myns="clitype:System.Environment"
```

An example of a namespace declaration in XSLT that identifies the class to be loaded as Trade.Forward.Scrip:

```
xmlns:myns="clitype:Trade.Forward.Scrip?asm=forward;version=10.6.2.1"
```

An example of a namespace declaration in XQuery that identifies the system class MyManagedDLL.testClass:. Two cases are distinguished:

1. When the assembly is loaded from the GAC:

```
declare namespace cs="clitype:MyManagedDLL.testClass?asm=MyManagedDLL;
ver=1.2.3.4;loc=neutral;sn=b9f091b72dccfba8";
```

2. When the assembly is loaded from the DLL (complete and partial references below):

```
declare namespace cs="clitype:MyManagedDLL.testClass?from=file:///C:/Altova
Projects/extFunctions/MyManagedDLL.dll;
```

declare namespace cs="clitype:MyManagedDLL.testClass?from=MyManagedDLL.dll;

XSLT example

Here is a complete XSLT example that calls functions in system class System. Math:

```
<xsl:stylesheet version="2.0"</pre>
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:fn="http://www.w3.org/2005/xpath-functions">
  <xsl:output method="xml" omit-xml-declaration="yes" />
  <xsl:template match="/">
     <math xmlns:math="clitype:System.Math">
        <sgrt><xsl:value-of select="math:Sgrt(9)"/></sgrt>
        <pi><xsl:value-of select="math:PI()"/></pi>
        <e><xsl:value-of select="math:E()"/></e>
         <pow><xsl:value-of select="math:Pow(math:PI(), math:E())"/></pow>
     </xsl:template>
</xsl:stylesheet>
```

The namespace declaration on the element math associates the prefix math: with the URI clitype: System. Math. The clitype: beginning of the URI indicates that what follows identifies either a system class or a loaded class. The math: prefix in the XPath expressions associates the extension functions with the URI (and, by extension, the class) System. Math. The extension functions identify methods in the class System. Math and supply arguments where required.

XQuery example

Here is an XQuery example fragment similar to the XSLT example above:

```
<math xmlns:math="clitype:System.Math">
  {math:Sqrt(9)}
```

As with the XSLT example above, the namespace declaration identifies the .NET class, in this case a system class. The XQuery expression identifies the method to be called and supplies the argument.

19.2.2.2.1 .NET: Constructors

An extension function can be used to call a .NET constructor. All constructors are called with the pseudofunction new(). If there is more than one constructor for a class, then the constructor that most closely matches the number of arguments supplied is selected. If no constructor is deemed to match the supplied argument/s, then a 'No constructor found' error is returned.

Constructors that return XPath/XQuery datatypes

If the result of a .NET constructor call can be implicitly converted to XPath/XQuery datatypes (276), then the .NET extension function will return a sequence that is an XPath/XQuery datatype.

Constructors that return .NET objects

If the result of a .NET constructor call cannot be converted to a suitable XPath/XQuery datatype, then the constructor creates a wrapped .NET object with a type that is the name of the class returning that object. For example, if a constructor for the class <code>System.DateTime</code> is called (with <code>System.DateTime.new()</code>), then an object having a type <code>System.DateTime</code> is returned.

The lexical format of the returned object may not match the lexical format of a required XPath datatype. In such cases, the returned value would need to be: (i) converted to the lexical format of the required XPath datatype; and (ii) cast to the required XPath datatype.

There are three things that can be done with a .NET object created by a constructor:

It can be used within a variable:

```
<xsl:variable name="currentdate" select="date:new(2008, 4, 29)"
xmlns:date="clitype:System.DateTime" />
```

- It can be passed to an extension function (see <u>Instance Method and Instance Fields</u> (2008): <xsl:value-of select="date:ToString(date:new(2008, 4, 29))" xmlns:date="clitype:System.DateTime" />
- It can be converted to a string, number, or boolean:
- <xsl:value-of select="xs:integer(date:get_Month(date:new(2008, 4, 29)))"

 xmlns:date="clitype:System.DateTime" />

19.2.2.2.2 NET: Static Methods and Static Fields

A static method is called directly by its name and by supplying the arguments for the method. The name used in the call must exactly match a public static method in the class specified. If the method name and the number of arguments that were given in the function call matches more than one method in a class, then the types of the supplied arguments are evaluated for the best match. If a match cannot be found unambiguously, an error is reported.

Note: A field in a .NET class is considered to be a method without any argument. A property is called using the syntax get PropertyName().

Examples

```
An XSLT example showing a call to a method with one argument (System.Math.Sin(arg)): <xsl:value-of select="math:Sin(30)" xmlns:math="clitype:System.Math"/>
```

```
An XSLT example showing a call to a field (considered a method with no argument)
```

```
(System.Double.MaxValue()):
<xsl:value-of select="double:MaxValue()" xmlns:double="clitype:System.Double"/>
```

```
An XSLT example showing a call to a property (syntax is get_PropertyName()) (System.String()): <xsl:value-of select="string:get_Length('my string')" xmlns:string="clitype:System.String"/>
```

An XQuery example showing a call to a method with one argument (System.Math.Sin(arg)):

```
<sin xmlns:math="clitype:System.Math">
   { math:Sin(30) }
</sin>
```

19.2.2.2.3 .NET: Instance Methods and Instance Fields

An instance method has a .NET object passed to it as the first argument of the method call. This .NET object typically would be created by using an extension function (for example a constructor call) or a stylesheet parameter/variable. An XSLT example of this kind would be:

```
<xsl:stylesheet version="2.0"</pre>
   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:fn="http://www.w3.org/2005/xpath-functions">
   <xsl:output method="xml" omit-xml-declaration="yes"/>
   <xsl:template match="/">
      <xsl:variable name="releasedate"</pre>
         select="date:new(2008, 4, 29)"
         xmlns:date="clitype:System.DateTime"/>
      <doc>
         <date>
            <xsl:value-of select="date:ToString(date:new(2008, 4, 29))"</pre>
               xmlns:date="clitype:System.DateTime"/>
         </date>
         <date>
            <xsl:value-of select="date:ToString($releasedate)"</pre>
               xmlns:date="clitype:System.DateTime"/>
         </date>
      </doc>
   </xsl:template>
</xsl:stylesheet>
```

In the example above, a System.DateTime constructor (new (2008, 4, 29)) is used to create a .NET object of type System.DateTime. This object is created twice, once as the value of the variable releasedate, a second time as the first and only argument of the System, DateTime, ToString() method. The instance method System.DateTime.ToString() is called twice, both times with the System.DateTime constructor (new (2008, 4, 29)) as its first and only argument. In one of these instances, the variable releasedate is used to get the .NET object.

Instance methods and instance fields

The difference between an instance method and an instance field is theoretical. In an instance method, a .NET object is directly passed as an argument; in an instance field, a parameter or variable is passed instead though the parameter or variable may itself contain a .NET object. For example, in the example above, the variable releasedate contains a .NET object, and it is this variable that is passed as the argument of ToString() in the second date element constructor. Therefore, the ToString() instance in the first date element is an instance method while the second is considered to be an instance field. The result produced in both instances, however, is the same.

19.2.2.2.4 Datatypes: XPath/XQuery to .NET

When a .NET extension function is used within an XPath/XQuery expression, the datatypes of the function's arguments are important for determining which one of multiple .NET methods having the same name is called.

In .NET, the following rules are followed:

- If there is more than one method with the same name in a class, then the methods available for selection are reduced to those that have the same number of arguments as the function call.
- The XPath/XQuery string, number, and boolean datatypes (see list below) are implicitly converted to a corresponding .NET datatype. If the supplied XPath/XQuery type can be converted to more than one .NET type (for example, xs:integer), then that .NET type is selected which is declared for the selected method. For example, if the .NET method being called is fx(double) and the supplied XPath/XQuery datatype is xs:integer, then xs:integer will be converted to .NETs double datatype.

The table below lists the implicit conversions of XPath/XQuery string, number, and boolean types to .NET datatypes.

xs:string	StringValue, string	
xs:boolean	BooleanValue, bool	
xs:integer	IntegerValue, decimal, long, integer, short, byte, double, float	
xs:float	FloatValue, float, double	
xs:double	DoubleValue, double	
xs:decimal	DecimalValue, decimal, double, float	

Subtypes of the XML Schema datatypes listed above (and which are used in XPath and XQuery) will also be converted to the .NET type/s corresponding to that subtype's ancestor type.

In some cases, it might not be possible to select the correct .NET method based on the supplied information. For example, consider the following case.

- The supplied argument is an xs:untypedAtomic value of 10 and it is intended for the method mymethod(float).
- However, there is another method in the class which takes an argument of another datatype: mymethod(double).
- Since the method names are the same and the supplied type (xs:untypedAtomic) could be converted correctly to either float or double, it is possible that xs:untypedAtomic is converted to double instead of float.
- Consequently the method selected will not be the required method and might not produce the expected result. To work around this, you can create a user-defined method with a different name and use this method.

Types that are not covered in the list above (for example xs:date) will not be converted and will generate an error.

19.2.2.2.5 Datatypes: .NET to XPath/XQuery

When a .NET method returns a value and the datatype of the value is a string, numeric or boolean type, then it is converted to the corresponding XPath/XQuery type. For example, .NETs decimal datatype is converted to xsd:decimal.

When a .NET object or a datatype other than string, numeric or boolean is returned, you can ensure conversion to the required XPath/XQuery type by first using a .NET method (for example System. DateTime. ToString()) to convert the .NET object to a string. In XPath/XQuery, the string can be modified to fit the lexical representation of the required type and then converted to the required type (for example, by using the cast as expression).

19.2.2.3 MSXSL Scripts for XSLT

The <msxsl:script> element contains user-defined functions and variables that can be called from within XPath expressions in the XSLT stylesheet. The <msxsl:script> is a top-level element, that is, it must be a child element of <xsl:stylesheet> or <xsl:transform>.

The <msxsl:script> element must be in the namespace urn:schemas-microsoft-com:xslt (see example below).

Scripting language and namespace

The scripting language used within the block is specified in the <msxsl:script> element's language attribute and the namespace to be used for function calls from XPath expressions is identified with the implementsprefix attribute (see below).

```
<msxsl:script language="scripting-language" implements-prefix="user-namespace-prefix">
   function-1 or variable-1
   function-n or variable-n
</msxsl:script>
```

The <msxsl:script> element interacts with the Windows Scripting Runtime, so only languages that are installed on your machine may be used within the <msxsl:script> element. The .NET Framework 2.0 platform or higher must be installed for MSXSL scripts to be used. Consequently, the .NET scripting languages can be used within the <msxsl:script> element.

The language attribute accepts the same values as the language attribute on the HTML <script> element. If the language attribute is not specified, then Microsoft JScript is assumed as the default.

The implements-prefix attribute takes a value that is a prefix of a declared in-scope namespace. This namespace typically will be a user namespace that has been reserved for a function library. All functions and variables defined within the <msxsl:script> element will be in the namespace identified by the prefix specified in the implements-prefix attribute. When a function is called from within an XPath expression, the fully qualified function name must be in the same namespace as the function definition.

Example

Here is an example of a complete XSLT stylesheet that uses a function defined within a <msxsl:script> element.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"</pre>
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:fn="http://www.w3.org/2005/xpath-functions"
  xmlns:msxsl="urn:schemas-microsoft-com:xslt"
  xmlns:user="http://mycompany.com/mynamespace">
  <msxsl:script language="VBScript" implements-prefix="user">
    <! [CDATA[
    ' Input: A currency value: the wholesale price
    ' Returns: The retail price: the input value plus 20% margin,
    ' rounded to the nearest cent
    dim a as integer = 13
    Function AddMargin(WholesalePrice) as integer
      AddMargin = WholesalePrice * 1.2 + a
    End Function
  11>
  </msxsl:script>
  <xsl:template match="/">
    <html>
      <body>
        <q>
          <br/>b>Total Retail Price =
            $<xsl:value-of select="user:AddMargin(50)"/>
          </b>
          <br/>br/>
          <br/>b>Total Wholesale Price =
            $<xsl:value-of select="50"/>
          </b>
        </p>
      </body>
    </html>
  </xsl:template>
</xsl:stylesheet>
```

Datatypes

The values of parameters passed into and out of the script block are limited to XPath datatypes. This restriction does not apply to data passed among functions and variables within the script block.

Assemblies

An assembly can be imported into the script by using the msxsl:assembly element. The assembly is identified via a name or a URI. The assembly is imported when the stylesheet is compiled. Here is a simple representation of how the msxsl:assembly element is to be used.

```
<msxsl:script>
  <msxsl:assembly name="myAssembly.assemblyName" />
  <msxsl:assembly href="pathToAssembly" />
  . . .
</msxsl:script>
```

The assembly name can be a full name, such as:

```
"system.Math, Version=3.1.4500.1 Culture=neutral PublicKeyToken=a46b3f648229c514"
or a short name, such as "myAssembly.Draw".
```

Namespaces

Namespaces can be declared with the msxsl:using element. This enables assembly classes to be written in the script without their namespaces, thus saving you some tedious typing. Here is how the msxsl:using element is used so as to declare namespaces.

```
<msxsl:script>
  <msxsl:using namespace="myAssemblyNS.NamespaceName" />
  . . .
</msxsl:script>
```

The value of the namespace attribute is the name of the namespace.

19.3 Datatypes in DB-Generated XML Schemas

When an XML Schema is generated from a database (DB), the datatypes specific to that DB are converted to XML Schema datatypes. The mappings of DB datatypes to XML Schema datatypes for commonly used DBs are given in this Appendix. Select from the list below.

- ADO 1284
- MS Access 1285
- MS SQL Server 1286
- MySQL 1286
- ODBC 1287
- Oracle 1288
- Sybase 1289

19.3.1 ADO

When an XML Schema is generated from an ADO database (DB), the ADO DB datatypes are converted to XML Schema datatypes as listed in the table below.

ADO Datatype	XML Schema Datatype
adGUID	xs:ID
adChar	xs:string
adWChar	xs:string
adVarChar	xs:string
adWVarChar	xs:string
adLongVarChar	xs:string
adWLongVarChar	xs:string
adVarWChar	xs:string
adBoolean	xs:boolean
adSingle	xs:float
adDouble	xs:double
adNumeric	xs:decimal
adCurrency	xs:decimal
adDBTimeStamp	xs:dateTime
adDate	xs:date
adBinary	xs:base64Binary
adVarBinary	xs:base64Binary

adLongVarBinary	xs:base64Binary
adInteger	xs:Integer
adUnsignedInt	xs:unsignedInt
adSmallInt	xs:short
adUnsignedSmallInt	xs:unsignedShort
adBigInt	xs:long
adUnsignedBigInt	xs:unsignedLong
adTinyInt	xs:byte
adUnsignedTinyInt	xs:unsignedByte

19.3.2 **MS Access**

When an XML Schema is generated from an MS Access database (DB), the MS Access DB datatypes are converted to XML Schema datatypes as listed in the table below.

MS Access Datatype	XML Schema Datatype
GUID	xs:ID
char	xs:string
varchar	xs:string
memo	xs:string
bit	xs:boolean
Number(single)	xs:float
Number(double)	xs:double
Decimal	xs:decimal
Currency	xs:decimal
Date/Time	xs:dateTime
Number(Long Integer)	xs:integer
Number(Integer)	xs:short
Number(Byte)	xs:byte
OLE Object	xs:base64Binary

19.3.3 MS SQL Server

When an XML Schema is generated from an MS SQL Server database (DB), the MS SQL Server DB datatypes are converted to XML Schema datatypes as listed in the table below.

MS SQL Server Datatype	XML Schema Datatype
uniqueidentifier	xs:ID
char	xs:string
nchar	xs:string
varchar	xs:string
nvarchar	xs:string
text	xs:string
ntext	xs:string
sysname	xs:string
bit	xs:boolean
real	xs:float
float	xs:double
decimal	xs:decimal
money	xs:decimal
smallmoney	xs:decimal
datetime	xs:dateTime
smalldatetime	xs:dateTime
binary	xs:base64Binary
varbinary	xs:base64Binary
image	xs:base64Binary
integer	xs:integer
smallint	xs:short
bigint	xs:long
tinyint	xs:byte

19.3.4 MySQL

When an XML Schema is generated from a MySQL database (DB), the MySQL DB datatypes are converted to XML Schema datatypes as listed in the table below.

MySQL Datatype	XML Schema Datatype
char	xs:string
varchar	xs:string
text	xs:string
tinytext	xs:string
mediumtext	xs:string
longtext	xs:string
tinyint(1)	xs:boolean
float	xs:float
double	xs:double
decimal	xs:decimal
datetime	xs:dateTime
blob	xs:base64Binary
tinyblob	xs:base64Binary
mediumblob	xs:base64Binary
longblob	xs:base64Binary
smallint	xs:short
bigint	xs:long
tinyint	xs:byte

19.3.5 **ODBC**

When an XML Schema is generated from an ODBC database (DB), the ODBC DB datatypes are converted to XML Schema datatypes as listed in the table below.

ODBC Datatype	XML Schema Datatype
SQL_GUID	xs:ID
SQL_CHAR	xs:string
SQL_VARCHAR	xs:string
SQL_LONGVARCHAR	xs:string
SQL_BIT	xs:boolean
SQL_REAL	xs:float

SQL_DOUBLE	xs:double
SQL_DECIMAL	xs:decimal
SQL_TIMESTAMP	xs:dateTime
SQL_DATE	xs:date
SQL_BINARY	xs:base64Binary
SQL_VARBINARY	xs:base64Binary
SQL_LONGVARBINARY	xs:base64Binary
SQL_INTEGER	xs:integer
SQL_SMALLINT	xs:short
SQL_BIGINT	xs:long
SQL_TINYINT	xs:byte

19.3.6 **Oracle**

When an XML Schema is generated from an Oracle database (DB), the Oracle DB datatypes are converted to XML Schema datatypes as listed in the table below.

Oracle Datatype	XML Schema Datatype
ROWID	xs:ID
CHAR	xs:string
NCHAR	xs:string
VARCHAR2	xs:string
NVARCHAR2	xs:string
CLOB	xs:string
NCLOB	xs:string
NUMBER (with check constraint applied)*	xs:boolean
NUMBER	xs:decimal
FLOAT	xs:double
DATE	xs:dateTime
INTERVAL YEAR TO MONTH	xs:gYearMonth
BLOB	xs:base64Binary

* If a check constraint is applied to a column of datatype NUMBER, and the check constraint checks for the

values 0 or 1, then the NUMBER datatype for this column will be converted to an XML Schema datatype of xs:boolean. This mechanism is useful for generating an xs:boolean datatype in the generated XML Schema.

19.3.7 **Sybase**

When an XML Schema is generated from a Sybase database (DB), the Sybase DB datatypes are converted to XML Schema datatypes as listed in the table below.

Subsec Detature	VMI Cohomo Detetimo
Sybase Datatype	XML Schema Datatype
char	xs:string
nchar	xs:string
varchar	xs:string
nvarchar	xs:string
text	xs:string
sysname-varchar(30)	xs:string
bit	xs:boolean
real	xs:float
float	xs:float
double	xs:double
decimal	xs:decimal
money	xs:decimal
smallmoney	xs:decimal
datetime	xs:dateTime
smalldatetime	xs:dateTime
timestamp	xs:dateTime
binary<=255	xs:base64Binary
varbinary<=255	xs:base64Binary
image	xs:base64Binary
integer	xs:integer
smallint	xs:short
tinyint	xs:byte

1290 Appendices Technical Data

19.4 Technical Data

This section contains information on some technical aspects of your software. This information is organized into the following sections:

- OS and Memory Requirements 1290
- Altova Engines 1290
- Unicode Support 1291
- Internet Usage 1291

19.4.1 OS and Memory Requirements

Operating System

Altova software applications are available for the following platforms:

- Windows 10, Windows 11
- Windows Server 2016 or newer

Memory

Since the software is written in C++ it does not require the overhead of a Java Runtime Environment and typically requires less memory than comparable Java-based applications. However, each document is loaded fully into memory so as to parse it completely and to improve viewing and editing speed. As a result, the memory requirement increases with the size of the document.

Memory requirements are also influenced by the unlimited Undo history. When repeatedly cutting and pasting large selections in large documents, available memory can rapidly be depleted.

19.4.2 Altova Engines

XML Validator

When opening an XML document, the application uses its built-in XML validator to check for well-formedness, to validate the document against a schema (if specified), and to build trees and infosets. The XML validator is also used to provide intelligent editing help while you edit documents and to dynamically display any validation error that may occur.

The built-in XML validator implements the Final Recommendation of the W3C's XML Schema 1.0 and 1.1 specifications. New developments recommended by the W3C's XML Schema Working Group are continuously being incorporated in the XML validator, so that Altova products give you a state-of-the-art development environment.

XSLT and XQuery Engines

Altova products use the Altova XSLT 1.0, 2.0, and 3.0 Engines and the Altova XQuery 1.0 and 3.1 Engines. If one of these engines is included in the product, then documentation about implementation-specific behavior for each engine is given in the appendices of the documentation.

Appendices Technical Data 1291

Note: Altova MapForce generates code using the XSLT 1.0, 2.0 and XQuery 1.0 engines.

19.4.3 Unicode Support

Altova's XML products provide full Unicode support. To edit an XML document, you will also need a font that supports the Unicode characters being used by that document.

Please note that most fonts only contain a very specific subset of the entire Unicode range and are therefore typically targeted at the corresponding writing system. If some text appears garbled, the reason could be that the font you have selected does not contain the required glyphs. So it is useful to have a font that covers the entire Unicode range, especially when editing XML documents in different languages or writing systems. A typical Unicode font found on Windows PCs is Arial Unicode MS.

In the /Examples folder of your application folder you will find an XHTML file called UnicodeUTF-8.html that contains the following sentence in a number of different languages and writing systems:

- When the world wants to talk, it speaks Unicode
- Wenn die Welt miteinander spricht, spricht sie Unicode
- 世界的に話すなら、Unicode です。

Opening this XHTML file will give you a quick impression of Unicode's possibilities and also indicate what writing systems are supported by the fonts available on your PC.

19.4.4 Internet Usage

Altova applications will initiate Internet connections on your behalf in the following situations:

- If you click the "Request evaluation key-code" in the Registration dialog (**Help | Software Activation**), the three fields in the registration dialog box are transferred to our web server by means of a regular http (port 80) connection and the free evaluation key-code is sent back to the customer via regular SMTP e-mail.
- In some Altova products, you can open a file over the Internet (File | Open | Switch to URL). In this case, the document is retrieved using one of the following protocol methods and connections: HTTP (normally port 80), FTP (normally port 20/21), HTTPS (normally port 443). You could also run an HTTP server on port 8080. (In the URL dialog, specify the port after the server name and a colon.)
- If you open an XML document that refers to an XML Schema or DTD and the document is specified through a URL, the referenced schema document is also retrieved through a HTTP connection (port 80) or another protocol specified in the URL (see Point 2 above). A schema document will also be retrieved when an XML file is validated. Note that validation might happen automatically upon opening a document if you have instructed the application to do this (in the File tab of the Options dialog (Tools | Options)).
- In Altova applications using WSDL and SOAP, web service connections are defined by the WSDL documents.
- If you are using the **Send by Mail** command (**File | Send by Mail**) in XMLSpy, the current selection or file is sent by means of any MAPI-compliant mail program installed on the user's PC.
- As part of Software Activation and LiveUpdate as further described in the Altova Software License Agreement.

1292 Appendices License Information

19.5 License Information

This section contains information about:

- the distribution of this software product
- software activation and license metering
- the license agreement governing the use of this product

Please read this information carefully. It is binding upon you since you agreed to these terms when you installed this software product.

To view the terms of any Altova license, go to the Altova Legal Information page at the Altova website.

19.5.1 Electronic Software Distribution

This product is available through electronic software distribution, a distribution method that provides the following unique benefits:

- You can evaluate the software free-of-charge for 30 days before making a purchasing decision. (Note: Altova MobileTogether Designer is licensed free of charge.)
- Once you decide to buy the software, you can place your order online at the <u>Altova website</u> and get a
 fully licensed product within minutes.
- When you place an online order, you always get the latest version of our software.
- The product package includes an onscreen help system that can be accessed from within the
 application interface. The latest version of the user manual is available at www.altova.com in (i) HTML
 format for online browsing, and (ii) PDF format for download (and to print if you prefer to have the
 documentation on paper).

30-day evaluation period

After downloading this product, you can evaluate it for a period of up to 30 days free of charge. About 20 days into the evaluation period, the software will start to remind you that it has not yet been licensed. The reminder message will be displayed once each time you start the application. If you would like to continue using the program after the 30-day evaluation period, you must purchase a product license, which is delivered in the form of a license file containing a key code. Unlock the product by uploading the license file in the Software Activation dialog of your product.

You can purchase product licenses at https://shop.altova.com/.

Helping Others within Your Organization to Evaluate the Software

If you wish to distribute the evaluation version within your company network, or if you plan to use it on a PC that is not connected to the Internet, you may distribute only the installer file, provided that this file is not modified in any way. Any person who accesses the software installer that you have provided must request their own 30-day evaluation license key code and after expiration of their evaluation period, must also purchase a license in order to be able to continue using the product.

Appendices License Information 1293

19.5.2 Software Activation and License Metering

As part of Altova's Software Activation, the software may use your internal network and Internet connection for the purpose of transmitting license-related data at the time of installation, registration, use, or update to an Altova-operated license server and validating the authenticity of the license-related data in order to protect Altova against unlicensed or illegal use of the software and to improve customer service. Activation is based on the exchange of license related data such as operating system, IP address, date/time, software version, and computer name, along with other information between your computer and an Altova license server.

Your Altova product has a built-in license metering module that further helps you avoid any unintentional violation of the End User License Agreement. Your product is licensed either as a single-user or multi-user installation, and the license-metering module makes sure that no more than the licensed number of users use the application concurrently.

This license-metering technology uses your local area network (LAN) to communicate between instances of the application running on different computers.

Single license

When the application starts up, as part of the license metering process, the software sends a short broadcast datagram to find any other instance of the product running on another computer in the same network segment. If it doesn't get any response, it will open a port for listening to other instances of the application.

Multi-user license

If more than one instance of the application is used within the same LAN, these instances will briefly communicate with each other on startup. These instances exchange key-codes in order to help you to better determine that the number of concurrent licenses purchased is not accidentally violated. This is the same kind of license metering technology that is common in the Unix world and with a number of database development tools. It allows Altova customers to purchase reasonably-priced concurrent-use multi-user licenses.

We have also designed the applications so that they send few and small network packets so as to not put a burden on your network. The TCP/IP ports (2799) used by your Altova product are officially registered with the IANA (see the <u>IANA Service Name Registry</u> for details) and our license-metering module is tested and proven technology.

If you are using a firewall, you may notice communications on port 2799 between the computers that are running Altova products. You are, of course, free to block such traffic between different groups in your organization, as long as you can ensure by other means, that your license agreement is not violated.

Note about certificates

Your Altova application contacts the Altova licensing server (link.altova.com) via HTTPS. For this communication, Altova uses a registered SSL certificate. If this certificate is replaced (for example, by your IT department or an external agency), then your Altova application will warn you about the connection being insecure. You could use the replacement certificate to start your Altova application, but you would be doing this at your own risk. If you see a *Non-secure connection* warning message, check the origin of the certificate and consult your IT team (who would be able to decide whether the interception and replacement of the Altova certificate should continue or not).

1294 Appendices License Information

If your organization needs to use its own certificate (for example, to monitor communication to and from client machines), then we recommend that you install Altova's free license management software, Altova LicenseServer, on your network. Under this setup, client machines can continue to use your organization's certificates, while Altova LicenseServer can be allowed to use the Altova certificate for communication with Altova.

19.5.3 Altova End-User License Agreement

- The Altova End-User License Agreement is available here: https://www.altova.com/legal/eula
- Altova's Privacy Policy is available here: https://www.altova.com/privacy

19.5.4 Packaging License Files with StyleVision Installer

If you want to perform a silent installation of StyleVision, you may want to modify the MSI database so that it includes your license file(s). This way, the installer will not only install the product but also license it. For details about how to achieve this, download this ZIP file from the Altova website and open the PDF document in it.
