2.2.9 Find and Replace ....................................................... 59

## 3 Quick Start Tutorial 60
3.1 Creating and Setting Up a New SPS .................................... 61
3.2 Inserting Dynamic Content (from XML Source) .................. 65
3.3 Inserting Static Content .................................................. 72
4 Usage Overview

4.1 SPS and Sources ................................................. 100
4.2 Creating the Design ............................................. 101
4.3 XSLT and XPath Versions ..................................... 102
4.4 Internet Explorer Compatibility ......................... 103
4.5 SPS and Authentic View ..................................... 105
4.6 Synchronizing StyleVision and Authentic .......... 107
4.7 Generated Files ................................................. 108
4.8 Projects in StyleVision ...................................... 110
4.9 Catalogs in StyleVision ...................................... 115
   4.9.1 How Catalogs Work .................................... 115
   4.9.2 Catalog Structure in StyleVision ................. 116
   4.9.3 Customizing Your Catalogs ......................... 117
   4.9.4 Variables for Windows System Locations ...... 119

5 SPS Content ........................................................................ 121

5.1 Inserting XML Content as Text ......................... 122
   5.1.1 Inserting Content with a Predefined Format .... 124
   5.1.2 Adding Elements in Authentic View ............... 125
   5.1.3 Rest-of-Contents .................................. 127
5.2 Inserting MS Word Content ................................. 129
5.3 Inserting MS Excel Content ................................. 132
5.4 User-Defined Templates ..................................... 134
5.5 User-Defined Elements, XML Text Blocks .......... 137
   5.5.1 User-Defined Elements .......................... 137
   5.5.2 User-Defined XML Text Blocks ............... 138
5.6 Tables ............................................................ 140
5.6.1 Static Tables.............................................................................................................................. 142
5.6.2 Dynamic Tables.......................................................................................................................... 143
5.6.3 Conditional Processing in Tables.............................................................................................. 147
5.6.4 Tables in Design View................................................................................................................ 148
5.6.5 Table Formatting......................................................................................................................... 150
5.6.6 Row and Column Display.......................................................................................................... 154
5.6.7 CALS/HTML Tables.................................................................................................................... 155
5.7 Lists................................................................................................................................................ 160
5.7.1 Static Lists................................................................................................................................... 160
5.7.2 Dynamic Lists............................................................................................................................ 162
5.8 Graphics.......................................................................................................................................... 165
5.8.1 Images: URIs and Inline Data.................................................................................................... 165
5.8.2 Image Types and Output.............................................................................................................. 167
5.8.3 Example: A Template for Images............................................................................................. 170
5.9 Form Controls.............................................................................................................................. 171
5.9.1 Input Fields, Multiline Input Fields.......................................................................................... 172
5.9.2 Check Boxes.............................................................................................................................. 172
5.9.3 Combo Boxes............................................................................................................................. 174
5.9.4 Radio Buttons, Buttons............................................................................................................. 177
5.10 Links.............................................................................................................................................. 179
5.11 Barcodes......................................................................................................................................... 180
5.12 Layout Modules............................................................................................................................ 184
5.12.1 Layout Containers.................................................................................................................... 184
5.12.2 Layout Boxes........................................................................................................................... 187
5.12.3 Lines........................................................................................................................................... 191
5.13 The Change-To Feature............................................................................................................... 194

6 SPS Structure................................................................................................................................ 197
6.1 Schema Sources............................................................................................................................ 199
6.1.1 DTds and XML Schemas........................................................................................................... 200
6.1.2 DB Schemas.............................................................................................................................. 205
6.1.3 User-Defined Schemas............................................................................................................. 206
6.2 Merging XML Data from Multiple Sources................................................................................ 209
6.3 Modular SPSs............................................................................................................................... 212
### 6.4 Templates and Design Fragments

- **6.4.1 Main Template** ........................................................................................................ 226
- **6.4.2 Global Templates** .................................................................................................. 226
- **6.4.3 User-Defined Templates** ...................................................................................... 230
- **6.4.4 Variable Templates** ............................................................................................... 233
- **6.4.5 Node-Template Operations** .................................................................................. 234
- **6.4.6 Design Fragments** ................................................................................................ 237

### 6.5 XSLT Templates

- **6.5.1 Inserting a New Document Template** .................................................................. 241
- **6.5.2 New Document Templates and Design Structure** .............................................. 244
- **6.5.3 URLs of New Document Templates** ..................................................................... 245
- **6.5.4 Preview Files and Output Document Files** ........................................................... 247
- **6.5.5 Document Properties and Styles** .......................................................................... 250

### 7 Advanced Features

**7.1 Auto-Calculations** ........................................................................................................ 252
- **7.1.1 Editing and Moving Auto-Calculations** ................................................................. 252
- **7.1.2 Updating Nodes with Auto-Calculations** ............................................................... 254
- **7.1.3 Auto-Calculations Based on Updated Nodes** ....................................................... 257
- **7.1.4 Example: An Invoice** ............................................................................................ 258

**7.2 Conditions** .................................................................................................................. 262
- **7.2.1 Setting Up the Conditions** .................................................................................... 262
- **7.2.2 Editing Conditions** ................................................................................................ 265
- **7.2.3 Output-Based Conditions** .................................................................................... 266
- **7.2.4 Conditions and Auto-Calculations** ....................................................................... 267

**7.3 Conditional Presence** .................................................................................................. 268

**7.4 Grouping** .................................................................................................................... 270
- **7.4.1 Example: Group-By (Persons.sps)** ...................................................................... 272
- **7.4.2 Example: Group-By (Scores.sps)** ......................................................................... 274

**7.5 Sorting** ........................................................................................................................ 278

1 Introduction

Altova StyleVision 2022 Professional Edition is an application for graphically designing and editing StyleVision Power Stylesheets, available in 64-bit and 32-bit versions. StyleVision® runs on Windows 7 SP1 with Platform Update, Windows 8, Windows 10, Windows 11, and Windows Server 2008 R2 SP1 with Platform Update or newer. Some functionality of StyleVision and Altova MissionKit can be integrated with applications of the Microsoft Office suite (MS Access, MS Excel, MS Word), version 2007 or newer.

A StyleVision Power Stylesheet (SPS) can be used for the following purposes:

- To control a graphical WYSIWYG view of XML documents in Authentic View, which is an XML document editor available in the following Altova products: Altova XMLSpy, Altova StyleVision, Altova Authentic Desktop, and Altova Authentic Browser. It enables you to easily create electronic forms based on XML documents.
- To enable the editing of databases (DBs) via Authentic View and to generate database reports in HTML, RTF, and Text format.
- To generate XSLT stylesheets based on the SPS design. (XSLT 1.0, XSLT 2.0, and XSLT 3.0 are supported.) The XSLT stylesheets can be used outside StyleVision to transform XML documents into outputs such as HTML and RTF (Rich Text Format, used by word processing applications such as MS Word).
- To generate, directly from within StyleVision, HTML, RTF, and Text output from an XML document. In the case of DB-based SPSs, StyleVision can additionally generate, for each SPS, an XML Schema based on the DB and an XML instance document that adheres to this schema and contains data from the DB.

Last updated: 19 October 2021
1.1 Product Features

The main product features of StyleVision are listed below:

General product features

Given below is a list of the main high-level features of StyleVision.

- Enterprise and Professional editions are each available as separate 64-bit and 32-bit applications.
- StyleVision functionality can be called via StyleVision Server.
- StyleVision functionality can be integrated in external applications, and StyleVision an integrated in Visual Studio and Eclipse.

Sources

SPS designs can be based on XML Schemas and DTDs. A design uses other source files, such as XML and CSS files. The following additional features concerning sources are supported:

- Altova Global Resources can be used to locate source files such as schema, XML, and CSS. The Global Resources mechanism enables faster and better development and testing by allowing developers to quickly change source data and to use the functionality of other Altova applications from within StyleVision.
- HTML documents can be converted to XML.

Interface

Given below are some general GUI features:

- Multiple SPS designs can be open simultaneously, with one being active at any given time. Each SPS design is shown in a separate tab.
- Template filters allow you to customize the display of the design document. With this feature you can disable the display of templates that are not currently being edited, thus increasing editing efficiency.
- Hide Markup in Design View: Markup tags in Design View can be hidden and collapsed, thus freeing up space in Design View.
- While designing the SPS, Authentic View, output views, and stylesheets can be displayed by clicking the respective tabs. This enables you to quickly preview the output and the XSLT code, and test Authentic View features.
- When an SPS is associated with an XML source document or source DB, the source document can be edited directly in the Authentic View of StyleVision.

Databases

The following DB features are supported:

- DB reports can either be viewed in StyleVision or saved as HTML and RTF files.
- IBM DB2 databases, which contain XML columns, are supported.
- A DB can be queried directly from StyleVision.
Output
Various output formats are supported depending upon the edition that has been installed. The following output-related features are supported:

- **XSLT versions 1.0, 2.0, and 3.0** are supported.
- In the Enterprise and Professional Editions, **multiple output formats** (HTML, RTF, and Text) are generated from a single SPS design.
- Conditions can be set on SPS components to **process them differently for different outputs**. With this level of granularity, different outputs can be flexibly structured to take in the requirements of that particular output.
- Both **XSLT files and output files** can be **generated and saved**, either directly from within the GUI or via StyleVision Server.
- Altova has developed a special **PXF File format** that enables an SPS file to be saved together with related source and data files. This enables entire SPS projects to be transported rather than just the SPS file.
- **ASPX Interface for Web Applications**: With this feature, HTML web pages can be quickly updated. StyleVision generates, from an SPS, all the files necessary for an ASPX application. When the web page (a .aspx file) is refreshed, the source data (including any updates) is dynamically transformed via XSLT to the web page.

SPS design features
Given below is a list of the main StyleVision features specific to designing the SPS.

- The SPS can contain **static text**, which you enter in the SPS, and **dynamic text**, which is selected from the **source document**.
- **Dynamic content** is inserted in the design by dragging-and-dropping nodes from the **schema source**. Design Elements (paragraphs, lists, images, etc) can also be inserted first, and an XML node from the schema tree can be assigned to the Design Element afterwards.
- **Dynamic content** can be inserted as text, or in the form of a **data-entry device** (such as an input field or combo box). When inserted as a data-entry device such as a combo box, additional possibilities are available. For example, the value of the node can be selected (by the Authentic View user) from a list of enumerations.
- The **structure of the design** is specified and controlled in a single **main template**. This structure can be modified by optional templates for individual elements—known as **global templates** because they can be applied globally for that element.
- **Global templates** can also be created for individual datatypes, thus enabling processing to be handled also on the basis of types.
- **Multiple Document Output**: The output generated by the SPS can be designed to be split into multiple documents. In the design, New Document templates are created and content placed in them. Each New Document template generates a separate document in the output.
- **User-Defined Templates**: A template can be generated for a sequence of items by an XPath expression you specify. These items may be atomic values or nodes. An XPath expression enables the selection of nodes to be more specific, allowing conditions and filters to be used for the selection.
- **User-Defined Elements**: This feature is intended to enable presentation language elements (such as HTML, XSL, and XSL-FO) to be freely inserted at any location in the design.
- **User-Defined XML Text Blocks**: XML Text blocks can be freely inserted at any location in the design, and these blocks will be created at that location in the generated XSLT stylesheet.
- **Design Fragments** enable the modularization and re-use of templates within an SPS, and also across multiple SPSs (see modular SPSs), in a manner similar to the way functions are used.
- **SPS modules** can be added to other SPS modules, thus making objects defined in one SPS module available to other modules. This enables re-use of module objects across multiple SPSs and makes maintenance easier.

- **XSLT Templates**: XSLT files can be imported into the generated stylesheets. If a node in the XML instance document is matched to a template in the imported XSLT file and no other template takes precedence over the imported template, then the imported template will be used. Additionally, named templates in the imported XSLT file can be called from within the design.

- **New from XSLT**: An SPS can be created from an XSLT-for-HTML or an XSLT-for-FO. Template structure and styling in the XSLT will be created in the SPS. You can then modify the SPS components and add content and formatting to the SPS.

- **User-Defined XPath Functions**: The user can define XPath functions which can be used anywhere in the document where XPath functions may be used.

- **Document Sections**: Documents can be divided into sections, with each section having its own properties, such as page layout properties. This enables different parts of a document to be presented differently.

- **Layout Containers**: A Layout Container is a block in which Design Elements can be laid out and absolutely positioned within the block.

- **Blueprints**: Within a Layout Container an image of a form can be used as an underlay blueprint for the design. With the help of a blueprint, an existing design can be reproduced accurately.

- A common feature of XML documents is the repeating data structure. For example, an office department typically has several employees. The data for each employee would be stored in a data structure which is repeated for each employee. In the SPS, the **processing for each such data structure** is defined once and applied to each relevant node in turn (the employee node in our example).

- Multiple **tables of contents** can be inserted in XSLT 2.0 and 3.0 SPSs.

- Repeating data structures can also be inserted as **dynamic tables**. This provides looping in a structured, table format, with each loop through the data structure producing a row (or, if required, a column) of the table.

- A repeating element can be sorted on one or more sort-keys you select, and the sorted element set is sent to the output (HTML and RTF).

- **Variables**: A variable can now be declared on a template and take a value that is specified with an XPath expression. Previously, the value of a variable was limited to the selection of the node on which it was created. Variables in the 2010 version allow any XPath expression to be specified as the value of the variable.

- Nodes can be grouped on the basis of common data content (for example, the common value of an attribute value) and their positions.

- The **conditional templates** feature enables one of a set of templates to be processed according to what conditions in the XML document or system environment are fulfilled. This enables processing that is conditional on information contained in the source document or that cannot be known to the SPS document creator at the time of creation (for example, the date of processing). The available conditions are those that can be tested using XPath expressions.

- **Auto-Calculations** enable you to manipulate data from the source document/s and to display the result. This is useful, when you wish to perform calculations on numbers (for example, sum the prices in an invoice), manipulate strings (for example, change hyphens to slashes), generate content, etc. The available manipulations are those that can be effected using XPath expressions. Native Java and .NET functions can be used in the XPath expressions of Auto-Calculations.

- When data is edited in Authentic View, the result of Auto-Calculations can also be passed to a node in the source document. This procedure is referred to as **updating the XML node** (with the value of the Auto-Calculation).

- **Additional validation** enables individual XML document nodes to be validated (additionally to schema validation) against an XPath expression defined for that node. In this way, Authentic View users can be alerted when the data they enter is invalid; a customized error message for the node can indicate the problem.
Introduction

Altova StyleVision 2022 Professional Edition

- **Barcodes**: This new design component enables barcodes to be easily inserted in the design. Barcode images are generated on the fly and placed in the output documents.

- **Conditional presence**: Certain design components have a conditional presence property. A conditional design component will be created in the output only if the condition specified for it is fulfilled.

- **Images**: can be inserted in the design. The URI for the image can be static (entered in the SPS), or dynamic (taken from a node in the source document), or a combination of both static and dynamic parts.

- **Images from inline data**: Images can be generated from Base-16 and Base-64 encoded text in the XML document. Consequently, images can be stored directly in the source XML document as text. An SPS can now decode such text and render the image.

- Two types of **lists** can be created: static and dynamic. In a **static list**, each list item is defined in the SPS. In a **dynamic list**, a node is created as a list item; the values of all instances of that node are created as the items of the list.

- **Static and dynamic links**: can be inserted in the design. The target URI can be static (entered in the SPS), or dynamic (taken from a node in the source document), or a combination of both static and dynamic parts.

- **Static bookmarks** can be inserted. These serve as anchors that can be linked to with a hyperlink.

- **Parameters** can be declared globally for the entire SPS. A parameter is declared with a name and a string value, and can be used in XPath expressions in the SPS. The parameter value you declare is the default value. It can be overridden by a value passed via StyleVision Server.

- With the **Input Formatting** feature, the contents of numeric XML Schema datatype nodes can be formatted as required for Authentic View display and, in the case of some formats, optionally for output display. Input Formatting can also be used to format the result of an **Auto-Calculation**.

- **JavaScript functions** can be used in the SPS to provide user-defined functionality for Authentic View and HTML output.

- **Authentic Scripting**: Enables additional flexibility and interactivity in Authentic View.

- A number of **predefined HTML formats** are available via the GUI and can be applied to individual SPS components.

- A large number of CSS text formatting and layout properties can be applied to individual SPS components via the **Styles sidebar**.

- Additionally, CSS styles can be defined for HTML selectors at the **global level** of an SPS and in external CSS stylesheets. These style rules will be applied to Authentic View and HTML output, thus providing considerable formatting and layout flexibility.

- **Styles can also be assigned using XPath expressions**. This enables style property values to be selected from XML documents and to set property values conditionally.

- For paged output (typically RTF, PDF, and Word 2007-and-higher), a number of **page layout options**, such as orientation, margins, page-numbering, and headers and footers, can be specified in the SPS.
1.2 Authentic View in Altova Products

Authentic View is a graphical XML document editor available in the following Altova products:

* Altova XMLSpy
* Altova Authentic Desktop
* Altova Authentic Browser
* Altova StyleVision

In StyleVision, Authentic View can be viewed in the Authentic eForm tab of the Main Window.

What Is an SPS?

A StyleVision Power Stylesheet (or SPS) is an extended XSLT stylesheet which is used:

- to control the display and entry of data in the Authentic View of XML documents and databases (DBs); and
- to specify the output design of an XML document transformation.

An SPS is saved with the file extension .sps.

Design of the SPS

An SPS is created graphically in StyleVision. It is based on a schema (DTD or XML Schema); if the SPS is to be used with a DB, it is based on an XML Schema generated automatically by StyleVision from the DB structure. The design of the SPS is flexible. It can contain dynamic and static content. The dynamic content is the data in one XML document or DB. The static content is content entered directly in the SPS. Dynamic content can be included in the design either as straight text or within components such as input fields, combo boxes, and tables. Additionally, dynamic content can be manipulated (using Auto-Calculations) and can be displayed if certain conditions in the source document are fulfilled. Different pieces of content can be placed at various and multiple locations in the SPS. Also, the SPS can contain various other components, such as images, hyperlinks, and JavaScript functions. Each component of the SPS can then be formatted for presentation as required.

The SPS and Authentic View

When a finished SPS is associated with an XML document or DB, that XML document or DB can be edited in Authentic View. Authentic View is an ideal solution for enabling the distributed and graphical editing of an XML document or DB. Multiple users can edit an XML document or DB in the graphical user interface presented by Authentic View. In StyleVision, as you design an SPS, you can preview and test the SPS (in the Authentic View tab for that SPS). For a detailed description of how SPSs work with Authentic View, see SPS and Authentic View.

The SPS and XSLT stylesheets

After you have completed designing the SPS, you can generate XSLT stylesheets based on the design you have created. StyleVision supports XSLT 1.0, XSLT 2.0 and XSLT 3.0, and from a single SPS, you can generate XSLT stylesheets for HTML, RTF, XSL-FO, Text, and Word 2007-and-higher output (XSL-FO, Text, and Word 2007-and-higher in Enterprise edition only; RTF and Text in Enterprise and Professional Editions; in Basic Edition only HTML output is supported). The generated XSLT stylesheets can be used in external transformations to transform XML documents based on the same schema as the SPS from which the XSLT stylesheet was generated. For more information about procedures used with XSLT stylesheets, see the section Generated Files.

The SPS and output

You can also use StyleVision to directly generate output (HTML, RTF, Text, XSL-FO, and PDF in Enterprise Edition; HTML and RTF in Professional Edition; and HTML in Basic Edition). The tabs for Output Views display the output for the active SPS document directly in the StyleVision GUI. The required output can also be generated to file from within the GUI via the File | Save Generated Files command or via StyleVision Server.
Authentic View in Altova Products

Authentic View is a graphical XML document editor available in the following Altova products:

* Altova XMLSpy
* Altova Authentic Desktop
* Altova Authentic Browser
* Altova StyleVision
1.4 Setting up StyleVision

Altova StyleVision runs on Windows 7 SP1 with Platform Update, Windows 8, Windows 10, Windows 11. After downloading StyleVision from the Altova website, double-click the executable (.exe) file to run the setup program. The setup program will install StyleVision at the desired location. The Altova XSLT Engines (1.0 and 2.0) are built into StyleVision and are used for all internal transformations. You, therefore, do not need to install an XSLT Engine additionally to your StyleVision installation.

You will, however, need to have the following components installed:

- Internet Explorer 5.5 or later, for Authentic View, HTML Preview and Design View. Internet Explorer 6.0 and later has better XML support and is recommended.
- Microsoft Word 2000 or later, for RTF Preview. Microsoft Word 2003 or later is recommended. For copy-paste from Word documents (and of content that can be pasted into Word documents, such as Excel tables and HTML page content) Word 2007+ is required

Note: In this documentation, we use the abbreviation **Word 2007+** to refer to Microsoft Word 2007 or higher versions of this program.

Note: If there is a problem with an embedded preview, StyleVision will attempt to open the preview document in an external application (usually MS Word or Adobe Reader). An error message about the embedded preview will appear in StyleVision. If the preview document is opened in an external application, you will need to close the external application before regenerating the temporary output document, otherwise you will get an error message saying the file is being used by another process. You should also close the external application before closing the SPS design, otherwise StyleVision will not be able to close the temporary output document due to the file lock placed on the document by the external application.

**RaptorXML**

**RaptorXML** can be used to transform XML to the required output format.
1.5 Terminology

This section lists terms used in the StyleVision GUI and in this documentation. Terms are organized into the groups listed below, and within each group, they are listed alphabetically.

Altova product-related terms

A list of terms that relate to Altova products.

**Authentic View**  
An XML document editor view available in the following Altova products: Altova XMLSpy; Altova StyleVision; Altova Authentic Desktop; Altova Authentic Browser. For more details about Authentic View and Altova products, visit the [Altova website](https://www.altova.com).

**SPS**  
The abbreviated form of StyleVision Power Stylesheet, it is used throughout this documentation to refer to the design document created in StyleVision and saved as a file with the `.sps` extension. For a detailed description, see [What Is an SPS?](#).

**Global resource**  
An alias for a set of files, a set of folders, or a set of databases. Each alias has a set of configurations and each configuration is mapped to a resource. In StyleVision, when a global resource is used, the resource can be changed by changing the active configuration in StyleVision.

General XML terms

Definitions of certain XML terms as used in this documentation.

**schema**  
A schema *(with lowercase 's')* refers to any type of schema. Schemas supported by StyleVision are [XML Schema](#) *(capitalized)* and DTD.

**XML Schema**  
In this documentation, XML Schema *(capitalized)* is used to refer to schemas that are compliant with the [W3C's XML Schema specification](#). XML Schema is considered to be a subset of all schemas *(lowercased)*.

**URI and URL**  
In this documentation, the more general URI is used exclusively—even when the identifier has only a "locator" aspect, and even for identifiers that use the [http](#) scheme.

XSLT and XPath terms

There have been changes in terminology from XSLT 1.0 and XPath 1.0 to XSLT 2.0 and XPath 2.0. For example, what was the root node in XPath 1.0 is the document node in XPath 2.0. In this documentation, we use the newest, XSLT 3.0 and XPath 3.0, terminology.

**absolute XPath**  
A path expression that starts at the root node of the tree containing the context node. In StyleVision, when entering path expressions in dialogs, the expression can be entered as an absolute path if you check the Absolute XPath check box in the dialog. If this check box is unchecked, the path is relative to the context node.

**context item /**  
The context item is the item (node or string value) relative to which an expression is evaluated. A context node is a context item that is a node. The context item can change within an expression, for example, with each location step, or within a filter expression (predicate).
**context node**  
The current node is the node being currently processed. The current node is the same as the context node in expressions that do not have sub-expressions. But where there are sub-expressions, the context node may change. Note that the current() function is an XSLT function, not an XPath function.

**current node**  
The current node is the node being currently processed. The current node is the same as the context node in expressions that do not have sub-expressions. But where there are sub-expressions, the context node may change. Note that the current() function is an XSLT function, not an XPath function.

**document element**  
In a well-formed XML document, the outermost element is known as the document element. It is a child of the document node, and, in a well-formed XML document, there is only one document element. In the GUI the document element is referred to as the root element.

**document node**  
The document node represents and contains the entire document. It is the root node of the tree representation of the document, and it is represented in an XPath expression as: '

In the Schema Tree window of StyleVision, it is represented by the legend: '/ Root elements'.

**StyleVision-specific terms**  
Terms that refer to StyleVision mechanisms, concepts, and components.

**Blueprint image**  
A blueprint image is one that is used as the background image of a layout container, and would typically be the scan of a form. The SPS design can be modelled on the blueprint image, thus recreating the form design.

**dynamic items**  
Items that originate in XML data sources. Dynamic items may be text, tables, and lists; also images and hyperlinks (when the URIs are dynamic).

**global element**  
An element in the Global Elements list in the Schema Tree window. In an XML Schema, all elements defined as global elements will be listed in the Global Elements list. In a DTD, all elements are global elements and are listed in the Global Elements list. Global templates can be defined only for global elements.

**global template**  
A global template may be defined for a global element. Once defined, a global template can be used for that element wherever that element occurs in the document. Alternatively to the global template, processing for a global element may be defined in a local template.

**Layout container**  
A Layout Container is a design block in which design elements can be laid out and absolutely positioned. If a design is to be based on a form, it can be created as a Layout Container, so that design elements of the form can be absolutely positioned. Alternatively, a design can be free-flowing and have layout containers placed within the flow of the document.

**local template**  
A local template is the template that defines how an element (global or non-global) is processed within the main template. The local template applies to that particular occurrence of the element in the main template. Instead of the local template, a global template can be applied to a given occurrence of an element in the main template.

**main schema**  
One of the assigned schema sources is designated the main schema; the document node of the Working XML File associated with the main schema is used as the starting point for the main template.

**main template**  
The main entry-point template. In StyleVision, this template matches the document element and is the first to be evaluated by the XSLT processor. In the Schema Tree window, it is listed as the child of the document node. The main template defines the basic output document structure and defines how the input document/s are to be processed. It can contain local templates and can reference global templates.
output  The output produced by processing an XML document with an XSLT stylesheet. Output files that can be generated by StyleVision would be HTML and RTF format. Authentic View is not considered an output, and is referred to separately as Authentic View. XSLT stylesheets generated by StyleVision are also not considered output and are referred to separately as XSLT stylesheets.

static items  Items that originate in the SPS and not in XML data sources. Static items may be text, tables, and lists; also images, hyperlinks, and bookmarks (when the URIs are static).

SPS component  An SPS component can be: (i) a schema node (for example, an element node); (ii) a static SPS component such as an Auto-Calculation or a text string; or (iii) a predefined format (represented in the SPS by its start and end tags).

template  Defined loosely as a set of instructions for processing a node or group of nodes.

Template XML File  A Template XML File is assigned to an SPS in StyleVision (Enterprise and Professional editions). It is an XML file that provides the starting data of a new XML document created with a given SPS when that SPS is opened in Authentic View. The Template XML File must be conformant with the schema on which the SPS is based.

User-defined element  An element that is neither a node in the schema tree nor a predefined element or a design element, but one that is specified by the user. An element can be specified with attributes.

User-defined template  A template that is created for a sequence specified in an XPath expression.

User-defined XML text blocks  XML Text blocks can be freely inserted at any location in the design.

Working XML/XBRL File  A Working XML/XBRL File is an XML data file that is assigned to an SPS in StyleVision in order to preview the Authentic View and output of the XML document in StyleVision. Without a Working XML/XBRL File, the SPS in StyleVision will not have any dynamic XML data to process. If the SPS is based on a schema that has more than one global element, there can be ambiguity about which global element is the document element. Assigning a Working XML/XBRL File resolves such ambiguity (because a valid XML document will, by definition, have only one document element). Note that XBRL functionality is available only in the Enterprise edition.

XML document  XML document is used in two senses: (i) to refer to a specific XML document; (ii) to refer to any XML data source, including DB sources (from which XML data documents are generated for use with an SPS). Which sense is intended should be clear from the context.
1.6 About This Documentation

This documentation is the user manual delivered with StyleVision. It is available as the built-in Help system of StyleVision, can be viewed online at the Altova website, and can also be downloaded from there as a PDF, which you can print.

The user manual is organized into the following sections:

- An introduction, which explains what an SPS is and introduces the main features and concepts of StyleVision.
- A description of the user interface, which provides an overview of the StyleVision GUI.
- A tutorial section, which is a hands-on exercise to familiarize you with StyleVision features.
- Usage Overview, which describes usage at a high level: for example, schema sources used to create an SPS, the broad design process, Authentic View deployment, and projects.
- SPS File Content, which explains how static (stylesheet-originated) and dynamic (XML document-originated) components are created and edited in the SPS.
- SPS File Structure, which shows how an SPS file can be structured and modularized, and describes the handling of StyleVision's templates.
- SPS File Advanced Features, which describes advanced design features, such as the automatic generation of calculations, the setting up of conditions, grouping and sorting on user-defined criteria, and how to build tables of contents and cross-references in the output document.
- SPS File Presentation, which explains how SPS components are formatted and laid out.
- SPS File Additional Editing Functionality, which describes a range of additional features that can make your SPS more powerful. These features include: global resources for leveraging functionality in other Altova products, additional validation, scripts, and variables and parameters.
- SPS File and Databases, which explains how databases can be used with SPSs.
- Authentic View, which describes how XML documents are edited in Authentic View. The StyleVision GUI contains an Authentic View preview tab, in which you can immediately test the Authentic View output.
- Automated Processing, which explains how the generation of output files can be automated.
- StyleVision's integration features, which contains the documentation for integrating StyleVision in other applications. There is also information on how to use StyleVision in Visual Studio and Eclipse.
- A reference section containing descriptions of all symbols and commands used in StyleVision.
- Appendices containing information about the Altova XSLT Engine information and the conversion of DB datatypes to XML Schema datatypes; technical data about StyleVision; and license information.

How to use

We suggest you read the Introduction, User Interface and Usage Overview sections first in order to get an overview of StyleVision features and general usage. Doing the tutorial next would provide hands-on experience of creating an SPS. The SPS File sections (SPS File Content, SPS File Structure, SPS File Advanced Features, SPS File Presentation, SPS File Additional Functionality, SPS File and Databases) provide detailed descriptions of how to use various StyleVision features. For subsequent reference, the Reference section provides a concise description of all toolbar icon, design symbols, and menu commands, organized according to toolbar and menu. The Authentic View section provides information about editing in Authentic View.

File paths in Windows 7, Windows 8, and Windows 10

File paths given in this documentation will not be the same for all operating systems. You should note the
following correspondences:

- **(My) Documents folder**: Located by default at the following locations. Example files are located in a sub-folder of this folder.

<table>
<thead>
<tr>
<th>Windows 7/8/10</th>
<th>C:\Users&lt;username&gt;\Documents</th>
</tr>
</thead>
</table>

- **Application folder**: The Application folder is the folder where your Altova application is located. The path to the Application folder is, by default, the following.

<table>
<thead>
<tr>
<th>Windows 7/8/10</th>
<th>C:\Program Files\Altova\</th>
</tr>
</thead>
<tbody>
<tr>
<td>32-bit version on 64-bit OS</td>
<td>C:\Program Files (x86)\Altova\</td>
</tr>
</tbody>
</table>

**Note**: StyleVision is also supported on Windows Server 2008 R2 SP1 with Platform Update or newer.

**Support options**

Should you have any question or problem related to StyleVision, the following support options are available:

1. Check the Help (this documentation). The Help file contains a full text-search feature, besides being fully indexed.
2. Check the FAQs and Discussion Forum at the Altova Website.
3. Contact Altova's Support Center.

**Commonly used abbreviations**

The following abbreviations are used frequently in this documentation:

- **SPS**: StyleVision Power Stylesheet
- **DB**: Database
- **CSS**: Cascading Style Sheets
- **FAQ**: Frequently Asked Questions
2 User Interface

The StyleVision GUI (illustration below, in which not all sidebars are shown) consists of the following parts:

- **A menu bar.** Click on a menu to display the items in that menu. All menus and their items are described in the User Reference section. The menu bar also contains the Minimize, Restore, and Close Active Document buttons.

- **A toolbar area.** The various toolbars and the command shortcuts in each toolbar are described in the User Reference section.

- **A tabbed Main Window,** which displays one or more open SPS documents at a time. In this window, you can edit the design of the SPS, edit the content of Authentic View (in the Authentic eForm tab), and preview the XSLT stylesheets and output.

- **The Design Sidebars—the Design Overview, Schema Tree, Design Tree, Style Repository, Styles, Properties, and Project windows—which can be docked within the application GUI or made to float on the screen.**

- **A status bar,** which displays application status information. If you are using the 64-bit version of StyleVision, this is indicated in the status bar with the suffix (x64) after the application name. There is no suffix for the 32-bit version.

The **Main Window** and **Design sidebars** are described in more detail in the sub-sections of this section.

**Note:** The menu bar and toolbars can be moved by dragging their handles to the required location.
2.1 Main Window

The **Main Window** *(illustration below)* is where the SPS design, Authentic View, XSLT stylesheets, and output previews are displayed.

![Main Window illustration](image)

**SPS documents in the Main Window**

- Multiple SPS documents can be open in StyleVision, though only one can be active at any time. The names of all open documents are shown in tabs at the bottom of the Main Window, with the tab of the active document being highlighted.
- To make an open document active, click its tab. Alternatively, use the options in the Windows menu.
- If so many documents are open that all document tabs are not visible in the document-tab bar, then click the appropriate scroll button (at the right of the document-tab bar; see *illustration above*) to scroll the tabs into view.
- To close the active document, click the **Close Document** button in the menu bar at the top right of the application window (or select **File|Close**).

**Document views**

A document is displayed in the following views, one of which can be active at a time:

- **Design View** *(Design View)*, in which you design the SPS and edit JavaScript functions for use in that SPS. The view can be toggled between the design document and the JavaScript Editor by clicking the dropdown menu arrow and selecting Design or JavaScript, as required.
- **Authentic View** *(Authentic eForm tab)*, which enables you to immediately see the Authentic View of an XML document (the *Working XML File*). The SPS is dynamically applied to the *Working XML File*, thus enabling you to try out Authentic View.
- **Output Views** *(HTML, Text, and RTF output)*. These views are a preview of the actual output format and of the XSLT stylesheet used to generate that output. The view can be toggled between the output preview and the XSLT stylesheet by clicking the dropdown menu arrow and making the appropriate selection.
Each of the views listed above is available as a tab at the bottom of the Main Window in the Views Bar. To select a view, click on its tab. The tab of the selected view is highlighted.

### 2.1.1 Design View

The **Design View** *(illustration below)* is the view in which the SPS is designed. In Design View, you create the design of the output document by (i) inserting content (using the sidebars, the keyboard, and the various content creation and editing features provided in the menus and toolbars); and (ii) formatting the content using the various formatting features provided in the sidebars and menus. These aspects of the Design View are explained in more detail below.

Design View can also be switched to a JavaScript Editor or (Authentic) Scripting Editor. In the JavaScript Editor you can create and edit JavaScript functions which then become available in the GUI for use in the SPS. In the Scripting Editor you can create and edit scripts for Authentic View. To switch to the JavaScript Editor or (Authentic) Scripting Editor, click the dropdown button in the Design tab *(see illustration)* and select JavaScript or (Authentic) Scripting Editor from the dropdown menu. To switch back to Design View, click the dropdown button in the JavaScript or (Authentic) Scripting Editor tab and select Design from the dropdown menu.

In Design View, the SPS can have several templates: the main template, global templates, page layout templates, and Design Fragments. You can control which of these template types is displayed in Design View by using Template Display Filters, which are available as toolbar icons. These display filters will help you optimize and switch between different displays of your SPS.

**Displaying markup tags**

The display of markup tags in Design View can be controlled via the markup icons *(below).*
The icons shown above are toggles. They are, from left: (i) Show small design markups (tags without names); and (ii) Show large design markups (tags with names). When small markup is switched on, the path to a node is displayed when you mouseover that node.

2.1.2 Authentic View

In the Authentic View tab of the Main Window (the Authentic eForm tab), you can view and edit the Working XML File in its Authentic View. This view enables you (i) to see how your Authentic XML document will look, and (ii) to test the Authentic View created by the SPS. This is particularly useful if you wish to test the dynamic features of Authentic View. For example, you could test how Authentic View behaves when you:

- Add new elements and attributes
- Add new paragraphs or table rows
- Change values that affect conditional templates

Authentic View and the Working XML File

In order for Authentic View to be displayed, a Working XML File must be assigned to the active SPS document. This Working XML File must be valid according to the schema on which the SPS is based.

StyleVision creates a temporary XML file that is based on the Working XML File, and it is this temporary file that is displayed in the Authentic View tab of the Main Window. Modifications that you make in Authentic View will modify the temporary XML file. The Working XML File itself will not be modified until you explicitly save the modifications (with the menu command File | Save Authentic XML Data).

If no Working XML File is assigned, you will be prompted to assign a Working XML File when you click the Authentic View tab.

Authentic View limitations

The Authentic View in the Main Window is similar to the full-fledged Authentic View available in XMLSpy and Authentic Desktop except in the following major respects:
• Authentic View entry helpers are not available in the GUI. To insert or append nodes, you must right-click and use the context menus.
• CALS/HTML tables are not available for insertion.
• Text state icons are not available.

To test these features, you should use the full-fledged Authentic View in XMLSpy or Authentic Desktop. A full description of how to use Authentic View is given in the section Editing in Authentic View. For additional information, please see the Authentic View tutorial in the XMLSpy or Authentic Desktop user manual.

2.1.3 Output Views

There are three Output View tabs, one each for HTML, RTF, and Text outputs. Each output view tab (illustration below) displays: (i) the XSLT stylesheet for that output; and (ii) a preview of the output produced by transforming the Working XML File with the XSLT stylesheet.

Note: In order for the different views to work correctly, you will need to install programs relevant to each view as described in the section Setting up StyleVision.

In an Output View tab, the view can be switched between the XSLT stylesheet and the output preview by clicking the dropdown button in the Output View tab and selecting the XSLT option or the output preview option as required.

XSLT view
The XSLT view displays the XSLT stylesheet generated for that output format from the currently active SPS. The stylesheet is generated afresh each time the XSLT view is selected.

A stylesheet in an Output View tab is displayed with line-numbering and expandable/collapsible elements; click the + and – icons in the left margin to expand/collapse elements. The stylesheet in XSLT view cannot be edited, but can be searched (select Edit | Find) and text from it can be copied to the clipboard (with Edit | Copy).
Note: The XSLT stylesheets generated from the SPS can be separately generated and saved using the File | Save Generated Files command.

Output preview
The Output preview displays the output produced by transforming the Working XML File with the XSLT stylesheet for that output format. The output is generated afresh each time the Output preview tab is clicked. Note that it is the saved version of the Working XML File that is transformed—not the temporary version that is edited with Authentic View. This means that any modifications made in Authentic View will be reflected in the Output preview only after these modifications have been saved to the Working XML File (File | Save Authentic XML Data).

If no Working XML File is assigned when the Output preview is selected in the Output View tab, you will be prompted to assign a Working XML File. For DB-based SPSs, there is no need to assign a Working XML File since a temporary non-editable XML file is automatically generated when the DB is loaded and this XML file is used as the Working XML File.

Note: The output files generated from the SPS can be separately generated and saved using the File | Save Generated Files command.
2.2 Sidebars

The Sidebars (also called sidebar windows or windows) are GUI components that help you design the SPS and provide you with information related to the active view. Each sidebar (listed below) is described in a subsection of this section.

- Design Overview
- Schema Tree
- Design Tree
- Style Repository
- Styles
- Properties
- Project
- Messages
- Find and Replace

Layout of the views

The layout of a view refers to what sidebars are available in that view and how these sidebars are positioned within the GUI. Layouts can be customized for separate view categories, and the customization consists of two parts: (i) switching on or off the display of individual sidebars in a view (via the View menu or by right-clicking the sidebar's title bar and selecting Hide); (ii) positioning the sidebar within the GUI as required. The layout defined in this way for a view category is retained for that particular view category till changed. So, for example, if in Design View, all the sidebars except the Styles sidebar are switched on, then this layout is retained for Design View over multiple view changes, till the Design View layout is changed. Note that the layout defined for any output preview (HTML, Text, and RTF Previews) applies to all output previews. The view categories are: (i) no document open; (ii) Design View; (iii) Output Views; and (iv) Authentic View.

Docking and floating the Sidebar windows

Sidebar windows can be docked in the StyleVision GUI or can be made to float on your screen. To dock a window, drag the window by its title bar and drop it on any one of the four inner or four outer arrowheads that appear when you start to drag. The inner arrowheads dock the dragged window relative to the window in which the inner arrowheads appear. The four outer arrowheads dock the dragged window at each of the four edges of the interface window. To make a window float, (i) double-click the title bar; or (ii) drag the title bar and drop it anywhere on the screen except on the arrowheads that appear when you start to drag.

Alternatively, you can also use the following mechanisms. To float a docked window, click the Menu button at the top-right of a docked window (see screenshot below) and select Floating. This menu can also be accessed by right-clicking the title bar of the docked window.
To dock a floating window, right-click the title bar of the floating window and select Docking from the menu that appears; the window will be docked in the position in which it was last docked.

Auto-Hiding Design sidebar windows
A docked window can be auto-hidden. When a sidebar window is auto-hidden, it is minimized to a tab at the edge of the GUI. In the screenshot below, five sidebars have been auto-hidden: two at the left edge of the GUI, two at the bottom edge, and one at the right edge.

Placing the cursor over the tab causes that window to roll out into the GUI and over the Main Window. In the screenshot below, placing the cursor over the Styles tab causes the Styles sidebar to roll out into the Main Window.
Moving the cursor out of the rolled-out window and from over its tab causes the window to roll back into the tab at the edge of the GUI.

The Auto-Hide feature is useful if you wish to move seldom-used sidebars out of the GUI while at the same time allowing you easy access to them should you need them. This enables you to create more screen space for the Main Window while still allowing easy access to Design sidebar windows.

To auto-hide a window, in a docked window, click the Auto Hide button (the drawing pin icon) at the top right of the window (screenshot below). Alternatively, in the Menu, select Auto Hide; (to display the Menu, right-click the title bar of the window or click the Menu button in the title bar of the docked window).

The window will be auto-hidden.

To switch the Auto-Hide feature for a particular window off, place the cursor over the tab so that the window rolls out, and then click the Auto Hide button (screenshot below). Alternatively, in the Menu, deselect Auto Hide; (to display the Menu, right-click the title bar of the window or click the Menu button in the title bar of the window).
Note: When the Auto-Hide feature of a sidebar window is off, the drawing pin icon of that window points downwards; when the feature is on, the drawing pin icon points left.

Hiding (closing) sidebar windows

When a sidebar window is hidden it is no longer visible in the GUI, in either its maximized form (docked or floating) or in its minimized form (as a tab at an edge of the GUI, which is done using the Auto-Hide feature).

To hide a window, click the Close button at the top right of a docked or floating window. Alternatively, in the Menu select Hide; (to display the Menu, right-click the title bar of the window or click the Menu button in the title bar of the window).

To make a hidden (or closed) window visible again, select the name of the Design sidebar in the View menu. The Design sidebar window is made visible in the position at which it was (docked or floating) when it was hidden.

2.2.1 Design Overview

The Design Overview sidebar (screenshot below) enables you to add schema sources, global parameters, SPS modules, and CSS files to the active SPS. It gives you an overview of these components and enables you to manage them conveniently in one location.

Adding schema sources

Schema sources may be added to an empty SPS. A schema source is added by clicking the command Add New Source under the Sources heading. This pops up a menu (screenshot below) that enables you to add: (i)
an XML Schema or DTD or an XML Schema that is automatically generated by StyleVision from an XML file; (ii) a schema generated by StyleVision from a DB; or (iii) a user-defined schema.

The Working XML File and Template XML File
When a schema is added, it is listed under the Sources item. Each schema has two sub-items:

- The Working XML File
- The Template XML File

Adding modules, CSS files, parameters, and XSLT files
Click the respective Add New commands at the bottom of the Modules, CSS Files, Parameters and XSLT Files sections to add a new item to the respective section.

Design Overview features
The following features are common to each section (Sources, Parameters, etc) in the Design Overview sidebar:

- Each section can be expanded or collapsed by clicking the triangular arrowhead to the left of the section name.
- Files in the Sources, Modules, and CSS Files sections are listed with only their file names. When you mouseover a file name, the full file path is displayed in a popup.
- Items that are listed in gray are present in an imported module, not in the SPS file currently active in the GUI.
- Each section also has a Add New Item command at the bottom of the section, which enables you to add a new item to that section. For example, clicking the Add New Parameter command adds a new parameter to the SPS and to the Parameters list in the Design Overview.
- Each item in a section has a context menu which can be accessed either by right-clicking that item or clicking its Context Menu icon (the downward-pointing arrow to the right of the item).
- The Remove icon in the context menu removes the selected item. This command is also available in context menus if the command is applicable.
- The context menu command Edit File in XMLSpy opens the selected file in the Altova application XMLSpy.
- The context menu commands, Move Up and Move Down, are applicable only when one of multiple modules in the Modules section is selected. Each button moves the selected module, respectively, up or down relative to the immediately adjacent module.

Sources
The Sources section lists the schema that the SPS is based on and the Working XML File and Template XML File assigned to the SPS. You can change each of these file selections by accessing its context menu (by right-clicking or clicking the Context Menu icon), and then selecting the appropriate Assign... option.
Modules
The Modules section lists the SPS modules used by the active SPS. New modules are appended to the list by clicking the Add New Module command and browsing for the required SPS file. Since the order in which the modules are listed is significant, if more than one module is listed, the Move Up / Move Down command/s (in the context menu of a module) can be used to change the order. The context menu also provides a command for opening the selected module in StyleVision.

Note: The Design Overview sidebar provides an overview of the modules, enabling you to manage modules at the file level. The various module objects (objects inside the modules), however, are listed in the Design Tree sidebar.

CSS Files
The CSS Files section lists the CSS files used by the active SPS. New CSS files are appended to the list by clicking the Add New CSS File command and browsing for the required CSS file. Since the order in which the CSS files are listed is significant, if more than one CSS file is listed, the Move Up / Move Down command/s (in the context menu) become active when a CSS file is selected. The selected CSS file can be moved up or down by clicking the required command. The context menu also provides a command for opening the selected module in XSLSpy.

Note: The Design Overview sidebar provides an overview of the CSS files, enabling you to manage CSS files at the file level. The various CSS rules inside the CSS files, however, are listed in the Style Repository sidebar.

Parameters
The Parameters section lists the global parameters in the SPS. You can add new parameters using the Add New Parameter command at the bottom of the section. Double-clicking the parameter name or value enables you to edit the name or value, respectively. To remove a parameter, select the parameter and then click the Remove command in the context menu.

XSLT Files
The XSLT Files section lists the XSLT files that have been imported into the SPS. XSLT templates in these XSLT files will be available to the stylesheet as global templates. For a complete description of how this works, see XSLT Templates.

2.2.2 Schema Tree
The Schema Tree sidebar (screenshot below) enables you to do the following:

- Select multiple root elements (document elements) for a schema.
- Drag nodes (elements, attributes, global types) from a schema tree and drop them into the design. These nodes represent the XML content that is to be included in the output.
- View listings of all global elements and types in the schema source. Enables a global element or global type to be created as a global template.
- View a listing of all namespaces used in the SPS.
- Insert and edit Design Fragments.
• Insert and and edit user-defined XPath functions for the SPS.

Root elements

For each schema, under the $XML heading, the selected Root elements (or document elements) are listed. This list consists of all the root elements you select for the schema (see below for how to do this). Each root element can be expanded to show its content model tree. It is from the nodes in these root element trees that the content of the main template is created. Note that the entry point of the main template is the document node of the main schema, which you can select or change at any time (see below for how to do this).

To select the root elements for a schema, do the following: Click the Select button at the right of the Root Elements item. This pops up the Select Root Elements dialog (screenshot below), in which you can select which of the global elements in the schema is/are to be the root elements. See SPS Structure | Schema Sources for an explanation of the possibilities offered by a selection of multiple root elements.
Additionally, all the global elements in the schema are listed under the All Global Elements item. For each global element, a global template can be created.

**Global elements and global types**

Global elements and global types can be used to create global templates which can be re-used in other templates. Additionally, global types can also be used directly in templates.

**Design Fragments**

All the Design Fragments in the document are listed under this item and can be viewed when the Design Fragments item is expanded. The following Design Fragment functionality is available:

- Creating a Design Fragment by clicking the Add icon of the Design Fragments item.
- Double-clicking the name of a Design Fragment in the Schema Tree enables the name of that Design Fragment to be edited.
- A Design Fragment can be enabled or disabled by, respectively, checking or unchecking the check box next to the Design Fragment.
- A Design Fragment can be dragged from the schema tree into the design.

See the section Design Fragments for information about working with Design Fragments.

**User-defined XPath Functions**

A user-defined XPath function can be added by clicking the Add icon of the XPath Functions item. After an XPath function has been created, it is listed in the Schema Tree. Double-clicking an XPath function opens the function in its dialog for editing. The following XPath functionality is available:

- An XPath function can be enabled or disabled by, respectively, checking or unchecking the check box next to the XPath Functions item.
- Right-clicking an XPath function also opens a context menu which contains commands to rename and remove an XPath function.

See the section, User-Defined XPath Functions, for detailed information about working with XPath functions.

Namespaces
The namespaces used in the SPS are listed under the Namespaces heading together with their prefixes. The namespaces in this list come from two sources: (i) namespaces defined in the referenced schema or schemas (see note below); and (ii) namespaces that are added to every newly created SPS by default. Referring to such a list can be very useful when writing XPath expressions. Additionally, you can set an XPath default namespace for the entire SPS by double-clicking the value field of the xpath-default-ns entry and then entering the namespace.

Note: If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Toolbar and schema tree icons
The following toolbar icons are shortcuts for common Schema Tree sidebar commands.

In a user-defined schema, adds a child element to the document element or appends a sibling element to the selected element. More commands for building a user-defined schema are available by clicking the dropdown arrow of the icon.

Make/Remove Global Template, enabled when a global element or global type is selected.

Remove the selected item.

Synchronize tree toggle. When toggled on (icon has border), selecting a node in the tree selects (i) the corresponding node in the design, and (ii) the corresponding node in the Design Tree if the Synchronize Tree icon in the Design Tree window is toggled on. When toggled off, the corresponding node in the design is not selected. Switch the toggle off if dragging a node from the tree and dropping it to the desired location in the design proves difficult.

Auto-collapses other items in the schema tree when the Synchronize Tree toggle is turned on and an item is selected in the design. Note that this toggle is enabled only when the Synchronize Tree toggle is turned on.

Symbols used in schema trees
Given below is a list of the symbols in schema trees.

Element.

Attribute.

Element with child elements. Double-clicking the element or the +/- symbol to its left causes the element to expand/collapse.
DB Filter applied. Applies only to top-level data table elements in the schema tree.

Global types can be either complex or simple. Complex types are indicated with a cyan icon, simple types with a brown icon.

2.2.3 Design Tree

The Design Tree sidebar (screenshot below) provides an overview of the SPS design.

At the root of the Design Tree is the name of the SPS file; the location of the file is displayed in a pop-up when you mouseover. The next level of the Design Tree is organized into the following categories:

- **Scripts**, which shows all the JavaScript functions that have been defined for the SPS using the JavaScript Editor of StyleVision.
- **Main Template**, which displays a detailed structure of the main template.
- **Global Templates**, which lists the global templates in the current SPS, as well as the global templates in all included SPS modules.
- **Design Fragments**, which shows all the Design Fragments in the design, and enables you to create, edit, rename, and delete them.
- **XSLT Templates**, which provides the capability to view XSLT templates in imported XSLT files.
- **User-Defined XPath Functions**, which enables you to create, edit, rename, and remove your own XPath functions.

**Toolbar icons**

The following toolbar icons are shortcuts for common Design Tree sidebar commands.

- Adds a Design Fragment, main template, or layout item to the design. Clicking the left-hand part of the icon adds a Design Fragment. Clicking the dropdown arrow drops down a list with commands to add a Design Fragment or any of various layout items.
Remove the selected item; icon is active when item in the Global Templates or Layout sub-trees is selected.

Synchronize tree toggle. When toggled on (icon has border), selecting a node in the tree selects (i) the corresponding node in the design, and (ii) the corresponding node in the schema tree if the Synchronize Tree icon in the schema tree is toggled on. When toggled off, the corresponding nodes in the design and schema tree are not selected.

Auto-collapses other items in the design tree when the Synchronize Tree toggle is turned on and an item is selected in the design. Note that this toggle is enabled only when the Synchronize Tree toggle is turned on.

Modifying the Design Tree display
The display of the Design Tree can be modified via the context menu (screenshot below), which pops up on right-clicking an item in the Design Tree.

<table>
<thead>
<tr>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove</td>
</tr>
<tr>
<td>Make Design Fragment</td>
</tr>
<tr>
<td>Expand All</td>
</tr>
</tbody>
</table>

The **Remove** command removes the selected Design Tree item from the Design Tree. **Make Design Fragment** creates a Design Fragment in the design and adds an item for it in the Design Tree. **Expand All** expands all the items of the Design Tree.

Scripts and Main Template
The Scripts listing displays all the scripts in the Design, including those in imported modules. The Main Template listing displays a tree of the main template. Items in the tree and the design can be removed by right-clicking the item and selecting **Remove**.

Global Templates
The **Global Templates** item lists all global templates in the current SPS and in all added SPS modules. Global templates defined in the current SPS are displayed in black, while global templates that have been defined in added modules are displayed in gray (see screenshot below). Each global template has a check box to its left, which enables you to activate or deactivate it. When a global template is deactivated, it is removed from the design.
A global template in the current SPS (not one in an added module) can be removed by selecting it and clicking the **Remove** button in the toolbar or the **Remove** command in the context menu. The component is removed from the design and the tree.

---

**Design Fragments**

The **Design Fragments** item lists all the Design Fragments in the current SPS and in all added SPS modules. Design Fragments defined in the current SPS are displayed in black, while Design Fragments that have been defined in added modules are displayed in gray (*see screenshot below*). Each Design Fragment has a check box to its left, which enables you to activate or deactivate it. A Design Fragment in the current SPS (not one in an added module) can be removed by selecting it and clicking the **Remove** command in the context menu. The component is removed from the design and the tree.

---

A Design Fragment can be added by clicking the Add icon ‡ to the right of the Design Fragments item. Each Design Fragment is designed as a tree with expandable/collapsible nodes. Any component in a Design Fragment tree (that is defined in the current SPS) can be removed by selecting it and clicking the **Remove** button in the toolbar or the **Remove** command in the context menu. The component is removed from the design and the tree.
XSLT Templates

In the Design Tree sidebar (screenshot below), the XSLT Templates contained in the imported XSLT file are displayed under the XSLT Templates heading.

![Design Tree Screenshot]

There are two types of imported XSLT templates: (i) match templates (indicated by Match), and (ii) named templates (indicated by Name). In the Design Tree, these two types are listed with (i) the value of the select attribute of match templates, and (ii) by the value of the name attribute of named templates, respectively. For a complete description of how XSLT Templates work, see XSLT Templates.

2.2.4 Style Repository

In the Style Repository sidebar (screenshot below), you can assign external CSS stylesheets and define global CSS styles for the SPS. Style rules in external CSS stylesheets and globally defined CSS styles are applied to Authentic View and the HTML output document.
The Style Repository sidebar contains two listings, **External** and **Global**, each in the form of a tree. The External listing contains a list of external CSS stylesheets associated with the SPS. The Global listing contains a list of all the global styles associated with the SPS.

The structure of the listings in the Style Repository is as follows:

**External**
- CSS-1.css (Location given in popup that appears on mouseover)
- Media (can be defined in Style Repository window)
- Rules (non-editable; must be edited in CSS file)
  - Selector-1
    - Property-1
    - ...
    - Property-N
  - ...
  - Selector-N
  + ...
  + CSS-N.css

**Global**
- Selector-1
  + Selector-1 Properties
  - ...
  + Selector-N

**Precedence of style rules**

If a global style rule and a style rule in an external CSS stylesheet have selectors that identify the same document component, then the global style rule has precedence over that in the external stylesheet, and will be applied. If two or more global style rules select the same document component, then the rule that is listed last from among these rules will be applied. Likewise, if two or more style rules in the external stylesheets select the same document component, then the last of these rules in the last of the containing stylesheets will be applied.
Managing styles in the Style Repository

In the Style Repository sidebar you can do the following, using either the icons in the toolbar and/or items in the context menu:

*Add:* The Add icon adds a new external stylesheet entry to the External tree or a new global style entry to the Global tree, respectively, according to whether the External or Global tree was selected. The new entry is appended to the list of already existing entries in the tree. The Add command is also available in the context menu. For more details about using external stylesheets and global styles, see Working with CSS Styles. Note that an external CSS stylesheet can also be added or a stylesheet removed via the Design Overview sidebar.

*Insert:* The Insert icon inserts a new external stylesheet entry above the selected external stylesheet (in the External tree) or a new global style entry above the selected global style (in the Global tree). The Insert command is also available in the context menu. For more details about using external stylesheets and global styles, see Working with CSS Styles.

*Move Up/Down:* The Move Up icon and Move Down icon move the selected external stylesheet or global style respectively up and down relative to the other entries in its tree. These commands are useful for changing the priority of external stylesheets relative to each other and of global style rules relative to each other. The Move Up and Move Down commands are also available in the context menu. For more details about how to change the precedence of styles, see Working with CSS Styles.

*Views of a selector’s styles:* Any selector, whether in an external stylesheet or defined globally, can be displayed in a view obtained by using three view settings. These settings are: List Non-Empty, Expand All, and Collapse All, and they are available as toolbar buttons and context menu commands: Toggling the List Non-Empty setting on causes only those style properties to be listed that have a value defined for them. Otherwise all available style properties are displayed (which could make the view very cluttered). The Expand All and Collapse All settings combine with the List Non-Empty setting, and respectively expand and collapse all the style definitions of the selected selector. These commands are also available in the context menu.

*Toggle Important:* Clicking the Toggle Important icon sets the CSS value !important on or off for the selected CSS rule.

*Reload All:* The Reload All icon reloads all the external CSS stylesheets.

*Reset:* The Reset icon deletes the selected external stylesheet or global style.

Editing CSS styles in the Style Repository

The following editing mechanisms are provided in the Style Repository:

- You can add and remove a CSS Stylesheet, and you can specify the media to which each external CSS stylesheet applies. How to do this is explained in the section External CSS Stylesheets.
- Global styles can have their selectors and properties directly edited in the Style Repository window. How this is done is described in the section Defining CSS Styles Globally.
2.2.5 Styles

The Styles sidebar (screenshot below) enables CSS styles to be defined locally for SPS components selected in the Design View. This is as opposed to styles which are set globally in the Styles Repository sidebar.

The Styles sidebar is divided into two broad parts:

- The left-hand-side, Styles-For column, in which the selected component types are listed. You should note that when a selection is made in Design View, it could contain several components. The selected components are listed in the Styles-For column, organized by component type. One of these component types may be selected at a time for styling. If there is only one instance of the component type, then that one instance is selected for styling. If there are several instances of the component type, then all the selected instances can be styled together. The defined styles are applied locally to each instance. If you wish to style only one specific instance, then select that specific component instance in Design View and style it locally in the Styles sidebar. You can also select a component range by selecting the start-of-range and then the end-of-range component with the Shift-key pressed. For detailed information about the selection of component types, see Defining CSS Styles Locally.

- The right-hand-side, Style Definitions pane, in which CSS styles are defined for the component type/s selected in the Styles-For column. The Style Definitions pane can be displayed in three views (see below for description). For the details of how to set style definitions, see Setting CSS Style Values. The XPath icon toggles on and off the application of XPath expressions as the source of style values. If a style property is selected and if the XPath icon is toggled on, then an XPath expression can be entered for this property and the return value of the XPath expression is used as the value of that style property. In this way, the value of a node in an XML document can be returned at runtime as the value of a property. When the XPath icon is toggled off, a static value can be entered as the value of the property.

Settings for Definitions-View

The view of definitions can be changed to suit your editing needs. Three view-settings (listed below) are available as buttons in the toolbar and as commands in context menus.
- **List Non-Empty**: When this setting is toggled on, for the component type selected in the left-hand column, only those properties with values defined for them are displayed, in alphabetical order. Otherwise all properties are displayed. This setting is very useful if you wish to see what properties are defined for a particular component type. If you wish to define new properties for the selected component type, this setting must be toggled off so that you can access the required property.

- **Expand All**: For the component type selected in the left-hand column, all the properties displayed in the right-hand pane are expanded. This setting can be combined with the List Non-Empty setting.

- **Collapse All**: For the component type selected in the left-hand column of the window, all the properties displayed in the right-hand pane are collapsed. This setting can be combined with the List Non-Empty setting.

---

**Toggle Important and Reset toolbar icons**

Clicking the Toggle Important icon sets the CSS value `!important` on or off for the selected CSS rule. Clicking the Reset icon resets the value of the selected property.

### 2.2.6 Properties

The Properties sidebar (:screenshot below:) enables properties to be defined for SPS components selected in Design View.

The Properties sidebar is divided into two broad parts:
The **Properties-For column**, in which the selected component-types are listed. One of these component types may be selected at a time and properties assigned for it. (In the screenshot above, the template component is selected.) For detailed information about how components with properties are grouped, see the section **Components and their Property Groups** below.

The **Property Definitions pane**, in which component properties are defined for the component type selected in the Properties For column. The Property Definitions pane can be displayed in three views (see below). For the details of what properties are in each property group, see the section **Property Groups** below.

### Settings for Definitions-View

The view of definitions can be changed to suit your editing needs. Three view-settings (listed below) are available as buttons in the toolbar and as commands in context menus.

- **List Non-Empty**:
  When this setting is toggled on, for the component type selected in the left-hand column, only those properties with values defined for them are displayed, in alphabetical order. Otherwise all properties are displayed. This setting is very useful if you wish to see what properties are defined for a particular component type. If you wish to define new properties for the selected component type, this setting must be toggled off so that you can access the required property.

- **Expand All**:
  For the component type selected in the left-hand column, all the properties displayed in the right-hand pane are expanded. This setting can be combined with the **List Non-Empty** setting.

- **Collapse All**:
  For the component type selected in the left-hand column of the window, all the properties displayed in the right-hand pane are collapsed. This setting can be combined with the **List Non-Empty** setting.

### Reset toolbar icon

Clicking the Reset icon resets the value of the selected property to its default.

### Components and their property groups

The availability of property groups is context-sensitive. What property groups are available depends on what design component is selected. The table below lists SPS components and the property groups they have.

<table>
<thead>
<tr>
<th>Component</th>
<th>Property Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Template</td>
<td>Template; Authentic</td>
</tr>
<tr>
<td>Content</td>
<td>Content; Authentic; Common; Event</td>
</tr>
<tr>
<td>Text</td>
<td>Text; Common; Event</td>
</tr>
<tr>
<td>Auto-Calculation</td>
<td>AutoCalc; Authentic; Common; Event</td>
</tr>
<tr>
<td>Condition Branch</td>
<td>When</td>
</tr>
<tr>
<td>Data-Entry Device</td>
<td>Authentic; Common; [Data-Entry Device]; Event; HTML</td>
</tr>
</tbody>
</table>
The following points about component types should be noted:

- Template components are the main template, global templates, and all schema nodes in the design.
- Content components are the content and rest-of-contents placeholders. These represent the text content of a node or nodes from the XML document.
- A text component is a single string of static text. A single string extends between any two components other than text components, and includes whitespace, if any is present.
- Data-entry devices are input field, multiline input fields, combo boxes, check boxes, radio buttons and buttons; their properties cover the data-entry device as well as the contents of the data-entry device, if any.
- A table component refers to the table structure in the design. Note that it contains sub-components, which are considered components in their own right. The sub-components are: row, column, cell, header, and footer.
- A paragraph component is any predefined format.
The table below contains descriptions of each property group.

<table>
<thead>
<tr>
<th>Property Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AutoCalc</strong></td>
<td>These properties are enabled when an Auto-Calculation is selected. The Value Formatting property specifies the formatting of an Auto-Calculation that is a numeric or date datatype. The XPath property specifies the XPath expression that is used for the Auto-Calculation.</td>
</tr>
<tr>
<td><strong>Authentic</strong></td>
<td>These are SPS-specific properties that are available for templates, contents, AutoCalculations, data-entry devices, images, links, tables, and paragraphs. What properties within the group are available are component-specific. For more details, see Authentic Node Properties.</td>
</tr>
<tr>
<td><strong>Common</strong></td>
<td>The Common property group is available for all component types except the Template and AutoCalc component types. It contains the following properties that can be defined for the component: class (a class name), dir (the writing direction), id (a unique ID), lang (the language), and title (a name).</td>
</tr>
<tr>
<td><strong>Data-Entry Device</strong></td>
<td>Specifies the value range of combo boxes, check boxes, and radio buttons. Note that this property group does not apply to input fields and buttons.</td>
</tr>
<tr>
<td><strong>Event</strong></td>
<td>Contains properties that enable JavaScript functions to be defined for the following client-side HTML events: onclick, ondblclick, onkeydown, onkeypress, onkeyup, onmousedown, onmousemove, onmouseout, onmouseover, onmouseup.</td>
</tr>
<tr>
<td><strong>HTML</strong></td>
<td>Available for the following component types: data-entry devices, image, link, table, paragraphs. Note that there are different types of data-entry devices and paragraphs, and that tables have sub-components. These properties are HTML properties that can be set on the corresponding HTML elements (img, table, p, div, etc). The available properties therefore vary according to the component selected. Values for these properties can be selected using XPath expressions.</td>
</tr>
</tbody>
</table>

In addition, there are component-specific properties for images, links, paragraphs and other predefined formats, and condition branches. These properties are described in the respective sections.

**Setting property values**

Property values can be entered in one, two, or three ways, depending on the property:

- Entered directly in the Value column. To do this, select a property, double-click in its Value column, enter the value using the keyboard, and press Enter or click anywhere in the GUI.
- By selecting a value from the dropdown list of the combo box for that property. Click the down arrow of the combo box to drop down the list of property-value options.
- By using the Edit button at the right-hand side of the Value column for that property. Clicking the Edit button pops up a dialog relevant to that property.

For some properties, in the Common and HTML groups of properties, XPath expressions can be used to provide the values of the property. The XPath icon toggles on and off the application of XPath expressions.
as the source of property values. With a property selected, if the XPath icon is toggled on, then an XPath expression can be entered for this property and the return value of the XPath expression is used as the value of that property. In this way, the value of a node in an XML document can be returned, at runtime, as the value of a property. When the XPath icon is toggled off, a static value can be entered as the value of the property. Also see Style Properties Via XPath.

Modifying or deleting a property value

To modify a property value, use any of the applicable methods described in the previous paragraph, Setting Property Values. To delete a property value, select the property and click the Reset icon in the toolbar of the Properties sidebar.

2.2.7 Project

StyleVision projects are an efficient way of grouping, managing, and working with related files. Once collected in a project, files can be accessed easily from the Project sidebar when designing an SPS. For example, an SPS file can be dragged from the Project sidebar to the Design Tree sidebar and created there as a module; or an image file can be dropped into the design as a static image; or a CSS stylesheet can be dragged to the Style Repository sidebar as an external stylesheet.

A complete description of how to work with projects is given in the section Projects in StyleVision.

The Project sidebar (screenshot below) shows the currently active project. Commands in the Project menu apply to the currently active project. The currently active project can be changed by either creating a new project (Project | New Project) or by opening an existing project (Project | Open Project). These two commands are also available as the first and second buttons in the toolbar of the Project sidebar (see screenshot below). You can name a newly created project when you save it (Project | Save Project; third button in the toolbar of the Project sidebar).

The Add Files button in the toolbar (fourth button in the screenshot below) contains the commands shown in the screenshot below. These commands enable files and folders to be added to the active project and are described in the User Reference. A useful command is the Add Active and Related Files command, which
adds to the project all the files related to the currently active SPS. For example, with the tutorial file, QuickStart.sps active, clicking this command will add all related files as shown in the screenshot above.

![Project Dialog](image)

The **Project Properties** button (fifth button in the toolbar) pops up the Properties dialog of (i) the project; (ii) a folder; or (iii) a file, depending on which type of these three items is currently selected in the Project sidebar. If the project or a file is selected, the Properties dialog displays the location of the file. The Properties dialog of a folder allows you to edit the name of the folder and to specify the file extensions to associate with that folder; only files with the associated file extensions are displayed in that project folder. See [Projects in StyleVision](#) for details.

### 2.2.8 Messages

When StyleVision is opened for the first time, the Messages sidebar (*screenshot below*) is displayed below the Main Window of the GUI. To toggle the Messages sidebar on and off, click **View | Messages**.

![Messages](image)

The Messages sidebar displays warnings in Design View and Authentic View. In Design View, the warnings relate to various aspects related to the SPS document, from a missing Working XML File to errors in the design structure. In Authentic View, the warnings are about the validity of the XML data entered, whether valid according to the underlying schema or according to additional validation criteria.
2.2.9 Find and Replace

The Find and Replace sidebar enables you to search in design text, styles, properties, and XPath expressions for strings that you enter directly or construct with regular expressions. The searches apply to Design View. The searching mechanism is the same as that used in the Find dialog that is accessed via the menu command Edit | Find. The results of the search are displayed in the sidebar. You can click on a result to go to the corresponding location in the design. To toggle the Find and Replace sidebar on and off, click View | Find & Replace.

For more information about the Find mechanism, see its description in the topic Find, Find Next, Replace.

Finding
Enter the term you want to search for in the Find field. Then click the dropdown arrow of the Find button to select the search options. The following options are available:

- **Where to search:** (i) in the text of the design; (ii) in styles (entered via the Styles sidebar); (iii) in properties (entered via the Properties sidebar); in XPath expressions.
- **Case and/or whole-word matches:** These are toggle options.
- **Regular expressions:** Your entry will be treated as a regular expression. For a description of how to use regular expressions, see the topic Find, Find Next, Replace.

Results
The results are organized into groups for (i) Design text, (ii) Styles, (iii) Properties, and (iv) XPath expressions (see screenshot above). Each result item is structured to show the found item's hierarchy. You can click the found item or any of the links in its hierarchy to go to that item in Design View.

The results pane has a toolbar with icons for the following commands, from left: Go to next and previous items; copy items to the clipboard; find in the results pane; clear the results pane.

Replacing
The Replace button replaces all the found items with the string in the Replace field.
3 Quick Start Tutorial

The objective of this tutorial is to take you quickly through the key steps in creating an effective SPS. It starts with a section on creating and setting up the SPS, shows you how to insert content in the SPS, how to format the components of the SPS, and how to use two powerful SPS features: Auto-Calculations and conditions. Along the way you will get to know how to structure your output efficiently and how to use a variety of structural and presentation features.

Files required
Files related to this Quick Start tutorial are in the (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\QuickStart:

- QuickStart.xsd, the XML Schema file on which the SPS is based.
- QuickStart.xml, the Working XML File, which is the source of the data displayed in the output previews.
- QuickStart.sps, which is the finished SPS file; you can compare the SPS file you create with this file.
- QuickStart.css, which is the external CSS stylesheet used in the tutorial.
- NewsItems.BMP, an image file that is used in the SPS.

Doing the tutorial
It is best to start at the beginning of the tutorial and work your way through the sections. Also, you should open the XSD and XML files before starting the tutorial and take a look at their structure and contents. Keep the XSD and XML files open while doing the tutorial, so that you can refer to them. Save your SPS document with a name other than QuickStart.sps (say MyQuickStart.sps) so that you do not overwrite the supplied SPS file. And, of course, remember to save after successfully completing every part.
3.1 Creating and Setting Up a New SPS

In this section, you will learn:

- How to create a new SPS document
- How to add a schema source for the SPS
- How to select the XSLT version of the SPS
- How to assign the Working XML File
- How to specify the output encoding
- How to save the SPS document

Files in this section

Files referred to in this section are located in the (My) Documents folder, C:\Documents and Settings<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\QuickStart:

- QuickStart.xsd, the XML Schema file on which the SPS is based.
- QuickStart.xml, the Working XML File, which is the source of the data displayed in the output previews.
- QuickStart.sps, which is the finished SPS file; you can compare the SPS file you create with this file.

Creating a new SPS document

Create a new SPS document by clicking File | New | New (Empty) or select New (Empty) in the dropdown list of the New icon in the application toolbar. The Create New Design dialog pops up.

The Create New Design dialog (screenshot below) prompts you to select either: (i) a free-flowing document design, or (ii) a form-based document design (in which components are positioned absolutely, as in a layout program).
In a free-flowing document design, document content is laid out to fit the output media object or viewer (paper or screen). Items in the document content can only be placed relative to each other, and not absolutely. This kind of design is suited for documents such as reports, articles, and books.

In a form-based document, a single Layout Container is created, in which design components can be positioned absolutely. The dimensions of the Layout Container are user-defined, and Layout Boxes can be positioned absolutely within the Layout Container and document content can be placed within individual Layout Boxes. If you wish the design of your SPS to replicate a specific form-based design, you can use an image of the original form as a blueprint image. The blueprint image can then be included as the background image of the Layout Container. The blueprint image is used to help you design your form; it will not be included in the output.

You will be creating a free-flowing document, so select this option by clicking the Create a free-flow document radio button, then click OK.

A new document titled SPS1.sps is created and displayed in Design View (screenshot below).
Adding a schema source

For this SPS, you will use the schema, QuickStart.xsd. To add this schema as the schema source, do the following:

1. In the Design Overview sidebar, under the Sources heading, click the Add New Source command (screenshot above). In the menu that pops up (screenshot below), select Add XML Schema/DTD/XML.

2. In the Open dialog that pops up browse for the file QuickStart.xsd in the (My) Documents folder (see above), and click Open.
3. You will be prompted to select a Working XML File. Select the option to select the file from the filesystem, then browse for the file QuickStart.xml in the (My) Documents folder (see above), and click Open. The schema will be added as a schema source in the Design Overview sidebar and in the Schema Tree sidebar (screenshot below). Also, in the Design Overview, the Working XML File you chose will be assigned to the schema.
You should note the following points: (i) In Design Overview, the $XML entry for the schema source lists the schema and the Working XML File and Template XML File; (ii) In the Schema Tree sidebar, the Root Elements tree would list the one or more root elements (document elements) you select from among the global elements defined in the schema. In the case of this schema, the element presswatch is selected by default because it is the one global element in the schema that lies clearly at the top of the hierarchy defined in the schema; (iii) All global elements in the schema are listed in the All Global Elements tree.

Selecting the XSLT version

For this SPS you will use XSLT 2.0. To specify the XSLT version, in the application toolbar, click the icon.

Assigning or changing the Working XML File

While adding the XML Schema to the SPS in the previous step, you also assigned a Working XML File to the schema. A Working XML File provides the SPS with a source of XML data to process. To assign, change, or unassign a Working XML File for a given schema, in the Design Overview sidebar, right-click anywhere in the Working XML File line you wish to modify (or click the Context Menu icon at the right), and select the required command from the context menu that pops up. The Working XML File is now assigned, and the filename is entered in the Design Overview. Before proceeding, ensure that you have correctly assigned the file QuickStart.xml, which is in the (My) Documents folder, as the Working XML File.

Specifying the encoding of output

In the Default Encoding tab of the Options dialog (Tools | Options), set the HTML encoding to Unicode UTF-8 and RTF encoding to UTF-8.

Saving the SPS document

After you have set up the SPS as described above, save it as MyQuickStart.sps in the (My) Documents folder. Do this via the menu command File | Save Design or Ctrl+S. In the Save Design dialog that pops up, select the Save as SPS option, and enter the name of the SPS file to save.
3.2 Inserting Dynamic Content (from XML Source)

This section introduces mechanisms to insert data from nodes in the XML document. In it you will learn how to drag element and attribute nodes from the schema tree into the design and create these nodes as contents. When a node is created as contents, the data in it is output as a string which is the concatenation of the content of that element's child text nodes and the text nodes of all descendant elements.

Inserting element contents

In your SPS, do the following:

1. In the Schema Tree sidebar, expand the schema tree up to the children of the `newsitem` element (screenshot below).

   ![Schema Tree Screenshot]

2. Select the `headline` element (notice that the element's datatype is displayed in a pop-up when you mouseover; screenshot above). Drag the `headline` element into Design View, and, when the arrow cursor turns to an insertion point, drop it into the main template.

3. In the context menu that pops up, select Create Contents. The start and end tags of the `headline` element are inserted at the point where you dropped the `headline` element, and they contain the content placeholder. The `headline` tags are surrounded by the start and end tags of the ancestor elements of `headline` (screenshot below).

4. In the design put elements on different lines (by pressing Enter) as shown in the screenshot below.
Click the HTML tab to see a preview of the HTML output (screenshot below). The HTML preview shows the contents of the headline child elements of newsitem, each as a text string.

NanoNull Inc Launches Version 2.0 of NanoPower

NanoNull Inc Jumps 3% on Release of New NanoPower Version

NanoNull Shares Up 10% on Month Following New NanoPower Version

NanoDiamonds Project to Go Ahead

You should also check the preview of Authentic View and the RTF output.

**Note:** You can also create the contents of a node by using the following steps: (i) Click the the Insert Contents icon in the Insert Design Elements toolbar, (ii) Click the location in the design where you wish to insert the content, (iii) Select, from the Schema Selector tree that pops up, the node for which you wish to create contents.

**Inserting attribute contents**

When an element is inserted into the design as contents, the contents of its attributes are not automatically inserted. You must explicitly drag the attribute node into the design for the attribute's value to be output. In your SPS, now do the following:

1. Place the cursor after the end tag of the headline element and press **Enter**. This produces an empty line (screenshot below).
2. In the Schema Tree sidebar, expand the **dateline** element (screen shot below).

![Schema Tree](image)

Notice that the **dateline** element has two child elements, **date** and **place**, and that the **place** element has two attributes, **city** and **country**.

3. Drag the **dateline** element into the design and drop it at the beginning of the newly created empty line (screen shot below).
4. Switch to HTML Preview and look carefully at the output of dateline (screenshot below).

Notice that while the contents of the date children of dateline elements have been output, no contents have been output for the place children of dateline. This is because the place data is contained in the attributes of the place element (in the attributes city and country) and attribute contents are not output when the attribute's parent element is processed.

5. In Design View, go to the menu command Authentic | Auto-Add Date Picker, and toggle it off to deactivate the auto-addition of the date picker. (The icon will have no border when toggled off.) This step is required if the date picker is not to be inserted automatically when a node of type xs:date or xs:dateTime is inserted into the design (which you will do in the next step). Drag the date element from the Schema Tree sidebar and drop it (create it as contents) in between the start and end tags of the dateline element.

6. Select the city attribute of the dateline/place element (screenshot below) in the Schema Tree sidebar.
7. Drag the @city attribute node into Design View, and drop it (create as contents) just after the end tag of the date element.
8. Drag the @country attribute node into Design View, and drop it (create as contents) just after the end tag of the @city attribute.

When you are done, the SPS design should look something like this:

![Schema Tree Diagram]

The HTML Preview will look like this:
Quick Start Tutorial Inserting Dynamic Content (from XML Source)

NanoNull Inc Launches Version 2.0 of NanoPower
2006-04-01 Boston USA

NanoNull Inc Jumps 3% on Release of New NanoPower Version
2006-04-01 New York USA

NanoNull Shares Up 10% on Month Following New NanoPower Version
2006-04-25 New York USA

NanoDiamonds Project to Go Ahead
2006-05-06 London UK

Notice that the values of the @city and @country attributes are now included in the output.

Adding more dynamic content

The contents of elements and attributes from the XML data source can be inserted anywhere in the design using the method described above. To complete this section, add the synopsis and source elements to the design so that the design now looks like this:

Notice that the synopsis element has been placed before the source element, which is not the order in which the elements are in the schema. After you have added the synopsis and source elements to the design, check the HTML preview to see the output. This is an important point to note: That the order in which nodes...
are placed in the main template is the order in which they will appear in the output (see the section, Templates and Design Fragments, for more information about structuring the output document).

Another important point to note at this stage is the form in which a node is created in the design. In the HTML preview, you will see that all the nodes included in the design have been sent to the output as text strings. Alternatively to being output as a text string, a node can be output in some other form, for example, as a table or a combo box. In this section, you have, by creating all the nodes as (contents), specified that the output form of all nodes are text strings. In the section, Using Conditions, you will learn how to create a node as a combo box, and in the section, Using Global Templates and Rest-of-Contents, how to create a node as a (dynamic) table.

Make sure to save the file before moving to the next section.
3.3 Inserting Static Content

Static content is content you enter or insert directly in the design—as opposed to content that comes from the XML source. A variety of static components can be placed in an SPS design. In this part of the tutorial, you will learn how to insert the following static components:

- An image
- A horizontal line
- Text

Inserting a static image

The static image to insert is in the (My) Documents folder:

C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\QuickStart\NewsItems.BMP. It will be used as the header of the document. To insert this image at the head of the document, do the following:

1. Place the cursor between the start-tags of newsitems and newsitem (screenshot below).

Notice that the cursor is within the newsitems element but outside the newsitem element. It will therefore be inserted in the output once, at the start of processing of the newsitems element (because there is only one newsitems element defined in the schema).

2. Right-click, and select Insert | Image. The Insert Image dialog pops up (screenshot below).

3. In the Static tab, click the Absolute Path check box, then browse for the file NewsItems.BMP and select it.

4. Click OK to finish.

The HTML preview will look something like this:
Inserting horizontal lines

The first horizontal line you will insert is between the document header and document body. Do this as follows:

1. Place the cursor immediately after the recently inserted static image.
2. Right-click, and select **Insert | Horizontal Line**. A horizontal line is inserted.

Set properties for the line as follows:

1. With the line selected in **Design View**, in the **Properties sidebar**, select the **line** component (in the Properties For column) and then the **HTML** group of properties.
2. Assign **color** and **size** properties for the line.
3. With the line selected in **Design View**, in the **Styles sidebar**, select the **line** component and then the **box** group of properties. Define a **margin-bottom** property of **12pt**.
4. Check the output in **HTML Preview**.

Now insert a horizontal line at the end of each news item. To do this the cursor would have to be placed immediately before the end-tag of the **newsitem** element. This will cause the line to be output at the end of each **newsitem** element. You can change the thickness of the line by setting the line's **size** property to a number with no unit (in the Properties sidebar, select **line**, and set a value of, say **3**).

Inserting static text

You have already added static text to your design. When you pressed the **Enter** key to obtain new lines (in the section **Inserting Dynamic Content (from XML Source)**), whitespace (static text) was added. In this section, you will add a few static text characters to your design.

The SPS you have designed up to this point will produce output which looks something like this:
Summary of News Items

NanoNull Inc Launches Version 2.0 of NanoPower
2006-04-01 Boston, USA
NanoNull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips, and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.
NewTech Online

Notice that in the output of the dateline element, the contents of the date element and place/@city and place/@country attributes are run together without spacing. You can add the spacing as static text. In the design, place the cursor after the date element and enter a colon and a space. Next, enter a comma and space after the @city attribute (screenshot below).

This part of the output will now look like this:

Summary of News Items

NanoNull Inc Launches Version 2.0 of NanoPower
2006-04-01: Boston, USA

Notice the colon, spacing and comma in the dateline output. All of these text items are static text items that were inserted directly in the design.

You will now add one more item of static text. In the design, type in the string "Source: " just before the start-tag of the source element (screenshot below).
Formatting static text

To format static text, highlight the text to be formatted and specify local style properties. In the design, highlight the text "Source:" that you just typed. In the Styles sidebar (screenshot below), notice that the text component is selected. Now expand the font group of properties as shown in the screenshot below, and, for the font-style property, select the italic option from the dropdown menu.

![Styles Sidebar](image)

The static text (that is, the string "Source:" ) will be give an italic style in the design, and will look like this:

```
Source: [source] (content) [source]
```

The output will look like this in HTML Preview:
Summary of News Items

NanoNull Inc Launches Version 2.0 of NanoPower
2006-04-01: Boston, USA
NanoNull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips; and higher precision sand-filtering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.
Source: NewTech Online

If you think there is too little vertical space between the source item and the horizontal line separating two newsitem elements, then, in the design, insert a blank line between the source and the horizontal line (by pressing Enter).

After you are done, save the file.

In this section you have learned how to insert static content and format it. In the next section you will learn more about how design components can be formatted using CSS principles and properties.
### 3.4 Formatting the Content

StyleVision offers a powerful and flexible styling mechanism, based on CSS, for formatting components in the design. The following are the key aspects of StyleVision's styling mechanism:

- CSS style rules can be defined for both block components and inline components.
- **Predefined formats** are block components that have inherent styles and can be used as wrappers for a group of components that need to be treated as a block. The inherent styles of these predefined formats can be overridden by styles you specify locally on each component. This is in keeping with the cascading principle of CSS.
- Class attributes can be declared on components in the design, and the class can be used as a selector of external or global style rules.
- You can specify styles at three levels. These are, in increasing order of priority: (i) style rules in external stylesheets, (ii) global style rules, and (iii) local style rules. Note, however, that certain types of selectors in external and global style rules, such as name-based selectors (h1, a, img, etc), will apply only to Authentic View and HTML output, not to RTF output. Rules that have class selectors will apply to HTML, RTF, PDF, and Word 2007+ formats.

In this section, you will learn how to:

- Assign predefined formats
- Assign a component a class attribute
- Define styles in an external CSS stylesheet and add this stylesheet to the style repository of the SPS
- Define global style rules
- Define local styles for a selection of multiple design components
- Define local styles for a single component

#### Assigning predefined formats

One reason to assign a predefined format is to give a component the inherent styling of that predefined format. In the design, select the headline element and then select **Enclose with | Special Paragraph | Heading 3 (h3)** (alternatively use the Predefined Formats combo box in the toolbar). The predefined format tags are created around the headline element (screenshot below).

![Screenshot of predefined format](image)

Notice that the font properties of the contents change and that vertical spacing is added above and below the predefined format. These property values are inherent in the h3 predefined format.

Another use of predefined formats is to group design components in a block so that they can be formatted as a block or assigned inline properties as a group. The most convenient predefined property for this purpose is the div predefined format, which creates a block without spacing above or below. In your design, assign the newsitem, dateline, synopsis, and source nodes separate div components. Your design should look something like the screenshot below. Note that the static text "Source: " is also included in the div component that contains the source element, and that the entire newsitem element is inside a div component.
You have now grouped components together in different div blocks. Later in this section, you will learn how to assign styles to such blocks of grouped components.

### Assigning components to class attributes

A style rule can be defined for a class of components. For example, all headers can be defined to have a set of common properties (for example, a particular font-family, font-weight, and color). To do this you must do two things: (i) assign the components that are to have the common properties to a single class; (ii) define the styling properties for that class.

In your design, select the h3 tag, and, in the Styles sidebar, select 1 paragraph (to select the predefined format), and the common group of properties. Expand the common group of properties, then double-click in the Value field of the class property and enter header.
This particular instance of the h3 format is now assigned to a class named header. When you define styling properties for the header class (styles from an external stylesheet or global SPS styles), these properties will be applied to all components in the SPS that have the header class.

Adding an external CSS stylesheet to the style repository
Style rules in an external CSS stylesheet can be applied to components in the SPS design. External stylesheets must, however, first be added to the style repository in order for rules in them to be applied to components. In the Style Repository sidebar (in Design View), do the following:

1. Select the External item.
2. Click the Add button in the toolbar of the Style Repository sidebar. This pops up the Open dialog.
3. Browse for the file C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\QuickStart\QuickStart.css, which is in the (My) Documents folder, and click Open.

The stylesheet is added to the style repository. It contains the following rules that are relevant at this stage:

```
.header {
    font-family: "Arial", sans-serif;
    font-weight: bold;
    color: red;
}

h3 {
    font-size: 12pt;
}
```

The style rules for the header class and h3 element are combined and produce the following HTML output for the headline element.

---

**NanoNull Inc Launches Version 2.0 of NanoPower**

2006-04-01: Boston, USA  
NanoNull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. The highlights of the new version of NanoPower are improved chip design capabilities in NanoSoft, the software used to design computer chips, and higher precision sandfiltering processes in NanoMeld, the hardware in which the transformation from sand to silicon chips is executed.  
Source: NewTech Online

---

Defining global style rules
Global style rules can be defined for the entire SPS using CSS selectors. The rules are defined directly in the Style Repository sidebar. Create a global style rule for the header class as follows:

1. With Design View active in the Style Repository sidebar, select the Global item.
2. Click the Add button in the toolbar. This creates an empty rule for the wildcard selector (*), which is highlighted.

3. Type in .header to replace the wildcard as the selector.

4. Expand the color group of properties, and select green from the dropdown list of the color property values (screenshot below).

![Style Repository](image)

Where the global style rule defines a property that is also defined in the external stylesheet (the color property), the property value in the global rule takes precedence. In the HTML preview, the contents of the headline will therefore be green. Other property definitions from the external stylesheet (not over-ridden by a property in a global style rule) are retained (in this case, font-family and font-weight).

---

**NanoNull Inc Launches Version 2.0 of NanoPower**

2006-04-01: Boston, USA

*Source: NewTech Online*
Defining local styles for multiple components at once

Local styles can be defined for multiple components at once. In your design, to specify that the entire text contents of a news item should have Arial as its font, click the div component surrounding the newsitem element and, in the Styles sidebar, in the Styles For column, select 1 paragraph. Then, in the font group of properties, assign Arial as the font-family. This property setting will be inherited by all five descendant predefined formats.

Now, in the design, select the three div components surrounding the dateline, synopsis, and source nodes (by keeping the Shift key pressed as you click each div component). In the Styles sidebar, select 3 paragraphs, then the font group of properties, and set a font-size of 10pt. (The h3 component was not selected because it already has the required font-size of 12pt.)

Finally, in the design, select the div component surrounding the dateline element. In the Styles For column of the Styles sidebar, select 1 paragraph. In the font group of properties, set font-weight to bold and font-style to italic. In the color group of properties, set color to gray. The output of the dateline will look like this:

2006-04-01: Boston, USA

Notice that the styling defined for the div component has been applied to the static text within the div component as well (that is, to the colon and the comma).

Defining local styles for a single component

A local style defined on a single component overrides all other styles defined at higher levels of the SPS for that component. In the design, select the headline element and assign it a color of navy (color property in the color group of style properties). The locally defined property (color:navy) overrides the global style for the .header class (color:green).

Select the div component surrounding the source element. In the Styles sidebar, with the 1 paragraph item in the Styles For column selected, set the color property (in the color group of style properties) to gray. In the font group of style properties, set font-weight to bold. These values are applied to the static text. Remember that in the last section the static text "Source: " was assigned a font-style value of italic. The new properties (font-weight:bold and color:gray) are additional to the font-style:italic property.

Now, in Design View, select the (content) placeholder of the source element. In the Styles For column, with 1 content selected, set the color property (in the color group of style properties) to black. In the font group of properties, set font-weight to normal. The new properties are set on the contents placeholder node of the source element and override the properties defined on the div component (see screenshot below).

Completing the formatting

To complete the formatting in this section, select the div component on the synopsis element and, in the Predefined Formats combo box in the toolbar, select p. This gives the block the inherent styles of HTML's p element. The HTML preview should now look something like this:
NanoNull Inc Launches Version 2.0 of NanoPower

2006-04-01: Boston, USA

NanoNull Inc today launched version 2.0 of its market-leading NanoPower line of hardware and software. After you are done, save the file.
3.5 Using Auto-Calculations

Auto-Calculations are a powerful mechanism for providing additional information from the available XML data. In this section you will add two pieces of information to the design: the total number of news items and the time period covered by the news items in the XML document. Neither piece of information is directly available in the XML document but has to be calculated or manipulated from the available data.

Counting the news item nodes
In the design, do the following:

1. Create space, as shown in the screenshot below, for a line of static text (on which the Auto-Calculation will also be placed). Use the Return key to add new lines and insert a horizontal line below the space you create (see screenshot).

2. Type in the static text "Total number of news items: " as shown in the screenshot above.
3. Apply local styling of your choice to the static text. Do this as described in the section Formatting the Content.
4. Place the cursor after the colon and select Insert | Auto-Calculation | Value. This pops up the Edit XPATH Expression dialog (screenshot below). (Alternatively, you can right-click and select the command in the context menu.)
5. In the schema tree, note that the context node is `newsitems`, which is highlighted. Now, in the Expression text box either type in the expression `count(newsitem)` or build the expression using the entry-helper panes below the Expression text box. (Double-click the `count` function (found in the Sequence group of functions) to enter it, then (in the expression in the text box) place the cursor within the parentheses of the function and double-click the `newsitem` node in the schema tree. You can see what the XPath expression returns by clicking the Evaluator button. The result of the evaluation will be in the Results pane (see screenshot below). For a detailed description of the Edit XPath Expression dialog, see the section **Edit XPath Expression**.
6. Click **OK** to finish. The Auto-Calculation is inserted in the design at the cursor location *(screenshot below)*. Format the Auto-Calculation using **local styles**.

![Screenshot of the Edit XPath Expression dialog]

**Summary of News Items**

*Total number of news items: =*(AutoCalc)*

Your HTML output will look like this:
Displaying the period covered by news items

The period covered by all the news items together can be obtained by getting the date of the earliest news item and the date of the latest news item. This can be achieved with XPath expressions like those given below. The first expression below outputs the contents of the date node. The second expression is a refinement, outputting just the month and year values in the date node. You can use either of these.

- `concat(min(//date), ' to ', max(//date)).`
- `concat(month-from-date(min(//date)), '/', year-from-date(min(//date)), ' to ', month-from-date(max(//date)), '/', year-from-date(max(//date)))`

In the design, insert the static text and Auto-Calculation as shown in the screenshot below. Apply whatever local styling you like.

<table>
<thead>
<tr>
<th>Total number of news items:</th>
<th>(AutoCalc)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Period covered by news items:</td>
<td>(AutoCalc)</td>
</tr>
</tbody>
</table>

The HTML preview will look something like this:

<table>
<thead>
<tr>
<th>Total number of news items: 4</th>
</tr>
</thead>
</table>

After you are done, save the file.
3.6 Using Conditions

If you look at QuickStart.xml, you will see that each newsitem element has a metainfo child element, which in turn can contain one or more relevance child elements. In the SPS design, you can create a combo box that has a dropdown list which you can populate with unique relevance element values. When the Authentic View user selects an item from the dropdown list in the combo box, that item can be passed as a value to a node in the XML document. A condition can test what the user selection is (by looking up that node) and provide appropriate processing (displays) for each user selection. In this section, you will create a conditional template that displays those news items that have a relevance element that matches the user selection.

We will proceed as follows:

1. Create a combo box in which the Authentic View user can select the byrelevance value. The values in the dropdown list of the combo box are obtained by using an XPath expression, which dynamically compiles a list of all unique relevance node values.
2. Insert a condition around the newsitem element. This condition selects all newsitem elements that have a relevance element with content matching the content of the byrelevance node. The content that is surrounded by a branch of a condition is known as a conditional template.
3. Within the conditional template, list each relevance node of that news item.
4. Highlight the relevance element (in the list of relevance elements) that matches the byrelevance element. This is done by creating a condition to select such relevance elements and then applying special formatting to this conditional template.
5. In the condition for the newsitem element, insert a branch that selects all news items.

Creating the combo box to select unique node values

In the XML document, the node that will contain the user selection is /presswatch/selection/byrelevance. This is the node you will create as the combo box. Do this as follows:

1. Insert the static text "Select by relevance: " at the head of the document and just below the second Auto-Calculation (screenshot below).

   Total number of news items: =AutoCalc
   Period covered by news items: =AutoCalc
   Select by relevance: |

2. Drag the byrelevance node from the Schema Tree sidebar (screenshot below), and drop it after the newly entered static text.
3. In the context menu that appears, select Create Combo Box. This pops up the dialog shown below.
4. In the Edit Combo Box dialog (*screenshot above*), select Use XPath Expression and then Use the Same XPath for XML Values and Visible Entries. In the XPath for XML Values and Visible Entries, enter the XPath expression: `distinct-values(//relevance)`. This expression selects unique values of all `relevance` elements in the XML document.

5. Click OK to finish. The combo box is inserted and the design will look something like this:

   ![Combo Box Inserted](image)

6. Switch to Authentic View (*screenshot below*). When you click the dropdown arrow of the combo box, notice that the list contains the unique values of all `relevance` nodes (*screenshot below*). Check this against the XML document. This is a dynamic listing that will be augmented each time a new `relevance` value is added to the XML document.

   ![Authentic View](image)

**Inserting a condition to display news items having the selected relevance**

The condition selects `newsitem` elements that have a `metainfo/relevance` element with a value that is the same as that selected by the user (and passed to the `/presswatch/selection/byrelevance` element). Insert the condition as follows:

1. Select the contents of the `newsitem` part of the design which is to be contained inside the condition (highlighted in the screenshot below).
2. Select the menu command (or context menu command) **Enclose with | Condition**. This pops up the **Edit XPath Expression dialog**.

3. Enter the expression `metainfo/relevance=/presswatch/selection/byrelevance`. This expression evaluates to true when the value of the `metainfo/relevance` descendant of the current `newsitem` is the same as the value of the `/presswatch/selection/byrelevance` element (the user selection).

4. Click **OK**. The condition is created around the contents of the `newsitem` element (**screenshot below**).

![Diagram](image.png)

Note that there is a single branch in this condition. News items for which the condition test evaluates to true are displayed, those for which the condition test does not evaluate to true are not displayed. The condition in this case, therefore, works as a filter. Later in this section, you will add a second branch to this condition.

**Inserting the relevance node as a list**

In order to display the `relevance` nodes of each `newsitem` element, insert them in the design as follows (see **screenshot below**):
1. Create some vertical space below the div component for the source element and within the end-tag of the conditional template.
2. Type in the static text "Relevance:" and create a predefined format of div around it (highlight the static text and insert the predefined format).
3. Drag the relevance element from the Root elements tree in the Schema Tree sidebar and drop it into the design below the static text Relevance:
4. Create it as a list. (In the context menu that pops up when you drop the node in the design, select Bullets and Numbering, and then select the desired list format.)
5. Apply text formatting to the contents of the list. When you are done, the design should look something like this:

Now, in Authentic View, check the results for different selections of relevance; use the combo box to change the selection.

Making the selected relevance element bold

Some news items have more than one relevance element. In such cases, the design would be improved if the relevance that matches the user-selection were visually highlighted while the others were not. You can do this in the following way:

1. Select the relevance element in the design.
2. Insert a condition, giving it an XPath expression of: ./presswatch/selection/byrelevance. This creates a condition with a single branch (screenshot below) that selects relevance elements that match the byrelevance element.
3. Select the contents placeholder and give it a local formatting (in the Styles sidebar) of bold (font group) and yellow background-color (color group).

4. Right-click the condition and, from the context menu, select Copy Branch.

5. In the Edit XPath Expression dialog that pops up, check the Otherwise check box (top right-hand side).

6. Click OK to finish. A new branch (Otherwise) is created (screenshot below). This condition branch selects all relevance elements that do not match the byrelevance element.

7. Notice that the contents of the Otherwise branch are a copy of the first branch; the contents placeholder is bold and has a yellow background. Remove this formatting (bold and background-color) from the contents placeholder.

You have put a condition with two branches (each with its conditional template) that carries out the following test on each relevance element: If the contents of relevance match those of /presswatch/selection/byrelevance, then the contents of relevance are displayed bold and with a yellow background. Otherwise (the second branch) they are displayed normal. Check this in Authentic View.

Modifying the combo box and inserting a second condition branch

In the combo box where the Authentic View user selects a byrelevance value, there is no dropdown list option for selecting all news items. To include this option do the following:

1. In Design View, select the combo box.
2. In the Properties sidebar, with combobox selected in the Properties For column, click the Edit button of the Combo box entry value property (in the combo box group of properties).
3. In the Edit Combo Box dialog that pops up, modify the XPath expression from distinct-values(/relevance) to distinct-values(/relevance), 'All'. This adds the string All to the sequence of items returned by the XPath expression.
4. Check the dropdown list of the combo box in Authentic View (screenshot below).
Now if the user selection is \texttt{All}, then this value (\texttt{All}) is passed to the node /presswatch/selection/byrelevance. The idea is that when the byrelevance node contains the value \texttt{All}, all news items should be displayed.

The condition that displays the news item template has a single branch with the expression \texttt{metainfo/relevance=/presswatch/selection/byrelevance}. Since no \texttt{metainfo/relevance} node has the value \texttt{All}, no news item will be displayed when \texttt{All} is the value of the byrelevance node. What you have to do is create a second branch for the condition, which will test for a value of \texttt{All}. By creating the news item template within this branch, you will be outputting the news item if the test is true. Do this as follows:

1. In Design View, select the news item condition.
2. Right-click the condition and, from the context menu, select \texttt{Copy Branch}.
3. In the \texttt{Edit XPath Expression} dialog that pops up, enter the expression: \texttt{/presswatch/selection/byrelevance='All'}.
4. Click \texttt{OK} to finish. A second branch is created.

The second branch has as its contents the same template as the first branch. What the second branch does is output the news item template if the user selection is \texttt{All}.

After you have completed this section, save the design.
3.7 Using Global Templates and Rest-of-Contents

Global templates are useful for specifying the processing of an element globally. This enables the rules of the global template (defined in one location) to be used at multiple locations in the stylesheet. A global template can be used in two ways:

- The rules of the global template can be copied to the local template.
- A local template (in the main template) can pass processing of that node to the global template. After the global template is executed, processing resumes in the main template. In this case, the global template is said to be invoked or used from the main template.

There are two mechanisms that are used to invoke a global template from the main template:

- A local template references a global template.
- A \texttt{(rest-of-contents)} instruction in the main template applies templates to the descendant elements of the current element (that is, to the rest-of-contents of the current element). If a global template exists for one of the descendant elements, the global template is applied for that element. Otherwise the built-in template for elements is applied. (The built-in template for elements processes child elements and outputs the text content of elements. As a result, the text content of all descendants elements will be output. Note that the values of attributes are not output.)

In this section, you will create a design for the team-members’ template using the rest-of-contents instruction and a global template for the \texttt{member}.

\textbf{Inserting the rest-of-contents instruction}

The broad structure of the schema is shown in the screenshot below.

The document element \texttt{presswatch} contains three children: (i) \texttt{selection}; (ii) \texttt{newsitems}; and (iii) \texttt{team}. The main template you have created this far processes the \texttt{/presswatch} element. Within the \texttt{presswatch} element,
only the `newsitems` element is processed. The `selection` and `team` elements are not processed within the `presswatch` element (although `selection` has been processed within the `newsitems` element). Inserting the rest-of-contents instruction within `presswatch` will therefore cause the `selection` and `team` elements to be processed.

Insert the rest-of-contents instruction in the design by placing the cursor between the end-tags of `newsitems` and `presswatch`, and selecting the menu command or context menu command Insert | Rest of Contents. The rest-of-contents placeholder is inserted (screenshot below).

If you look at the HTML preview, you will see a string of text (screenshot below):

```
AllAndrewBentinckabentinck@nanonull.comNadiaEdwardsnedwar
```

This string is the result of the application of the built-in templates to the `selection` and `team` elements. The built-in template for elements processes child elements. The built-in template for text nodes outputs the text in the text node. The combined effect of these two built-in templates is to output the text content of all the descendant nodes of the `selection` and `team` elements. The text `All` comes from `selection/byrelevance`, and is followed by the text output of `team/member` descendant nodes, first, last, email, in document order. Note that the `id` attribute of `member` is not output (because, as an attribute, it is not considered a child of `member`).

Creating a global template for `selection`

Since the content of `selection` is not required in the output, you should create an empty global template for `selection` so that its contents are not processed. Do this as follows:

1. In Design View, right-click `selection` in the All Global Elements tree in the Schema Tree sidebar. A global template for `selection` is created (screenshot below).

2. In the context menu that pops up, select Make / Remove Global Template. A global template for `selection` is created (screenshot below).

3. In the global template, click the contents placeholder and press the Delete key of your keyboard. The contents placeholder is deleted.

4. Check the HTML preview. The text `All` is no longer present in the line of text output by the built-in templates (screenshot below).

```
AndrewBentinckabentinck@nanonull.comNadiaEdwardsnedwar
```
Since the global template for selection is empty, the child elements of selection are not processed.

Creating a global template for team/member

The objective is to create a table to display details of the members of the press monitoring team. This table will be created in a global template for the team element. Do this as follows:

1. Create a global template for the element team (right-click team in the All Global Elements list of the Schema Tree sidebar and select Make / Remove Global Template).
2. In the All Global Elements list, expand the team element and drag its member child element into the global template of team (in the design).
3. In the context menu that pops up when you drop the element into the global template of team, select Create Table. This pops up the Create Dynamic Table dialog (screenshot below).

4. In the attributes/elements list deselect @id, department and telephone (see screenshot), and click OK. The dynamic table is created.
5. Place the cursor in a cell of the table body, and in the Properties sidebar, with table selected in the Properties For column, specify table properties as shown in the screenshot below.
6. Set additional properties as required in the Properties and Styles sidebars. For example, a background color can be set for the header row by placing the cursor in the header row, and with \texttt{trow} selected in the Styles For column of the Styles sidebar, specifying a value for the \texttt{background-color} property (\texttt{color} group). You can also edit the headers, which are strings of static text. Also, if the content placeholder of the \texttt{team} element is still present in the global template, delete it.

The HTML preview of the table will look something like this:

<table>
<thead>
<tr>
<th>First</th>
<th>Last</th>
<th>Email</th>
</tr>
</thead>
<tbody>
<tr>
<td>Andrew</td>
<td>Bentinck</td>
<td><a href="mailto:a.bentinck@nanonull.com">a.bentinck@nanonull.com</a></td>
</tr>
<tr>
<td>Nadia</td>
<td>Edwards</td>
<td><a href="mailto:n.edwards@nanonull.com">n.edwards@nanonull.com</a></td>
</tr>
<tr>
<td>John</td>
<td>Edwards</td>
<td><a href="mailto:j.edwards@nanonull.com">j.edwards@nanonull.com</a></td>
</tr>
<tr>
<td>Janet</td>
<td>Ashe</td>
<td><a href="mailto:j.ashe@nanonull.com">j.ashe@nanonull.com</a></td>
</tr>
</tbody>
</table>
### 3.8 That's It!

Congratulations for having successfully completed the tutorial. You have learned the most important aspects of creating an SPS:

- How to create the structure of the document (main template and global templates).
- How to insert dynamic and static content in the design, using a variety of dynamic and static SPS components.
- How to use CSS styles, in external stylesheets, in global style rules, and in local style rules.
- How to use Auto-Calculations to derive additional information from the available XML data.
- How to use conditions to filter the XML data and how to obtain different outputs depending on values in the XML data.
- How to use global templates and rest-of-contents.

For a more detailed description of these features, see the corresponding sections in the following four sections:

- SPS File: Content
- SPS File: Structure
- SPS File: Advanced Features
- SPS File: Presentation
- SPS File: Additional Functionality

These sections also contain descriptions of several other StyleVision features not encountered in the Quick Start tutorial.

### Using the SPS

After completing the SPS, you should also try out the two main uses of SPS:

- Editing XML documents in the Authentic View of XMLSpy or Authentic Desktop. (The Enterprise and Professional editions contain an Authentic View preview tab, which does not have a few features such as sidebars and Text State Icons.) These two products provide a full-feature Authentic View, in which you can try out the sidebars and context menu. To edit QuickStart.xml in Authentic View in XMLSpy or Authentic Desktop, associate the XML file with MyQuickStart.sps and switch to Authentic View.
- Generating XSLT stylesheets for transforming the XML file to HTML, Text output. The XSLT stylesheets can be generated using the File | Save Generated Files command or via the command line. Try generating XSLT stylesheets from MyQuickStart.sps and then using these stylesheets to transform QuickStart.xml.
4 Usage Overview

Objectives

SPS documents that you create in StyleVision can be used for two broad purposes:

- To control the display of XML source documents in Authentic View and to enable data to be entered in XML documents or DBs via the Authentic View interface.
- To generate XSLT stylesheets for HTML, Text, and RTF output.

In this way, the SPS can be used to enable XML document editing and to generate HTML, Text, and RTF output from the edited XML document. Additionally, the generated XSLT stylesheets can be used to transform other XML documents based on the same schema as the SPS.

Steps for creating an SPS

Given below is an outline of the steps involved in creating a new SPS.

1. Assign a schema to the newly created empty SPS. The schema may be: (i) a schema file (DTD or XML Schema); (ii) an XML Schema generated from a DB (Enterprise and Professional editions only); (iii) a schema based on an XBRL taxonomy (Enterprise edition only); (iv) a user-defined schema (created directly in StyleVision). This is done in the Design Overview sidebar. Alternatively, a new SPS can be created directly with a schema via the File | New command.

3. Select the required XSLT version. In order to generate Text output, the XSLT version must be XSLT 2.0 or XSLT 3.0.

4. Select the Internet Explorer Compatibility to match the installed Internet Explorer version.

5. The SPS document is designed in Design View using the various design components available to the designer. The design process consists of creating a document structure and defining presentation properties. If print output is required, then additional print formatting properties can be specified.

6. The Authentic View and outputs are tested. If modifications to the design are required, these are made and the SPS document is re-tested.

7. If XSLT files or output files are required, these are generated.

8. If required, assign a Template XML File. The Template XML File provides the starting data for a new XML document that can be edited in Authentic View using the SPS.

9. The SPS is deployed for use among multiple Authentic View users.
4.1 SPS and Sources

Creating a new SPS file
To create a new SPS document, select an option from under the File | New (Ctrl+N) command or click the New Design icon in the Standard toolbar. A new SPS document is created and is displayed in Design View. The new document is given a provisional name of SPSX.sps, where X is an integer corresponding to the position of that SPS document in the sequence of new documents created since the application was started.

After a new SPS document is created, the source files for the SPS must be assigned.

Assigning source files for the SPS
There are three types of source files that can be assigned to an SPS:

- **Schema sources**
- **Working XML File**
- **Template XML File**

These source file assignments are made in the Design Overview sidebar. How to make the assignments is described in the section, Design Overview. The significant points about each type of source file are given below.

Schema sources
A schema source file must be assigned to an SPS so that a structure for the design document can be created. Schema sources are assigned in the Design Overview sidebar. A schema may be an XML Schema file (.xsd file), an XML Schema generated from an XML file, an XML Schema generated from a DB file, a DTD, or a user-defined schema. For each schema, one optional Working XML File and one optional Template XML File can be assigned.

Note: If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Working XML File
An SPS can, optionally, have a Working XML File associated with it. The function of the Working XML File is to provide the XML data source for output previews in StyleVision, and it must therefore be valid according to the schema with which it is associated. The Working XML File is assigned in the Design Overview sidebar.

Template XML File
An SPS can have a Template XML File optionally associated with it. The function of the Template XML File is to provide the starting data of the new XML document that is created each time that SPS is opened in the Authentic View of a product other than StyleVision. The Template XML File must be valid according to the schema with which it is associated. It is assigned in the Design Overview sidebar.
4.2 Creating the Design

In the SPS design, you specify:

1. **What content** (from the XML document or DB) should go to the output; additionally content can be inserted directly in the SPS for inclusion in the output;
2. **How the output should be structured**; and
3. **What presentation (formatting) properties** are applied to the various parts of the output.

Content for output

The content for the output can come from:

1. The XML document or DB to which the SPS is applied. Content from the XML document is included in the SPS by dragging the required XML data node from the relevant schema tree in the Schema Tree sidebar and dropping this node at the desired place in the SPS.
2. An external XML document that is accessible to the application (that is, to StyleVision or an Authentic View product). By using the doc() function of XPath 2.0 in an Auto-Calculation, content from external XML document sources can be accessed. An XML document accessed via the doc() function in an XPath expression does not need to be referenced via the Schema Sources associations.
3. The SPS itself. Text and other content (such as images and tables) can be inserted directly in the SPS using the keyboard and other GUI features. Such input is independent of the XML document.
4. Manipulated dynamic (XML source) data, with the manipulations being achieved using XPath expressions. Manipulations are typically achieved with Auto-Calculations.
5. For the HTML output, JavaScript functions can be used to generate content.

Structure of output

In the SPS design, the structure of the output can be controlled by using either: (i) a procedural approach, in which the output structure is specified in an entry-level template (StyleVision's main template) and can be independent of the structure of the XML document; (ii) a declarative approach, in which template rules are declared for various nodes (StyleVision's global templates), thus generating an output that follows the structure of the XML document; or (iii) a combination of the procedural and declarative approaches. In Design View, you can use a mix of main template and global templates to obtain the desired structure for the output document. The use of Modular SPSs and Design Fragments provides additional flexibility in the way an SPS is structured.

Presentation (or formatting) of the output

In Design View, presentation properties are applied to design components using CSS styles. Styles can be defined locally on the component, for HTML selectors declared at the document level, and for HTML selectors declared in an external CSS stylesheet. Additionally, certain HTML elements can be applied to components using predefined formats. Specifying presentation properties is described in detail in the section, Presentation Procedures.
4.3 XSLT and XPath Versions

An SPS is essentially an XSLT stylesheet. For each SPS, you must set the XSLT version: 1.0, 2.0, or 3.0. You do this by clicking the appropriate toolbar icon: XSLT 1.0 or XSLT 2.0 or XSLT 3.0. The selection you make determines two things:

- Which of the three XSLT engines in StyleVision is used for transformations; StyleVision has separate XSLT 1.0, XSLT 2.0, and XSLT 3.0 engines.
- What XSLT functionality (1.0, 2.0, or 3.0) is displayed in the interface and allowed in the SPS. For example, XSLT 3.0 uses XPath 3.0, which is a much more powerful language than XPath 1.0 (which is used in XSLT 1.0) or XPath 2.0 (which is used in XSLT 2.0). Additionally, some SPS features, such as the table-of-contents feature, is available only with XSLT 2.0 and XSLT 3.0.

Note: In order to generate Text output, the XSLT version must be XSLT 2.0 or XSLT 3.0.

XSLT transformations

XSLT transformations in StyleVision are used: (i) to generate output views in the interface; and (ii) to generate and save output files (HTML, Text, and RTF) from within the interface and via StyleVision Server. The XSLT engine used for transformations (Altova XSLT 1.0, 2.0, or 3.0 Engines) corresponds to the XSLT version selected in the SPS.

XSLT functionality in GUI

The functionality appropriate for each XSLT version relates mostly to the use of the correct XPath version (XPath 1.0 for XSLT 1.0, XPath 2.0 for XSLT 2.0, XPath 3.0 for XSLT 3.0). XPath expressions are widely used in StyleVision—most commonly in features such as Auto-Calculations and Conditional Templates—and there are interface mechanisms that require, and help you build, XPath expressions. The functionality of the correct XPath version is automatically made available in the interface according to the XSLT version you select.
4.4 Internet Explorer Compatibility

Internet Explorer (IE) must be installed on the StyleVision machine to correctly display the SPS design (in Design View) and output previews (in Authentic View and HTML Preview). Given below are notes about the IE versions that are supported:

- Internet Explorer 5.5 or higher
- Internet Explorer 6.0 and higher has better XML support and is recommended.
- Internet Explorer 9 (IE9) or higher provides additional features, such as support for more image formats and for new CSS styles. If you plan to use these additional features in your design, you might want to consider using IE9.

IE9 feature-support in StyleVision

The following features of IE9 or higher are supported in StyleVision:

- Additional image formats supported: TIFF, JPEG XR, and SVG. (SVG documents must be in XML format and must be in the SVG namespace.) These image formats will be displayed in IE9, but not in older versions of IE. For a complete listing of images supported in the various outputs, see Image Types and Output.
- Support for new CSS styles (including CSS3 styles), which are listed below. Application of these styles is limited to Authentic View and HTML output.
  - `background-clip`
  - `background-origin`
  - `background-size`
  - `box-sizing`
  - `box-shadow`
  - `border-radius` (border-*radius)
  - `font-stretch`
  - `ruby-align`
  - `ruby-overhang`
  - `ruby-position`
  - `overflow-x`, `overflow-y`
  - `outline` (outline-color, outline-style, outline-width)
  - `text-align-last` (partial)
  - `text-overflow` (partial)

- Support for the new CSS length function `calc()`
- Support for the new CSS color functions `rgba()`, `hsl()` and `hsla()`
- Support for the new CSS length units `rem`, `vw`, `vm`, `vh` and `ch`
- HTML5 elements that are supported by IE9 can be inserted in the design as user-defined elements.

Design View and IE versions

You can set up Design View for a specific IE version by specifying, in the Properties dialog, the IE version with which you wish Design View to be compatible. This has the following effects:

- All CSS styles that can be rendered by the selected IE version will be automatically displayed in the Styles sidebars of StyleVision. (Note, however, that if IE9 is selected, then IE9 must be installed for the IE9-supported CSS styles to be available in the design interface.) For example, if IE9 is installed...
and IE9 is selected as the compatibility version, then the CSS3 styles supported in IE9 will be available in the design interface.

- HTML elements corresponding to the selected IE version can be entered as predefined formats or as user-defined elements. The HTML element will be rendered in Authentic View and HTML Preview according to how the installed IE version renders this element. For example, if IE9 is installed and IE9 selected as the compatibility version, then the supported HTML5 elements will be rendered in Authentic View and HTML Preview.

**Setting up Design View for a specific IE version**

To set up Design View for a specific IE version, select the menu command File | Properties and, in the Output tab, select the required IE (compatibility) version. See File | Properties for details.

**Compatibility of older SPS designs with IE9**

If you open an SPS design that has been created for an older IE version, and if the newer IE9 version or higher is installed on the StyleVision machine, then StyleVision will detect the newer version and ask in a dialog whether you wish to change the compatibility to IE9-compatibility. Changing to the new compatibility will provide additional Design View options as indicated above. The appearance of the document in Design View, Authentic View and HTML output will remain unchanged except for table columns, which are handled differently by IE9. If you change the IE compatibility to IE9-compatibility, then check whether the table columns are generated as required. If not, you can modify the properties of the table columns or switch, in the Properties dialog, the IE compatibility back to that of the previously selected IE version.
4.5 SPS and Authentic View

One of the core uses of the SPS you create with StyleVision is to control the input of data and the display of an XML document in Authentic View, which is a document view available in Altova products. With Authentic View, users who are unfamiliar with XML can easily enter and edit XML document content correctly.

A document creation and editing process that involves Authentic View consists of two separate stages:

- **Document design.** The Authentic View of the XML document, which is graphical view, is designed in StyleVision. The design document is an SPS. The SPS not only processes the XML document for display in Authentic View and for final output; it also provides mechanisms, in Authentic View, for inputting data into the XML file or DB.

- **Content editing.** This SPS created in the document design stage is linked to the XML document to be edited. (The XML document must be valid according to the schema on which the SPS is based.) An XML document which is linked to an SPS is presented graphically in the Authentic View of an Altova product as the Authentic View of that XML document. When a new Authentic XML document is created, it can be assigned an SPS and then be edited in Authentic View using the document template (Template XML File) and controls specified in the SPS. If an existing XML document is opened and assigned an SPS, the existing data is displayed in Authentic View according to the design in the SPS, and the document can be edited in Authentic View.

The user of Authentic View is not expected to be knowledgeable about either XML or the schema being used for the document. The document display in Authentic View should make content editing as easy and non-technical as possible. It is, therefore, the task of the person who designs the SPS to produce a user-friendly Authentic View display. For detailed information about using Authentic View, see the Authentic View documentation in the user manual of XMLSpy or Authentic Desktop.
SPSs for standard industry schemas

Altova’s Authentic View package includes SPSs for a number of standard industry schemas. Users can therefore immediately create an XML document based on a standard schema in Authentic View. The screenshot below shows a partial Authentic View of the NCA Invoice standard.

You can easily customize any of the supplied standard industry SPSs, which are available in the Examples/IndustryStandards folder of your application folder.
4.6 Synchronizing StyleVision and Authentic

Each new release of StyleVision contains features that add to the power and capability of Authentic View. However, the following must be taken into account:

- An SPS file created with a later version of StyleVision might be incompatible with an older version of Authentic View.
- New SPS file functionality (created using a later version of StyleVision) will be interpretable only by a corresponding version (or later) of Authentic View.

So, if a later version of StyleVision is used to create an SPS file, all deployed Authentic View products must be synchronized with this version of StyleVision. This means, for example, that if StyleVision 2008 release 2 was used to create an SPS file, then Authentic Desktop 2008 release 2 (or another Authentic View product from this release) must be used to properly edit this SPS file.

Note that a later version of an Authentic View product will be able to interpret SPSs created with previous versions of StyleVision.

Synchronization steps when a deployed SPS file is modified using a later version of StyleVision

If an SPS is already deployed among multiple Authentic View users, and if, subsequently, new Authentic View functionality is added to the SPS using a later version of StyleVision, then the developer should go about the task of synchronization in the following sequence:

1. The developer obtains a license key for the new version of Authentic View for himself.
2. The developer successfully tests SPS modifications using the new StyleVision and Authentic View pair.
3. The new version of the Authentic View product is distributed to all Authentic View users.
4. Only after all three steps above have been successfully carried out, should the modified SPS be deployed to Authentic View users.
4.7 Generated Files

In StyleVision, XSLT stylesheets and output files can be generated using the File | Save Generated Files command or StyleVision Server. Alternatively, if you wish only to validate or transform XML using XSLT, you can do this directly with RaptorXML(+XBRL) Server.

The following files can be generated from StyleVision:

- XSLT stylesheets based on the SPS design. Separate XSLT stylesheets are generated for HTML, Text, and RTF output.
- Output files, generated by processing the Working XML File assigned in the SPS with the XSLT stylesheets generated from the SPS.

The markup for the output is contained in the SPS. The data for the output is contained in the XML document or DB. It is the XSLT stylesheet that brings markup and data together in the output. Both the XSLT stylesheets as well as the actual output can be previewed in StyleVision in the Output Views.

Note: If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Altova website: XML reporting

Output documents

Given below are important points to note about the generated documents:

- **HTML output and stylesheets**: (1) The formatting and layout of the generated HTML document will be identical to the HTML Preview of StyleVision and near-identical to the Authentic View of the XML document. (2) Data-input devices (text input fields, check boxes, etc) in the HTML file do not allow input. These data-input devices are intended for XML data input in Authentic View and, though they are translated unchanged into the graphical HTML equivalents, they cannot be used for data-entry in the HTML document.

Altova website: XML to HTML

- **RTF output and stylesheets**: (1) The RTF design requires specifications for paged media. You can provide these specifications (cover page design, left/right pagination, etc) in the Properties sidebar and the Design Tree sidebar. (2) If data-input devices have been used in the SPS, then, where possible, these are rendered as graphics on the RTF page. When a data-entry device cannot easily be simulated as a graphic (e.g. check boxes), a substitute presentation is used.

- **Text output and stylesheets**: Since the plain text format does not use formatting, style properties in the design are not passed to the text output.

RTF output

RTF output is generated from your XML file in a single step by processing the XML document with the XSLT-for-RTF file generated from the SPS. The properties of the RTF output are defined in the SPS, and you can preview the output in the RTF Preview window. To obtain the RTF file, you must generate it (using File | Save Generated Files or StyleVision Server).
**Note:** If there is a problem with an embedded preview, StyleVision will attempt to open the preview document in an external application (usually MS Word or Adobe Reader). An error message about the embedded preview will appear in StyleVision. If the preview document is opened in an external application, you will need to close the external application before regenerating the temporary output document, otherwise you will get an error message saying the file is being used by another process. You should also close the external application before closing the SPS design, otherwise StyleVision will not be able to close the temporary output document due to the file lock placed on the document by the external application.

**Text output**

Since Text output generates plain text, note the following points:

- Style and page layout properties that are defined in the design will not be applied to the Text output.
- In order to generate Text output, the XSLT version selected for the SPS must be XSLT 2.0 or XSLT 3.0.
4.8 Projects in StyleVision

Files that are related to each other can be collected in a project in the Project sidebar (screenshot below). This enables the files in a project to be accessed easily when designing an SPS. For example, an SPS file can be dragged from the Project sidebar to the Design Tree sidebar and created there as a module; or an image file can be dropped into the design as a static image; or a CSS stylesheet can be dragged to the Style Repository sidebar as an external stylesheet.

Creating and saving a project

A new project is created using the Project | Create Project command. When it is created, a project contains separate folders for separate types (see screenshot above). File types are assigned to a folder via the folder's Properties dialog. A project is named when it is saved (with the extension .svp) for the first time. To subsequently change the name of a project, you change the project file's name at its location, using an application such as Windows File Explorer.

Project folders

Folders can be added both to the main project folder as well as to folders within the main project folder and to sub-folders down to an unlimited number of levels. Three types of folders can be added: (i) a project folder; (ii) an external folder (which is added by browsing and selecting); (iii) an external web folder (which is added via a URL). Each of these three folder types is added to the main project folder using the following Project commands, respectively: (i) Add Project Folder to Project; (ii) Add External Project Folder to Project; (iii) Add External Web Folder to Project. To add each of these folder types to a folder or sub-folder within the main project, select the relevant command from the context menu for that folder or sub-folder.

Each folder can be assigned one or more file types in its Properties dialog (screenshot below). To pop up the Properties dialog, right-click the folder for its context menu, and select Properties.
In the Properties dialog, you can edit the folder name and the file type extensions for that folder (each file type extension must be separated by a semi-colon). Project folder names can also be edited by selecting the folder in the Project sidebar, pressing $F2$, and editing the name. When a folder has file type extensions defined for it, files with that extension, when added using the Add File to Project command, are added to the folder. If more than one folder has the same file type extension defined, the file is added to the first folder in the Project sidebar having that extension. In the Project sidebar, folders can be reordered using drag-and-drop. However, on the first level (that is at the level immediately below the main project folder), folders are ordered as follows: (i) project folders; (ii) external folders; (iii) external web folders.

Project files

Files can be added both to the main project folder as well as to folders and sub-folders within the main project folder. Files can be added using the following commands in the Project menu:

- **Add Files to Project**: One or more files are selected in a Browse window for addition. Each of the added files goes into the first folder for which its file type extension has been defined.
- **Add Global Resource to Project**: A file is added via a global resource.
- **Add URL to Project**: A file is added via its URL (which is defined in the Add URL to Project dialog).
- **Add Active File to Project**: The active (SPS) file is added to the first folder in the Project sidebar that has .sps defined as its file type extension.
- **Add Active and Related Files to Project**: The active (SPS) file plus related files, such as the schema/s, Working XML Files, CSS files, static image files, etc, are added to the project, in their respective folders as determined by the file type extensions of the folders. This is a very useful command for quickly gathering into a project all the files relevant to a given design.
- **Properties**: When any project file is selected, clicking the Properties icon in the Project Window toolbar or selecting the Properties command from the context menu pops up a window that displays the location of the file. XML files additionally enable you to select an SPS with which the file can be associated (see screenshot below).

When an SPS file is associated with an XML file that is in a project, double-clicking that XML file in the Project window will open the associated SPS file with the XML file assigned as the Working XML File.
of the SPS. This is useful if multiple XML files use a single SPS. This feature helps to speed up your work by cutting out the bother of browsing for the SPS file and/or Working XML File.

The commands listed above add files to the main project according to the file type extensions of the folders in the main project folder. To add files to specific folders or sub-folders, right-click the required folder, and in the context menu that pops up, select the corresponding command. Within a folder, files are listed in alphabetical order. Note files can also be dragged to another folder. To see the location of a file, click the Properties command in its context menu.

Global resources
A global resource of file- or folder-type can be added to a folder. A file-type global resource is an alias for a file resource. An alias can have multiple configurations with each configuration pointing to a file resource. So if a global resource is used in a project, it can link to any of the target resources, depending on which configuration is currently active in StyleVision. A folder-type global resource, similarly, is an alias that can target any one of multiple folders according to the configuration that is currently active. If a folder-type global resource is used in the design to identify a file (say, a Working XML File or CSS file), the folder-type global resource will identify a folder only; the path from that folder to the required file will need to be specified additionally. For more information on how to use global resources, see Using Global Resources.

Drag-and-drop
In the Project sidebar, a folder can be dragged to another folder or to another location within the same folder. A file can be dragged to another folder, but cannot be moved within the same folder (within which files are arranged alphabetically). Additionally, files and folders can be dragged from Windows File Explorer to the Project sidebar.

Using projects
Files in a project can be used in various ways depending on what kind of file it is. For each file in the Project sidebar, the actions available are listed in its context menu (right-click to display). Additionally, dragging the file to a location where an action can be executed pops up a menu that contains the relevant command/s; in the case of some commands, the command is executed directly the file is dropped at the relevant location. Given below is a list of available actions for various file types.

SPS Files

- **Open Design** opens the SPS in a new design window. (This command also becomes available when you drag an SPS file from the Project sidebar into Design View.)
- **Import as Module** imports the SPS as a module in the currently active SPS; the imported file will be listed under the Modules heading in the Design Tree. (You can also import the file as a module by dragging it to the Modules heading in the Design Overview sidebar.)

XML Files

- **Edit File in XMLSpy** opens the XML file in XMLSpy.
- **Create New Design** creates a new SPS. The schema for the SPS is an XML Schema generated from the XML document. The Working XML File of the SPS is the XML file. (You can also drag the file into the Main Template bar of Design View to use this command.)
- **Assign as Working XML File** assigns the XML File as the Working XML File of the SPS. (You can also drag the file to the Working XML entry of the Design Overview sidebar to add it as the Working XML File.)
• **Assign as Template XML File** assigns the XML File as the Template XML File of the SPS. (You can also drag the file to the Template XML entry of the Design Overview sidebar to add it as the Template XML File.)

  • **Note:** When an XML file is double-clicked, one of three actions will be executed according to what is specified in the Project tab of the Options dialog: (i) Edit file in XMLSpy; (ii) Create a new design based on the XML file; (iii) Ask the user which action to execute.

**XML Schema / DTD Files**

• **Edit File in XMLSpy** opens the schema file in XMLSpy.

• **Create New Design** creates a new SPS based on the selected schema. (You can also drag the file into the Main Template bar of Design View to create a new SPS with the selected schema as the schema source.)

• **Assign as Schema File** assigns the selected schema as the schema source of the currently active SPS, replacing the current schema source. This command is most useful for quickly changing schemas, for example, if the schema location has changed or to correct a wrong assignment. (To use this command, you can also drag the file to the Schema entry of the Design Overview sidebar.)

  • **Note:** When a schema file is double-clicked, one of three actions will be executed according to what is specified in the Project tab of the Options dialog: (i) Edit file in XMLSpy; (ii) Create a new design based on the schema file; (iii) Ask the user which action to execute.

**CSS Files**

• **Edit File in XMLSpy** opens the CSS file in XMLSpy.

• **Import into Style Repository** adds the CSS file to the External CSS files of the Style Repository (External heading in the Styles Repository sidebar). (You can also drag the file to the External heading in the Styles Repository sidebar to import the file into the style repository.)

**HTML Files**

• **Edit File in XMLSpy** opens the HTML file in XMLSpy.

• **Open** opens the HTML file in the default browser.

• **Create New Design** creates a new SPS, in which you can create the schema based on the HTML document. (You can also drag the file into Design View to use this command.)

**Image Files**

• **Open** opens the image file in the default image viewer / editing application.

• **Insert Image in Design** inserts the image as a static image in the SPS. (You can also insert the image at a particular location by dragging it there.)

**All file types**

• **Explore Containing Folder** opens a Windows File Explorer window displaying the contents of the folder in which the selected file is located.

• **Cut, Copy, Paste, Delete** commands work in the standard Windows way, cutting and copying the selected file to the clipboard; pasting files from the clipboard; and deleting. These commands also work for a selection of multiple files.

• **Select All** selects all the files in the project.

• **Properties** pops up the Properties dialog, in which the location of the file is given.
Find in project
You can search for project files and folders using their names or a part of their name. If the search is successful, files or folders that are located are highlighted one by one.

To start a search, select the project folder in the Project sidebar that you wish to search, then select the command Edit | Find (or the shortcut Ctrl+F). In the Find dialog that pops up (screenshot below) enter the text string you wish to search for and select or deselect the search options (explained below) according to your requirements.

The following search options are available:

- Whole-word matching is more restricted since the entire string must match an entire word in the file or folder name. In file names, the parts before and after the dot (without the dot) are also each treated as a word.
- It can be specified that casing in the search string must exactly match the text string in the file or folder name.
- Folder names can be included in the search. Otherwise, only file names are searched.
- External folders [Exclamation mark] can be included or excluded from the search. External folders are actual folders on the system or network, as opposed to project folders, which are created within the project and not on the system.

If the search is successful, the first matching item is highlighted in the Project sidebar. You can then browse through all the returned matching items by clicking the Find Next and Find Prev buttons in the Find dialog.
4.9  Catalogs in StyleVision

The XML catalog mechanism enables files to be retrieved from local folders, thus increasing the overall processing speed, as well as improving the portability of documents—since only the catalog file URIs then need to be changed. See the section How Catalogs Work for details.

Altova’s XML products use a catalog mechanism to quickly access and load commonly used files, such as DTDs and XML Schemas. This catalog mechanism can be customized and extended by the user, and it is described in the sections Catalog Structure in StyleVision and Customizing your Catalogs. The section Variables for Windows System Locations list Windows variables for common system locations. These variables can be used in catalog files to locate commonly used folders.

This section is organized into the following sub-sections:

- How Catalogs Work
- Catalog Structure in StyleVision
- Customizing your Catalogs
- Variables for Windows System Locations

For more information on catalogs, see the XML Catalogs specification.

4.9.1  How Catalogs Work

Catalogs can be used to redirect both DTDs and XML Schemas. While the concept behind the mechanisms of both cases is the same, the details are different and are explained below.

DTDs

Catalogs are commonly used to redirect a call to a DTD to a local URI. This is achieved by mapping, in the catalog file, public or system identifiers to the required local URI. So when the DOCTYPE declaration in an XML file is read, its public or system identifier locates the required local resource via the catalog file mapping.

For popular schemas, the PUBLIC identifier is usually pre-defined, thus requiring only that the URI in the catalog file map the PUBLIC identifier to the correct local copy. When the XML document is parsed, the PUBLIC identifier in it is read. If this identifier is found in a catalog file, then the corresponding URL in the catalog file will be looked up and the schema will be read from this location. So, for example, if the following SVG file is opened in StyleVision:

```xml
<?xml version="1.0" standalone="no"?>
<!DOCTYPE svg PUBLIC "-//W3C//DTD SVG 1.1//EN" "http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd">
<svg width="20" height="20" xml:space="preserve">
  <g style="fill:red; stroke:#000000">
    <rect x="0" y="0" width="15" height="15"/>
    <rect x="5" y="5" width="15" height="15"/>
  </g>
</svg>
```

© 2015-2021 Altova GmbH  Altova StyleVision 2022 Professional Edition
The catalog is searched for the PUBLIC identifier of this SVG file. Let’s say the catalog file contains the following entry:

```xml
<catalog>
  ...
  <public publicId="-//W3C//DTD SVG 1.1//EN" uri="schemas/svg/svg11.dtd"/>
  ...
</catalog>
```

In this case, there is a match for the PUBLIC identifier. As a result, the lookup for the SVG DTD is redirected to the URL `schemas/svg/svg11.dtd` (which is relative to the catalog file). This is a local file that will be used as the DTD for the SVG file. If there is no mapping for the Public ID in the catalog, then the URL in the XML document will be used (in the SVG file example above, this is the Internet URL: http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd).

**XML Schemas**

In StyleVision, you can also use catalogs with XML Schemas. In the XML instance file, the reference to the schema will occur in the `xsi:schemaLocation` attribute of the XML document’s top-level element. For example,

```xml
xsi:schemaLocation="http://www.xmlspy.com/schemas/orgchart OrgChart.xsd"
```

The value of the `xsi:schemaLocation` attribute has two parts: a namespace part (green above) and a URI part (highlighted). The namespace part is used in the catalog to map to the alternative resource. For example, the following catalog entry redirects the schema reference above to a schema at an alternative location.

```xml
<uri name="http://www.xmlspy.com/schemas/orgchart" uri="C:\MySchemas\OrgChart.xsd"/>
```

Normally, the URI part of the `xsi:schemaLocation` attribute’s value is a path to the actual schema location. However, if the schema is referenced via a catalog, the URI part need not point to an actual XML Schema but must exist so that the lexical validity of the `xsi:schemaLocation` attribute is maintained. A value of `foo`, for example, would be sufficient for the URI part of the attribute’s value to be valid.

### 4.9.2 Catalog Structure in StyleVision

When StyleVision starts, it loads a file called `RootCatalog.xml` (structure shown in listing below), which contains a list of catalog files that will be looked up. You can modify this file and enter as many catalog files to look up as you like, each of which is referenced in a `nextCatalog` element. These catalog files are looked up and the URIs in them are resolved according to their mappings.

**Listing of RootCatalog.xml**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog"
    xmlns:spy="http://www.altova.com/catalog_ext"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="urn:oasis:names:tc:entity:xmlns:xml:catalog Catalog.xsd">
  <nextCatalog catalog="%PersonalFolder%/Altova/%AppAndVersionName%/CustomCatalog.xml"/>
  <!-- Include all catalogs under common schemas folder on the first directory level -->
  <nextCatalog spy:recurseFrom="%CommonSchemasFolder%" catalog="catalog.xml" spy:depth="1"/>
</catalog>
```
The listing above references a custom catalog (named CustomCatalog.xml) and a set of catalogs that locate commonly used schemas (such as W3C XML Schemas and the SVG schema).

- **CustomCatalog.xml** is located in your Personal Folder (located via the variable %PersonalFolder%). It is a skeleton file in which you can create your own mappings. You can add mappings to CustomCatalog.xml for any schema you require that is not addressed by the catalog files in the Common Schemas Folder. Do this by using the supported elements of the OASIS catalog mechanism (see next section).
- The Common Schemas Folder (located via the variable %CommonSchemasFolder%) contains a set of commonly used schemas. Inside each of these schema folders is a catalog.xml file that maps public and/or system identifiers to URIs that point to locally saved copies of the respective schemas.
- **CoreCatalog.xml** is located in the StyleVision application folder, and is used to locate schemas and stylesheets used by StyleVision-specific processes, such as StyleVision Power Stylesheets which are stylesheets used to generate Altova's Authentic View of XML documents.

### Location variables

The variables that are used in RootCatalog.xml (listing above) have the following values:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%PersonalFolder%</td>
<td>Personal folder of the current user, for example C:\Users&lt;name&gt;\Documents</td>
</tr>
<tr>
<td>%CommonSchemasFolder%</td>
<td>C:\ProgramData\Altova\Common2022\Schemas</td>
</tr>
<tr>
<td>%ApplicationWritableDataFolder%</td>
<td>C:\ProgramData\Altova</td>
</tr>
</tbody>
</table>

### Location of catalog files and schemas

Note the locations of the various catalog files.

- RootCatalog.xml and CoreCatalog.xml are in the StyleVision application folder.
- CustomCatalog.xml is located in your MyDocuments\Altova\StyleVision folder.
- The catalog.xml files are each in a specific schema folder, these schema folders being inside the Common Schemas Folder.

### 4.9.3 Customizing Your Catalogs

When creating entries in CustomCatalog.xml (or any other catalog file that is to be read by StyleVision), use only the following elements of the OASIS catalog specification. Each of the elements below is listed with an explanation of their attribute values. For a more detailed explanation, see the [XML Catalogs specification](https://www.oasis-open.org/specsxml/catalogs). Note that each element can take the xml:base attribute, which is used to specify the base URI of that element.

- `<public publicId="PublicID of Resource" uri="URL of local file"/>
- `<system systemId="SystemID of Resource" uri="URL of local file"/>
- `<uri name="filename" uri="URL of file identified by filename"/>
• `<rewriteURI uriStartString="StartString of URI to rewrite" rewritePrefix="String to replace StartString"/>
• `<rewriteSystem systemIdStartString="StartString of SystemID" rewritePrefix="Replacement string to locate resource locally"/>

Note the following points:

• In cases where there is no public identifier, as with most stylesheets, the system identifier can be directly mapped to a URL via the `system` element.
• A URI can be mapped to another URI using the `uri` element.
• The `rewriteURI` and `rewriteSystem` elements enable the rewriting of the starting part of a URI or system identifier, respectively. This allows the start of a filepath to be replaced and consequently enables the targeting of another directory. For more information on these elements, see the XML Catalogs specification.

From release 2014 onwards, StyleVision adheres closely to the XML Catalogs specification (OASIS Standard V1.1, 7 October 2005) specification. This specification strictly separates external-identifier look-ups (those with a Public ID or System ID) from URI look-ups (URIs that are not Public IDs or System IDs). Namespace URIs must therefore be considered simply URIs—not Public IDs or System IDs—and must be used as URI look-ups rather than external-identifier look-ups. In StyleVision versions prior to version 2014, schema namespace URIs were translated through `<public>` mappings. From version 2014 onwards, `<uri>` mappings have to be used.

How StyleVision finds a referenced schema

A schema is referenced in an XML document via the `xsi:schemaLocation` attribute (shown below). The value of the `xsi:schemaLocation` attribute has two parts: a namespace part (green) and a URI part (highlighted).

`xsi:schemaLocation="http://www.xmlspy.com/schemas/orgchart OrgChart.xsd"

Given below are the steps, followed sequentially by StyleVision, to find a referenced schema. The schema is loaded at the first successful step.

1. Look up the catalog for the URI part of the `xsi:schemaLocation` value. If a mapping is found, including in `rewriteURI` mappings, use the resulting URI for schema loading.
2. Look up the catalog for the namespace part of the `xsi:schemaLocation` value. If a mapping is found, including in `rewriteURI` mappings, use the resulting URI for schema loading.
3. Use the URI part of the `xsi:schemaLocation` value for schema loading.

XML Schema specifications

XML Schema specification information is built into StyleVision and the validity of XML Schema (.xsd) documents is checked against this internal information. In an XML Schema document, therefore, no references should be made to any schema that defines the XML Schema specification.

The `catalog.xml` file in the `%AltovaCommonSchemasFolder%\Schemas\schema` folder contains references to DTDs that implement older XML Schema specifications. You should not validate your XML Schema documents against these schemas. The referenced files are included solely to provide StyleVision with entry helper info for
4.9.4 Variables for Windows System Locations

Shell environment variables can be used in the `nextCatalog` element to specify the path to various system locations (see `RootCatalog.xml` listing above). The following shell environment variables are supported:

- `%PersonalFolder%` - Full path to the Personal folder of the current user, for example `C:\Users\<name>\Documents`
- `%CommonSchemasFolder%` - Full path to the `CommonSchemas` folder of the current user, for example `C:\ProgramData\Altova\Common2022\Schemas`
- `%ApplicationWritableDataFolder%` - Full path to the Application Writable Data folder of the current user, for example `C:\ProgramData\Altova`
- `%AltovaCommonFolder%` - Full path to the `AltovaCommon` folder of the current user, for example `C:\Program Files\Altova\Common2022`
- `%DesktopFolder%` - Full path to the Desktop folder of the current user.
- `%ProgramMenuFolder%` - Full path to the Program Menu folder of the current user.
- `%StartMenuFolder%` - Full path to the Start Menu folder of the current user.
- `%StartUpFolder%` - Full path to the Start Up folder of the current user.
- `%TemplateFolder%` - Full path to the Template folder of the current user.
- `%AdminToolsFolder%` - Full path to the file system directory that stores administrative tools of the current user.
- `%AppDataFolder%` - Full path to the Application Data folder of the current user.
- `%CommonAppDataFolder%` - Full path to the file directory containing application data of all users.
- `%FavoritesFolder%` - Full path of the Favorites folder of the current user.
- `%PersonalFolder%` - Full path to the Personal folder of the current user.
- `%SendToFolder%` - Full path to the SendTo folder of the current user.
- `%FontsFolder%` - Full path to the System Fonts folder.
- `%ProgramFilesFolder%` - Full path to the Program Files folder of the current user.
%CommonFilesFolder%

Full path to the Common Files folder of the current user.

%WindowsFolder%

Full path to the Windows folder of the current user.

%SystemFolder%

Full path to the System folder of the current user.

%LocalAppDataFolder%

Full path to the file system directory that serves as the data repository for local (nonroaming) applications.

%MyPicturesFolder%

Full path to the MyPictures folder.
5  SPS Content

This section describes in detail the core procedures used to create and edit SPS document components that are used to create locations in the document design for XML data content. The procedures are listed below and described in detail in the sub-sections of this section. These mechanisms are used to design any kind of template: main, global, or named.

- **Inserting XML Content as Text**. XML data can be inserted in the design by dragging the relevant nodes (element, attribute, type, or CDATA) into the design and creating them as (contents) or (rest-of-contents).
- **Inserting MS Word Content**.
- **User-Defined Templates**.
- **User-Defined Elements, XML Text Blocks**.
- **Working with Tables**. Tables can be inserted by (i) the SPS designer, directly in the SPS design (static tables) or using XML document sub-structures, and (ii) the Authentic View user.
- **Creating Lists**. Static lists, where the list structure is entered in the SPS design, and dynamic lists, where an XML document sub-structure is created as a list, provide powerful data-ordering capabilities.
- **Using Graphics**. Graphics can be inserted in the SPS design using a variety of methods to determine the target URI (static, dynamic, a combination of both, and unparsed entity URIs).
- **Using Data-Entry Devices (or Form Controls)**. XML data can be input by the Authentic View user via data-entry devices such as input fields and combo boxes. This provides a layer of user help as well as of input constraints. Individual nodes in the XML document can be created as data-entry devices.
- **Links**.
- **Barcodes**.
- **Layout Modules**.
- **The Change-To Feature**. This feature enables a different node to be selected as the match for a template and allows a node to be changed to another content type.
5.1 Inserting XML Content as Text

Data from a node in the XML document is included in the design by dragging the corresponding schema node from the Schema Tree window and dropping it into the design. When the schema node is dropped into the design, a menu pops up with options for how the node is to be created in the design (screenshot below).

Types of schema nodes
Schema nodes that can be dropped from the Schema Tree sidebar into the design are of three types: (i) element nodes; (ii) attribute nodes; and (iii) datatype nodes.

Using the Insert Contents toolbar icon
The Insert Contents icon in the Insert Design Elements toolbar also enables you to insert the contents of a node in the design. Insert contents as follows:

1. Select the Insert Contents icon.
2. Click the location in the design where you wish to insert contents. The Insert Contents Selector pops up (screenshot below).
3. The context of the insertion location in the design is displayed in the XPath Context field. Select the node for which you wish to create contents.

4. Click OK. The contents placeholder is created. If the node you selected is anything other than the context node, additional template tags with the path to the selected node will be created around the contents placeholder.

Outputting text content of nodes

To output the text contents of the node, the node should be created as contents. When a node is created as contents, the node will look something like this in the design document:

```
<Desc (content)>
```

In the screenshot above, the Desc element has been created as contents. The output will display the text content of Desc. If Desc has descendant elements, such as Bold and Italic, then the text content of the descendant elements will also be output as part of the contents of Desc. Note that attribute nodes of Desc are not considered its child nodes, and the contents of the attribute nodes will therefore not be output as part of the contents of Desc. Attribute nodes have to be explicitly inserted in order to be processed.
CDATA sections

If CDATA sections are present in the XML document they will be output, and in Authentic View, are indicated with tags when markup is switched on (using the menu command Authentic | Markup). CDATA sections can also be inserted in the XML document when editing the document in Authentic View (via the context menu).

![CDATA][This is CDATA Text.]]

**Note:** In Authentic View, CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). They can only be entered within elements that are displayed in Authentic View as text content components.

In this section

In the sub-sections of this section, we describe other aspects of inserting XML content as text:

- How the text content of a node can be marked up with a predefined format directly when the node is inserted.
- How the structure of the source schema determines the effect of Authentic View usage.
- How descendant nodes not explicitly included within a node can be included for processing. See Rest-of-Contents.

**Note:** You can create an empty template rule by deleting the (content) placeholder of a node. An empty template rule is useful if you wish to define that some node not be processed, i.e. produce no output.

### 5.1.1 Inserting Content with a Predefined Format

The text content of a node can be directly inserted with the markup of one of StyleVision's predefined formats. To do this, drag the node from the Schema Tree window and drop it at the desired location. In the menu that pops up, select **Create Paragraph** (screenshot below).

![Create Paragraph](screenshot below)

The predefined format can be changed by selecting the predefined format tag and then choosing some other predefined format from the **Format combo box in the toolbar** (screenshot below) or using the menu command Insert | Format.
The predefined format can also be changed by changing the value of the `paragraph type` property of the `paragraph group` of properties in the Properties window, or by changing the paragraph type via the node-template's context menu command. 

Each paragraph type has particular formatting features that can be used to advantage. Note that the `pre` format type enables carriage returns and linefeeds to be output as such instead of them being normalized to whitespace.

### 5.1.2 Adding Elements in Authentic View

When creating elements in the design, the way you create the elements determines how Authentic View will respond to user actions like pressing the Tab key and clicking the `Add...` prompt. The basic issue is what elements are created in Authentic View when an element is added by the user. For example, when the user adds an element (say, by clicking the `Insert Element` icon in the Elements sidebar), what child elements are created automatically?

The most important point to bear in mind is that Authentic View follows the structure specified in the underlying schema. In order to ensure that Authentic View implements the schema structure correctly there are a few design rules you should keep in mind. These are explained below.

#### Unambiguous content model

A content model is considered unambiguous when it consists of a single sequence (with `maxOccurs=1`) of child elements (with no choices, groups, substitutions, etc). In such cases, when the element is added, the sequence of child elements is unambiguously known, and they are automatically added. In the screenshot example below, the three child elements are all mandatory and can occur only once.

When the element `parent` is added in Authentic View, its child elements are automatically inserted (screenshot below). Pressing the tab key takes you to the next element in the sequence.

If the `e2` element were optional, then, when the element `parent` is added in Authentic View, the elements `e1` and `e3` are automatically inserted, and the element `e2` appears in the Elements sidebar so that it can be inserted if desired (screenshot below). Pressing the tab key in `e1` takes the user to `e3`.

© 2015-2021 Altova GmbH Altova StyleVision 2022 Professional Edition
The above content model scenario is the only scenario Authentic View considers unambiguous. All other cases are considered ambiguous, and in order for Authentic View to disambiguate and efficiently display the desired elements the design must adhere to a few simple rules. These are explained below.

**Ambiguous content model**

For Authentic View to correctly and efficiently display elements while an XML document is being edited, the SPS must adhere to the following rules.

- Child elements will be displayed in the order in which they are laid out in the design.
- In order for Authentic View to disambiguate among sibling child elements, all child elements should be laid out in the design document in the required order and within a single parent node. If the sibling relationship is to be maintained in Authentic View, it is incorrect usage to lay out each child element of a single parent inside multiple instances of the parent node.

These two rules are illustrated with the following example.

We consider a content model of an element `parent`, which consists of a single sequence of mandatory child elements. This content model is similar to the unambiguous content model discussed above, with one difference: the single sequence is optional, which makes the content model ambiguous—because the presence of the sequence is not a certainty. If you create a design document as shown in the screenshot below, there will be ambiguity in Authentic View.

The Authentic View of the `parent` element will look like this (since the sequence is optional):

![Authentic View of parent element](image)

Clicking `add...` pops up a menu of the three child elements:

![Menu of child elements](image)

If you select one of these elements, it will be inserted (screenshot below), but since Authentic View cannot disambiguate the sequence it does not insert any of the remaining two elements, nor does it offer you the opportunity of inserting them:

![Resulting Authentic View](image)
The **correct** way to design this content model (following the rules given above) would be to explicitly create the required nodes in the desired order within the single parent node. The design document would look like this:

```xml
<parent>
  <e1>(contents)<e1>
  <e2>(contents)<e2>
  <e3>(contents)<e3>
  <parent>
</parent>
```

Note that all three child elements are placed **inside a single parent node**. The design shown above would produce the following Authentic View:

```xml
<parent>
  <add e1>
  <add e2>
  <add e3>
  <parent>
</parent>
```

The Authentic View user clicks the respective **add element** prompt to insert the element and its content.

**Note:**

- If an element can occur multiple times, and if the rules above are followed, then the element appears in the sidebar till the number of occurrences in Authentic View equals the maximum number of occurrences allowed by the schema (`maxOccurs`).
- Creating each child element inside a separate parent node (*see screenshot below*) not only creates isolated child–parent relationships for each child element so instantiated; it also increases processing time because the parent node has to be re-traversed in order to locate each child element.

```xml
<parent>
  <add e1>
  <add e2>
  <add e3>
  <parent>
</parent>
```

### 5.1.3 Rest-of-Contents

The **rest-of-contents** placeholder applies templates to all the remaining child elements of the element for which the template has been created. As an example consider the following:

- An element **parent** has 4 child elements, **child1** to **child4**.
In the template for element `parent`, some processing has been explicitly defined for the `child1` and `child4` child elements.

This results in only the `child1` and `child4` child elements being processed. The elements `child2` and `child3` will not be processed. Now, if the `rest-of-contents` placeholder is inserted within the template for `parent`, then, not only will `child1` and `child4` be processed using the explicitly defined processing rules in the template. Additionally, templates will be applied for the `child2` and `child3` child elements. If global templates for these are defined then the global templates will be used. Otherwise the built-in default templates (for element, attribute, and text nodes) will be applied.

Important: It is important to note what nodes are selected for `rest-of-contents`.

- As described with the example above, all child element nodes and child text nodes are selected by the `rest-of-contents` placeholder. (Even invalid child nodes in the XML document will be processed.)
- Attribute nodes are not selected; they are not child nodes, that is, they are not on the child axis of XPath.
- If a global template of a child element is used in the parent template, then the child element does not count as having been used locally. As a result, the `rest-of-contents` placeholder will also select such child elements. However, if a global template of a child element is "copied locally", then this usage counts as local usage, and the child element will not be selected by the `rest-of-contents` placeholder.

Note: You can create an empty template rule by deleting the `(content)` placeholder of a node. An empty template rule is useful if you wish to define that some node not be processed, i.e. produce no output.
5.2 Inserting MS Word Content

If Microsoft Word 2007+ is installed on your machine, then content can be pasted from Word documents into the design as static content. The Word content will be inserted within suitably corresponding design components, and text formatting properties will be carried over from the Word content. For example, text content that is in a Word paragraph block will be inserted within a Paragraph component, and the formatting of the text will be preserved (see screenshots below).

Accelerate XML Development

Today, eXtensible Markup Language (XML) technologies play a critical role in all software development projects. XML has received widespread support and adoption in the computer industry because of its simplicity, extensibility, interoperability, and flexibility, all of which stem from its power to represent data independent of programming language, platform, or operating system. In XML-based applications, XML is used alongside complementary technologies such as XML Schema, XSLT, XQuery, Web services, and others. Today’s developer needs a tool for creating, editing, and debugging these XML-related technologies in an efficient, standards-based manner.

Altova XMLSpy 2007 delivers all the power you need to create the most advanced XML applications, yet at the same time it’s flexible enough to allow you to work with XML using the views and options that best suit your specific requirements and preferences. XMLSpy 2007 increases productivity by allowing you to develop higher quality, standards-conformant XML-based applications more quickly than ever before.

Word content.

In XML-based applications, XML is used alongside complementary technologies such as XML Schema, XSLT, XQuery, Web services, and others. Today’s developer needs a tool for creating, editing, and debugging these XML-related technologies in an efficient, standards-based manner.

Altova XMLSpy 2007 delivers all the power you need to create the most advanced XML applications, yet at the same time it’s flexible enough to allow you to work with XML using the views and options that best suit your specific requirements and preferences. XMLSpy 2007 increases productivity by allowing you to develop higher quality, standards-conformant XML-based applications more quickly than ever before.

Word content pasted into a design. A suitable paragraph format has been applied and text formatting has been preserved.

Note: In addition to Word content, any content that can be pasted into a Word document can also be pasted into a StyleVision design. This includes MS Excel tables and HTML page content.

Note: To create an SPS that contains static content from an entire Word document, create a new SPS with the File | New | New from Word 2007+ command.

Supported Word features
The following Word structures and formats are supported when Word content is copy-pasted into a design:

- Formatted text
  - Different fonts, size, weights, style, text-decoration, etc.
  - Color
  - Background color
  - Border around text
- Paragraphs
- Page breaks
- Horizontal line
- Hyperlinks
- Bookmarks
- Tables
  - Rows spans, colspans
  - Formatted/rich content
  - Nested tables
  - Headers, footers
• Lists, sublists
  o Bulletted: different styles
  o Enumerated: different styles
• Images
5.3 Inserting MS Excel Content

If Microsoft Excel 2007+ is installed on your machine, then content can be pasted from Excel documents into the design as static content. The Excel content will be inserted as static tables and other suitably corresponding design components. Formatting properties will be preserved (see screenshots below). Each Excel sheet is inserted as a separate static table.

![Excel Sheet](image)

Excel sheet.
Excel content imported into a design as a static table with text formatting preserved.

**Note:** In addition to Excel content, any content that can be pasted into an Excel document can also be pasted into a StyleVision design. This includes MS Word content and HTML page content.

**Note:** To create an SPS that contains static content from an entire Excel document, create a new SPS with the File | New | New from Excel 2007+ command.
5.4 User-Defined Templates

User-Defined Templates are templates for items generated by an XPath expression you specify. These items may be atomic values or nodes. In the screenshot below, which shows three User-Defined Templates, note the User-Defined Template icon on the left-hand side of the tags (a green person symbol). User-Defined Templates are very useful because they provide extraordinary flexibility for creating templates. Note, however, that content generated by User-Defined Templates cannot be edited in Authentic View.

The XPath expression of each of the three User-Defined templates shown in the screenshot above do the following:

- Selects a node in a source schema. By using an XPath expression, any node in any of the schema sources can be reached from within any context node. If StyleVision can unambiguously target the specified node, the template will be changed automatically from a User-Defined Template to a normal template, enabling Authentic View editing. If it is a User-Defined Template, this will be indicated by the green User-Defined Template icon on the left-hand side of the template tags.
- Selects a node that fulfills a condition specified by the `for` construct of XPath 2.0 and XPath 3.0. Such templates can never resolve to normal templates (but will remain User-Defined Templates) because the `for` construct does not allow StyleVision to unambiguously resolve the target from only the schema information it currently has at its disposal.
- Selects a sequence of atomic values `{1, 2, 3}`. While it is allowed to create a template for an atomic value, you cannot use the `contents` placeholder within such a template. This is because the `xsl:apply-templates` instruction (which is what the `contents` placeholder generates) can only be applied to node items (not atomic values). You could, however, use an Auto-Calculation in combination with some design element such as a list. For example, the User-Defined Template at left would generate the output at right.

Note: If the SPS uses XSLT 1.0, then the XPath expression you enter must return a node-set. Otherwise an error is reported.
Advantage of using XPath to select template node

The advantage of selecting a schema node via an XPath expression (User-Defined Templates) is that the power of XPath's path selector mechanism can be used to select any node or sequence of items, as well as to filter or set conditions for the node selection. As a result, specific XML document nodes can be targeted for any given template. For instance, the XPath expression //Office/Department[@Location="NY"] will select only those Department nodes that have a Location attribute with a value of NY. Also see the other examples in this section.

Note: If an XPath expression contains multiple location path steps, then it is significant—especially for grouping and sorting—whether brackets are placed around the multiple location path steps or not. For example, the XPath expression //Org/Office/Dept will be processed differently than (/Org/Office/Dept). For the former expression (without brackets), the processor loops through each location step. For the latter expression (with brackets), all the Dept elements of all Office elements are returned in one undifferentiated nodeset.

<table>
<thead>
<tr>
<th>Brackets</th>
<th>Underlying XSLT Mechanism</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>&lt;xsl:for-each select=&quot;Org&quot;&gt; &lt;xsl:for-each select=&quot;Office&quot;&gt; &lt;xsl:for-each select=&quot;Dept&quot;&gt; ... &lt;/xsl:for-each&gt; &lt;/xsl:for-each&gt;</td>
<td>Each Office element has its own Dept population. So grouping and sorting can be done within each Office.</td>
</tr>
<tr>
<td>Yes</td>
<td>&lt;xsl:for-each select=&quot;/Org/Office/Dept&quot;&gt; ... &lt;/xsl:for-each&gt;</td>
<td>The Dept population extends over all Office elements and across Org.</td>
</tr>
</tbody>
</table>

This difference in evaluating XPath expressions can be significant for grouping and sorting.

Inserting a User-Defined Template

To insert a User-Defined Template, do the following:

1. Click the Insert User-Defined Template icon in the Insert Design Elements toolbar and then click the design location where you wish to insert the template. Alternatively, right-click the design location where you wish to insert the template and, from the context menu that appears, select the Insert User-Defined Template command.
2. In the Edit XPath Expression dialog that pops up, enter the XPath expression you want, and click OK. Note that the context node of the XPath expression will be the node within which you have clicked. An empty node template will be created. Sometimes a joined node is created. When a node is joined, the targeted instance nodes are selected as if at a single level, whereas if a node is not joined (that is if it is split into multiple hierarchic levels), then the node selection is done by looping through each instance node at every split level. The nodeset returned in both cases of selection (joined and split) is the same unless a grouping or sorting criterion is specified. For a discussion of the effect joined nodes have on the grouping and sorting mechanisms, see Node-Template Operations.
Editing a Template Match
The node selection of any node template (user-defined or normal) can be changed by using an XPath expression to select the new match expression. To edit the template match of a node template, right-click the node template, then select the Edit Template Match command. This pops up the Edit XPath Expression dialog, in which you enter the XPath expression to select the new node. Then click OK.

Adding nodes to User-Defined Templates
If a node from the schema tree is added to a User-Defined Template, the context for the new node will not be known if the User-Defined Template has been created for a node or sequence that cannot be placed in the context of the schema source of the SPS. You will therefore be prompted (screenshot below) about how the new node should be referenced: (i) by its name (essentially, a relative path), or (ii) by a full path from the root of the schema source.

Prompting for advice on how to proceed is the default behavior. This default behavior can be changed in the Design tab of the Tool | Options dialog.
5.5 User-Defined Elements, XML Text Blocks

User-Defined Elements and User-Defined XML Text Blocks enable, respectively, (i) any element, and (ii) any XML text block to be inserted into the design. The advantage of these features is that designers are not restricted to adding XML elements and design elements from source schemas and the palette of StyleVision design elements. They can create (i) templates for elements they define (User-Defined Elements), and (ii) independent and self-contained XML code (User-Defined Blocks) that creates objects independently (for example ActiveX objects).

There is one important difference between User-Defined Elements and User-Defined XML Text Blocks. A User-Defined Element is created in the design as a template node for a single XML element (with attributes). All content of this template must be explicitly created. This content consists of the various design elements available to the SPS. A User-Defined XML Text Block may not contain any design element; it is an independent, self-contained block. Since a User-Defined Element is created empty, it does not lend itself for the creation of an object requiring a number of lines of code. For the latter purpose, User-Defined XML Text Blocks should be used.

Note: User-Defined Elements and User-Defined Text Blocks are supported in Authentic View only in the Enterprise Editions of Altova products.

5.5.1 User-Defined Elements

User-Defined Elements are elements that you can generate in the output without these elements needing to be in any of the schema sources of the SPS. This means that an element from any namespace (HTML or XSL-FO for example) can be inserted at any location in the design. SPS design elements can then be inserted within the inserted element.

Note: User-Defined Elements are supported in Authentic View only in the Enterprise Editions of Altova products.

Inserting User-Defined Elements

The mechanism for using User-Defined Elements is as follows:

1. Right-click at the location in the design where you wish to insert the User-Defined Element.
2. From the context menu that appears, select Insert User-Defined Item | User-Defined Element.
3. In the dialog that appears (screenshot below), enter the element name, the desired attribute-value pairs, and, a namespace declaration for the element if the document does not contain one.
In the screenshot above an XSL-FO element called leader is created. It has been given a prefix of fo:, which is bound to the namespace declaration `xmlns:fo="http://www.w3.org/1999/XSL/Format"`. The element has a number of attributes, including `leader-length` and `rule-style`, each with its respective value. The element, its attributes, and its namespace declaration must be entered without the angular tag brackets.

4. Click OK to insert the element in the design. The element is displayed in the design as an empty template with start and end tags (screenshot below).

5. You can now add content to the template as for any other template. The User-Defined Element may contain static content, dynamic content from the XML document, as well as more additional User-Defined Elements.

**Note:** A User-Defined Element that is intended for a particular output should be enclosed in a suitable output-based condition so as to avoid unexpected results in alternative outputs.

### 5.5.2 User-Defined XML Text Blocks

A User-Defined XML Text Block is an XML fragment that will be inserted into the XSLT code generated by the SPS. It is placed in the SPS design as a self-contained block to which no design element may be added. Such an XML Text Block should therefore be applicable as XSLT code at the location in the stylesheet at which it occurs.

The usefulness of this feature is that it provides the stylesheet designer a mechanism with which to insert XSLT fragments and customized code in the design. For example, an ActiveX object can be inserted within an HTML SCRIPT element.

**Note:** This feature will be enabled only in Enterprise editions of Authentic View (that is, in the Enterprise editions of StyleVision, Authentic Desktop, Authentic Browser, and XMLSpy).
Inserting User-Defined XML Text Blocks

To insert an XML Text Block, do the following:

1. Right-click at the location in the design where you wish to insert the User-Defined Block.
2. From the context menu that appears, select Insert User-Defined Item | User-Defined Block.
3. In the dialog that now appears (screenshot below), enter the XML Text Block you wish to insert. Note that the XML text block should be well-formed XML to be accepted by the dialog.

   ![Edit User XML Text dialog](image)

   In the screenshot above an XML Text Block is added that generates an HTML ordered list.

4. Click OK to insert the element in the design. The XML Text Block is displayed in the design as a text box.

   **Note:** An XML Text Block that is intended for a particular output should be enclosed in a suitable output-based condition so as to avoid unexpected results in alternative outputs.
5.6 Tables

In an SPS design, two types of tables may be used: SPS tables and CALS/HTML tables. There are differences between the two types, and it is important to understand these. This section contains a detailed description of how to use both types of tables.

SPS tables

An SPS table is a component of an SPS design. It is structured and formatted in the design. It can be created anywhere in the design and any number of SPS tables can be created.

SPS tables are entirely presentational devices and are represented using the presentational vocabulary of Authentic View and the output format. The structure of an SPS table is not represented by nodes in the XML document—although the content of table cells may come from nodes in the XML document.

There are two types of SPS tables:

- **Static tables** are built up, step-by-step, by the person designing the SPS. After the table structure is created, the content of each cell is defined separately. The content of cells can come from random locations in the schema tree and even can be of different types. Note that the rows of a static table do not represent a repeating data structure. This is why the table is said to be static: it has a fixed structure that does not change with the XML content.

- **Dynamic tables** are intended for data structures in the XML document that repeat. They can be created for schema elements that have a substructure—that is, at least one child attribute or element. Any element with a substructure repeats if there is more than one instance of it. Each instance of the element would be a row in the dynamic table, and all or some of its child elements or attributes would be the columns of the table. A dynamic table's structure, therefore, reflects the content of the XML file and changes dynamically with the content.

CALS/HTML tables

The content model of a CALS table or HTML table is defined in the XML document—by extension in the DTD or schema—and follows the respective specification (CALS or HTML). In the SPS design you can then specify that CALS/HTML table/s are to be processed as tables. The XML data structure that represents the CALS/HTML table will in these cases generate table markup for the respective output formats. The formatting of CALS/HTML tables can be specified in the XML instance document or the SPS, or in both.

Shown below is the HTML Preview of an HTML table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Phone</th>
</tr>
</thead>
<tbody>
<tr>
<td>John Merrimack</td>
<td>6517890</td>
</tr>
<tr>
<td>Joe Concord</td>
<td>6402387</td>
</tr>
</tbody>
</table>

The HTML code fragment for the XML table shown in the illustration above looks like this:

```html
<table border="1" width="40%">
  <tbody>
    <tr>
      <td>Name</td>
      <td>Phone</td>
    </tr>
    <tr>
      <td>John Merrimack</td>
      <td>6517890</td>
    </tr>
    <tr>
      <td>Joe Concord</td>
      <td>6402387</td>
    </tr>
  </tbody>
</table>
```
The original XML document might look like this:

```xml
<phonenumberlist border="1" width="40%">
  <items>
    <person>
      <data>Name</data>
      <data>Phone</data>
    </person>
    <person>
      <data>Name</data>
      <data>Phone</data>
    </person>
    <person>
      <data>Name</data>
      <data>Phone</data>
    </person>
  </items>
</phonenumberlist>
```

Note that element names in the XML document do not need to have table semantics; the **table structure**, however, must correspond to the HTML or CALS table model. Also note the following:

- Note that only one XML element can correspond to the HTML column element `<td/>`.
- A CALS/HTML table can be inserted at any location in the XML document where, according to the schema, the element corresponding to the table element is allowed.
- In Authentic View, data is entered directly into table cells. This data is stored as the content of the corresponding CALS/HTML table element.
- The formatting properties of a CALS/HTML table could come from the XML document, or they could be specified in the SPS design.

**Summary for the designer**

From the document designer's perspective, the following points should be noted:

- **The structure** of an SPS table is defined in the SPS. The structure of a CALS/HTML table on the other hand is specified in the schema and must follow that of the CALS/HTML table model; the element names in the schema may, however, be different than those in the CALS or HTML table models.
- **Colspans and rowspans** in SPS tables are specified in the SPS. But in CALS/HTML tables, colspans and rowspans are specified in the XML instance document.
- **Table formatting** of SPS tables is specified in the SPS. The formatting of CALS/HTML tables is specified in the XML instance document and/or the SPS.

### 5.6.1 Static Tables

To create a static table, do the following:

1. Use one of the following commands: **Table | Insert Table** or **Insert | Table**, or click the **Insert Table** icon in the Insert Design Elements toolbar.
2. All of these commands pop up the Create Table dialog (*screenshot below*).

![Create Table Dialog](image1)

Click **Static Table**.

3. The Insert Table dialog (*screenshot below*) pops up, in which you specify the dimensions of the table and specify whether the table should occupy the whole available width.

![Insert Table Dialog](image2)

4. Click OK. An empty table with the specified dimensions, as shown below, is created.

```
+---+---+---+---+---+
|   |   |   |   |   |
+---+---+---+---+---+
|   |   |   |   |   |
+---+---+---+---+---+
|   |   |   |   |   |
+---+---+---+---+---+
```

5. You can now enter content into table cells using regular StyleVision features. Cell content could be text, or elements dragged from the schema tree, or objects such as images and nested tables. The figure below shows a table containing nested tables.
Static SPS tables are especially well-suited for organizing XML data that is randomly situated in the schema hierarchy, or for static content (content not derived from an XML source).

Deleting columns, rows, and tables
To delete a column, row, or table, place the cursor in the column, row, or table to be deleted, and click the menu item Table | Delete Column, Table | Delete Row, or Table | Delete Table, respectively. If you have nested tables, these commands will apply, respectively, to the column, row, and table containing the cursor.

Toolbar table editing icons
The table editing icons, which are by default in the second row of the toolbar, are shortcuts to the Table menu commands. These commands allow you to insert, delete, edit the structure of, and assign formatting properties to the static table. These icons can also be used for dynamic SPS tables. They cannot be used for CALS/HTML tables, since CALS/HTML tables are not formatted in this way.

5.6.2 Dynamic Tables
To insert a dynamic table, do the following:

1. Use one of the following commands: Table | Insert Table or Insert | Table, or click the Insert Table icon in the Insert Design Elements toolbar.
2. All of these commands pop up the Create Table dialog (screenshot below). If you clicked the Insert Table icon in the toolbar, the Create Table dialog will pop up when you click at the location in the design where you want to insert the table.

Click Dynamic Table.

3. In the XPath Selector dialog (screenshot below) that pops up, notice that the XPath Context is the context of the insertion location, and it cannot be changed in the dialog. Select the node that is to be created as the dynamic table. In the screenshot below, the context node is n1:Department, and the n1:Person node has been selected as the node to be created as a table.
If you select the User-defined XPath option, then you can enter an XPath expression to select the node to be created as the dynamic table.

4. Click **OK**. The Create Dynamic Table dialog (*screenshot below*) pops up.
5. The child elements and attributes of the element that has been dragged into the Design window are displayed in the "Select rows/columns" list and can be created as columns of the table. Deselect the child nodes that you do not want and select any attribute/element you want to include as columns. (In the figure above, the elements Shares, LeaveTotal, LeaveUsed and LeaveLeft have been deselected.) An explanation of the other options is given below. Click OK when done. Note that columns are created only for child elements and attributes, and for no descendant on a lower level.

**Note:** If you specified a User-defined XPath to select the node to be created as the dynamic table, then StyleVision will probably not know unambiguously which node is being targeted. Consequently, the Create Dynamic Table will, in such cases, not display a list of child attributes/elements to select as the fields (columns) of the table. The table that is created will therefore have to be manually populated with node content. This node content should be child attributes/elements of the node selected to be created as the table.

**Note:** Another way of creating a schema node as a table is to drag the node from the schema tree into the design and to specify, when it is dropped, that it be created as a table.

**Table grows down or right**
When a table grows top-down, this is what it would look like:

<table>
<thead>
<tr>
<th>name</th>
<th>street</th>
<th>city</th>
<th>state</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="">ipo:name</a></td>
<td><a href="">ipo:street</a></td>
<td><a href="">ipo:city</a></td>
<td><a href="">ipo:state</a></td>
<td><a href="">ipo:zip</a></td>
</tr>
</tbody>
</table>

When a table grows left-right it looks like this:
Headers and footers

Columns and rows can be given headers, which will be the names of the column and row elements. Column headers are created at the top of each column. Row headers are created on the left hand side of a row. To include headers, check the Create Header check-box. If the table grows top-down, creating a header, creates a header row above the table body. If the table grows left-right, creating a header, creates a column header to the left of the table body.

To include footers, check the Create Footer check-box. Footers, like headers, can be created both for columns (at the bottom of columns) and rows (on the right hand side of a row). The footer of numeric columns or rows will sum each column or row if the Summary for Numeric Fields check box is checked.

Via the Table menu, header and footer cells can be joined and split, and rows and columns can be inserted, appended, and deleted; this gives you considerable flexibility in structuring headers and footers. Additionally, headers and footers can contain any type of static or dynamic content, including conditional templates and auto-calculations.

**Note:** Headers and footers must be created when the dynamic table is defined. You do this by checking the Create Header and Create Footer options in the Create Dynamic Table dialog. Appending or inserting a row within a dynamic table does not create headers or footers but an extra row. The difference is significant. With the Create Header/Footer commands, real headers and footers are added to the top and bottom of a table, respectively. If a row is inserted or appended, then the row occurs for each occurrence of the element that has been created as a dynamic table.

Nested dynamic tables

You can nest one dynamic table within another dynamic table if the element for which the nested dynamic table is to be created is a child of the element that has been created as the containing dynamic table. Do the following:

1. Create the outer dynamic table so that the child element to be created as a dynamic table is created as a column.
2. In the dynamic table in Design View, right-click the child element.
3. Select **Change to | Table**. This pops up the Create Dynamic Table dialog.
4. Define the properties of the nested dynamic table.

To nest a dynamic table in a static table, drag the element to be created as a dynamic table into the required cell of the static table. When you drop it, select **Create Table** from the context menu that appears.

Tables for elements with text content

To create columns (or rows) for child elements, the element being created as a table must have a child element or attribute node. Having a child text node does not work. If you have this kind of situation, then
create a child element called, say, Text, and put your text node in the TableElement/Text elements. Now you will be able to create TableElement as a dynamic table. This table will have one column for Text elements. Each row will therefore contain one cell containing the text node in Text, and the rows of the table will correspond to the occurrences of the TableElement element.

Contents of table body cells
When you create a dynamic table, you can create the node content as any one of a number of StyleVision components. In the examples above, the table body cells were created as contents; in the Create Dynamic Table dialog, the option for Display Cells As is contents. They could also have been created as data-entry devices. There are two points to note here:

- The setting you select is a global setting for all the table body cells. If you wish to have an individual cell appear differently, edit the cell after you have created the table: right-click in the cell and, in the context menu that appears, select "Change to" and then select the required cell content type.
- If you create cells as element contents, and if the element has descendant elements, then the content of the cell will be a concatenation of the text strings of the element and all its descendant elements.

Deleting columns, rows, and tables
To delete a column, row, or table, place the cursor in the column, row, or table to be deleted, and click the menu item Table | Delete Column, Table | Delete Row, or Table | Delete Table, respectively. If you have nested tables, the table immediately containing the cursor will be deleted when the Table | Delete Table command is used.

Toolbar table editing icons
The table editing icons in the toolbar are shortcuts to the Table menu commands. These commands allow you to insert, delete, edit the structure of, and assign formatting properties to the dynamic table. These icons can also be used for static tables. They cannot be used for CALS/HTML tables, since CALS/HTML tables are not formatted in this way. CALS/HTML tables can only be enabled in StyleVision.

Creating dynamic tables in global templates
You can also create dynamic tables on elements inside global templates. The process works in the same way as for Main Template elements (described above). The important point to note is that, in a global template, a dynamic table can only be created for descendant elements of the global template node; it cannot be created for the global template node itself. For example, if you wish to create a dynamic table for the element authors within a global template, then this dynamic table must be created within the global template of the parent element of authors, say contributors. It cannot be created within the global template of the authors element.

5.6.3 Conditional Processing in Tables

Conditional processing can be set on individual columns and rows of static and dynamic tables, as well as on column and row headers, to display or hide the column, row, or header depending on the truth of the condition. If the condition evaluates to true, the column, row, or header is displayed. Otherwise it is not.
Adding and editing conditional processing

To add conditional processing to a column, row, or header, right click the respective design component and select Edit Conditional Processing. (In the screenshot below, the column-header design-component at top left is shown highlighted in blue; the second-column design-component is shown outlined in blue; the only row component is below the column-header design-component.)

Clicking the Edit Conditional Processing command pops up the Edit XPath Expression dialog, in which you enter the XPath expression of the condition. Here are some ways in which conditional processing could be used.

- On a column, row, or table, enter the XPath expression false() to hide the column, true() to display it.
- A column is output only if the sum of all the values in that column exceeds a certain integer value.
- A column or row is output only if no cell in that column or row, respectively, is empty.
- A column or row is output only if a certain cell-value exists in that column or row, respectively.

To edit an already created condition, right click the respective design component and select Edit Conditional Processing. In the Edit XPath Expression dialog that pops up, edit the XPath expression that tests the truth of the condition.

Removing conditional processing

To remove the conditional processing of a column, row, or header, right click the respective design component and select Clear Conditional Processing.

5.6.4 Tables in Design View

The main components of static and dynamic SPS tables are as shown in the screenshots below with the table markup (Table | View Table Markup) switched on.

The screenshot above shows a simple table that grows top-down and that has a header and footer.
A column is indicated with a rectangle containing a downward-pointing arrowhead. Column indicators are located at the top of columns. To select an entire column—say, to assign a formatting property to that entire column—click the column indicator of that column.

A row is indicated with a rectangle containing a rightward-pointing arrow. Click a row indicator to select that entire row.

In tables that grow top-down (screenshot above), headers and footers are indicated with icons pointing up and down, respectively. In tables that grow left-right, headers and footers are indicated with icons pointing left and right, respectively (screenshot below).

To select the entire table, click in the top left corner of the table (in the screenshots above and below, the location where the arrow cursor points).

When any table row or column is selected, it is highlighted with a dark blue background. In the screenshot above, the footer is selected.

In tables that grow top-down, the element for which the table has been created is shown at the extreme left, outside the column-row grid (screenshot above). In tables that grow left-right, the element for which the table has been created is shown at the top, outside the column-row grid (screenshot below).

After a column or row or table has been selected, styles and/or properties can be set for the selection in the Styles and Properties Windows.

Drag-and-drop functionality
The columns and rows of an SPS table (static or dynamic) can be dragged to alternative locations within the same table and dropped there.

Enclosing and removing templates on rows and columns
A row or column can be enclosed with a template by right-clicking the row or column indicator and, from the context menu that pops up (screenshot below), selecting Enclose With | Template or Enclose With | User-Defined Template. In the next step, you can select a node from the schema tree or enter an XPath expression for a User-Defined Template. A template will be created around the row or column.

A template that is around a row or column can also be removed while leaving the row or column itself intact. To do this, select the template tag and press the Delete key.

The enclosing with, and removing, templates feature is useful if you wish to remove a template without removing the contents of a row or column, and then, if required, enclosing the row or column with another template.
Enclosing with a [User-Defined Template](#) also allows the use of interesting template-match results within the row or column (via Auto-Calculations, for example).

### 5.6.5 Table Formatting

Static and dynamic tables can be formatted using:

- HTML table formatting properties (in the Properties sidebar)
- CSS (styling) properties (in the Styles sidebar).

**Note:** For Text output, tables will be generated using a [user-selected character as the cell separator](#). The default character is the semicolon. It can be changed in the XSD/XSLT tab of the [Properties dialog](#).

**Properties sidebar**

The HTML table formatting properties are available in the Properties sidebar (screenshot below). These properties are available in the *HTML* group of properties for the table component and its sub-components (body, row, column, and cell).
### Styles sidebar

The CSS table formatting properties are available in the Styles sidebar (screenshot below). CSS properties are available for the table component and its sub-components (body, row, column, and cell).

![CSS table formatting properties in the Styles sidebar](image)

**Note:** If all table cells in a row are empty, Internet Explorer collapses the row and the row might therefore not be visible. In this case, you should use the HTML workaround of putting a non-breaking space in the appropriate cell/s.

### Vertical text

Text in table cells can be rotated 90 degrees clockwise or anti-clockwise, so that the text is vertical, reading from top-to-bottom or bottom-to-top, respectively. To do this, in the design, select the content in the table cell that is to be rotated and, in the Properties sidebar (screenshot below), select tcell. In the **Table Cell** group of properties, select the required value for the **Orientation** property.

![Properties sidebar for table cell](image)
Note the following points:

- The rotation will be applied to the output, but will not be displayed in the design.
- This property is intended to be applied to text and should not be used for other content.
- Besides being applicable to text in table cells, the property can also be applied to text in Text boxes.

Table formatting via Properties and Styles

Some formatting properties are available in both the Properties sidebar as well as in the Styles sidebar. The table below lists some of the more important table properties available in both sidebars.

<table>
<thead>
<tr>
<th>Table component</th>
<th>Properties sidebar</th>
<th>Styles sidebar</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>border, frame, rules; cellpadding, cellspacing; bgcolor; height, width <em>(overridden by height, width in Styles sidebar if the latter exist)</em>; align</td>
<td>borders and padding in Box styles; height, width in Details group <em>(they override height and width in Properties sidebar)</em>; color, font, and text styles</td>
</tr>
<tr>
<td>Body</td>
<td>align, valign</td>
<td>height, vertical-align; color, font, and text styles</td>
</tr>
<tr>
<td>Column</td>
<td>align, valign</td>
<td>width, vertical-align; color, font, and text styles; box styles</td>
</tr>
<tr>
<td>Row</td>
<td>align, valign</td>
<td>height, vertical-align; color, font, and text styles; box styles</td>
</tr>
<tr>
<td>Cell</td>
<td>align, valign</td>
<td>height, width, vertical-align; color, font, and text styles; box styles</td>
</tr>
</tbody>
</table>

Height and width

The height and width of tables, rows, columns, and cells must be set in the Styles sidebar (in the Details group of styles). When a table, column, or row is resized in the display by using the mouse, the altered values are entered automatically in the appropriate style in the Styles sidebar. Note, however, that the height and width styles are not supported for cells that are spanned (row-spanned or column-spanned).

Centering a table

To center a table, set the align property in the HTML group of table properties to center. The align property can be accessed by selecting the table, then selecting the menu command Table | Table Properties. Alternatively, the property is available in the HTML group of properties in the Properties sidebar.

Centering the table in the PDF output will require additional settings according to the FOP processor you are using. According to the FO specification the correct way to center a table is to surround the fo:table element with an fo:table-and-caption element and to set the text-align attribute of the fo:table-and-caption element to center. StyleVision does not automatically create an fo:table-and-caption element when a table is inserted in the design, but you can add this element as a User-Defined Element. If you are using the Apache FOP processor, however, you should note that the fo:table-and-caption element might not be supported, depending on which FOP version you are using. In this case there is a simple workaround: Make the table a fixed-width table. Do this by specifying a length value, such as 4in or 120mm, as the value of the
Giving alternating rows different background colors

If you want alternating background colors for the rows of your dynamic table, do the following:

1. Select the row indicator of the row for which alternating background colors are required. Bear in mind that, this being a dynamic table, one element is being created as a row, and the design contains a single row, which corresponds to the element being created as a table.
2. With the row indicator selected, in the Properties sidebar, click the Properties for: trow.
3. Select the bgcolor property.
4. Click the XPath icon in the toolbar of the Properties window, and, in the Edit XPath Expression dialog that appears, enter an XPath expression similar to this:

   
   if ( position() mod 2 = 0 ) then "white" else "gray"

   This XPath expression specifies a bgcolor of white for even-numbered rows and a bgcolor of gray for odd-numbered rows

You can extend the above principle to provide even more complex formatting.

Numbering the rows of a dynamic table

You can number the rows of a dynamic table by using the position() function of XPath. To do this, first insert a column in the table to hold the numbers, then insert an Auto-Calculation in the cell of this column with an XPath of: position(). Since the context node is the element that corresponds to the row of the dynamic table, the position() function returns the position of each row element in the set of all row elements.

Table headers and footers in PDF output

If a table flows over on to more than one page, then the table header and footer appear on each page that contains the table. The following points should be noted:

- If the footer contains Auto-Calculations, the footer that appears at the end of the table segment on each page contains the Auto-Calculations for the whole table—not those for only the table segment on that page.
- The header and footer will not be turned off for individual pages (for example, if you want a footer only at the end of the table and not at the end of each page).

In order to omit the header or footer being displayed each time the page breaks, use the table-omit-header-at-break and/or table-omit-footer-at-break properties (attributes) on the table element. These properties are available in the Styles sidebar, in the XSL-FO group of properties for the table. To omit the header or footer when the page breaks, specify a value of true for the respective attribute. (Note that the default value is false. So not specifying these properties has the effect of inserting headers and footers whenever there is a break.)

Hyphenating content of table cells

If you wish to hyphenate text in table cells, you must explicitly set the hyphenate option for the respective block/s.
5.6.6 Row and Column Display

For tables, the following row and column display options are available in the HTML output only. These features are not supported in Authentic View and they require XSLT 2.0 or XSLT 3.0 to be selected as the XSLT version of the SPS.

- Empty rows and columns can be automatically hidden.
- Each column can have a Close button, which enables the user to hide individual columns.
- Row elements with descendant relationships can be displayed with expand/collapse buttons.

**Hiding empty rows and columns by default**

To hide empty rows and/or columns in the HTML output, do the following:

1. In Design View, select the table or any part of it (column, row, cell).
2. In the Properties sidebar, select properties for Table, and the Table group of properties (screenshot below).
3. Select the required value for the Hide Columns and Hide Rows properties. The options for each of these two properties are the same: Never, If empty, and If body empty. The If empty option hides the column or row if the entire column/row (including header and footer) is empty. If body empty requires only that the body be empty.

**Note:** If a non-XBRL table has row or column spans (where cells of a row or a column have been joined), the hiding of empty rows and columns might not work.

**User interaction to hide columns expand/collapse rows**

It can be specified in the design that each table column contain a Close button in the HTML output (see screenshot below). The user can then hide individual columns by clicking the Close button. After the user hides a column, a plus symbol appears in the first column (see screenshot below). Clicking this symbol re-displays all hidden columns.
Also, row elements that have descendant elements can be displayed in the HTML output with an expand/collapse (plus/minus) symbol next to it (see screenshot above). Clicking these symbols in the HTML output expands or collapses that row element. In the design, you can specify indentation for individual rows using CSS properties.

The settings for these two features are made in the Interactive group of properties of the Table properties (screenshot below).

The options for both properties are Yes (to add the feature) and No (to not add the feature).

5.6.7 CALS/HTML Tables

A CALS/HTML table is a hierarchical XML structure, the elements of which: (i) define the structure of a CALS or HTML table, (ii) specify the formatting of that table, and (iii) contain the cell contents of that table. This XML structure must correspond exactly to the CALS or HTML table model.

To create a CALS/HTML table in the design, do the following:

1. Define the XML structure as a CALS/HTML table structure
2. Specify formatting styles for the table
3. Insert the CALS/HTML table in the SPS design
Enabling CALS/HTML table structures for output

An XML document may have a data structure that defines the structure and content of a table. For example, the following XML data structure corresponds to the HTML table model and in fact has the same element names as those in the HTML table model:

```xml
<table>
  <tbody>
    <tr>
      <td/>
    </tr>
  </tbody>
</table>
```

Alternatively, the XML data structure could have a structure corresponding to the HTML table model but different element names than in the HTML table model. For example:

```xml
<semester>
  <subject>
    <class>
      <student/>
    </class>
  </subject>
</semester>
```

This table structure, which is defined in the XML document, can be used to directly generate a table in the various output formats. To do this you need to define this XML data structure as a CALS or HTML table. If the XML data structure is not defined as a CALS or HTML (the default), the elements in the data structure will be treated as ordinary non-table elements and no table markup will be added to the output document.

To enable CALS/HTML table markup in the output do the following:

1. Select the command **Table | Edit CALS/HTML Tables**.
2. In the dialog that pops up (screenshot below), add an entry for the XML data structure you wish to use as a CALS/HTML table, according to whether the data structure follows the CALS or HTML table model. (For information about the CALS table model, see the [CALS table model at OASIS](https://docs.oasis-open.org/cals/cals-collation/202106/c01-draft-cals-collation-20210606-c01.pdf). For an example of a table element having an HTML table structure, open HTMLTable1.sps, which is in the Basics folder of the Examples project folder (in the Project window of the GUI).) So, if you wish to enable an element in your schema as a CALS or an HTML table element, click the Add CALS/HTML table button in the top left part of the dialog and then select either the **Add CALS Table** command or the **Add HTML Table** command. (In the screenshot below, the elements `table` and `informaltable` have been enabled as CALS tables (as well as HTML tables).) Click **OK** to confirm.
3. A dialog (Edit CALS Table or Edit HTML table) appears showing the elements of the table type you selected (screenshot below). The element names that are listed in this dialog are, by default, the element names in the selected table model (CALS or HTML). If the SPS schema contains elements with the same names as the names of the CALS/HTML table model, then the names are shown in black (as in the screenshot below). If a listed element name is not present in the SPS schema, that element name is listed in red. You can change a listed element name to match a schema name by double-clicking in the relevant Element Name field and editing the name.

4. Click OK to define this XML data structure as a CALS or HTML table.
5. You can add entries for as many XML data structures as you like (see screenshot in Step 2 above). The same main element can be used once each for CALS and HTML table types.
6. After you have finished defining the XML data structures you wish to enable as CALS/HTML tables, click OK to finish.

If a CALS/HTML table has been defined and the XML data structure is correctly inserted as a CALS/HTML table, then the data structure will be sent to the output as a table. To remove a CALS/HTML table...
definition, in the Edit CALS/HTML table dialog select the definition you wish to delete and click the Delete button at the top right of the Define CALS/HTML Tables pane.

Table formatting

CALS/HTML tables receive their formatting in two ways:

1. From formatting attributes in the source XML document. The CALS and HTML table models allow for formatting attributes. If such attributes exist in the source XML document they are passed to the presentation attributes of the output's table markup.

2. Each individual element in the table can be formatted in the Styles column of the Edit CALS Table dialog or Edit HTML Table dialog (see screenshot below).

![Edit HTML Table](image)

To assign a style to a particular element, click the Add Styles button for that element and assign the required styles in the Styles sidebar that pops up. Each style is added as an individual CSS attribute to the particular element. Note that a style added via the style attribute will have higher priority than a style added as an individual CSS attribute (such as bgcolor). For example, in `<thead style="background-color: red" bgcolor="blue"/>` the `style="background-color: red"` attribute will have priority over the `bgcolor="blue"` attribute.

To remove a style that has been assigned to an element in the CALS/HTML table definition, select that element (for example in the screenshot above the `thead` element has been selected) and click the Delete button. The styles for that element will be removed.

Inserting a CALS/HTML table in the design

A CALS/HTML table structure can be inserted in the design in two ways:

1. The parent of the table element is inserted in the design as (contents). When the contents of the parent are processed, the table element will be processed. If CALS/HTML table output is enabled, then the element is output as a table. Otherwise it is output as text.

2. The table element can be dragged from the Schema Tree. When it is dropped at the desired location in the design, it can be created as a CALS/HTML table (with the Create CALS/HTML Table command).
If the element has not been defined as a CALS/HTML table, the Insert CALS/HTML Tables dialog (screenshot below) pops up and you can define the element as a CALS or HTML table.

![Insert CALS/HTML Table dialog](screenshot below)

If the element has been created in the design as a CALS/HTML table, a placeholder for the CALS/HTML table design element is inserted at the location (screenshot below).

![Sample HTML table](screenshot below)

**Global templates of table elements**

If global templates of the following table elements are created they will be used in the CALS/HTML table output. For CALS tables: title and entry. For HTML tables: caption, th, and td.

**Example files**

Example files are in the the Examples project folder (in the Project window of the GUI).
5.7 Lists

There are two types of lists that can be created in the SPS:

- **Static lists**, which are lists, the contents of which are entered directly in the SPS. The list structure is not dynamically derived from the structure of the XML document.
- **Dynamic lists**, which are lists that derive their structure and contents dynamically from the XML document.

How to create these two list types are described in detail in the sub-sections of this section.

5.7.1 Static Lists

A static list is one in which list item contents are entered directly in the SPS. To create a static list, do the following:

1. Place the cursor at the location in the design where you wish to create the static list and select the Insert | Bullets and Numbering menu command (or click the Bullets and Numbering icon in the Insert Design Elements toolbar). This pops up a dialog asking whether you wish to create a static list or dynamic list (screenshot below).

2. Click **Static List**. This pops up the Bullets and Numbering dialog (screenshot below).
3. Select the desired list item marker and click OK. An empty list item is created.
4. Type in the text of the first list item.
5. Press Enter to create a new list item.

To create a nested list, place the cursor inside the list item that is to contain the nested list and click the Insert Bullets and Numbering menu command. Then use the procedure described above once again.

Note: You can also create a static list by placing the cursor at the location where the list is to be created and clicking either the Bullets icon or Numbering icon in the Bullets or Numbering icons in the Formatting toolbar. The first list item will be created at the cursor insertion point.

Changing static text to a list
To change static text to a list, do the following:

Highlight the text you wish to change to a list, select the command Enclose With Bullets and Numbering, choose the desired marker type, and click OK. If the text contains a CR-LF, carriage-return and/or linefeed (inserted by pressing the Enter key), then separate list items are created for each text fragment separated by a CR-LF. If a text fragment within a line is highlighted, then that text is created as the list-item of a single-item list; you can add an unlimited number of additional list items by clicking Enter as many times as required. Note that the Enclose With Bullets and Numbering command can also be accessed via the context menu.

Lists in Text output
When a list is generated in Text output, each list item is indicated by a minus symbol at the start of the list item.
5.7.2 Dynamic Lists

Dynamic lists display the content of a set of sibling nodes of the same name, with each node represented as a single list item in the list. The element, the instances of which are to appear as the list items of the list, is created as the list. The mechanism and usage are explained below.

General usage mechanism

- Any element can be created as a list.
- When an element is created as a list, the instances of that element are created as the items of the list. For example, if in a department element, there are several person elements (i.e. instances), and you wanted to create a list of all the persons in the department, then you must create the person element as the list.
- Once the list has been created for the element, you can modify the appearance or content of the list or list item by inserting additional static or dynamic content such as text, Auto-Calculations, dynamic content, etc.

Creating a dynamic list

Create a dynamic list as follows:

1. Place the cursor at the location in the design where you wish to create the dynamic list and select the Insert | Bullets and Numbering menu command. This pops up a dialog asking whether you wish to create a static list or dynamic list (screenshot below).

![Dynamic List Dialog](image)

2. Click Dynamic List. This pops up the XPath Selector dialog (screenshot below).

3. In the XPath Selector dialog, notice that the XPath Context is the context of the insertion location, and that it cannot be changed in the dialog. Select the node that is to be created as the dynamic list. In the screenshot below, the context node is n1:Department, and the n1:Person node has been selected as the node to be created as a list. This means that the content of each n1:Person node will be created as an item in the list.
If you select the User-defined XPath option, then you can enter an XPath expression to select the node to be created as the dynamic table. Clicking OK pops up the Bullets and Numbering dialog described in the next step.

4. In the the Bullets and Numbering dialog, select the kind of list you wish to create. You can choose from a bulleted list (with a bullet, circle, or square as the list item marker), or a numbered list. Clicking OK creates the list with the type of list item marker you selected.
Lists in Text output

When a list is generated in Text output, each list item is indicated by a minus symbol at the start of the list item.
5.8 Graphics

There are two ways in which graphics are used in an SPS:

- As images in the design document, and
- As Authentic View toolbar icons for applying markup to the XML document.

Note: Graphics are not rendered in Text output.

When inserting images in the design document, the location of the image can be specified directly in the SPS (by the SPS designer) or can be taken or derived from a node in the XML document. How to specify the location of the image is described in the section Image URIs. What type of images are supported in the various outputs are listed in the section Image Types and Output. The section Reference | Authentic Menu | Custom toolbar buttons describes how toolbar icons for Authentic View can be defined.

Image properties
Images can be set in the Properties window. Do this as follows. Select the image in the design. Then, in the Properties window, (i) select image in the Properties for column, (ii) select the required property group, and (iii) within the selected property group, select the the required property. For example, to set the height and width of the image, set the height and width properties in the HTML group of properties.

5.8.1 Images: URIs and Inline Data

Images can be inserted at any location in the design document. These images will be displayed in Authentic View and the output documents; in Design View, inserted images are indicated with thumbnails or placeholders.

To insert an image, click the Insert | Image menu command, which pops up the Insert Image dialog (screenshot below).

Images can be accessed in two ways:

- The image is a file, which is accessed by entering its URI in the Insert Image dialog.
The image is encoded as Base-16 or Base-64 text in an XML file.

Inserting an image file

An image file is inserted in the design by specifying its URI. This file is accessed at runtime and placed in the document. There are three ways in which the URI of the image can be entered in the Insert Image dialog (screenshot above):

- In the Static tab, the URI is entered directly as an absolute or relative URI. For example, `nanonull.gif` (relative URI; see section below), and `C:/images/nanonull.gif` (absolute URI).
- In the Dynamic tab, as an XPath expression that selects a node containing either (i) a URI (absolute or relative), or (ii) an unparsed entity name. For example, the entry `image/@location` would select the location attribute of the image element that is the child of the context node (that is, the node within which the image is inserted). The location node in the XML document would contain the image URI. How to use unparsed entities is described in the section Unparsed Entity URIs.
- In the Static and Dynamic tab, an XPath expression in the Dynamic part can be prefixed and/or suffixed with static entries (text). For example, the static prefix could be `C:/XYZCompany/Personnel/Photos/`; the dynamic part could be `concat(First, Last)`; and the static suffix could be `.png`. This would result in an absolute URI something like: `C:/XYZCompany/Personnel/Photos/JohnDoe.png`.

Inserting an image that is encoded text

An image can be stored in an XML file as Base-16 or Base-64 encoded text. The advantage of this is that the image does not have to be accessed from a separate file (linked to it), but is present as text in the source XML file. To insert an image that is available as encoded text in the XML source, use the Inline Data tab of the Insert Image dialog (see screenshot below).

![Insert Image Dialog](image)

Use an XPath expression to locate the node in the XML document that contains the encoded text of the image. Select an option from the Image Format combo box to indicate in what format the image file must be generated. (An image file is generated from the encoded text data, and this file is then used in the output document.) In the Encoding combo box, select the encoding that has been used in the source XML. This enables StyleVision to correctly read the encoded text (by using the encoding format you specify).

The Image File Settings dialog (accessed by clicking the Image File Settings button) enables you to give a name for the image file that will be created. You can choose not to provide a name, in which case StyleVision will, by default, generate a name.
Accessing the image for output

The image is accessed in different ways and at different times in the processes that produce the different output documents. The following points should be noted:

- Note the output formats available for your edition: (i) HTML in Basic Edition; (ii) HTML and RTF in Professional; (iii) HTML, RTF, PDF, and Word 2007+ in Enterprise Edition.
- For Design View and Authentic View in StyleVision, as well as for Authentic View in Altova products, you can set, in the Properties dialog, whether relative paths to images should be relative to the SPS or to the XML file.
- For HTML output, the URI of the image is passed to the HTML file and the image is accessed by the browser. So, if the path to the image is relative, it must be relative to the location of the HTML file. For the HTML Preview in StyleVision, a temporary HTML file is created in the same folder as the SPS file, so, for rendition in HTML Preview, relative paths must be relative to this location.
- For RTF output, the URI of the image is passed as an object link to the RTF file and is accessed by the RTF application (typically MS Word) when the file is opened. If the URI is relative, it must be relative to the location of the RTF file. For the RTF Preview in StyleVision, a temporary RTF file is created in the same folder as the SPS file, so, for rendition in RTF Preview, relative paths must be relative to this location.
- Whether the URI is relative or absolute, the image must be physically accessible to the process that renders it.

Editing image properties

To edit an image, right-click the image placeholder in Design View, and select Edit URL from the context menu. This pops up the Edit Image dialog, which is the same as the Insert Image dialog (screenshot above) and in which you can make the required modifications. The Edit Image dialog can also be accessed via the URL property of the image group of properties in the Properties window. The image group of properties also includes the alt property, which specifies alternative text for the image.

Deleting images

To delete an image, select the image and press the Delete key.

5.8.2 Image Types and Output

The table below shows the image types supported by StyleVision in the various output formats supported by StyleVision. Note that different editions of StyleVision support different sets of output formats: Enterprise Edition, HTML, Authentic, RTF, PDF, and Word 2007+; Professional Edition, HTML, Authentic, RTF; Basic Edition, HTML.

<table>
<thead>
<tr>
<th>Image Type</th>
<th>Authentic</th>
<th>HTML</th>
<th>RTF</th>
<th>PDF</th>
<th>Word 2007+</th>
</tr>
</thead>
<tbody>
<tr>
<td>JPEG</td>

<td>No</td>
</tr>
<tr>
<td>JPEG XR</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

* See notes immediately below

Note the following points:

- In Design View, images will be displayed only if their location is a static URL (i.e. directly entered in the SPS).
- For the display of TIFF and SVG images in Authentic View and HTML View, Internet Explorer 9 or higher is required.
- In RTF output, TIFF images can only be linked, not embedded. So re-sizing is not possible.
- SVG documents must be in XML format and must be in the SVG namespace.
- FOP reports an error if an image file cannot be located and does not generate a PDF.
- If FOP is being used to produce PDF, rendering PNG images requires that the JIMI image library be installed and accessible to FOP.
- For more details about FOP's graphics handling, visit the FOP website.

Example file

An example file, Images.sps, is located in the folder:

```
C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\Images
```

Image resizing in RTF output

Resizing an image in the RTF output is only supported for JPG and PNG images. The following points should be noted:

- Resizing is supported only in designs that use XSLT 2.0 or XSLT 3.0, not XSLT 1.0.
- The `height` and `width` attributes of the image must be set in the Details group of the Styles sidebar. The `height` and `width` attributes in the HTML group of the Properties sidebar are not used.
- Only absolute units (px, cm, in, etc) are supported. Percentage values and `auto` are not supported.
- JPG and PNG images are embedded in the RTF file. This embedding is implemented using a proprietary Altova XSLT 2.0 extension functionality.

Image embedding in RTF

In the RTF output, images can either be embedded (when XSLT 2.0 or XSLT 3.0 is used) or linked. This setting is made for each SPS individually. To embed images, do the following:

1. With the required SPS active, open the Properties dialog (`File` | `Properties`).
2. Check the Embed Images check box (default setting is checked). Note that images will only be embedded if XSLT 2.0 or XSLT 3.0 is set as the XSLT version of the active SPS.
3. Click `OK` and save the SPS. The setting is saved for the active SPS.

To make this setting for another SPS, make this SPS active and repeat the steps listed above.
If the Embed Images check box is not checked, images will be linked according to the image file path specified in the images properties (select the image and select URL in the Properties sidebar). For information about how paths are resolved, see the section Image URLs.

**Note:** The RTF format supports embedded images only for EMF, JPG, and PNG files.

**SVG images in HTML**

When an external SVG file with code for mouse events is used as an image, the SVG file is rendered within the image and will no longer be interactive. This limitation can be overcome by using the external SVG image file as an object or by including the SVG code fragment as a User-Defined XML Block.

Given below are the three ways in which SVG images can be included in a web page.

1. **External SVG inserted as image**: This generates an `<img>` in the generated HTML file, and interactivity will be lost.
2. **External SVG inserted as an object via the User-Defined Element feature** (see screenshot below). Be sure to insert the `type` attribute correctly: `ke type="image/svg+xml"`. When inserted in this way, the SVG object is still interactive and the mouse hover-functionality will work.

![Edit User-Defined Element](image)

3. **Inline SVG inserted via a User-Defined XML Block**. See screenshot below for an example of an SVG code fragment. In this case, interactivity will work. Note that the `svg` element does not need to be in the SVG namespace if the output method is HTML 4.0 or 5.0, but the namespace is required if the output method is XHTML.
5.8.3 Example: A Template for Images

The StyleVision package contains an SPS file that demonstrates the use of images in StyleVision. This file is in the (My) Documents folder: C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\Images\Images.sps. The Images document (Images.xml and Images.sps) consists of three parts:

- The first part shows how text state icons can be used in Authentic View (can be created in Enterprise and Professional editions only). When you open the file Images.xml in the Authentic View of XMLSpy, Authentic Desktop, or Authentic Browser, you can try out the use of text state icons. Note that text state icons are not available in the Authentic Preview of StyleVision, so you cannot try out this feature in StyleVision. How to create text state icons is described in the Reference | Authnetic Menu | Custom toolbar buttons section of this user manual.

- The second part contains a table showing which image formats are supported in the various StyleVision output formats. In Design View, only images with static URIs will be displayed. All the image formats listed in the table are displayed in Part 3 of the Images document.

- In Part 3, all the popular image formats supported by StyleVision are displayed one below the other. After opening the file Images.sps in StyleVision, you can switch among the various previews of StyleVision to see how each image is displayed in that preview. Since the location of the image is in an XML node, you can also enter the location of your own images in Authentic View and test their appearances in the preview windows.
5.9 Form Controls

Nodes in the XML document can be created as data-entry devices (such as input fields and combo boxes). Data-entry devices are intended for easier editing in Authentic View. For example, an input field makes it clear to the Authentic View user that input is expected in this location while a combo box lists, as well as restricts, the values a user can enter. When data is entered into a data-entry device, the data is inserted into the XML document as element content or as an attribute's value. In the HTML, Text, and RTF output, the data-entry device is rendered as an object that is the same as that displayed in Authentic View, or a near-equivalent. Note that data-entry devices accept input to the XML document and, therefore, will not work in the HTML output.

General mechanism

Given below is a list of the data-entry devices available in StyleVision, together with (i) an explanation of how data is entered in the XML document for each device and (ii) how the data-entry devices will be output in plain text format.

<table>
<thead>
<tr>
<th>Data-Entry Device</th>
<th>Data in XML File</th>
<th>Output to Plain Text Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input Field (Text Box)</td>
<td>Text entered by user</td>
<td>Text entered by user</td>
</tr>
<tr>
<td>Multiline Input Field</td>
<td>Text entered by user</td>
<td>Text entered by user</td>
</tr>
<tr>
<td>Combo box</td>
<td>User selection is mapped to a value.</td>
<td>Selected value</td>
</tr>
<tr>
<td>Check box</td>
<td>User selection is mapped to a value.</td>
<td>[] (unselected); [x] (selected)</td>
</tr>
<tr>
<td>Radio button</td>
<td>User selection is mapped to a value.</td>
<td>() (unselected); (o) (selected)</td>
</tr>
<tr>
<td>Button</td>
<td>User selection is mapped to a value.</td>
<td>Button text</td>
</tr>
</tbody>
</table>

The text values entered in the input fields are entered directly into the XML document as XML content. For the other data-entry devices, the Authentic View user's selection is mapped to a value. StyleVision enables you to define the list of options the user will see and the XML value to which each option is mapped. Typically, you will define the options and their corresponding values in a dialog.

General usage

To create a data-entry device, do the following:

1. Drag a node from the Schema Tree window into Design View and drop it at the desired location.
2. From the context menu that appears, select the data-entry device you wish to create the node as.
3. For some data-entry devices, a dialog pops up. In these cases, enter the required information in the dialog, and click OK.

To reopen and edit the properties of a data-entry device, select the data-entry device (not the node containing it), and edit its properties in the Properties sidebar.

Note:
- Data can be entered in data-entry devices only in Authentic View.
- Data-entry devices can also be created by changing the current component type of a node to a data-entry device. To do this right-click the node and select Change to.
In the HTML and RTF output, the entry selected by the user is displayed in the output. Changing the value of a data-entry device in the HTML document does not change the text value in either the XML document or HTML document.

In the case of some data-entry devices, such as check boxes, where the device cannot correctly be rendered in print, an alternative rendition is implemented.

5.9.1 Input Fields, Multiline Input Fields

You can insert an Input Field or a Multiline Input Field in your SPS when you drop a node from the Schema Sources window into Design View. The text that the Authentic View user enters into these fields is entered into the XML node for which the field was created. The content of that node is displayed in the input field or multiline input field.

Editing the properties of input fields

You can modify the HTML properties of input fields by selecting the input field and then modifying its HTML properties in the Properties sidebar (see screenshot below).

For example, with the input field selected, in the Properties window select editfield, select the HTML group of properties and the maxlength property. Then double-click in the Value field of maxlength and enter a value.

Note: CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). CDATA sections can only be entered within elements that are displayed in Authentic View as text content components.

5.9.2 Check Boxes

You can create a check box as a data-entry device. This enables you to constrain user input to one of two choices. In the Edit Check Box dialog (shown below), you specify the XML values to map to the checked and unchecked events.
In the above screenshot, an element called Name has been created as a check box. If the Authentic View user checks the check box, a value of true will be entered as the value of the element Name. If the value is unchecked, then the value false is entered as the XML value of Name (as defined in the dialog).

Note: When a new Name (or check box) element is created in Authentic View, its XML value is empty (it is not the Unchecked Value). The Unchecked Value is entered only after the check box has first been checked, and then unchecked. To have a default value in a node, create a Template XML file that contains the default value.

Note: Check boxes in Text output are displayed as square brackets: [ ] for unselected check boxes; [x] for selected check boxes.

Accessing the Edit Check Box dialog

If you are creating a new check box, when you create the node as a check box, the Edit Check Box dialog pops up. To access the Edit Check Box dialog afterwards, do the following:

1. Select the check box in the design.
2. In the Properties sidebar, select the checkbox item and then the checkbox group of properties (see screenshot below).
3. Click the Edit button of the check values property. This pops up the Edit Check Box dialog.

**Note:** You can modify the HTML properties of a check box by selecting it and then modifying its HTML properties in the Properties sidebar.

### 5.9.3 Combo Boxes

A combo box presents the Authentic View user with a list of options entries in a dropdown list. The selected option is mapped to a value that is entered in the XML document. The mapping of drop-down list entry to XML value is specified in the SPS.

Mappings can be made in the Edit Combo Box dialog in one of three ways:

- From the schema enumerations for the selected node. In this case, the visible entry (in the dropdown list) will be the same as the XML value.
- From a list defined in the Edit Combo Box dialog. You enter the visible entry and the corresponding XML value, which may be different.
- From the result sequence of an XPath expression relative to the current node. The items in the result sequence are displayed as the entries of the drop-down list, and the list entry selected by the Authentic View user is entered as the value of the node. This is a powerful method of using dynamic entries in the combo box. The node that you create as the combo box is important. For example, say you have a `NameList` element that may contain an unlimited number of `Name` elements, which themselves have `First` and `Last` children elements. If you create the `Name` element as a combo box, and select the `Last` child element for the list values, then, in Authentic View, you will get as many combo boxes as there are `Name` elements and each combo box will have the `Last` child as its dropdown menu entry. In order to get a single combo box with all the `Last` elements in the dropdown menu list, you must create the single `NameList` element as the combo box, and select the `Last` element in the XPath expression.

**Accessing the Edit Combo Box dialog**

If you are creating a new combo box, when you create the node as a combo box, the Edit Combo Box dialog pops up. You can also insert a combo box with the (Insert | Insert Form Controls | Combo Box) menu command. To access the Edit Combo Box dialog afterwards, do the following:

1. Select the combo box in the design.
2. In the Properties sidebar, select the combo box item and then the combo box group of properties (see screenshot below).
3. Click the Edit button of the content origin property. This pops up the Edit Combo Box dialog.

**Using the Edit Combo Box dialog**

The Edit Combo Box dialog is shown below.
To define the entries and values for the combo box, do the following:

1. Select the method with which you wish to define the entries and values by clicking the appropriate radio button: (i) schema enumerations, (ii) list of values, or (iii) XPath expressions to select values.
2. If you select Schema Enumerations, the enumerations assigned to that node in the schema are entered automatically as (i) the visible entries of the drop-down list of the combo box, and (ii) the corresponding XML values (screenshot below). Visible Entries are the entries in the drop-down list of the combo box. Each drop-down list entry has a corresponding XML value. The XML value corresponding to the visible entry that the Authentic user selects will be the XML value that is entered in the XML file. Both visible entries and XML values are grayed out in the list of values because they are both obtained from the schema enumerations and cannot be edited.
If you select *Use List of Values*, you can insert, append, edit, and delete any number of entries for the drop-down list of the combo box as well as for the corresponding XML values. These edits are carried out in the pane below the *Use List of Values* radio button. You could also use an XPath expression to create the visible entries and XML values. The items in the sequence returned by the XPath expression will be used for visible entries and XML values. You can specify: (i) that the same XPath expression be used for visible entries and XML values, or (ii) that different XPath expressions be used. In the latter case, a one-to-one index mapping between the items of the two sequences determines the correspondence of visible entry to XML value. If the number of items in the two sequences are not equal, an error is reported.

3. If you wish to have the items that appear in the drop-down list of the combo box in Authentic View sorted, check the *Sort Values in Authentic* check box.

4. Click **OK** to finish.

**Note**
- Using an XPath expression to select the items of the combo box drop-down list enables you to create combo boxes with dynamic entries from the XML file itself.
- If the items in the drop-down list of the combo box are obtained from schema enumerations, they will be sorted alphabetically by default. If the items are obtained from an XML data file, they will appear in document order by default. If the items are obtained from a DB, the DB schema must be set as the main schema. If items are obtained from a DB that is not the main schema, a template for the DB row targeted by the XPath expression must be included in the design, even if the template must be empty. Additionally, in such cases, make sure that all instances of the targeted row are fetched.
- Combo boxes in Text output displayed the selected value.

### 5.9.4 Radio Buttons, Buttons

There are two types of button: radio buttons and buttons. Radio buttons allow the Authentic View user to enter data into the XML file. Buttons do not allow data-entry in Authentic View, but are useful for triggering events in the HTML output.

#### Radio buttons

Inserting radio buttons in the SPS allows you to give the user a choice among multiple alternatives. Each radio button you insert maps to one XML value. The user selects one radio button. The radio buttons for a node are mutually exclusive; only one may be selected at a time, and the associated XML value is entered as the value of the node. The way to use this feature is to create the node for which the data-entry is required multiple times as a radio button. For each radio button enter (i) some static text to indicate its value to the user, and (ii) an XML value for each radio button. To edit the XML value of a radio button, in the Properties sidebar, select the
radio button item, then click the Edit button of the radio button property. This pops up the Edit Radio Button dialog.

Buttons
The button option allows you to insert a button and specify the text on the button. This is useful if you wish to associate scripts with button events in the generated HTML output. Note, however, that a button does not map to any XML value and does not allow data entry in Authentic View. However, the value of the parent node of a button can be selected by the Authentic View user, and the SPS can be designed to modify presentation based on what the Authentic View user selects.

Note: You can modify the HTML properties of a radio button or button by selecting it and then modifying its HTML properties in the Properties sidebar.

Note: Radio buttons in Text output are displayed as parentheses: () for unselected radio buttons; (o) for selected radio buttons. Buttons generate only the button text in Text output.
5.10 Links

Links (or hyperlinks) can be created to bookmarks located in the document as well as to external resources like Web pages. Links can also be created to dynamically generated anchors. StyleVision offers considerable flexibility in the way target URIs for hyperlinks can be built.

The section, Bookmarks and Hyperlinks, describes how to create static and dynamic bookmarks in the document and how to link to bookmarks as well as to external documents.

Note: Links are not rendered in Text output.
5.11 Barcodes

The Barcode design element is supported in XSLT 2.0 or XSLT 3.0 mode (not XSLT 1.0) and enables barcodes (screenshot below) to be generated in the output document. At the location in the design document where you wish to enter the barcode, insert the Barcode design element and specify its properties.

Important: For barcodes to work, a Java Runtime Environment must be installed. This must be version 1.4 or later in a bit version that corresponds to the bit version of the StyleVision package installed on your system: 32-bit or 64-bit.

Important: For barcodes to be generated in the output, you must use Altova's XSLT processor to generate the output. This is because the barcodes in an SPS are generated by calling special Java extension functions that are not part of the XSLT standard. Altova's XSLT processors support these specific extension functions, whereas other XSLT processors very probably do not. As a result, barcodes will not be generated if processed with a non-Altova XSLT processor. The Altova XSLT processor is packaged with StyleVision, and is automatically called when you generate output via the Generate commands in the File menu. Alternatively, you can use RaptorXML Server, which is an Altova's standalone XSLT processor.

Note: Barcodes are not rendered in Text output.

Inserting a barcode

To insert a barcode in your design, do the following:

1. At the location where you wish to insert the barcode, right-click and select the command Insert Barcode. Alternatively, select the command Insert | Insert Barcode or click the Barcode icon in the toolbar and click the location in the design where you wish to insert the barcode. You can also drag and drop an element from the Schema Tree into the Design View and then select 'Create Barcode'. The Insert Barcode dialog pops up (screenshot below).
2. Two properties, Type and Text, are mandatory; the others are optional and/or have appropriate default values. The Type property, the value of which can be selected from a dropdown list (see screenshot above), specifies the type of the barcode, for example EAN-13 (which includes ISBN barcodes) and UPC-A. The Text property specifies the value that will generate the barcode, for example, an ISBN number. The various barcode properties are described below. Set the required properties and any other properties that you want. Note that, if you wish to use a value in the XML file as the value of a property, you can enter an XPath expression to locate the XML node you wish to access. Do this as follows: Select the property, toggle on the XPath button in the toolbar of the Properties dialog, and then enter the XPath expression in the Edit XPath Expression dialog. The XPath expression will be evaluated within the current context node.

3. After setting the properties, click OK. The barcode image will be inserted. The generated barcode (see screenshot below) can be immediately viewed in any of the output previews.

Note: Barcode images are generated as PNG files.
Barcode properties

The following barcode properties can be specified. The Type and Text properties must be set; the other properties are optional. Note that different properties are available for different barcode types.

- **Type**: The barcode system under which the message will be interpreted, such as EAN and UPC.
- **Text**: The value that will be used to generate the barcode pattern.
- **SetModuleWidth**: The width of the bars in the code.
- **SetBarHeight**: The height of the bars.
- **SetHeight**: The height of the barcode graphic.
- **DoQuietZone**: Yes or No values determine whether the "quiet zone" (or padding) around the barcode, which is specified in the SetQuietZone and SetVerticalQuietZone properties, will be implemented.
- **SetQuietZone**: Sets the "quiet zone" (or padding) around the barcode. In the case of one-dimensional barcodes, the value specified here is applied to the horizontal dimension. In the case of two-dimensional barcodes, the value is applied to both horizontal and vertical dimensions. The value of the vertical dimension can be overridden by the value specified in the SetVerticalQuietZone property. A length unit of millimeters (mm) is required. Example: 2mm.
- **SetVerticalQuietZone**: Sets the "quiet zone" (or padding) for the vertical dimension on two-dimensional barcodes. A length unit of millimeters (mm) is required. Example: 2mm.
- **SetMsgPosition**: Specifies where the message text appears relative to the barcode. Values are top, bottom, and none (no message is generated).
- **SetPattern**: Sets a pattern for the message text so that the text is readable. A long string of numbers, for example, would be difficult to read. The syntax for patterns is given below.
- **SetFontName**: The font in which text should appear.
- **SetFontSize**: The font-size in which text should appear.
- **SetChecksumMode**: The following values are available: (i) Add: the checksum is automatically added to the message; (ii) Check: the checksum is checked while rendering the barcode (assumes the checksum is present); (iii) Ignore: no checksum processing is done; (iv) Auto: enables the barcode type's default behaviour.
- **Orientation**: Whether the barcode should be rotated. The options are in steps of 90 degrees counterclockwise.
- **PixelDensity**: Specifies the density of the pixels in the barcode image. Higher pixel density provides sharper images.
- **GeneratedImageSettings**: Enables you to set a name for the generated barcode image file. If no name is specified, a name is generated automatically by StyleVision.

Pattern syntax

Patterns are used to make the input message string more readable in the barcode. In the pattern, each character of the input message text is represented by the underscore "_". Any other characters included in the pattern are inserted at the corresponding locations in the output message text. The backslash "\" is an escape symbol. So, the combination of "\?" will insert the character '?' in the output message text, where '?' can be any character. The character '!' can be used to delete a character from the original message. These points of pattern syntax are illustrated with the examples below.

<table>
<thead>
<tr>
<th>Input message text</th>
<th>Pattern</th>
<th>Output message text</th>
</tr>
</thead>
<tbody>
<tr>
<td>123456</td>
<td>__ __ __</td>
<td>12 34 56</td>
</tr>
</tbody>
</table>
Generating output files

The barcode image files that are generated for the output are saved to locations that are specified in the Paths tab of the Properties dialog (screenshot below), which is accessed with the menu command File | Properties.

Barcode image files for previews may be created in the same directory as the SPS file or as the Working XML File. These are temporary files, which are deleted when the SPS is closed. Barcode image files that are created when output is generated using the File | Save Generated File command can be created at any location. Their target location is specified in the pane, Location of Additionally Generated Files (see screenshot above).
5.12 Layout Modules

Layout Modules are objects containing a layout. The module as a whole is inserted in the SPS design and occurs as a block within the document flow. Within a Layout Module, multiple Layout Boxes, each containing standard SPS design elements, can be placed according to design requirements. Using Layout Modules, therefore, designers can create a layout just as they would using an artboard-based graphical design application.

The steps for creating a Layout Module are as follows:

1. **Insert a Layout Container**. The Layout Container can occupy the entire width of a page or can have any other dimensions you want. It can contain a blueprint of the design to serve as design guide and it can be formatted (in the Styles sidebar) using styles for the Layout Container.

2. **Insert one or more Layout Boxes** in the Layout Container. Layout Boxes can contain multiple design elements (including static text, schema nodes, Auto-Calculations, images, lists, etc), and they can be formatted (in the Styles sidebar) using styles for the Layout Box. Layout Boxes can also be moved relative to each other within the Layout Container and can be positioned in front of or behind each other.

3. **Lines** can be drawn, formatted, positioned and moved to the front or back of the stack of layout objects (Layout Boxes and other Lines).

**Note:** Layout Modules are not rendered in Text output.

Form-based designs

When you create a new SPS, you are offered the choice of creating a free-flowing design or a form-based design. A form-based design is essentially an SPS design consisting of a Layout Container.

**Note:** Layout Modules are supported in Authentic View only in the Enterprise Editions of Altova products.

5.12.1 Layout Containers

A Layout Container has the following properties:

- It can be inserted within the flow of a document, that is, within a template. Or it can be inserted as the container within which the document design is created.
- It can have the same dimensions as the page dimensions defined for that section (the Auto-Fit to Page property of Layout Containers). Or it can have any other dimensions you specify. See the Layout Container size section below for details.
- A **layout grid** and a **zoom feature** make the positioning of objects in the Layout Container easier.
- It can have **style properties**, such as borders, background colors, font-properties for the whole container, etc.
- It can contain **Layout Boxes and Lines**, but no other design element. (All design elements must be placed within Layout Boxes.)
- It can contain a **blueprint**, which is an image placed on the artboard to serve as a reference template for the designer. The design can then be built to match the blueprint exactly.

**Note:** Layout Containers are supported in Authentic View only in the Enterprise Editions of Altova products.
Inserting a Layout Container
To insert a Layout Container, click the Insert Layout Container icon in the Insert Design Elements toolbar and click the location in the design where the Layout Container is to be inserted. A dialog appears asking whether you wish to auto-fit the Layout Container to the page. If you click Yes, the Layout Container will have the same size as the page dimensions defined in the page layout properties of that particular document section. If you click No, then a Layout Container with a default size of 3.5in x 5.0in is created.

Note that a Layout Container can also be created at the time you create an SPS.

Layout Container size
There are two sets of properties that affect the size of the Layout Container:

- The Auto-Fit Page Size property (Properties sidebar, screenshot below) can be set to yes to create a Layout Container having the same dimensions as those specified for pages in that document section. A value of no for this property creates a Layout Container with a customizable size.

- The height and width properties of the Details group of Layout Container styles (in the Styles sidebar) specify the dimensions of the Layout Container. The dimensions can also be modified directly in the design by dragging the right and bottom margins of the Layout Container. Note that the height and width properties will take effect only when the Auto-Fit Page Size property has a value of no.

Layout Container Grid
The Layout Container has a grid to aid in spacing items in the layout. The following settings control usage of the grid:

- Show/Hide Grid: A toggle command in the Insert Design Elements toolbar switches the display of the grid on and off.
- Grid Size: In the Design tab of the Options dialog (Tools | Options) units for horizontal and vertical lengths can be specified. Note that if very large length units are selected, the grid might not be clearly visible.
- Snap to Grid: A toggle command in the Insert Design Elements toolbar enables or disables the Snap to Grid function. When the Snap to Grid feature is enabled, the top and left edges of Layout Boxes and the endpoints of Layout Lines align with grid lines and points, respectively.
Zooming
To help position objects more accurately, you can magnify the view. Do this by changing the Zoom factor in the Zoom combo box (in the Standard toolbar), or by pressing the Ctrl key and scrolling with the mouse.

Layout Container style properties
There are two types of style properties that can be applied to Layout Containers:

- Those applied to the Layout Container alone and which are not inheritable, such as the border and background-color properties.
- Those that are inheritable by the Layout Boxes in the Layout Container, such as font properties.

The style properties of a Layout Container are set in the Layout Container styles in the Styles sidebar (screenshot above).

Layout Container contents
The only design items that can be contained in a Layout Container are Layout Boxes and Lines. Additionally, a blueprint (which is not a design element) can be placed in the Layout Container as a design aid. All design elements must be placed in a Layout Box.
Blueprints

One blueprint can be placed in a Layout Container at a time to aid the designer in creating the SPS. The blueprint is an image file that can be placed to exactly fit the size of the Layout Container. Alternatively, if the blueprint image is smaller than the Layout Container, it can be offset to the desired location in the design (see Blueprint image properties screenshot below). The designer can use the blueprint by reproducing the SPS design over the blueprint design. In this way the designer will be able to place design elements in the layout exactly as in the blueprint. The blueprint will appear only in Design View, but not in any output view: this is because its purpose is only to aid in the design of the SPS.

The blueprint's properties can be controlled via the Blueprint image group of properties of the Layout Container properties (in the Properties sidebar, screenshot below).

The opacity of the blueprint in the Layout Container can be specified so that the blueprint does not interfere with the viewing of the design. The display of the blueprint image can also be switched off with the Show Image property if required.

5.12.2 Layout Boxes

Every design element in a layout (such as static text, schema nodes, Auto-Calculations, images, lists, etc) must be placed in a Layout Box. The Layout Boxes containing design elements are laid out as required in the Layout Container. Note that a design element cannot be placed directly in a Layout Container; it must be placed in a Layout Box.

This section describes how Layout Boxes are used and is organized into the following sub-sections:

- Inserting Layout Boxes
- Selecting and moving Layout Boxes
- Modifying the size of the Layout Box
- Defining Layout Box style properties
Inserting content in the Layout Box

A Layout Box can be inserted only in a Layout Container. To add a Layout Box, first click the Insert Layout Box icon in the Insert Design Elements toolbar, then click on the location inside the Layout Container where you wish to insert the Layout Box. A Layout Box will be inserted, with its top left corner positioned at the point where you clicked. The box will be transparent, will have no borders, and will have default text.

Selecting and moving a Layout Box

To select a Layout Box, place the cursor over the left border or top border of the Layout Box so that the cursor becomes a crossed double arrow. When this happens, click to select the Layout Box. If you keep the mouse button depressed, you can move the Layout Box to another location within its Layout Container. You can also move a Layout Box left, right, up, or down by selecting it, and then pressing the cursor key for the required direction. When the Layout Box is selected, its properties and styles are displayed in the respective sidebars.

Layout Box size

Each Layout Box has a property called Auto-Resize (see screenshot below). When the value of this property is set to yes, the Layout Box automatically resizes to exactly accommodate any static content (including markup) that is inserted in it in the Design View. When the value of Auto-Resize is set to no, the size of the Layout Box does not automatically change when content is inserted in it.

To change the size of the Layout Box manually, drag its right border and bottom border. You can also change the size of a Layout Box by using the cursor keys to move the right and bottom borders of the box. To do this first select the Layout Box. Then do the following: (i) to move the right border, keep the Shift key depressed and press the right or left cursor key till the required size is obtained; (ii) to move the bottom border, keep the Shift key depressed and press the top or bottom cursor key.

The Additional Height and Additional Width properties give the lengths that are additional to the optimal dimensions as determined by auto-resizing. The additional lengths are obtained when a Layout Box is manually resized. Conversely, by changing the values of these two properties, the size of the Layout Box can be changed.
**Note:** In a Layout Box a linefeed is obtained by pressing the **Enter** key. This is significant, because if content is added that does not contain a linefeed, then the length of the current line increases, thus increasing the optimal width of the Layout Box and—incidentally—affecting the *Additional Width* value, which is calculated with reference to the optimal width.

**Layout Box style properties**

The style properties of a Layout Box are set in the *Layout Box* styles in the Styles sidebar (*screenshot below*). The styles are displayed when the Layout Box is selected, and can then be edited.

![Styles](screenshot)

**Note:** The *background-color* value of *transparent* can be selected in the dropdown list of the property's combo box (it is not available in the color palette). The significance of this value in a situation where the Layout Box is part of a stack is explained below.

**Inserting content in a Layout Box**

Any type of design element can be inserted in a Layout Box, and is inserted just as it normally would be in an SPS. Note, however, that neither a Layout Container nor a Layout Line can be inserted in a Layout Box. The following points should be noted:

- When design elements are inserted that require a context node, the current node will be taken as the context node. The current node is the node within which the Layout Module has been created.
- Text content in a layout box can be rotated 90 degrees clockwise or anti-clockwise, so that the text is vertical, reading from top-to-bottom or bottom-to-top, respectively. To do this, in the design, select the text that is to be rotated and, in the Properties sidebar (*screenshot below*), select **Layout Box**. In the *Layout Box* group of properties, select the required value for the *Orientation* property.
Note the following points:

- The rotation will be applied to the output, but will not be displayed in the design.
- This property can also be applied to text in table cells.

Stacking order of Layout Boxes

Layout Boxes can be placed one over the other. When one Layout Box is placed on top of another, then, if it is opaque, it hides that part of the Layout Box which it covers. This behavior can be extended to a stack of several Layout Boxes. In such a stack, only the topmost Layout Box will be fully visible; the others will be partially or fully covered.

Layout Boxes can be sent backward or brought forward using the Order menu commands in the context menu of the selected Layout Box. Using these commands a Layout Box can be ordered: (i) relative to its nearest neighbor on the stack (the Bring Forward and Send Backward commands), or (ii) relative to the entire stack (the Bring to Front and Send to Back commands). In the screenshot above, the stacking order from front to back is as follows:

- Left stack: orange, green, blue
- Right stack: blue, green, orange

Note that Layout Boxes with transparent backgrounds (the default background of Layout Boxes) might appear to not move relative to each other, especially if more than one box in the stack is transparent and if boxes have no borders. The screenshot below presents some ways in which transparency affects stacking.
5.12.3 Lines

Lines can be inserted in a Layout Container (but not in Layout Boxes), then selected, re-sized and moved around within the Layout Container, assigned properties, and moved backwards and forwards in a stack of layout items consisting of Layout Boxes and other Lines.

Inserting a Line
To add a Line to a Layout Container, do the following:

1. Click the Insert Line icon in the Insert Design Elements toolbar.
2. Click on the location inside the Layout Container where you wish to locate the start point of the line.
3. Without releasing the mouse button, draw the line from the start point to the desired end point. Then release the mouse button.

A black line will be inserted, with a dot at each end indicating the start and end points respectively.

Selecting, moving, and sizing a Line
In the Main Window, you can carry out the following-drag-and-drop functions:

- To select a Line, click any part of the Line (the cursor becomes a crossed double arrow when it is over the Line). Once a Line is selected, its properties are displayed in the Properties sidebar and can be edited there (see below).
- To move a Line, select it and drag it to the desired location. You can also move a line left, right, up, or down by selecting it, and then pressing the cursor key for the required direction.
- To graphically re-size or re-orient a Line, select either the start point or end point and re-position it to obtain a new size and/or orientation. You can also re-size or re-orient a Line by pressing Shift and the cursor keys: the right and left cursor keys move the right-hand endpoint right and left, the up and down cursor keys move the right-hand endpoint up and down, respectively.
Line properties

When a Line is selected its properties are displayed in the Properties sidebar (screenshot below), and the properties (listed below) can be edited in the sidebar. You can also right-click a Line to pop up the Properties sidebar with the properties of the Line in it.

The following Line properties can be edited in the Properties sidebar:

- **Color**: Specifies a color for the Line. The default is black.
- **Size and position**: The location of the start and end points of the Line can be specified using an x-y (horizontal-vertical) coordinate system. The reference frame is created with the top left corner of the Layout Container having the coordinates $(x=0, y=0)$.
- **Width**: Specifies the thickness of the Line.

Lines and stacking order

When a Line is in a stack consisting of Layout Boxes and other Lines, it can be sent backward or brought forward using the Order menu commands in the context menu of the selected Line. Using these commands a Line can be ordered: (i) relative to its nearest neighbor on the stack (the Bring Forward and Send Backward commands), or (ii) relative to the entire stack (the Bring to Front and Send to Back commands).
In the screenshot above, the stacking order from front to back is as follows: green box, red line, black line, blue box.
5.13 The Change-To Feature

The Change-To feature is available when a template or the contents of a template are selected, and enables you to change: (i) the node for which that template applies, or (ii) how the node is created in the design.

What can be changed with the Change-To feature

Either a node or its contents can be changed. In the image below left, the node is selected. In the image at right, the node’s contents are selected.

The n1:Name element in the screenshot above has been created as (content), and so the node’s contents are represented by the (content) placeholder. Alternatively, the node could have been created as another type of content, for example, as an input field or combo box. Other types of content can also be selected.

The Change-To command

Access the change to command by right-clicking your selection. In the context menu that pops up, select Change To (screenshot below).
Changing template matches

If a template is selected, you can change the node for which that template applies. This is useful if, for instance, the name of an element has been changed in the schema. When you mouse over the Change To command and select Template from the sub-menu that pops up, you are presented with a list of all the nodes that may be inserted as a child of the selected node’s parent element. Click one of these nodes to make the template apply to that node.

If the selected node has a content model that does not match that described in the template, there will be structural inconsistencies. Such inconsistencies are errors and are indicated with red strikethroughs in the tags of nodes that are invalid.

You can also change the template-match to match, not a node, but a variable template.

Changing the content type of the node

If a template or its contents are selected, then you can change the type of content the node is created as. On hovering over the Change To command in the context menu, the type of content that the selected node can be changed to is displayed as options in the sub-menu that pops up (screenshot below).
The screenshot above has been taken with a combo box selected.
6 SPS Structure

The structure of an SPS document is both input- as well as output-driven, and it is controlled by:

- Schema sources
- Modular SPSs
- Templates and Design Fragments

Input-driven structure: schemas and modular SPS files

By input-driven, we mean that the source schemas of SPS files specify the structure of the input document/s and that this structure is the structure on which the SPS document is based. For example, if a source schema specifies a structure that is a sequence of Office elements, then SPS design could have a template for the Office element. At processing time this template will be applied in turn to each Office element in the source data document.

Another example of how the source document structure drives the design of the SPS file can be seen in the use of tables. Say that an Office element contains multiple Person element children, and that each Person element contains a set of child elements such as Name, Address, Telephone, etc. Then a template in the form of a table can be created for the Person element. Each Person element can be presented in a separate row of the table (screenshot below), in which the columns are the details of the Person (the child elements of the Person element).

<table>
<thead>
<tr>
<th>First</th>
<th>Last</th>
<th>Title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Loby</td>
<td>Maise</td>
<td>Accounting Manager</td>
</tr>
<tr>
<td>Frank</td>
<td>Further</td>
<td>Accounts Receivable</td>
</tr>
<tr>
<td>Vernon</td>
<td>Callaby</td>
<td>Office Manager</td>
</tr>
</tbody>
</table>

Such a template is possible because of the structure of the Person element and because the Person elements are siblings. In the table template a single row is designed for the Person element, and this processing (the row design) is applied in turn to each Person element in the source document, creating a new row for each Person element, with the child elements forming the columns of the table.

How to use various kinds of schema sources is described in the section, Schema Sources.

Additionally, StyleVision allows SPSs to be re-used as modules within other SPSs. In this way, modules can be included within a structure and can modify it. However, a schema structure contained in a module must fit in with the structure of the underlying schema of the containing SPS. How to work with modular SPSs is described in the section, Modular SPSs.

Output-driven structure: templates and design fragments

While the schema sources provide the structure of the input data document, the actual design of the output document is what is specified in the SPS document. This design is contained in one document template called the main template. The main template typically contains several component templates and can reference global templates. Templates are described in the section, Templates and Design Fragments.
This composability (of multiple templates) is further enhanced by a StyleVision feature called Design Fragments, which enables specific processing to be assigned to a document fragment that can be re-used. A Design Fragment is different than a global template in that: (i) it can be composed of multiple templates; and (ii) identical content with different processing can be created in separate design fragments, either of which can be used in a template according to the situation. For example, in some processing situations, an Email node might be required as a link that opens an empty email; in other cases the Email element could be required in bold and in red. Two separate design fragments could provide the respective processing, and both can be re-used as required.

Design fragments are described in detail in the section, Design Fragments.
6.1 Schema Sources

The schema sources are the starting point of the design, and design structure can be influenced by: (i) choices you make during schema selection, and (ii) the root elements you select in the schema.

Schema selection

The selection of the schema for a new SPS file can be done in the following ways:

1. Click File | New and directly select a schema source to add via one of the methods (except New (empty)) available in the menu that pops up.
2. Click File | New, select New (empty) from the menu that pops up. After the new SPS is created and displayed in the GUI, in the Design Overview sidebar, select the Add New Schema command. This pops up a menu listing the methods you can use to add different types of schemas (screenshot below). Each command in this menu is described in the sub-sections of this section.

   ![Add XML Schema/DTD/XML...](image)
   ![Add DB Schema...](image)
   ![Add Schema for XML Column in DB table...](image)
   ![Add User Defined Schema](image)

The schema source can be selected from a file, from a DB, or be user-defined. An important point to consider is whether you will be using global templates, and whether elements you wish to create as global templates are defined as global elements in the schema. When adding a DTD from file, remember that all elements defined in the DTD are global elements. When adding an XML Schema from file, it is worth checking what elements are defined as global elements and, should you wish to make any change to the schema, whether this is permitted in your XML environment. When a DB is selected, during the import process, you can select what tables from the DB to import. This selection determines the structure of the XML Schema that will be generated from the DB.

**Note:** If you wish to add a namespace to an SPS or to an XSLT stylesheet being generated from an SPS, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based.

Root elements

If a schema source has multiple global elements, then multiple root elements (document elements) can be selected for use in the design. This enables the SPS design to have templates that match multiple document elements. The advantage of this is that if an SPS, say UniversalSPS.sps, based on UniversalSchema.xsd has one template each for its two root elements, Element-A and Element-B, then this one SPS can be used with an XML instance document which has Element-A as its document element as well as with another XML instance document which has Element-B as its document element. For each XML instance, the relevant template is used, while the other is not used. This is because for the document element of each XML instance document, there is only one template in the SPS which matches that document element. For example, the document element /Element-A will be matched by the template which selects /Element-A but not by that which selects /Element-B. In this connection, it is important to remember that if multiple global elements are defined in the schema, an XML document with any one of these global elements as its document element is valid (assuming of course that its substructure is valid according to the schema).
To set up the SPS to use multiple root elements (document elements), click the button to the right of the /Root elements entry of the schema. The following dialog pops up.

The dialog lists all the global elements in the schema. Select the global elements that you wish to use as root elements (document elements) and click OK. The selected element/s will be available as root document elements and will be displayed in the Root Elements list. A template can now be created for each of these document elements. Each of these templates serves as an alternative root element template. When an XML document is processed with this SPS, only one of the alternative root element templates will be used: the one that matches the root (or document) element of the XML document.

So, when an XML document having Element-A as its document element is processed with this SPS, then the root template in the SPS that matches Element-A is triggered, while all the other root element templates in the SPS are ignored. If an XML document having Element-B as its document element is processed, then the root template in the SPS that matches Element-B is triggered, while all other root element templates in the SPS are ignored. In this way a single SPS can be used to process two or more XML documents, each of which has a different root (or document) element.

### 6.1.1 DTDs and XML Schemas

An SPS can be based on an XML Schema or DTD. An XML Schema or DTD can be created as a schema source in one of the following ways:

- The XML Schema or DTD is is created as a schema source directly when the SPS is created (File | New | New from XML Schema / DTD / XML).
- The XML Schema or DTD is added to an empty SPS (in the Design Overview sidebar).

The respective commands prompt you to browse for the XML Schema or DTD. If the schema is valid, it is created as a schema source in the Schema Sources tree of the Schema Tree sidebar. Alternatively, an XML
file can be selected. If an XML Schema (..xsd) or DTD file is associated with the XML file, then the XML Schema or DTD file is loaded as the source schema and the XML file is loaded as the Working XML File. If no schema is associated with the XML file, a dialog pops up asking whether you wish to generate an XML Schema based on the structure and contents of the XML file or browse for an existing schema. If you choose to generate a schema, the generated schema will be loaded as the source schema, and the XML file will be loaded as the Working XML File.

Selecting and saving files via URLs and Global Resources

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Click Switch to URL or Global Resource to go to one of these selection processes.

Selecting files via URLs

To select a file via a URL (either for opening or saving), do the following:

1. Click the Switch to URL command. This switches to the URL mode of the Open or Save dialog.
2. Enter the URL you want to access in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.

3. If the server is password protected, enter your User-ID and password in the User and Password fields.

4. Click Browse to view and navigate the directory structure of the server.

5. In the folder tree, browse for the file you want to load and click it.
The file URL appears in the File URL field (see screenshot above). The Open or Save button only becomes active at this point.

6. Click **Open** to load the file or **Save** to save it.

**Note the following:**

- The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.
- To give you more control over the loading process when opening a file, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

**Microsoft® SharePoint® Server Notes**

Note the following points about files on Microsoft® SharePoint® Servers:

- In the directory structure that appears in the Available Files pane (screenshot below), file icons have symbols that indicate the check-in/check-out status of files.
Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

- The various file icons are shown below:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Icon" /></td>
<td>Checked in. Available for check-out.</td>
</tr>
<tr>
<td><img src="image2.png" alt="Icon" /></td>
<td>Checked out by another user. Not available for check-out.</td>
</tr>
<tr>
<td><img src="image3.png" alt="Icon" /></td>
<td>Checked out locally. Can be edited and checked-in.</td>
</tr>
</tbody>
</table>

- After you check out a file, you can edit it in your Altova application and save it using **File | Save** (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot above), or via the context menu that pops up when you right-click the file tab in the Main Window of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out
command in the context menu. This has the effect of returning the file unchanged to the server.

- If you check out a file in one Altova application, you cannot check it out in another Altova application. The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: Check In and Undo Check Out.

▼ Opening and saving files via Global Resources

To open or save a file via a global resource, click Global Resource. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, Using Global Resources. For a general description of Global Resources, see the Global Resources section in this documentation.

The anyType datatype of XML Schema

If an element in the XML Schema has been assigned the anyType datatype of XML Schema or if it has not been assigned any datatype, then the schema tree in the Schema Tree will show this element as having all the global elements of that schema as possible children. For example, if an element called email has not been assigned any datatype, then it will be displayed in the schema tree with all global elements as possible children, such as, for example: person, address, city, tel, etc. To avoid this, assign the email element a datatype such as xs:string.

6.1.2  DB Schemas

An SPS can be based on a schema that is generated from a DB or have a DB-based schema (DB schema) as one of its schema sources. A DB schema can be created as a schema source in one of the following ways:

- The DB schema is generated for a new SPS when the SPS is created directly from a DB (File | New | New from DB or File | New | New from XML Column in DB Table).
- The DB schema is added to a new empty SPS that has no schema sources (in the Design Overview sidebar).

The respective DB-schema-generation commands generate a temporary XML Schema from the selected DB and creates the schema as a schema source in the Schema Tree sidebar, or the command loads a DB-based schema (DB schema) from an XML DB. An element extraneous to the DB, called DB, is created as the document element, and the DB structure is created within this document element. During the schema creation process, you will be prompted to select which tables or data from the database you wish to import. These database tables will be created in the XML Schema as children of the DB element and also as items in the Global Templates list.

Creating the XML Schema from a DB

Creating the XML Schema from a DB consists of two steps:

- Connecting to a Database. This consists essentially of browsing for the DB file (if it is a MS Access DB), or building a connection string (all other DBs except MS Access).
• **DB Data Selection**. In this step, the table or data structure from the database is selected. In the case of non-XML DBs, the temporary XML Schema that is generated and the XML file that is created will be based on the selected data tables.

After the schema source appears in the Schema Tree window, you can start designing the SPS. A temporary XML File is created each time an output preview tab is clicked. The XML file is structured according to the generated XML Schema and contains data from the selected DB tables.

### 6.1.3 User-Defined Schemas

You can quickly create a user-defined schema in the **Schema Tree sidebar**. This is useful if you have an XML document that is not based on any schema and you wish to create an SPS for this XML document.

To add and create a user-defined schema, in the Schema Tree sidebar, do the following:

1. Click **File | New | New (empty)**. In the **Design Overview sidebar**, click the Add New Source command (under the Sources heading), and select **Add User-Defined Schema** (screenshot below).

   - Add XML Schema/DTD/XML...
   - Add DB Schema...
   - Add Schema for XML Column in DB table...
   - Add User Defined Schema

   The new schema is created and is indicated with the parameter $USER (screenshot below).

2. In the Root Elements tree, there is a single **root element (document element)** called UserRoot.
3. Double-click UserRoot and rename it to match the **document element** of the XML document for which you are building this schema.
4. To assign a child element or an attribute to the document element, select the document element (UserRoot), and click, respectively, (i) the drop-Append New Element icon in the toolbar of the Schema Tree sidebar; and (ii) the dropdown arrow of the Append New Element icon | the Append New Attribute command. Alternatively, you can right-click and select the required command from the context menu. When an element is selected, appending and inserting an element, adds the new element as a sibling element, respectively, after and before the selected element. You can also add a
child element and a child attribute. When an attribute is selected, you can append or insert another attribute, respectively, after and before the selected attribute. After the new element or attribute is added to the tree, type in the desired name. You can also drag nodes to the desired location (described in the next step). In the screenshot below, the Article element is the document element. The elements Title, Para, Bold, and Italic, and the attributes ID and Author have been added at the child level of Article.

5. To move the elements Bold and Italic, and the attribute ID to the level of children of Para, select each individually and drag to the Para element. When a bent downward-pointing arrow appears, drop the dragged node. It will be created as a "child" of Para (screenshot below).
6. When any element other than the document element is selected, adding a new element or attribute adds the new node at the same level as the selected element. Drag a node (element or attribute) into an element node to create it as a "child" of the element node.

**Editing node names and deleting nodes**

To edit the name of an element or attribute, double-click in the name and edit the name. To delete a node, select it and click the Remove icon in the toolbar. Alternatively, select **Remove** from the context menu.
### 6.2 Merging XML Data from Multiple Sources

XML data from multiple source XML files can be merged when XSLT 2.0 or 3.0 is used as the XSLT version of the SPS.

Typically, the merging of data will be based on a common piece of data, such as an ID. For example, an employee in a company, who is identified by a personal ID number, can have his or her personal data stored in multiple XML files held by the personnel department: (i) personal details, (ii) payroll, (iii) work and leave, (iv) courses attended, etc. Data from these different files can be merged in a single output document using the personal ID number as a key.

**Note:** The Enterprise Edition enables you to include multiple schema sources, so XML nodes from other schemas can be selected using the parameter name for the corresponding schema (as is the case in the example below). In the Professional and Basic Editions, the `doc()` function of XPath 2.0 can be used to locate the required XML file and the XML node within that file. The `doc()` function of XPath 2.0 provides access to the document root of external XML documents, and thus enables node content from external XML documents to be inserted in the output. An Auto-Calculation that uses the `doc()` function can, therefore, also be used to merge XML data (see example below).

#### Example

The (My) Documents folder, `C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples`, contains an example SPS file (`MergeData_2_Files.sps`) that shows how data from different source XML files can be merged. The SPS selects data from an order (`MergeOrder.xml`, listed below) that a fictitious customer places.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<Order xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:noNamespaceSchemaLocation="MergeOrder.xsd">
  <Item partNum="238-KK" quantity="3" shipDate="2000-01-07" comment="With no inclusions, please."/>
  <Item partNum="748-OT" quantity="1" shipDate="2000-02-14" comment="Valentine's day packaging."/>
  <Item partNum="229-OB" quantity="1" shipDate="1999-12-05"/>
  <Item partNum="833-AA" quantity="2" shipDate="1999-12-05" comment="Need this for the holidays!"/>
</Order>
```

The value of the `/Order/Item/@partNum` attribute in this file (see above) is used to select the ordered products from the catalog of articles stored in another file, `MergeArticles.xml` (see listing below).

```xml
<?xml version="1.0" encoding="UTF-8"?>
<Articles xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
          xsi:noNamespaceSchemaLocation="MergeArticles.xsd">
  <Article PartNum="833-AA">
    <ProductName>Lapis necklace</ProductName>
    <Price>99.95</Price>
  </Article>
  <Article PartNum="748-OT">
    <ProductName>Diamond heart</ProductName>
    <Price>248.90</Price>
  </Article>
  <Article PartNum="783-KL">
    <!-- Article content -->
  </Article>
</Articles>
```
The way the merging of the data is done is to set up a User-defined template within the /Order/Item template (see screenshot below) that selects the corresponding Article element in the MergeArticles.xml file by using the part number of the ordered item to identify the article. The XPath expression (which is in the /Order/Item context) is: $Articles//Article[@PartNum=current()/@partNum]

This template will produce output something like that shown in the screenshot below.

Notice that while the quantity ordered of each item is taken from the file MergeOrder.xml, the name of the ordered article is taken from the file MergeArticles.xml. Also notice how the ProductName node is selected within the context of the /Articles/Article template.

The same result as that obtained above could also be achieved using an Auto-Calculation (see screenshot below). Drag the quantity attribute from the Schema Tree window and create it as contents. Then add an Auto-Calculation as shown in the screenshot and give the Auto-Calculation an XPath expression as described below.
The XPath expression of the Auto-Calculation could target the required node using either the parameter of another schema source or the `doc()` function:

```
$Articles//Article[@PartNum=current()/@partNum]/ProductName
```

or

```
doc('MergeArticles.xml')//Article[@PartNum=current()/@partNum]/ProductName
```

Notice that, while the first XPath expression above uses a parameter to refer to another XML Schema (a feature available only in the Enterprise Edition), the second expression uses the `doc()` function of XPath 2.0 (a feature available in the Professional and Basic editions as well).
6.3 Modular SPSs

The global templates of an SPS, as well as Design Fragments, JavaScript functions, and page layout items can be used in the design of another SPS. This enables:

1. The re-use of global templates and other components across multiple SPSs, the main advantages of which are single-source editing and consistency of output.
2. SPSs to be modularized, and thus to be more flexibly structured.

In any given SPS, one or more SPSs can be added as modules. Some types of components (or objects) in these modules are then available to the importing (or referring) SPS.

Available module objects

The section, Available Module Objects, not only describes the extent to which, and conditions under which, the various components of an SPS are available to an importing SPS. It also lists those components that are not available to the importing SPS. You should note that if an added module itself contains modules, then these are added recursively to the referring SPS. In this way, modularization can be extended to several levels and across a broad design structure.

Creating a modular SPS

To build a modularized SPS, first add the required SPS to the main SPS as a module. All the JavaScript functions, global templates, Design Fragments, and XPath functions in the added module are available to the referring SPS. Each of the available objects is listed in the Design Tree, under its respective heading (screenshot below), and can be activated or deactivated, respectively, by checking or unchecking its check box.
These objects can then be re-used in the referring SPS according to their respective inclusion mechanisms. Global templates typically would need merely to be activated in order for them to be applied in the referring SPS. Design fragments have to be dragged from the Design Tree to the required location. JavaScript functions are assigned via the Property window as event handlers for the selected design component. And available (activated) XPath functions can be used in XPath expressions.

How to create and work with a modular SPS is described in the section, Creating a Modular SPS.

**Terminology**

When an SPS is used within another module it is said to be added to the latter, and we call the process adding. The two SPSs are referred to, respectively, as the **added SPS module** and the **referring SPS module**. When an SPS module is added, its **objects** are added to the referring SPS module. These objects are called **module objects**, and are of the following types: global templates; Design Fragments; JavaScript functions; and page layout items.

### 6.3.1 Available Module Objects

This section lists the objects in **added SPS modules** that are available to the **referring SPS module**. The listing explains in what way each object is available to the referring SPS module and how it can be used there. For a step-by-step approach to creating modular SPSs, see the next section, Creating a Modular SPS. The section ends with a list of objects in the added SPS that are not available to the referring SPS module; this will help you to better understand how modular SPSs work.
Namespace declarations

Each SPS stores a list of namespace URIs and their prefixes. When an SPS is added as a module, the namespaces in it are compared to the namespaces in the schema source/s of the referring SPS. If a namespace URI in the added SPS matches a namespace URI in the schema source/s of the referring SPS, then the prefix used in the schema source of the referring SPS is adopted as the prefix for that namespace in the added SPS. If a namespace URI in the added SPS cannot be matched with any namespace URI in the schema source/s of the referring SPS, then an error message indicating this is displayed.

The screenshot above shows the various namespaces in an SPS, together with their prefixes, in the Schema Tree sidebar. These namespaces come from the source schema/s and cannot be edited.

Global templates

The global templates of the added SPS module are available to the referring SPS module and are displayed in the Design Tree sidebar (screenshot below). They are, by default, activated or deactivated (checked or unchecked), according to the respective activation status in the added module. If you wish to create a global template to override a global template from an added module, create the new global template by clicking the icon next to the Global Templates entry. In the Add New Global Template that pops up, select an element or attribute for which you wish to create the global template. Alternatively, enter an XPath expression that selects the required node in the schema. On clicking OK, you will be prompted as to whether the new global
The template should be activated in preference to the global template in the added module. The response you select activates either the newly created global template or the global template in the added module. You can switch your selection at any time by checking the other of the two global templates.

Note that the main template of added modules are not available. This means that if you plan to re-use a template via the modular approach, you must create it as a global template. If no global template is defined for a particular element and processing is invoked for that element, then the default processing for that element (XSLT's built-in templates) will be used.

**Design fragments**

Design fragments in the added SPS module are available to the referring SPS and are displayed in the Design Tree sidebar (screenshot above). When inserting a design fragment in the design, care should be taken to place the design fragment within the correct context node in the design.

**Added modules**

Each added SPS module also makes available to the referring SPS its own added modules, and their added modules, and so on. In this way, adding one module recursively makes available all modules that have been added to it, down multiple levels. Needless to say, these modules must together construct a content model that is valid according to the source schema/s of the referring SPS module. Modules are displayed and can be managed in the Design Overview sidebar.
Scripts
The scripts in all the added SPS modules are available for use in the referring SPS and are displayed in the Design Tree sidebar. In effect, the scripts of all the added modules are collected in a library that is now—in the referring SPS—available for selection in the Properties dialog.

CSS styles
The global styles present in added SPS modules are carried over to the referring SPS as global styles and the style rules are displayed in the Style Repository sidebar. The CSS files are also listed in the Design Overview sidebar. Similarly, external CSS files that were available to the added SPS module, are available to the referring SPS module.

Page layouts
The page layouts of an added module are available to the referring SPS and are displayed in the Design Tree sidebar.

Module objects that are not available to the referring SPS
The following objects of the added module are not available to the referring SPS:

- **Parameter definitions**: are ignored.
- **Schema sources**: The schema source on which the added SPS is based is ignored. Bear in mind that the content model of the document element of the added SPS must be contained within the content model of the referring SPS; otherwise it would not be possible to correctly use the added SPS as a module. If you wish, you could always add a user-defined schema to the referring SPS. The additional schema could accommodate the content model of the added global template/s.
- **Working XML File and Template XML File**: References to these files are ignored. The referring SPS uses its own Working XML and Template XML Files.
- **XPath default namespaces**: If they have been set on a module that is imported then they are not carried through to the importing SPS.

6.3.2 Creating a Modular SPS

Creating a modular SPS consists of four broad parts:

1. Design and save the SPS module to be added.
2. Add the module to the SPS in which it is to be used (that is, to the referring SPS module).
3. Activate or deactivate the added object/s as required.
4. Apply the required object wherever required.

The SPS module to be added
There are two points to bear in mind when creating an SPS that will be added to another:

1. The templates that can be used in the referring SPS module can only be global templates. This means that the templates you wish to re-use must be created as global templates in the SPS module that is to be added.
2. The document structure defined in the SPS module to be added must be valid within the content model defined by the source schema/s of the referring SPS. If an added template is not contained in the content model defined by the main schema of the SPS, its content model, however, can still be defined in a user-defined schema.

When creating the SPS module to be added, the schema on which you base the SPS could be one of the following:

- The main source schema of the referring SPS. In this case, when the SPS is added, the added global templates will be part of the content model of the referring SPS's main schema. The output of these global templates in Authentic View is, therefore, editable.
- A schema which defines a content model that is part of the content model defined by the main schema of the referring SPS. In this case, when the global templates are added, they will fit into the content model of the main schema of the referring SPS. The output of these global templates is editable in Authentic View.
- A schema which defines a content model that is not part of the content model defined by the main schema of the referring SPS. When this SPS module is added, its global templates will not be part of the content model of the main schema of the referring SPS. They can, however, be used to produce output if a user-defined schema is used that defines a content model that contains the content model of the global template/s. In Authentic View, however, the output of these global templates cannot be edited.

When defining the content models in your schemas, you should pay close attention to the namespaces used since these determine the expanded names of nodes.

You could use a Working XML File to test the output of the SPS module to be added. The reference to this Working XML File will be ignored by the referring SPS.

Adding the SPS module

To add a module to an SPS, in the Design Overview (screenshot below), click the Add New Module command, browse for the required SPS file in the dialog that appears, select it, and click Open.
The module is added to the SPS and is listed under the Modules heading in the Design Overview. In the screenshot above, the `BusinessAddressBook.sps` and `PersonalAddressBook.sps` modules have been added to the `AddressBook.sps` module (the active SPS). All the added module objects are listed in the Design Tree sidebar; added CSS files, though, are also also listed in the Design Overview. If the added modules themselves refer to modules, these latter, indirectly imported modules are listed under the Modules heading, but in gray. Information about which modules import an indirectly imported module is available in a pop-up that appears when you mouseover the indirectly imported module.

To open one of the added modules or indirectly imported modules quickly in StyleVision, right-click that module, and select Open Defining Module from the context menu that pops up.

**Order of added modules**

The order in which modules are added and listed is significant for the prioritizing of CSS styles. In keeping with the CSS cascade order, CSS style rules in a relatively later module (lower down the list) have priority over style rules defined in a relatively earlier module (higher up the list). CSS styles in the referring SPS module have priority over those in any added module. To change the relative position of an added module, right-click it in the Design Overview and click, as required, the Move Up or Move Down command in the context menu.

The module order is not significant for resolving conflicts among scripts, global templates, design fragments, and page layout items.

**File modification alerts**

If any added file (whether an SPS module, schema, or Working XML File) is modified after the referring SPS module has been opened, then a file modification pop-up will alert you to the change and ask whether the referring SPS module should be refreshed with the changes.
Activating/deactivating the added object

All module objects in all added modules (whether added directly or indirectly) are added to the referring SPS and are listed under the corresponding headings in the Design Tree: Scripts; Global Templates; Design Fragments; XSLT Templates; and XPath Functions. Next to each of these objects is a check box (see screenshot below), which you can check or uncheck to, respectively, activate or deactivate that object. When an object is deactivated, it is effectively removed from the SPS.

In the screenshot above, all the global templates used in the AddressBook.sps module are listed under the Global Templates heading. Those that have been added via other modules (whether directly or indirectly) are displayed in gray. Those that have been created directly in AddressBook.sps are displayed in black. The screenshot shows that only one global template, addr:Email, has been created in AddressBook.sps itself. All the other global templates have been added via other modules, and the file in which each of these is defined is listed next to its name.

Notice that there are two global templates for addr:Email, one created in the referring SPS (AddressBook.sps) itself, and the other created in the added module ContactPoints.sps. If more than one global template has the same (namespace-) expanded name, then only one of these will be active at a time. You can select which one by checking its check box. (Alternatively, you activate the global template from its context menu in Design View.) This mechanism is useful if you: (i) wish to override an added global template with one that you create in the referring SPS module, or (ii) wish to resolve a situation where a global template for one element is defined in more than one added module.

A global template that has been defined in the current SPS can be deleted by selecting it and clicking the Remove button. However, global templates that have been defined in an added module cannot be removed.
from the referring SPS. They must be removed by opening the added SPS and removing the global template there.

Individual scripts, Design Fragments, and page layout items can be activated and deactivated in the same way.

**Applying or using modular objects**

In the referring SPS module, you design your templates as usual. Each different type of added object is used or applied differently. You should, of course, ensure that each module object you wish to apply has been activated.

**Global templates**

When you wish to use a global template from any of the added SPS modules, you must make sure that this global template is indeed applied. This can be done in one of two ways, according to which one is appropriate for your design:

- In the main template, specify that the element template either uses the global template for that element or copies that global template locally. These two commands are available in the context menu that appears when you right-click the element tag in the design.
- In the main template, the contents or rest-of-contents placeholders cause templates to be applied, leading to the relevant global templates being processed.

**Design Fragments**

To use a Design Fragment, drag it from the Design Tree to the desired location in the main template or a global template. Make sure that the location where the Design Fragment is dropped is the correct context node for that Design Fragment. For details, see Design Fragments.

**Scripts**

All JavaScript functions (whether in an added module or created in the referring SPS) are available as event handlers, and can be set for a particular event via the Properties sidebar.

### 6.3.3 Example: An Address Book

The (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\ModularSPS, contains examples of modular SPSs. The example files in this folder comprise a project in which an address book containing business and personal contacts is modularized. The example not only demonstrates the mechanisms in which modularization is implemented, but also illustrates the main reasons why one would modularize.

- The complete address book is composed of two modules: (i) a business address book, and (ii) a personal address book, each of which has a separate SPS defining different designs. The two modules together make up the composite address book. Modularization in this case is used to compose: the modules are the components of a larger unit.
- Although the content model of each module (business and personal address books) differs slightly from the other, both have a common module, which is the ContactPoints module, consisting of the core contact details: address, telephone, fax, and email. The ContactPoints module can therefore be shared between the two address books (business and personal). Modularization in this case enables a single module to be used as a common unit within multiple other units.
- Further, the ContactPoints module can be modularized to provide more flexibility. In the example project, we have created a separate Address module to contain the postal address, which may have
one of three content models, depending on whether the address is in the EU, US, or elsewhere. The output for all three content models is defined in a single SPS. However, they could have been defined in separate SPSs, which would have provided finer granularity. In this case, modularization would provide more flexibility as modules could be re-used more easily.

The description of this project is organized into the following parts:

- **The schema files**
- **The XML data sources**
- **The SPS files**

### The schema files

When creating schemas for modular SPSs, the most important thing to bear in mind is to create the elements that you wish to re-use as global elements. The schema for the address book is `AddressBook.xsd`. This schema has been constructed by importing the schemas for the business address book (`BusinessAddressBook.xsd`) and personal address book (`PersonalAddressBook.xsd`). The `BusinessAddressBook.xsd` schema provides a content model for companies, while the `PersonalAddressBook.xsd` schema provides a content model for persons (see screenshot below).

Both schemas import the `ContactPoints.xsd` schema (see screenshot below), which defines a content model for contact details.
Finally, the ContactPoints.xsd schema (screenshot below) includes the Address.xsd schema, which defines the three address-type content models: for EU, US, and other addresses.

Imports are used when the imported schema belongs to a different namespace than the importing schema. Includes are used when the included schema belongs to the same namespace as the including schema.

Note: The screenshots above are of the schema in the Schema View of Altova's XMLSpy.

The XML data sources

The XML data is contained in the file AddressBook.xml. This file is structured so that the AddressBook element contains the companies and persons elements as its children. The content models of these two elements are defined in the schema files, BusinessAddressBook.xsd and PersonalAddressBook.xsd, respectively.
There are two additional XML data files, which correspond to the BusinessAddressBook.xsd and PersonalAddressBook.xsd schemas. These two XML files, BusinessAddressBook.xml and PersonalAddressBook.xml, are used as the Working XML Files of the corresponding SPS files.

The three XML files are the Working XML Files of the following SPS modules:

- AddressBook.xml  =>  AddressBook.sps, ContactPoints.sps, Address.sps
- BusinessAddressBook.xml  =>  BusinessAddressBook.sps
- PersonalAddressBook.xml  =>  PersonalAddressBook.sps

The SPS modules

The description of the SPS modules starts with the most basic module (Address.sps) and progresses in compositionally incremental steps to the complete address book (AddressBook.sps). All the SPS modules use AddressBook.xsd as its schema.

Address.sps

The key points to note are the use of the schema and the Working XML File.

- Address.sps uses AddressBook.xsd as its schema, but the schema could equally well have been Address.xsd, ContactPoints.xsd, BusinessAddressBook.xsd, or PersonalAddressBook.xsd—since the Address element is present in all these schemas and would be available as a global element. When the SPS module is added to another SPS module, the schema of the imported module is ignored, so which one is used is not important when the SPS is added as a module.
- The Working XML File is AddressBook.xml. Note that the main template in Address.sps specifies that only the Address element should be processed, and that global templates for Address-EU, Address-US, and Address-Other have been defined.

Because only the Address element is processed, the output previews show only the output of Address. When Address.sps is used as a module, the global templates are added and the main template is ignored.

ContactPoints.sps

This SPS imports one module. Note the use of global templates within other global templates and the main template.

- ContactPoints.sps uses AddressBook.xsd as its schema and AddressBook.xml as its Working XML File.
- Address.sps is added as a module, thus making the global templates of the Address-EU, Address-US, and Address-Other elements available.
- Global templates for the ContactPoints and Email elements are defined. Note that the ContactPoints definition uses the global template of Email (screenshot below).
The main template—required for the previews—uses the global template of the ContactPoints element, thus enabling previews of the ContactPoints output.

**BusinessAddressBook.sps and PersonalAddressBook.sps**

These SPSs each import one module, which in turn imports another. Note that the main template simply applies global templates.

- Each of these two modules uses AddressBook.xsd as its schema. The Working XML Files are, respectively, BusinessAddressBook.xml and PersonalAddressBook.xml.
- ContactPoints.sps is added as a module. This causes Address.sps to be indirectly imported. All the global templates in these two modules are available to the referring SPS module.
- In BusinessAddressBook.sps, global templates are defined for the Companies and Company elements. Note that the Company definition uses the global template of ContactPoints.
- In PersonalAddressBook.sps, global templates are defined for the Person and Persons elements. The Person definition uses the global template of ContactPoints.

**AddressBook.sps**

There are two global templates for the Email element; any one can be activated.

- AddressBook.sps uses AddressBook.xsd as its schema. The Working XML File is AddressBook.xml.
- BusinessAddressBook.sps and PersonalAddressBook.sps are added as modules, and this causes ContactPoints.sps and Address.sps to be indirectly imported.
- A global template is defined for the Email element. This means that there are now two global templates for Email, one in ContactPoints.sps and the other in AddressBook.sps (see screenshot below).
• In the Global Templates list in the Design Tree (screenshot above), you can select which of the two
global templates should be active. StyleVision allows only one to be active at a time. Whichever is
active is used within the ContactPoints global template.
• The main template contains some static content for the output header.
6.4 Templates and Design Fragments

The design document is composed of templates, and it is important to recognize the various types of templates that can be used.

- **Main templates and global templates:** The design document consists of one main template and, optionally, one or more global templates. Global templates can be referenced via the main template.
- **Node-templates and variable iterators:** These are the templates that constitute the main template and global templates. A node-template matches a node in a schema source.
- **Design fragments:** These are templates that are designed separately and re-used in various parts of the design (main template or global templates).

In this section, we describe the role that templates and design fragments play in the structure of the design. We are not concerned here with the presentation properties in the design, only the structure. In this section, we also do not consider additional structural items for paged media, such as cover pages, headers and footers. These are described in the section, Designing Print Output.

**Note:** In Design View, the SPS can have several templates: the main template, global templates, page layout templates, and Design Fragments. You can control which of these template types is displayed in Design View by using Template Display Filters, which are available as toolbar icons. These display filters will help you optimize and switch between different displays of your SPS.

### 6.4.1 Main Template

The main template determines the structure of the output. This means that the sequence in which the main template is laid out in the design is the sequence in which Authentic View and the output is laid out. In programming jargon, this is procedural processing. Processing starts at the beginning of the template and proceeds in sequence to the end. Along the way, nodes from the XML document are processed. The templates which process these nodes are called local templates. After a local template is processed, the processor moves to the next component in the main template, and so on. Occasionally, a node may reference a global template for its processing. In such cases, after the global template is executed for that node, the processor returns to the position in the main template from which it branched out and continues in sequence from the next component onwards.

The entry point for the main template is the document node of the schema. StyleVision offers the option of selecting multiple root elements (document elements). This means that within the main template, there can be local templates for each of the active document elements. The one that is executed during processing will be that for the element which is the document element of the XML instance document being processed.

### 6.4.2 Global Templates

A global template can be defined for any node or type in the schema, or for a node specified in an XPath pattern.
A global template specifies instructions for the selected node or type, and it is invoked by a call from the main template, design fragments, or other global templates. The processing model is similar to that of declarative programming languages, in that a single template is defined and invoked multiple times. In this way a single definition can be re-used multiple times. Global templates are invoked in two situations:

- When a node or type in the main template has been set to reference its global template (done by right-clicking the component in the design and selecting Make Global Template).
- When a (contents) or (rest-of-contents) is inserted within an element or type in a local template, and the rest of the content of that element or type includes a node or type for which a global template exists.

Global templates are useful if a node (or type) occurs within various elements or in various locations, and a single set of instructions is required for all occurrences. For example, assume that a para element must be formatted the same no matter whether it occurs in a chapter, section, appendix, or blockquote element. An effective approach would be to define a global template for para and then ensure, that in the main template the global template for the para element is processed wherever required (for example, by including //chapter/para in the main template and specifying that para reference its global template; or by including //chapter/title and then including (contents) or (rest-of-contents) so that the rest of the content of the chapter element is processed with the available global templates and default templates).

Creating a global template

Global templates can be created for any node or type in the schema, or for a node specified in an XPath pattern., and are created from the Schema Tree sidebar (screenshot below).

A global template can be created in any of the following ways:

- Click the Add New Global Template button located at the right of the Global Templates item in the Schema Tree (see screenshot above). This pops up the Add New Global Template dialog (screenshot below). You can select an element, an attribute, or a type from the schema tree shown in the dialog, or
you can enter an XPath pattern. (Note that global templates created for nodes selected with an XPath pattern are not supported in Authentic.) This selects the node that must be created as the global template. Click OK to finish. The template will be created and appended to the already existing templates in Design View and can then be edited. In the Schema Tree, the schema node or type will be marked with a plus sign icon in front of it.

- Right-click the schema node or type component in the Schema Tree (under Root Elements, All Global Elements, or All Global Types, as appropriate), and select the command **Make/Remove Global Template**. The template will be created and appended to the already existing templates in Design View and can then be edited. In the Schema Tree, the schema node or type will be marked with a plus sign icon in front of it.

- Global templates can also be created from templates in the main template in Design View. Right-click the template (either in Design View or the Schema Tree sidebar) and select the command **Make Global Template**. A global template is created from the selected template (it is appended to the templates in Design View) and the template in the main template is automatically defined to use this global template (see below for an explanation of how global templates are used).

A global template is located in Design View below the main template. It is indicated by a mauve bar containing the name of the node for which the global template has been created, followed by its type: (simple) or (complex). A global template is shown in the screenshot below.
Note that the processing of the global template is user-defined and could include both static and dynamic components, as well as the whole range of processing options available for processing of the main template.

**Using a global template**

After a global template has been created, it can be used when a node having the same qualified name is inserted into the document (When the node is dropped in the design, select the command **Use Global Template** from the menu that pops up.) by dropping . Alternatively, if a local template is present in the design and a global template exists for a node having the same qualified name, then the global template can be used instead of the local template. To use a global template for a local template, right-click the local template in Design View and select the command **Use Global Template**. When a global template is used, its processing instructions are called and used by the local template at runtime.

Wherever a global template is used in the design, an XPath pattern can be created on the global template to filter the nodeset it addresses. To create such a filter, right-click the global template tag in the design, and select **Edit XPath Filter** in the context menu that appears. This pops up the **Edit XPath Expression dialog**, in which the required expression can be entered.

**Recursive global templates**

Global templates can be recursive, that is, a global template can call itself. However, to guard against an endless loop in Authentic View, a property to limit the call-depth can be set. This property, the **Maximum Template-Call-Depth** property, is available in the Authentic tab of the Properties dialog of the SPS (**File | Properties**). It specifies the maximum number of template calls that may be made recursively when processing for the Authentic View output. If the number of template calls exceeds the number specified in the **Maximum Template-Call-Depth** property, an error is returned.

**Copying a global template locally**

After a global template has been created, its processing instructions can be copied directly to a template of the same qualified name in the main template. To do this, right-click the local template and select the command **Copy Global Template Locally**. Copying the global template locally is different than using the global template (at runtime) in that the processing instructions are merely copied in a one-time action. The global template has no further influence on the local template. Either, or both, the global template and local template can subsequently be modified independently of each other, without affecting the other. On the other hand, if it is specified that a global template should be *used* (at runtime) by a local template, then any modifications to the global template will be reflected in the local template at runtime.

**Activating and deactivating global templates**

A global template can be activated by checking its entry in the global templates listing in the Schema Tree sidebar. It can be deactivated by unchecking the entry. If a global template has been activated (the default setting when the global template was created), it is generated in the XSLT stylesheet. If it has been deactivated, it is not generated in the XSLT stylesheet but is still saved in the SPS design.

Any local template that uses a deactivated global template will then—since it is not able to reference the missing global template—fall back on the default templates of XSLT, which have the collective effect of outputting the contents of descendant text nodes.

The advantages of the activation/deactivation feature are: (i) Global templates do not have to be deleted if they are temporarily not required; they can be reactivated later when they are required; (ii) If there are name conflicts with templates from imported stylesheets, then the global template that is not required can be temporarily deactivated.
Removing a global template
To remove a global template, right-click the global template to be removed, either in Design View or the Schema Tree sidebar, and select the command Make/Remove Global Template.

Simple global templates and complex global templates
Global templates are of two types: simple and complex. Complex global templates are available for reasons of backward-compatibility. If a global template in an SPS created with a version of StyleVision prior to version 2006 contains a table or list, then that global template will typically be opened in StyleVision 2006 and later versions as a complex global template.

A complex global template is different than a simple global template in the way the node for which the global template was created is processed. When the first instance of the node is encountered in the document, the complex global template processes all subsequent instances of that node immediately afterwards. A simple global template, on the other hand, processes each node instance only when that node instance is individually encountered.

It is important to note that a simple global template will be automatically converted to a complex global template if a predefined format or newline is created around the element node for which the global template was created. This will result in the processing behaviour for complex global templates (described in the previous list item). To revert to the simple global template, the predefined format should be removed (by dragging the node outside the predefined format and then deleting the predefined format), or the newline should be removed (by deleting the item in the Design Tree sidebar), as the case may be. To avoid the automatic conversion from simple global template to complex global template, make sure that the predefined format or newline is added within the node tags of the element for which the simple global template was created.

Global templates in modular SPSs
When an SPS module is added to another SPS module, the global templates in the added module are available for use within the referring SPS. For more information about using modular SPSs, see the section Modular SPSs.

6.4.3 User-Defined Templates
User-Defined Templates are templates for items generated by an XPath expression you specify. These items may be atomic values or nodes. In the screenshot below, which shows three User-Defined Templates, note the User-Defined Template icon on the left-hand side of the tags (a green person symbol). User-Defined Templates are very useful because they provide extraordinary flexibility for creating templates. Note, however, that content generated by User-Defined Templates cannot be edited in Authentic View.
The XPath expression of each of the three User-Defined templates shown in the screenshot above do the following:

- Selects a node in a source schema. By using an XPath expression, any node in any of the schema sources can be reached from within any context node. If StyleVision can unambiguously target the specified node, the template will be changed automatically from a User-Defined Template to a normal template, enabling Authentic View editing. If it is a User-Defined Template, this will be indicated by the green User-Defined Template icon on the left-hand side of the template tags.

- Selects a node that fulfills a condition specified by the for construct of XPath 2.0 and XPath 3.0. Such templates can never resolve to normal templates (but will remain User-Defined Templates) because the for construct does not allow StyleVision to unambiguously resolve the target from only the schema information it currently has at its disposal.

- Selects a sequence of atomic values \{1, 2, 3\}. While it is allowed to create a template for an atomic value, you cannot use the contents placeholder within such a template. This is because the xsl:apply-templates instruction (which is what the contents placeholder generates) can only be applied to node items (not atomic values). You could, however, use an Auto-Calculation in combination with some design element such as a list. For example, the User-Defined Template at left would generate the output at right.

Note: If the SPS uses XSLT 1.0, then the XPath expression you enter must return a node-set. Otherwise an error is reported.

Advantage of using XPath to select template node

The advantage of selecting a schema node via an XPath expression (User-Defined Templates) is that the power of XPath's path selector mechanism can be used to select any node or sequence of items, as well as to filter or set conditions for the node selection. As a result, specific XML document nodes can be targeted for any given template. For instance, the XPath expression //Office/Department[@Location="NY"] will select only those Department nodes that have a Location attribute with a value of NY. Also see the other examples in this section.

Note: If an XPath expression contains multiple location path steps, then it is significant—especially for grouping and sorting—whether brackets are placed around the multiple location path steps or not. For example, the XPath expression //Org/Office/Dept will be processed differently than (/Org/Office/Dept). For the former expression (without brackets), the processor loops through each location step. For the latter expression (with brackets), all the Dept elements of all Office elements are returned in one undifferentiated nodeset.

<table>
<thead>
<tr>
<th>Brackets</th>
<th>Underlying XSLT Mechanism</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| No | `<xsl:for-each select="Org">  
  `<xsl:for-each select="Office">  
    `<xsl:for-each select="Dept">  
       ...  
    </xsl:for-each>  
  </xsl:for-each>  
</xsl:for-each>` | Each Office element has its own Dept population. So grouping and sorting can be done within each Office. |
| Yes | `<xsl:for-each select="/Org/Office/Dept">  
    ...  
</xsl:for-each>` | The Dept population extends over all Office elements and across Org. |

This difference in evaluating XPath expressions can be significant for grouping and sorting.

**Inserting a User-Defined Template**

To insert a User-Defined Template, do the following:

1. Click the **Insert User-Defined Template** icon in the Insert Design Elements toolbar and then click the design location where you wish to insert the template. Alternatively, right-click the design location where you wish to insert the template and, from the context menu that appears, select the **Insert User-Defined Template** command.
2. In the **Edit XPath Expression** dialog that pops up, enter the XPath expression you want, and click **OK**. Note that the context node of the XPath expression will be the node within which you have clicked. An empty node template will be created. Sometimes a joined node is created. When a node is joined, the targeted instance nodes are selected as if at a single level, whereas if a node is not joined (that is if it is split into multiple hierarchic levels), then the node selection is done by looping through each instance node at every split level. The noderset returned in both cases of selection (joined and split) is the same unless a grouping or sorting criterion is specified. For a discussion of the effect joined nodes have on the grouping and sorting mechanisms, see **Node-Template Operations**.

**Editing a Template Match**

The node selection of any node template (user-defined or normal) can be changed by using an XPath expression to select the new match expression. To edit the template match of a node template, right-click the node template, then select the **Edit Template Match** command. This pops up the Edit XPath Expression dialog, in which you enter the XPath expression to select the new node. Then click **OK**.

**Adding nodes to User-Defined Templates**

If a node from the schema tree is added to a User-Defined Template, the context for the new node will not be known if the User-Defined Template has been created for a node or sequence that cannot be placed in the context of the schema source of the SPS. You will therefore be prompted (**screenshot below**) about how the new node should be referenced: (i) by its name (essentially, a relative path), or (ii) by a full path from the root of the schema source.
Prompting for advice on how to proceed is the default behavior. This default behavior can be changed in the Design tab of the Tool | Options dialog.

### 6.4.4 Variable Templates

A Variable Template is a template that targets a variable and, by default outputs its content. It is inserted with the Insert | Variable Template or Enclose with | Variable command, which inserts, at the cursor insertion point, a template for a variable defined in the SPS. The variable template (screenshot below) contains a content placeholder by default, and this serves to output the contents of the variable. You can insert additional content (static as well as dynamic) in the variable template as required, or modify it as you would any other template. A variable template is indicated with a dollar symbol in its start and end tags.

![Screenshot of Insert Variable Template dialog]

To insert a variable template, do the following:

1. Place the cursor in the design at the location where the template is to be inserted.
2. Click the Insert | Variable Template command. This pops up the Insert Variable Template dialog (screenshot below).
3. The dialog contains a list of all the user-declared parameters and variables defined in the SPS. Select the variable for which you wish to add a variable template.
4. Click OK to finish.
6.4.5 Node-Template Operations

A node-template is a template in the design that specifies the processing for a node. In the design, node-templates are displayed with beige start and end tags (screenshot below). The type of node is indicated by a symbol inside the tags (for example: angular brackets for element nodes and equal-to signs for attribute nodes). The screenshot below contains two node-templates, both for elements: `metainfo` and `relevance`. Also see, *Nodes in the XML document*.

The operations that can be carried out on a node-template are accessible via the context menu of that node-template (accessed by right-clicking either the start or end tag of a node-template, see screenshot below).
The commands in this context menu are described below:

- **Global templates**
- **Template match**
- **XPath filters**
- **Group by, Sort by, Define variables, Template serves as level**
- **Create Design Fragment**
- **Remove Tag Only**
- **Edit, Enclose with, Change to**
- **Authentic properties**

These menu commands are described below. Note that for a given node-template, some commands might not be available; these are grayed out in the context menu.

**Global templates: make, use, copy locally**

A node-template in the main template can be changed to or associated with a global template via the following commands:

- **Make global template**: This option is available if the node-template represents an element that is defined as a global element in the schema. A global template will be created from the node-template. The node-template in the main template will use this global template and its tags will then be displayed in gray (indicating its use of the global template).
- **Use global template**: If a global template of the same qualified name as the node-template has been defined, the node-template will use the processing of the global template. The tags of the node-template will become gray.
- **Copy global template locally**: The processing instructions of a global template of the same qualified name as the node-template are copied physically to the node-template. The node-template is independent of the global template. Subsequently, both it and the global template can be modified independently of each other. Since the node-template does not reference a global template, it retains its beige color.

For more information, see the section **Global Templates**.

**Editing the template match**

The node for which a template has been created can be changed by using this command. The Edit Template Match command pops up the **Edit XPath Expression dialog**, in which you can enter an XPath expression that selects another node in the schema. You can also enter any XPath expression to change the template to a **User-Defined Template**.

**Edit/Clear XPath Filter**

An XPath filter enables you to filter the nodeset on which a node-template is applied. XPath filters can also be applied to **global templates**.

By default, a node-template will be applied to nodes (elements or attributes) corresponding to the node for which the node-template was created (having the same name and occurring at that point in the schema hierarchy). For example, a node-template for the /Personnel/Office node will select all the /Personnel/Office elements. If an XPath filter with the expression `/` is now created on the Office element (by right-clicking the Office element and editing its XPath Filter), this has the effect of adding a predicate expression to the Office element, so that the entire XPath expression would...
be: /Personnel/Office[1]. This XPath expression selects the first Office child of the Personnel element, effectively filtering out the other Office elements.

A filter can be added to any node-template and to multiple node-templates in the design. This enables you to have selections corresponding to such XPath expressions as: /Personnel/Office[@country='US']/Person[Title='Manager'] to select all managers in the US offices of the company. In this example, a filter each has been created on the Office and on the Person node-templates, respectively.

Wherever a global template is used—that is, called—an XPath filter can be applied to it. So, for every instance of a global template that is used, an XPath filter can be applied to the global template in order to restrict the targeted nodeset.

To add an XPath Filter to a node-template, right-click the node-template and select Edit XPath Filter. Enter the XPath filter expression without quotes, square brackets, or delimiters of any kind. Any valid XPath expression can be entered. For example:

- @country='US'
- Title='Manager'

After an XPath Filter has been created for a node-template, this is indicated by a filter symbol in the start tag of the node-template. In the screenshot below, the synopsis node-template has a filter.

Note: Each node-template supports one XPath Filter.

Group by, Sort by, Define variables, Template Serves as Level
The mechanisms behind these commands are described in detail in their respective sections:

- The Group by command enables instances of the node represented by the selected node-template to be grouped. The grouping mechanism is described in the section, Grouping.
- The Sort by command enables instances of the node represented by the selected node-template to be sorted. The sorting mechanism is described in the section, Sorting.
- The Define Variables command enables you to define variables that are on scope on the selected node-template. How to work with variables is described in the section, Variables.
- The Template Serves as Level command is a toggle command that creates/removes a level on the node-template. Levels can be specified at various levels in order to structure the document into a hierarchy. This structure can then be used to generate a table of contents (TOC), automatic numbering, and text references. These features are described in detail in the section, Table of Contents (TOC) and Referencing.

Create Design Fragment
Creates a Design Fragment template from the selected template. The resulting Design Fragment template is added to the Design Fragment templates at the bottom of the design, and added to the Design Tree and Schema Tree. The Design Fragment is also applied at that point in the design where it was created.
Remove (Template or Formatting) Tag Only

This command removes the selected template or formatting tag only. It does not remove any descendant nodes or formatting tags. This command is useful for removing a formatting tag or a parent element tag without removing all that is contained within the tag (which is what would happen if the Delete operation is carried out with a tag selected). Note, however, that removing a parent element might render descendant nodes of the deleted element invalid. In such cases, the invalid nodes are indicated with a red strike-through.

Edit, Enclose with, Change to

These commands are described below:

- **Edit**: Pops out a submenu with the familiar Windows commands: cut, copy, paste, and delete.
- **Enclose with**: The node-template can be enclosed within the following design components, each of which is described in a separate section of this documentation: paragraph, special paragraph, Bullets and Numbering, Hyperlink, Condition, TOC Bookmark and Level.
- **Change to**: The Change-To feature enables you to change: (i) the node for which that template applies, or (ii) how the node is created in the design. It is described in detail in the section, The Change-To Feature.

Edit Authentic Properties

Selecting this command pops up the Properties sidebar, in which certain properties (Authentic Properties) of the instantiated node in Authentic View can be defined. Authentic Properties are described in detail in the section, Authentic Node Properties.

6.4.6 Design Fragments

Design Fragments are useful for creating parts that can be re-used at different locations in the document, similar to the way functions are re-used. The usage mechanism is as follows:

1. Create the Design Fragment in the design
2. Fill out the contents of the Design Fragment
3. Insert the Design Fragment at a location in a template.

Creating a Design Fragment

To create a Design Fragment, do the following:

1. In the Design Tree or Schema Tree, click the Add New Design Fragment icon, which is located to the right of the Design Fragments item in the tree (see screenshot below). This adds a Design Fragment item in the Design Fragments list of the tree. (Also see note below.)
Notice that a Design Fragment template is created in the SPS design. This template is appended to the templates already in the design and indicated with a green header. (If you wish to see only the Design Fragments that are in the design, hide the main template and global templates by clicking their Show/Hide icons in StyleVision's Design Filter toolbar.) Additionally, the Design Fragment templates are also listed in the schema tree for ready access from there.

2. Double-click the Design Fragment item (either in the design tree or the schema tree) so as to edit its name. Name the Design Fragment as required and press Enter. The edited name is entered in the Design Tree (screenshot below) and in the template in the design.

3. In the design, create the contents of the Design Fragment template. How to do this is described in the next section.

Note: If you wish to create a Design Fragment from an already existing template, right-click that template and select the command Create Design Fragment from the context menu that pops up. This creates a Design Fragment template from the selected template at that point in the design. The Design Fragment template is also appended to the existing Design Fragment templates at the bottom of the design and added to the Design Tree and Schema Tree. Creating a Design Fragment in this way also applies it directly at the point where it was created, there is no need to insert it from the Design Tree or Schema Tree.

Creating the contents of a Design Fragment

The contents of the Design Fragment template are created as for any other template. To insert static content, place the cursor in the Design Fragment template and insert the required static content. To insert dynamic content, drag the required schema node into the Design Fragment template.

When dragging a node from the schema source you can drag the node either: (i) from the Global Elements tree, or (ii) from the Root Elements tree. The difference is significant. If a node is dragged from the Global Elements tree, it is created without its ancestor elements (in the screenshot below, see the EmailPerson Design Fragment) and, therefore, when used in a template, it will have to be used within the context of its parent. On the other hand, if a node is dragged from the Root Elements tree, it is created within a structure starting from the document node (in the screenshot below, see the EmailDocNode Design Fragment), and can therefore be used anywhere in a template.
The screenshot above shows two Design Fragment templates that produce identical output for the Person element. In the 'EmailPerson' Design Fragment template, the Person node has been created by dragging the global element Person into the EmailPerson template. In the 'EmailDocNode' Design Fragment template, the Person node has been dragged from the Root Elements tree, and is created with an absolute path (from $XML, the document node).

When these Design Fragment templates are inserted in the main template, care must be taken that the 'EmailPerson' template is called from within a context that is the parent of the Person node. You can experiment with these Design Fragments. They are in the example file Email.sps, which is in the (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\DesignFragments.

You can also define a parameter with a default value on the Design Fragment. The parameter can be assigned a different value in every Design Fragment instance. See Parameters for Design Fragments for details.

After you have completed the design, notice that the components of the design are also graphically depicted in the Design Tree.

**Inserting a Design Fragment in a template**

To insert a Design Fragment, drag the Design Fragment from the Design Tree or Schema Tree to the required location. The location at which the Design Fragment is dropped should be such that it provides a correct context. If the contents of the Design Fragment were created from a global element, then the correct context in the main template would be the parent of the node dragged into the Design Fragment. See Creating the contents of a Design Fragment above.

Alternatively, right-click at the location where the Design Fragment is to be inserted and select Insert Design Fragment from the context menu.

**Note:** If a Design Fragment is referenced in the main template and if the name of the Design Fragment is changed subsequently, then the reference in the main template will no longer be correct and an XSLT
error will result. In order to correct this, delete the original reference in the main template and create a fresh reference to the newly named Design Fragment.

Recursive design fragments
Design fragments can be recursive, that is, a design fragment can call itself. However, to guard against an endless loop in Authentic View, a property to limit the call-depth can be set. This property, the Maximum Call-Depth property, is available in the Authentic tab of the Properties dialog of the SPS (File | Properties). It specifies the maximum number of template calls that may be made recursively when processing for the Authentic View output. If the number of template calls exceeds the number specified in the Maximum Call-Depth property, an error is returned.

Deleting a Design Fragment
To delete a Design Fragment, select it in the Design Tree and click the Remove toolbar icon of the Design Tree.

Design Fragments in modular SPSs
When an SPS module is added to another SPS module, the Design Fragments in the added module are available for use within the referring SPS. For more information about using modular SPSs, see the section Modular SPSs.

Example file
For an example SPS, go to the (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\DesignFragments.
6.5 **XSLT Templates**

XSLT files can be imported into an SPS, and XSLT templates in them will be available to the stylesheet as global templates. If, during the processing of the XML document, one of the XML nodes matches a node in an imported XSLT template, then the imported XSLT template is applied to that node. If the imported XSLT file contains named templates, these are available for placement in the design.

Note the following points:

- Imported XSLT templates cannot be modified in StyleVision.
- XSLT templates are not supported in Authentic View.

**Importing the XSLT file**

To import an XSLT File, do the following:

1. In the Design Overview sidebar (*screenshot below*), click the **Add New XSLT File** link.

![Design Overview Screenshot](image1)

2. In the Open dialog that appears, browse for the required XSLT file, select it, and click **Open**. The XSLT file is imported. An `xsl:import` statement is added to the XSLT stylesheet, and, in the Design Tree sidebar (*screenshot below*), the XSLT Templates contained in the imported XSLT file are displayed under the XSLT Templates heading.

![Design Tree Screenshot](image2)
There are two types of imported XSLT templates: (i) match templates (indicated by Match), and (ii) named templates (indicated by Name). In the Design Tree, these two types are listed with (i) the value of the select attribute of match templates, and (ii) by the value of the name attribute of named templates, respectively.

**Match templates**

Match templates will be used when a template, in the course of processing, applies templates to a node in the XML document instance, and the match template is selected to be applied. This will happen when the qualified name of the XML node matches the qualified name of the imported match template. If a global template has been created in the SPS that has the same qualified name, then it has precedence over an imported template and will be used. If there are several imported XSLT files, the file imported first (and listed first in the XSLT code) has the lowest precedence, followed by the second lowest precedence for the file imported second, and so on.

**Named templates**

A named template can be dragged from the Design Tree to any location in the design. At this location, it will be created as an `xsl:call-template` element ([screenshot below](#)) that calls the named template.

```
<xsl:call-template name="BoldItalic" />
```

The effect of this in the output is to implement the named template at that location in the design. This can be useful for inserting content that is independent of both the XML instance document as well as of the XSLT stylesheet.
6.6 Multiple Document Output

You can design an SPS to produce multiple output-documents: a main output-document and one or more additional documents. This is particularly useful if you wish to modularize the output. Output-documents are created in the design by inserting a New Document template (see screenshot below). Content for each output-document is placed within its New Document template.

New Document templates can be created anywhere in the document design, thus allowing the output to be modularized at any level. So, for example, a report about the various branch offices of a global organization can have separate output-documents at each of the following levels: (i) world, (ii) continent, (iii) country, (iv) state, and/or (v) branch office. Each branch office, for example, can be presented in a separate output-document or all the branch offices in a country can appear together in a single country report. In the design, a New Document template would have to be created at each of the hierarchical levels for which separate output-documents are required. How to set up the correct document structure is described in the section, New Document Templates and Design Structure.

The multiple output-document feature is available in HTML, RTF, and Text formats. In Authentic View, which is intended as an editing view, content is displayed in a single document.

This description of multiple output-documents is organized into the following sub-sections:

- Inserting a New Document Template
- New Document Templates and Design Structure
- URLs of New Document Templates
- Preview and Output Document Files
- Document Properties and Styles
6.6.1 Inserting a New Document Template

A New Document template can be placed in an SPS design in one of two ways:

- A new output-document template can be inserted at any location in the design. In this case the content of the New Document is added to the template after inserting the template. To insert a New Document template, place the cursor at the desired location in the design and select the command Insert | Insert New Document or right-click the location and, from the context menu that pops up, select Insert New Document.

- A new output-document can be placed in the design by enclosing content with a New Document template. The New Document template will, in this case, contain the enclosed content when it is created. You can add to or modify this content in the design. To place a New Document template so that it encloses content, highlight the content to be enclosed and then select the command Enclose With | New Document. Alternatively, you can select the content to be enclosed, then right-click it, and, from the context menu that pops up, select the command Enclose With | New Document.

A New Document template with content is shown in the screenshot below.

Notice the following from the screenshot above:

1. The New Document template tags contain the URL (path and name) of the output-document it will generate. The filename suffix will be generated automatically according to the file type of the output format. For example, for the HTML output format, the filename suffix `.html` will be appended to the filename in the URL. Issues relevant to the assigning of URLs are discussed in the section, URLs of New Document Templates.

2. The New Document Template contains one Initial Document Section. Additional document sections can be added to the initial document section as described in the section, Document Sections.
6.6.2 New Document Templates and Design Structure

When creating multiple output-documents, you must create the different New Document templates on the appropriate nodes of the source document. Therefore, you must consider both the output structure as well as the input (source XML document) structure when designing multiple output-documents.

Main output document and additional output documents (output structure)

When the first New Document template is added to the design, all design content outside this New Document template is automatically assigned to a separate document. This separate document is considered to be the main output document, and, in the output previews of StyleVision, it is referred to as Main Output Document.

In the generated output-documents (created using the command File | Save Generated Files), the name of the main output document will be the name you assign it when generating the output-document files using the Save Generated Files command. The names of the additional output-document files will be the names assigned in the URLs of the respective New Document templates.

New Document templates and source document structure

When a New Document template is created, the hierarchical location where it is created is significant. Two possibilities exist:

1. The node within which the New Document template is created is processed only once. In this case the New Document template is also processed only once. The filename in the URL property of the New Document template can therefore be a static name.

2. The node within which the New Document template is created is processed multiple times. As a result, the New Document template will be processed as many times as the node is processed. An example of such a situation would be the following. An Office element has multiple Department element children (for its various departments). If a New Document template is created within the Department node in the design, then, since the Department node will be processed multiple times (for all the different Department elements in that Office element), the New Document template also will be processed multiple times, once for each Department element in the source XML document. The filename in the URL property of the New Document template must therefore be a dynamic name. Otherwise, the output-documents created for the Department elements will each have the same filename.

6.6.3 URLs of New Document Templates

In this section we describe how the URLs of New Document templates relate to design structure, how URLs are edited, and how multiple output-documents can be linked among each other.

URLs of New Document templates

If the New Document template is processed only once (see preceding section), then the template's URL property can be a static URL. In the screenshot below, since the New Document template is immediately within the document element ($XML), it will be processed only once. The URL has been given a static value of TableOfContents. This value will therefore be the filename of the output-document. Since no path has been prefixed to the filename, the file will be generated in the same directory as the Main Document File (see...
Multiple Document Outputs and Previews (for details). Alternatively, if the URL contained a path, the output-document will be saved to the location specified in the path.

If, on the other hand, a New Document template will be processed multiple times to generate multiple output-documents (see preceding section), then the template's URL property must be a dynamic URL that is selected with an XPath expression. In the screenshot below, the URL of the New Document template is the XPath expression: `body/header/para`. The New Document template is within the `topic` element, so it will be processed each time the `topic` element is processed. On every iteration through the `topic` element, the content of that `topic` element's `body/header/para` element will be assigned as the URL of the New Document template. This creates a new document for every `topic` element. Each of these documents has a different name, that of its `body/header/para` element (which is the text of the topic's header).
Editing the URL
When a New Document template is added to the design, it is created with a default URL. This is a static text string: DocumentX (where X is an integer). If you wish to edit the URL, right-click the New Document template and select the command Edit URL. This pops up the Properties dialog (screenshot below), in which you can edit the Value field of the URL without file ext property.

If you wish to enter a static URL, edit the Value field to contain the required URL text. If you wish to enter a dynamic URL, click in the Value field, click the XPath button in the toolbar of the Properties dialog, and enter the XPath expression you want. Note the following: (i) The context node for the XPath expression is the node within which the New Document template has been inserted. (ii) To prefix a path to the XPath location expression, use the concat() function of XPath. For example: concat('C:\MyOutput\', body\header\para). This example expression will generate the URL string: C:\MyOutput\filename. The appropriate file extension will be generated automatically according to the output format.

Linking the documents
Multiple output-documents can be linked to one another using bookmarks and hyperlinks. A bookmark can be placed at the head of a New Document Template or anywhere within the New Document Template. Hyperlinks can then be created in other documents to link back to the bookmark. If bookmarks are required on a node that is processed multiple times, then make sure that the name of the bookmark is generated dynamically. Otherwise (if a static bookmark name is given) multiple nodes in the output will have the same bookmark name.

A Table of Contents (TOC) can also be used to link documents. The TOC could be in a separate document (for example, the main document) and link to the various output-documents, while the output-documents could link back to the TOC.

6.6.4 Preview Files and Output Document Files
The output previews of a design document show each of the multiple output-documents that have been specified in the design as separate documents (see screenshot below).
The screenshot above shows the HTML Preview of an SPS document that has been designed to generate multiple output-documents. Each output document can be called up in the view window by either: (i) navigating through the available documents using the arrow buttons at top left, or (ii) selecting the required document from the dropdown list of the combo box (see screenshot above). Notice that the items of the dropdown list show the entire URL (path plus filename).

**Location of preview files**

The preview files are created by default in the directory in which the SPS file is created. This default setting can be changed in the Paths tab of the SPS file's Properties dialog (screenshot below), which is accessed with the File | Properties command. In this tab you can specify the directory of the Working XML File as an alternative location. If the URL of a New Document template contains a path, the location specified in this path will be used as the location of the respective preview files. If the location cannot be found, an error is returned. You should be aware of where the output-documents will be saved if you are setting up output-documents to link to each other.
In the Paths tab of the Properties dialog (see screenshot above), you can also specify where temporary additional files for previews, such as output-document files, and image and chart-image files, will be saved. Note that, if the URL of a New Document template contains a path, then the location specified in this path will be used.

Generating output (paths etc)

To generate the output-document files, do the following:

1. Mouse over the menu command **File | Save Generated Files** and click the required output format.
2. In the Save Generated File dialog that pops up browse for the folder in which you wish to save the generated file.
3. Enter the name of the Main Document File and click **Save**.

The location of all output-document files as well as other additionally generated files, such as image files and chart-image files, will be displayed in a pop-up window for your information.

The Main Document File will be saved to the folder location you selected in the Save Generated File dialog. All the multiple output-documents that were created with New Document templates and whose URLs have no path information will be saved to the same folder as the Main Document File. If a path was prefixed to the filename in
a New Document template's URL, the output document will be saved to the location specified in the URL. If that folder location does not exist an error will be generated.

6.6.5 Document Properties and Styles

In an SPS design, you can split the output into multiple documents. Each of these documents can be assigned separate document properties and document styles. These are specified in the Document Properties and Document Styles tabs, respectively (see screenshot below), of the Properties dialog of the document's Initial Document Section. To access the Properties dialog, click the Edit Properties link in the title bar of the Initial Document Section of the document for which you wish to set these properties. Document properties and document styles apply to the entire output document.

In the Document Properties tab, the Document Properties group of properties enable meta-information to be entered for the document. This meta-information will be saved to the respective output document and to the respective properties according to output format. For example, in the HTML output format, the properties are stored in the respective META tags of the HEAD element.

Document styles are described in the section Setting CSS Property Values.
7 Advanced Features

How to create the basic content and structure of the SPS design is described in the sections, SPS File Content and SPS File Structure. Very often, however, you will also need to modify or manipulate the content and/or structure of source data in particular ways. For example, you might wish to sort a group of nodes, say nodes containing personnel information, on a particular criterion, say the alphabetical order of employee last names. Or you might wish to group all customers in a database by city. Or add up a product's sales turnover in a particular city. Such functionality is provided in StyleVision's advanced features, and these are described in this section.

Given below is a list of StyleVision's SPS file advanced features:

- **Auto-Calculations**. Auto-Calculations are a powerful XPath-based mechanism to manipulate data and (i) present the manipulated data in the output as well as (ii) update nodes in the XML document with the result of the Auto-Calculation.
- **Conditions**. Processing of templates and the content of templates can be conditional upon data structures or values in the XML, or upon the result of an XPath expression.
- **Grouping**. Processing can be defined for a group of elements that are selected with an XPath expression.
- **Sorting**. A set of XML elements can be sorted on multiple sort-keys.
- **Parameters and Variables**. Parameters are declared at the global SPS level with a default value. These values can then be overridden at runtime by values passed to the stylesheet from the command line. Variables can be defined in the SPS and these variables can be referenced for use in the SPS.
- **Table of Contents (TOC) and Referencing**. Tables of Contents (TOCs) can be constructed at various locations in the document output, for all output formats. The TOC mechanism works by first selecting the items to be referenced in the TOC and then referencing these marked items in the TOC. Other features which use referencing are: (i) **Auto-Numbering** (repeating nodes in the document can be numbered automatically and the numbers formatted); (ii) **Text References** (text in the document can be marked for referencing and then referenced from elsewhere in the document); and (iii) **Bookmarks and Hyperlinks** (bookmarks mark key points in the output document, which can then be targeted by hyperlinks. Hyperlinks can also link to external resources using a variety of methods to determine the target URI (static, dynamic, a combination of both, and unparsed entity URIs)). All these referencing mechanisms are described in this section.
7.1 Auto-Calculations

The Auto-Calculation feature (i) displays the result of an XPath evaluation at any desired location in the output document, and (ii) optionally updates a node in the main XML document (the XML document being edited in Authentic View) with the result of the XPath evaluation.

The Auto-Calculation feature is a useful mechanism for:

- Inserting calculations involving operations on dynamic data values. For example, you can count the number of Employee elements in an Office element (with `count(Employee)`), or sum the values of all Price elements in each Invoice element (with `sum(Price)`), or join the FirstName and LastName elements of a Person element (with `concat(FirstName, ' ', LastName)`). In this way you can generate new data from dynamically changing data in the XML document, and send the generated data to the output.
- Displaying information derived from the structure of the document. For example, you can use the `position()` function of XPath to dynamically insert row numbers in a dynamic table, or to dynamically number the sections of a document. This has the advantage of automatically generating information based on dynamically changing document structures.
- Inserting data from external XML documents. The `doc()` function of XPath 2.0 provides access to the document root of external XML documents, and thus enables node content from the external XML document to be inserted in the output.
- Updating the value of nodes in the main XML document. For example, the node Addressee could be updated with an XPath expression like `concat(Title, ' ', FirstName, ' ', LastName)`.
- Presenting the contents of a node at any location in the design.

7.1.1 Editing and Moving Auto-Calculations

Creating Auto-Calculations

To create an Auto-Calculation, do the following:

1. Place the cursor as an insertion point at the location where the Auto-Calculation result is to be displayed and click **Insert | Auto-Calculation**. In the submenu that appears, select Value if the result is to appear as plain text, select Input Field if it is to appear within an input field (i.e. a text box), or select Multiline Input Field if it is to appear in a multiline text box. (Note that the output of the Auto-Calculation is displayed as a value, or in an Input Field. It is an output in Authentic View, and cannot be edited there.) The Edit XPath Expression dialog pops up (screenshot below).
2. In the Expression pane, enter the XPath expression for the Auto-Calculation via the keyboard. Alternatively, enter the expression by double-clicking nodes, operators, and/or functions in the respective panes of the dialog. It is important to be aware of the context node at the insertion point; the context node is highlighted in the schema source tree (in the screenshot above the context node, newsitems, is highlighted). If you have selected XSLT 1.0 as the version of the XSLT language for your SPS, then you must use XPath 1.0 expressions; if you have selected XSLT 2.0 or XSLT 3.0, then you must use, respectively, XPath 2.0 or XPath 3.0 expressions. For a detailed description of the Edit XPath Expression dialog, see the section Edit XPath Expression.

3. Optionally, if you wish to copy the value of the Auto-Calculation to a node in the XML document, you can select that node via an XPath expression. How to update nodes with the result of the Auto-Calculation is described in the section Updating Nodes with Auto-Calculations.

Click the OK button finish. In the Design tab, the Auto-Calculation symbol is displayed. To see the result of the Auto-Calculation, change to Authentic View or an Output View.

Editing Auto-Calculations

To edit the XPath expression of the Auto-Calculation, select the Auto-Calculation and, in the Properties sidebar, click the Edit button of the XPath property in the AutoCalc group of properties (screenshot below). This pops up the Edit XPath Expression dialog (screenshot above), in which you can edit the XPath expression.
Formatting Auto-Calculations

You can apply predefined formats and CSS styles to Auto-Calculations just as you would to normal text: select the Auto-Calculation and apply the formatting. Additionally, input formatting of an Auto-Calculation that is a numeric or date datatype can be specified via the Input Formatting property in the AutoCalc group of properties in the Properties window.

Note also that you can include carriage returns and/or line feeds (CR/LFs) in the XPath expression. If the Auto-Calculation is enclosed in the pre special paragraph type, the output of a CR/LF will produce a new line in the output (except in the RTF output). An example of such an XPath expression is:

\[\text{translate('a;b;c', ';', codepoints-to-string(13))}\]

Moving Auto-Calculations

You can move an Auto-Calculation to another location by clicking the Auto-Calculation (to select it) and dragging it to the new location. You can also use cut/copy-and-paste to move/copy an Auto-Calculation. Note, however, that the XPath expression will need to be changed if the context node in the new location is not the same as that in the previous location.

Summary of important points

Note the following points:

- An Auto-Calculation can be inserted anywhere in the Design Document.
- The point at which you insert the Auto-Calculation determines the context node for the XPath evaluation.
- In Authentic View, an Auto-Calculation is re-evaluated each time any value relevant to the calculation (that is, any node included in the XPath expression) changes.
- An Auto-Calculation result is non-editable in Authentic View or any other output view.
- Any node in the XML document can be updated with the result of the Auto-Calculation.

7.1.2 Updating Nodes with Auto-Calculations

You can copy the value (or result) of an Auto-Calculation to a node in the main XML document (the document being edited in Authentic View). You do this as follows:
1. Create the Auto-Calculation as described in Editing and Moving Auto-Calculations.

2. Select the Auto-Calculation and, in the Properties sidebar, click the Edit button of the Update XML node in Authentic property in the Authentic group of properties (screenshot below).

3. In the XPath Selector dialog that pops up (screenshot below), select the node to update and click OK to finish. If you wish the XPath expression to be absolute (that is, starting at the document root), check the Absolute XPath check box.
Alternatively, if you select the User-Defined XPath radio button, you can enter any XPath expression you like to select the node to be updated.

The XPath expression must select a single node. If the XPath expression selects multiple nodes, no node will be updated.

**IMPORTANT!**
For a node in the main XML document to be updated two conditions must be fulfilled:

1. The XPath expression for the Auto-Calculation must include at least one value that is related to an XML node, i.e. a dynamic value. For example, \texttt{Price*1.2}. This expression involves the element \texttt{Price}, and is therefore dynamic. If the XPath expression contains a static value (for example, \texttt{string("Nanonull, Inc."))}, then the Update XML Node feature will not work.
2. Any one of the nodes used in the XPath expression must be modified in Authentic View. So, if the XPath expression is \texttt{Price*1.2}, and the Auto-Calculation is set to update the \texttt{VATPrice} node, then the \texttt{Price} element must be modified in Authentic View in order for the \texttt{VATPrice} node to be updated.
Changing the node to update, cancelling the update

To change the node to update, click the *Edit* button of the *Update XML Node* property in the *Authentic* group of properties of the AutoCalculation (in the Properties window) and then select the required node from the Schema Selector dialog box that pops up. To delete the *Update XML Node* property, click the *Remove* button in the toolbar of the Properties window.

Should you use the Auto-Calculation or the updated node contents for display?

If there are no conditional templates involved, you can use either the Auto-Calculation or the contents of the updated node for display. It is immaterial which one you choose because the node update happens immediately after the Auto-Calculation is evaluated and there is no factor to complicate the update. You should, however, be aware that there is a different source for the content displayed in each of the two cases.

Hiding the Auto-Calculation

You may find yourself in the situation where you wish to use an Auto-Calculation to make a calculation in order to update a node with the value of the Auto-Calculation. In this case, one of the following scenarios arises:

- You wish to display the result just once. You cannot hide the Auto-Calculation since it would then not be evaluated. If there is no conditional template involved, it is best to display the Auto-Calculation and not display the contents of the updated node.
- You wish not to display the result, merely to update the node. The best way to handle this scenario is to apply text formatting to the Auto-Calculation, so that it is invisible on the output medium (for example, by applying a white color to an Auto-Calculation on a white background).

7.1.3 Auto-Calculations Based on Updated Nodes

If you wish to create an Auto-Calculation (second Auto-Calculation) that uses a node updated by another Auto-Calculation (first Auto-Calculation), there are two possible situations:

- The two Auto-Calculations are in the same template.
- The two Auto-Calculations are in different templates.

Auto-Calculations in the same template

When two Auto-Calculations are in the same template, the SPS applies the following procedure:

1. A node used in the XPath expression of the first Auto-Calculation is modified.
2. All node values in the XML document are read and all Auto-Calculations are executed.
3. Assuming that the first Auto-Calculation is executed correctly, it updates the specified XML node (call it Node-A). The second Auto-Calculation, which is based on Node-A, will be executed but will use the value of Node-A before Node-A was updated. This is because the value of Node-A was read before it was updated, and has not been read since then.
4. If the document is now edited in any way or if document views are changed (from and to Authentic View), then the values of nodes are read afresh and Auto-Calculations are executed.
5. The second Auto-Calculation is now carried out. (If this Auto-Calculation is intended to update a node, then, as is usual for node updates, a node used in the XPath expression will have to be changed before the update takes place.)
The time lag between the updating of Node-A and the evaluation of the second Auto-Calculation with the updated value of Node-A could be confusing for the Authentic View user. To ensure that this situation does not occur, it is best that the XPath expression of the second Auto-Calculation contain the XPath expression of the first Auto-Calculation—not the updated node itself. As a result, the second Auto-Calculation will execute with the input to the first Auto-Calculation and perform that Auto-calculation as part of its own Auto-Calculation. This enables it to be evaluated independently of the contents of Node-A.

Example
The first Auto-Calculation calculates the VAT amount of a product using the nodes for (i) the net price, and (ii) the VAT rate; it updates the VAT-amount node. The second Auto-Calculation calculates the gross price, which is the sum of net price and VAT amount; it updates the gross price node.

- The Auto-Calculation to calculate the VAT amount is: NetPrice * VATRate div 100. When the VAT rate of the product is entered, the Auto-Calculation is executed and updates the VATAmount node.
- If the Auto-Calculation to calculate the gross price is: NetPrice + VATAmount, then the Auto-Calculation will execute with the value of VATAmount that was read in before VATAmount was updated.
- If, however, the Auto-Calculation to calculate the gross price is: NetPrice + (NetPrice * VATRate div 100), then the Auto-Calculation will execute with the value of VATRate and will update the GrossPrice node. The updated VATAmount node has been left out of the second Auto-Calculation.

For a detailed example, see Example: An Invoice.

Auto-Calculations in different templates
When two Auto-Calculations are in different templates, a node updated by the first Auto-Calculation can be used by the second Auto-Calculation. This is because Auto-Calculations are calculated and nodes updated for each template separately. For an example of how this would work, see Example: An Invoice.

7.1.4 Example: An Invoice

The Invoice.sps example in the (My) Documents folder, demonstrates how Auto-Calculations can be used for the following purposes:

- Counting nodes
- Selecting a node based on input from the Authentic View user
- Updating the content of a node with the result of an Auto-Calculation
- Using the result of one Auto-Calculation in another Auto-Calculation

In the example file, the Auto-Calculations have been highlighted with a yellow background color (see screenshot below).

Counting nodes
In the Invoice example, each product in the list is numbered according to its position in the list of products that a customer has ordered (Product 1, Product 2, etc). This numbering is achieved with an Auto-Calculation (screenshot below).
In this particular case, the XPath expression `position()` would suffice to obtain the correct numbering. Another useful way to obtain the position of a node is to count the number of preceding siblings and add one. The XPath expression would be: `count(preceding-sibling::Product)+1`. The latter approach could prove useful in contexts where using the `position()` function is difficult to use or cannot be used. You can test this Auto-Calculation in the example file by deleting products, and/or adding and deleting new products.

**Selecting a node based on user input**

In the Invoice example, the user selects the category of product (Book, CD, DVD, or Electronics) via a combo box. This selection is entered in the `/Product/Category` node in the XML document. An Auto-Calculation then uses this value to reference a "lookup table" in the XML document and identify the node holding the VAT percentage for this product category. The XPath expression of this Auto-Calculation is:

```
for $i in Category return /Invoice/Categories/Category[. = $i]/@rate
```

The VAT percentage is displayed at the Auto-Calculation location in the output. In the Invoices example, the lookup table is stored in the same XML document as the invoice data. However, such a table can also be stored in a separate document, in which case it would be accessed using the `doc()` function of XPath 2.0. To test this Auto-Calculation, change the product type selection in any product's Category combo box; the VAT value will change accordingly (Book=10%; CD=15%; DVD=15%; Electronics=20%).

**Updating content of a node with the result of an Auto-Calculation**

The VAT percentage obtained by the Auto-Calculation from the lookup is dynamic and stored temporarily in memory (for use in Authentic View). The result of the Auto-Calculation can, however, be stored in the VAT node in the XML document. This has two advantages: (i) the content of the VAT node does not have to be entered by the user; it is entered automatically by the Auto-Calculation; (ii) each time the lookup table is modified, the changes will be reflected in the VAT node when Invoice.xml is opened in Authentic. To cause an Auto-Calculation to update a node, select the Auto-Calculation in Design View, and in the Properties window (screenshot below), click the Authentic | Update XML Node button. In the dialog that pops up, select the VAT node, and then click OK.
In Authentic View, when the user selects a different product category in the combo box, the Auto-Calculation obtains the VAT percentage by referencing the lookup table, displays the VAT percentage, and updates the VAT node.

**Using an Auto-Calculation-updated node in another Auto-Calculation**

The VAT percentage, obtained by the Auto-Calculation described above, is required to calculate the gross price (net price + VAT amount) of each product. The formula to use would be derived as follows:

\[
\text{Gross Price} = \text{Net Price} + \text{VAT-amount}
\]

Since \(\text{VAT-amount} = \text{Net Price} \times \text{VAT-percentage} \div 100\)

\[
\text{Gross Price} = \text{Net Price} + \left(\text{Net Price} \times \frac{\text{VAT-percentage}}{100}\right)
\]

The net price of a product is obtained from the PriceNet node. The VAT percentage is calculated by an Auto-Calculation as described above, and this Auto-Calculation updates the VAT node. The content of the VAT node can now be used in an Auto-Calculation to generate the gross price. The XPath expression to do this would be:

\[
\text{PriceNet} + \left(\text{PriceNet} \times \left(\frac{\text{VAT}}{100}\right)\right)
\]

The XPath expression can be viewed and edited in the Properties window. You can test the Auto-Calculation for the gross price by changing either the price or product category of any product. Notice that the gross price (price including VAT) of the product also changes.
In the Invoice SPS, the gross price Auto-Calculation updates the PriceGross node in the XML document. The updated PriceGross nodes can now be used in an Auto-Calculation that sums up the prices of all purchased products. The XPath expression would be: sum(Order/Product/PriceGross). In the Invoice SPS, this Auto-Calculation updates the PriceTotal node. You can test this Auto-Calculation by modifying the prices of individual products and seeing the effect on the price total.

An Auto-Calculation Exercise
Now add two Auto-Calculation components to the SPS yourself.

1. Create an Auto-Calculation that calculates a volume discount for the entire invoice. If the order amount (price total) exceeds Euro 100, Euro 300, or Euro 600, discounts of 5%, 10%, and 12% apply, respectively. Display the discount amount (see screenshot below) and update the DiscountAmount node in the XML document.
2. Create an Auto-Calculation that calculates the discounted bill amount. This amount would be the price total less the discount amount (as calculated in the previous Auto-Calculation). Display the bill amount (see screenshot below) and update the BillAmount node in the XML document.

Set up these components so that the Authentic View output is as shown in the screenshot below.

You can see these two additional Auto-Calculations in the file InvoiceWithDiscounts.sps, which is in the (My) Documents folder, C:Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\Auto-Calculations folder.
7.2 Conditions

You can insert conditions anywhere in the design, in both the main template and global templates. A condition is an SPS component that is made up of one or more branches, with each branch being defined by an XPath expression. For example, consider a condition composed of two branches. The XPath expression of the first branch tests whether the value of the Location attribute of the context node is "US". The XPath expression of the second branch tests whether the value of the Location attribute is "EU". Each branch contains a template—a condition template. When a node is processed with a condition, the first branch with a test that evaluates to true is executed, that is, its condition template is processed, and the condition is exited; no further branches of that condition are evaluated. In this way, you can use different templates depending on the value of a node. In the example just cited, different templates could be used for US and EU locations.

This section consists of the following topics:

- Setting Up the Conditions, which describes how to create a condition and its branches.
- Editing Conditions, about how to edit the XPath expressions of condition branches after they have been created.
- Conditions for Specific Outputs, which shows how conditions are used to produce different output for different output formats.
- Conditions and Auto-Calculations, explains usage issues when conditions and Auto-Calculations are used in combination.

7.2.1 Setting Up the Conditions

Setting up the condition consists of the following steps:

1. Create the condition with its first branch.
2. Create additional branches for alternative processing.
3. Create and edit the templates within the various branches of the condition.

Creating the condition with its first branch

Set up a condition as follows:

1. Place the cursor anywhere in the design or select a component and then select the menu command Insert | Condition. The Edit XPath Expression dialog pops up (screenshot below).
2. In the Expression pane, enter the XPath expression for the condition branch via the keyboard. Alternatively, enter the expression by double-clicking nodes, operators, and/or functions in the panes of the dialog. It is important to be aware of the context node at the insertion point; the context node is highlighted in the schema sources tree when the dialog pops up.

3. Click **OK** to finish. The condition is created with its first branch; the XPath expression you entered is the XPath expression of the first branch. If the condition was inserted at a text insertion point, the first branch is empty (there is no template within it; see *screenshot below*). If the condition was inserted with a component selected, the condition is created around the component, and that component becomes the template of the first branch.

To select the entire condition, click the cell with the question mark. To select the first branch, click the cell with the number one.

After creating a condition with one branch (which may or may not have a template within it), you can create as many additional branches as required.
Creating additional branches

Additional branches are created one at a time. An additional branch is created via the context menu (screenshot below) and can be created in two ways: (i) without any template within it (Add New Branch); and (ii) with a copy of an existing template within the new branch (Copy Branch).

To create a new branch, right-click any branch of the condition and select Add New Branch from the context menu. The Edit XPath Expression dialog will pop up. After entering an XPath expression and clicking OK, a new empty branch is added to the condition. This is indicated in the design by a new cell being added to the condition; the new cell has a number incremented by one over the last branch prior to the addition.

To create a copy of an existing branch, right-click the branch of the condition you wish to copy and select Copy Branch. The Edit XPath Expression dialog will pop up, containing the XPath expression of the branch being copied. After modifying the XPath expression and clicking OK, a new branch is added to the condition. The new branch contains a copy of the template of the branch that was copied. The new branch is indicated in the design by a new cell with a number incremented by one over the last branch prior to the addition.

The Otherwise branch

The Otherwise branch is an alternative catch-all to specify a certain type of processing (template) in the event that none of the defined branches evaluate to true. Without the Otherwise branch, you would either have to create branches for all possible eventualities or be prepared for the possibility that the conditional template is exited without any branch being executed.

To insert an Otherwise branch, use either the Add New Branch or Copy Branch commands as described above, and in the Edit XPath Expression dialog, click the Otherwise check box (see screenshot below).
Moving branches up and down

The order of the branches in the condition is important, because the first branch to evaluate to true is executed and the condition is then exited. To move branches up and down relative to each other, select the branch to be moved, then right-click and select Move Branch Up or Move Branch Down.

Deleting a branch

To delete a branch, select the branch to be deleted, then right-click and select Delete Branch.

7.2.2 Editing Conditions

To edit the XPath expression of a condition branch, do the following:

1. Select the condition branch (not the condition).
2. In the Properties sidebar, select condition branch in the Properties For column (screenshot below).
3. Click the Edit button of the XPath property in the When group of properties. This pops up the Edit XPath Expression dialog, in which you can edit the XPath expression for that branch of the condition.

### 7.2.3 Output-Based Conditions

Individual components in the document design can be processed differently for StyleVision’s different output formats (Authentic View, RTF, Text and HTML). For example, consider the case where you wish to create a link, which, in Authentic View should point to a file on a local system, but in the HTML output should point to a Web page. In this case, you can create one condition to process content for Authentic View output and a second condition to process content for HTML output. Or consider the case where you want some text to be included in the Authentic View output but not in the HTML output. A condition could be created with a branch for processing Authentic View output, and no branch for HTML output.

**Note:** Conditions for specific output can be placed around individual parts or components of the document, thus providing considerable flexibility in the way the different output documents are structured.

**Creating conditions for specific output**

To create conditions for specific output, do the following:

1. In Design View, select the component (or highlight the document part) which you wish to create differently for different output formats.
2. Right-click, and, from the context menu that pops up, select **Enclose with | Output-Based Condition**. This inserts the output condition with four branches, each having the same content (the selected component). Each branch represents a single output (Authentic View, RTF, Text, or HTML). To determine which branch represents which output, mouseover the branch tag or check the XPath expression of the selected branch (in the Properties sidebar, in the Condition Branch entry, click the Edit button).
3. Within each branch, define the required processing. If you wish not to have any processing for a particular output format, then delete the branch for that format (select the branch and press Delete, or select the branch and in the (right-click) context menu select **Delete Branch**).

**Note:** The output-based condition can also be created first and (static and/or dynamic) content for each branch inserted later. First insert the output-based condition at a cursor insertion point in the design. Then within the respective branches, insert the required static and/or dynamic content.
Editing the branches of an Output-Based Condition

The XPath expression of a branch of an output-based condition is $SV_OutputFormat = 'format', where format is one of the values: Authentic, RTF, Text, or HTML. You can edit the XPath expression of a condition branch (in the Properties sidebar, in the Condition Branch entry, click the Edit button ). For example, you could combine the Authentic View and HTML output formats in one condition branch (using the XPath expression: $SV_OutputFormat = 'Authentic' or $SV_OutputFormat = 'HTML').

You can also (a) delete one or more branches; (b) create an otherwise branch in a condition; and (c) move the branches up or down relative to each other, thus changing the relative priority of the branches. For information on how to carry out these actions, see Setting Up the Conditions and Editing Conditions.

Using the $SV_OutputFormat parameter

In the XSLT file generated for each output, $SV_OutputFormat is created as a global parameter and assigned the value appropriate to that output format (that is, Authentic, RTF, Text, or HTML). This parameter can be overridden by passing another value for it to the processor at runtime. This could be useful, if, for example, you wish to create two alternative HTML output options, one of which will be selected at runtime. You could then create condition branches $SV_OutputFormat = 'HTML-1' and $SV_OutputFormat = 'HTML-2'. At runtime you could pass the required parameter value (HTML-1 or HTML-2) to the processor.

7.2.4 Conditions and Auto-Calculation

When using Conditions and Auto-Calculations together, there are a few issues to bear in mind. The two most fundamental points to bear in mind are:

- Only Auto-Calculations in visible conditions—that is the branch selected as true—are evaluated.
- Auto-Calculations are evaluated before Conditions.

Here are a few guidelines that summarize these issues.

1. If an Auto-Calculation updates a node, and if that node is involved in a Condition (either by being in the XPath expression of a branch or in the content of a conditional template), then keep the Auto-Calculation outside the condition if possible. This ensures that the Auto-Calculation is always visible—no matter what branch of the condition is visible—and that the node will always be updated when the Auto-Calculation is triggered. If the Auto-Calculation were inside a branch that is not visible, then it would not be triggered and the node not updated.
2. If an Auto-Calculation must be placed inside a condition, ensure (i) that it is placed in every branch of the condition, and (ii) that the various branches of the condition cover all possible conditions. There should be no eventuality that is not covered by a condition in the Conditional Template; otherwise there is a risk (if the Auto-Calculation is not in any visible template) that the Auto-Calculation might not be triggered.
3. If you require different Auto-Calculations for different conditions, ensure that all possible eventualities for every Auto-Calculation are covered.
4. Remember that the order in which conditions are defined in a conditional template is significant. The first condition to evaluate to true is executed. The otherwise condition is a convenient catch-all for non-specific eventualities.
7.3 Conditional Presence

The Conditional Presence feature enables you to create certain design components if a specified condition is fulfilled. The design components that can be created conditionally are:

- Hyperlinks
- Bookmarks
- New Documents
- User-Defined Elements
- TOC Levels

Specifying conditional presence

To specify that one of these design components be created conditionally and to set the required condition, do the following:

1. Select the design component.
2. In the Common group of properties in the Properties sidebar of that design component (screenshot below), click the Edit XPath icon of the Conditional Presence property.

3. In the Edit XPath Expression dialog that pops up, enter the XPath expression that is required as the condition to be fulfilled in order for the design component to be implemented in the output.
4. Click OK to finish.

Note: When the condition is fulfilled, the design component is implemented. Otherwise it is not, but all content of the design component is output—without the presence of that design component. For example, in the screenshot above, a hyperlink is created to be conditionally present. The condition tests whether the current node is not empty. If the node is not empty, then the condition test evaluates to true and the hyperlink is created. The text of the hyperlink text is derived from the content of the Hyperlink design component. (The URL of the hyperlink is specified elsewhere, in the Hyperlink group of properties.) If the condition test evaluates to false, then the Hyperlink text (derived from the Hyperlink design component) is output, but as plain text and not as a hyperlink.
In the same way, in the case of the other design components that can be conditionally created, it is the design component itself that is conditionally created or not. The content of the design component is created in either event (whether the condition test evaluates to true or false).
7.4 Grouping

The grouping functionality is available in XSLT 2.0 and 3.0 SPSs and for HTML, Text, and RTF output. Grouping is not supported for Authentic View output.

Grouping enables items (typically nodes) to be processed in groups. For example, consider an inventory of cars, in which the details of each car is held under a car element. If, for example, the car element has a brand attribute, then cars can be grouped by brand. This can be useful for a variety of reasons. For example:

- All cars of a single brand can be presented together in the output, under the heading of its brand name.
- Operations can be carried out within a group and the results of that operation presented separately for each group. For example, the number of models available for each brand can be listed.

Additionally, a group can be further processed in sub-groups. For example, within each brand, cars can be grouped by model and then by year.

Grouping criteria

Items can be grouped using two general criteria: (i) a grouping key, which typically tests the value of a node, and (ii) the relative position of items. The following specific grouping criteria are available:

- group-by, which groups items on the basis of an XPath-defined key. For example, car elements can be grouped on the basis of their brand attributes. The grouping is set on the car element, and an XPath expression selects the brand attribute.
- group-adjacent uses a combination of grouping-key and position criteria. All adjacent items that have the same value for the grouping key are included in one group. If the grouping-key value of an item is different from that of the previous item, then this item starts a new group.
- group-starting-with starts a new group when a node matches a defined XPath pattern. If a node does not match the defined XPath pattern, then it is assigned to the current group.
- group-lying-with ends a group when a node matches a defined XPath pattern; the matching node is the last in that group. The next node starts a new group. If a node subsequent to that which starts a group does not match the defined XPath pattern it is assigned to the current group.

Creating groups

Groups can be created on either a node or a current-group template via the context menu. To create a group, right-click the node or current-group template, and in the context menu that appears, select the Group by command. This pops up the Define Output Grouping dialog (screenshot below).
In the dialog, check the Enable Grouping check box, then select the required Grouping Type and, in the Match text box, enter the XPath expression that defines the grouping key (for the group-by and group-adjacent options) or the desired match pattern (for the group-starting-with and group-ending-with options). When you click OK, a dialog pops up asking whether you wish to sort the group-set alphabetically (in ascending order). You can always sort group-sets subsequently or remove such sorting subsequently. The screenshot below shows nodes and current-group templates which have had grouping added to them.
In the screenshot above, the person node has been grouped and the resulting groups sorted. For example if the person elements have been grouped by department, then the various departments can be sorted in alphabetically ascending order. The groups thus created have been further grouped by creating grouping on the current-group() template. In this way person elements can be grouped, say, first by department, and then by employment grade.

**Sorting groups**

After confirming a grouping definition, a pop-up asks you to confirm whether the groups should be sorted in ascending order or not. You can set sorting subsequently at any time, or modify or delete, at any time, the sorting set at this stage.

To set, modify, or delete sorting subsequently, right-click the required grouping template and select **Sort by**. This pops up the Define Output Sort Order dialog. How to use this dialog is described in the section **Sorting**. The important point to note is that to sort groups on the basis of their grouping-key, you must select the XPath function current-grouping-key() as the sorting key. For examples, see the files described in the following sections.

**Viewing and editing grouping and sorting settings**

To view and edit the grouping and sorting settings on a template, right-click the template and select Group by or Sort by, respectively. This pops up the respective dialog, in which the settings can be viewed or modified.

**User-defined templates**

User-defined templates are templates that are applied to items selected by an XPath expression you specify. The nodes selected by the XPath expression of a user-defined template can also be grouped. In this case, the grouping is applied on the user-defined template.

### 7.4.1 Example: Group-By (Persons.sps)

The Persons.sps example is based on the Persons.xsd schema and uses Persons.xml as its Working XML File. It is located in the (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\Grouping\Persons\. The XML document structure is as follows: an employees document element can contain an unlimited number of person employees. Each person employee is structured according to this example:

```xml
<person first="Vernon" last="Callaby" department="Administration" grade="C"/>
```

In the design we group persons according to department. Each department is represented by a separate table and the departments are sorted in ascending alphabetical order. Within each department table, persons are grouped according to grade (sorted in ascending alphabetical order) and, within each grade, persons are listed on in ascending alphabetical order of their last names.

**Strategy**

The strategy for creating the groups is as follows. The grouping is created on the person element with the department attribute being the grouping-key. This causes the person elements to be ordered in groups based on the value of the department attribute. (If sorting is specified, then the department groups can be organized in alphabetical order, for example, Administration first, and so on.) Since the departments are to be created as
separate tables, the current-grouping (which is based on the department grouping-key) is created as a table. Now, within this grouped order of Person elements, we specify that each group must be further ordered with the grade attribute as the grouping-key.

Creating the SPS

The design was created as follows:

1. Drag the person element from the schema tree and create it as contents.
2. Right-click the person element tag and, in the context menu, select Group by.
3. In the Define Output Grouping dialog, select group-by, set the XPath expression in the Match text box to @department, and click Yes.
4. A dialog pops up asking whether the groups should be sorted. Since we wish the groups to be sorted according to the default ascending alphabetical sorting, click OK. (Sorting can always be set, modified, or deleted subsequently.)
5. Since each group (which is a department) is to be created in a separate table, create the current group as a table. Do this by right-clicking the current-group() tag (screenshot below), and selecting Change to | Table, selecting the child attributes @last and @grade as the columns of the table.
6. Re-organize the contents of the columns and cells of the table so that the first column contains @grade and the second column contains the @first and @last nodes (see screenshot below).
7. Within the current group, which is grouped by department, we wish to group by grade. So on the current-group() template, create a grouping for the grade attribute. Confirm the default sorting. A new current-group() template is created (see screenshot below).
8. Sort this current group (which is the sub-group of persons and grouped by grade), on the last attribute.
9. Set formatting for the table.
10. Above the table provide a heading for the table. Since each table represents a department, the name of
the department can be dynamically obtained from the current context by using an Auto-Calculation
with an XPath expression that calls the current-grouping-key() function of XPath 2.0/3.0.
11. Repeat the entire process, to create similar output, but this time grouping persons by grade and
then by department.

To view or modify the grouping or sorting of a template, right-click that template and select Group by or Sort
by from the context menu. This pops up the respective dialog, in which the settings can be viewed or modified.

7.4.2  Example: Group-By (Scores.sps)

The Scores.sps example is based on the Scores.xsd schema and uses Scores.xml as its Working XML File.
It is located in the (My) Documents folder, C:\Documents and Settings\<username>\My
Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\Grouping\Scores\. The XML
document structure is as follows: a results document element contains one or more group elements and one
or more match elements. A group element contains one or more team elements, and a match element is
structured according to this example:

<match group="A" date="2007-10-12">
    <team name="Brazil" for="2" points="3"/>
    <team name="Germany" for="1" points="0"/>
</match>

The design consists of three parts (screenshot below): (i) the match results presented by day (grouped
on //match/@date); (ii) the match results presented by group (grouped on //match/@group); and (iii) group
tables providing an overview of the standings by group (a dynamic table of the group element, with Auto-
Calculations to calculate the required data).
For the two sections containing the match results, we group matches by date and tournament-group. For members of each group (date and tournament group), we create borderless tables (for alignment purposes). So matches played on a single date will be in a separate table, and all the match results of a single tournament
group will be in a separate table (for example, Group A matches). For the group-tables section, the \texttt{group} element is created as a dynamic table, with Auto-Calculations providing the value of the required data.

### Creating the SPS

The design was created as follows:

1. Drag the \texttt{/results/match} element from the schema tree and create it as contents.
2. Right-click the \texttt{match} element tag and, in the context menu, select Group by.
3. In the Define Output Grouping dialog, select \texttt{group-by}, set the XPath expression in the Match text box to \texttt{@date}, and click \texttt{OK}.
4. A dialog pops up asking whether the groups should be sorted. Since we wish the groups to be sorted according to the default ascending alphabetical sorting, click \texttt{Yes}. (Sorting can always be set, modified, or deleted subsequently.)
5. Since each group (which is a date) is to be created in a separate table, create the current group as a table. Do this by right-clicking the \texttt{current-group()} tag, selecting \texttt{Change to | Table}, and then selecting the descendant nodes \texttt{team/@name} and \texttt{team/@for} as the columns of the table (see screenshot below).

![Screenshot of the design](image)

6. Set a hyphen in each cell that will be output if the match is not the last in the current group. Do this by using a conditional template with a condition set to \texttt{position() != last()}. This provides output such as: Brazil - Germany or 2 - 1.
7. Put an Auto-Calculation in the header that outputs the current grouping key for the respective group (XPath expression: \texttt{current-grouping-key()}).
8. Format the table as required.
9. To group the matches by tournament group, repeat the entire process, but group matches this time on the \texttt{group} attribute of \texttt{match}.
10. For the group tables (in the third section of the design), which contain the standings of each team in the group, create the \texttt{/results/group} element as a dynamic table. Add columns as required (using the \texttt{Table | Append Column} or \texttt{Table | Insert Column} commands). Set up Auto-Calculations in each column to calculate the required output (3 points for a win; 1 point for a draw; 0 points for a loss).
And, finally, sort the table in descending order of total points obtained. To see the XPath expressions used to obtain these results, right-click the Auto-Calculation or sorted template, and select, respectively, the **Edit XPath** and **Sort by** commands.
7.5  Sorting

The sorting functionality is available for HTML, Text, and RTF output. **Sorting is not supported for Authentic View output.**

A set of sibling element nodes of the same qualified name can be sorted on one or more sort-keys you select. For example, all the Person elements (within, say, a Company element) can be sorted on the LastName child element of the Person element. The sort-key must be a node in the document, and is typically a descendant node (element or attribute) of the element node being sorted. In the example mentioned, LastName is the sort-key.

If there are two elements in the set submitted for sorting that have sort-key nodes with the same value, then an additional sort-key could provide further sorting. In the Person example just cited, in addition to a first sort-key of LastName, a second sort-key of FirstName could be specified. So, for Person elements with the same LastName value, an additional sort could be done on FirstName. In this way, in an SPS, multiple sort instructions (each using one sort-key) can be defined for a single sort action.

The template is applied to the sorted set and the results are sent to the output in the sorted order. Sorting is supported in the HTML, Text, and RTF output.

**User-defined templates**

User-defined templates are templates that are applied to items selected by an XPath expression you specify. The nodes selected by the XPath expression of a user-defined template can also be sorted. In this case, the sorting is applied on the user-defined template.

**In this section**

- The **sorting mechanism** is described.
- An **example** demonstrates how sorting is used.

### 7.5.1  The Sorting Mechanism

Setting up a schema element node for sorting consists of two steps:

1. In Design View, select the schema element node that is to be sorted. Note that it is the instances of this element in the XML document that will be sorted. Often it might not immediately be apparent which element is to be sorted. For example, consider the structure shown in the screenshot below.

![Screenshot of XML structure](image)

Each `newsitem` has a `dateline` containing a `place` element with a `city` attribute. The `@city` nodes of all `newsitem` elements are to be output in alphabetical order. In the design, should the `@city` node be...
selected for sorting, or the place, dateline, or newsitem elements? With @city selected, there will be only the one city node that will be sorted. With place or dateline selected, again there will be just the one respective element to sort, since within their parents they occur singly. With newsitem selected, however, there will be multiple newsitem elements within the parent newsitems element. In this case, it is the newsitem element that should be sorted, using a sort-key of dateline/place/@city.

2. After selecting the element to sort, in the context menu (obtained by right-clicking the element selection), click the Sort Output command. This pops up the Define Output Sort Order dialog (screenshot below), in which you insert or append one or more sort instructions.

```
Define Output Sort Order

Define the sort order for HTML, RTF, and PDF output. The sort order does not apply to Authentic.

Each match entered must evaluate to a single element. A match that evaluates to several elements may cause a processing error.

Sort nodes: n1:Person

<table>
<thead>
<tr>
<th>Match</th>
<th>Data type</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>LastName</td>
<td>Text</td>
<td>Ascending</td>
</tr>
</tbody>
</table>
```

Each sort instruction contains: (i) a sort-key (entered in the Match column); (ii) the datatype that the sort-key node should be considered to be (text or number); (iii) and the order of the sorting (ascending or descending). The order in which the sort instructions are listed is significant. Sorting is carried out using each sort instruction in turn, starting with the first, and working down the list when multiple items have the same value. Any number of sort instructions are allowed.

For an example of how sorting is used, see Example: Sorting on Multiple Sort-Keys.

**User-defined templates**

User-defined templates are templates that are applied to items selected by an XPath expression you specify. The nodes selected by the XPath expression of a user-defined template can also be sorted. In this case, the sorting is applied on the user-defined template.

**A note about sort-keys**

The XPath expression you enter for the sort-key must select a single node for each element instance—not a nodeset (XPath 1.0) or a sequence of items (XPath 2.0 and XPath 3.0); the key for each element should be resolvable to a string or number value.

In an XSLT 2.0 or 3.0 SPS, if the sort-key returns a sequence of nodes, an XSLT processing error will be returned. So, in the Person example cited above, with a context node of Person, an XPath expression such
as: ../Person/LastName would return an error because this expression returns all the LastName elements contained in the parent of Person (assuming there is more than one Person element). The correct XPath expression, with Person as the context node, would be: LastName (since there is only one LastName node for each Person element).

In XSLT 1.0, the specification requires that when a nodeset is returned by the sort-key selector, the text value of the first node is used. StyleVision therefore returns no error if the XPath expression selects multiple nodes for the sort-key; the text of the first node is used and the other nodes are ignored. However, the first node selected might not be the desired sort-key. For example, the XPath expression ../Person/LastName of the example described above would not return an error. But neither would it sort, because it is the same value for each element in the entire sort loop (the text value of the first LastName node). An expression of the kind: location/@*, however, would sort, using the first attribute of the location child element as the sort-key. This kind of expression, however, is to be avoided, and a more precise selection of the sort-key (selecting a single node) is advised.

### 7.5.2 Example: Sorting on Multiple Sort-Keys

In the simple example below (available in the (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\Sorting\SortingOnTwoTextKeys.sps), team-members are listed in a table. Each member is listed with first name, last name, and email address in a row of the table. Let us say we wish to sort the list of members alphabetically, first on last name and then on first name. This is how one does it.

When the list is unsorted, the output order is the order in which the member elements are listed in the XML document (screenshot below, which is the HTML output).

<table>
<thead>
<tr>
<th>First</th>
<th>Last</th>
<th>Email</th>
</tr>
</thead>
<tbody>
<tr>
<td>Andrew</td>
<td>Bentinck</td>

</tr>
</tbody>
</table>

In Design View, right-click the member element (highlighted blue in screenshot below), and from the context menu that appears, select the Sort Output command.
This pops up the Define Output Sort Order dialog (screenshot below). Notice that the element selected for sorting, `member`, is named at the Sort Nodes entry. This node is also the context node for XPath expressions to select the sort-key. Click the Add Row button (at left of pane toolbar) to add the first sort instruction. In the row that is added, enter an XPath expression in the Match column to select the node `last`. Alternatively, click the Build button to build the XPath expression. The Datatype column enables you to select how the sort-key content is to be evaluated: as text or as a number. The Order column lists the order of the sort: ascending or descending. Select Text and Ascending. Click OK to finish.

In Design View, the `member` tag displays an icon indicating that it contains a sort filter. The HTML output of the team-member list, sorted on last name, is shown below. Notice that the two Edwards are not alphabetically sorted (Nadia is listed before John, which is the order in the XML document). A second sort-key is required to sort on first name.
In Design View, right-click the member tag and select the **Sort Output** command from the context menu. The Define Output Sort Order dialog pops up with the last sort instruction listed. To add another sort instruction, append a new row and enter the **first** element as its sort-key (screenshot below). Click **OK** to finish.

In the HTML output, the list is now sorted alphabetically on last name and then first name.

7.6 Parameters and Variables

Parameters and variables can be declared and referenced in the SPS. The difference between the two is that while a variable's value is defined when it is declared, a parameter can have a value passed to it (at run-time via the command line) that overrides the optional default value assigned when the parameter was declared.

In this section, we describe the functionality available for parameters and variables:

- **User-Declared Parameters** explains how user-defined parameters can be used in an SPS.
- **Parameters for Design Fragments** describes how parameters can be used with design fragments.
- **SPS Parameters for Sources** are a special type of parameter. They are automatically defined by StyleVision for schema sources (specifically, the Working XML Files of schemas). Since the name and value of such a parameter are known to the user, the parameter can be referenced within the SPS and a value passed to it at run-time from the command line.
- **Variables** enable you to: (i) declare a variable with a certain scope and define its value, and (ii) to reference the value of declared variables and create a template on a node or nodes selected by the variable.

7.6.1 User-Declared Parameters

In an SPS, user-declared parameters are declared globally with a name and a default string value. Once declared, they can be used in XPath expressions anywhere in the SPS. The default value of the parameter can be overridden for individual XSLT transformations by passing the XSLT stylesheet a new global value via StyleVision Server.

Use of parameters

User-declared parameters are useful in the following situations:

- If you wish to use one value in multiple locations or as an input for several calculations. In this case, you can save the required value as a parameter value and use the parameter in the required locations and calculations.
- If you wish to pass a value to the stylesheet at processing time. In the SPS (and stylesheet), you use a parameter with a default value. At processing time, you pass the desired value to the parameter via StyleVision Server.

Usage mechanism

Working with user-declared parameters in the SPS consists of two steps:

1. **Declaring the required parameters**.
2. **Referencing the declared parameters**.

Declaring parameters

All user-defined parameters are declared and edited in the Edit Parameters dialog (screenshot below). The Edit Parameters dialog is accessed via: the **Edit | Stylesheet Parameters** command and the **Parameters** button in the Edit Database Filters dialog (Edit | Edit DB Filter).
Declaring a parameter involves giving it a name and a string value—its default value. If no value is specified, the default value is an empty string.

To declare a parameter, do the following:

1. In the Edit Parameters dialog, append or insert a new parameter by clicking the Append or Insert buttons. A new line appears.
2. Enter the name of the parameter. Parameter names must begin with a letter, and can contain the characters A to Z, a to z, 0 to 9, and the underscore.
3. Enter a default value for that parameter. The value you enter is accepted as a text string.

You can insert any number of parameters and modify existing parameters at any time while editing either the SPS or Authentic View.

**Note:**
- The Edit Parameters dialog contains all the user-defined parameters in an SPS.
- Parameters can also be declared in the Design Overview sidebar.

### Referencing declared parameters

Parameters can be referenced in XPath expressions by prefixing a $ character before the parameter name. For example, you could reference a parameter in the XPath expression of an Auto-Calculation (e.g. `concat('www.', $company, '.com')`). If your SPS is DB-based, then you can also use parameters as the values of DB Filter criteria. The DB parameters, however, are declared and edited in the Edit Parameters dialog.

**Note:** While it is an error to reference an undeclared parameter, it is not an error to declare a parameter and not reference it.
Parameters for Design Fragments enable you to define a parameter on a design fragment you have created and to give this parameter a default value. At each location where this design fragment is used in the design, you can enter a different parameter value, thus enabling you to modify the output of individual design fragments.

For example, a design fragment named **EMailAddresses** can be created with a parameter named **Domain** that has a default value of **altova.com**. Now, say this parameter is used in an Auto-Calculation in the design fragment to generate the email addresses of company employees. For the EU addresses, we could use the design fragment **EMailAddresses** and edit the value of the **Domain** parameter to be **altova.eu**. In the same way, in the template for Japanese employees, we could edit the value of the **Domain** parameter to be **altova.jp**. For the US employees of the company, we could leave the parameter value of **Domain** unchanged, thus generating the default value of **altova.com**.

Using parameters for design fragments consists of two parts:

1. **Defining the parameter** with a default value on the design fragment where it is created.
2. **Editing the parameter value** where the design fragment is used.

These parts are explained in detail below.

**Note:** Parameters for Design Fragments are supported in Authentic View only in the Enterprise Editions of Altova products.

### Defining the parameter

Each design fragment can be assigned any number of parameters. To do this, click the Define Parameters link in the title bar of the design fragment (see screenshot below).

This pops up the Define Parameters for Design Fragments dialog (screenshot below). Click the **Append** or **Insert** icon at top left to add a parameter entry line. Enter or select the name, datatype, number of occurrences, and default value of the parameter. The **Occurrence** attribute of the parameter specifies the number of items returned by evaluating the XPath expression specified as the default value of the parameter. The **Occurrence** attribute is optional and is, by default, none or one. You can add as many parameters as you like.
There are two types of **Delete** icon. The Delete icon to the right of each parameter entry deletes the default value of that parameter. The **Delete** icon at the top right of the pane deletes the currently highlighted parameter.

**Note:** If the SPS uses XSLT 1.0, then the XPath expression you enter must return a node-set. Otherwise an error is reported.

**Using the parameter**

After a design fragment has been created, it can be inserted at multiple locations in the design (by dragging it from the Design Tree or Schema Tree). The screenshot below shows the design fragment **EmailPerson**, inserted after the **n1:Name** element.

If a parameter has been defined for this design fragment, then its value can be edited for this particular usage instance of the design fragment. Do this by right-clicking the design fragment and selecting the command **Edit Parameters**. This pops up the Edit Parameters for Design Fragments dialog (screenshot below).
You can edit the value of the parameter in this dialog. Click OK to finish. The new parameter value will be used in this usage instance of the design fragment. If the parameter value is not edited, the original (or default) parameter value will be used.

**Note:** If XSLT 1.0 is being used, then the XPath expression must return a node-set. Otherwise an error is reported.

### 7.6.3 SPS Parameters for Sources

An SPS can have multiple schema sources, where a schema could be a DTD or XML Schema on which an XML document is based, or an XML Schema that is generated from a DB and on which the DB is based.

In each SPS, there is one main schema, and, optionally, one or more additional schemas. When you add a new schema source, StyleVision automatically declares a parameter for that schema and assigns the parameter a value that is the URI of the Working XML File you assign to that schema. In the case of DBs, StyleVision generates a temporary XML file from the DB, and sets the parameter to target the document node of this temporary XML file.

**Referencing parameters for sources**

Each SPS parameter for a schema source addresses the document node of an XML file corresponding to that schema. In StyleVision, the XML file for each schema is the Working XML File or the XML file generated from a DB. SPS parameters for sources can therefore be used in two ways:

1. In XPath expressions within the SPS, to locate nodes in various documents. The parameter is used to identify the document, and subsequent locator steps in the XPath expression locate the required node within that document. For example, the expression `count($XML2/Department/Employee)` returns the number of Employee elements in all Department elements in the XML document that is the Working XML File assigned to the schema source designated `$XML2`.

2. On the command line, the URI of another XML file can be passed as the value of an SPS parameter for sources. Of course, the new XML file would have to be based on the schema represented by that parameter. For example, if `FileA.xml` and `FileB.xml` are both valid according to the same schema, and `FileA.xml` is the Working XML File assigned to a schema `$XML3` used in an SPS, then when an
XSLT transformation for that SPS is invoked from the command line, `FileB.xml` can be substituted for `FileA.xml` by using the parameter `$XML3="FileB.xml"`. You should also note that, on the command line, values should be entered for all SPS parameters for sources except the parameter for the main schema. The XML file corresponding to the main schema will be the entry point for the XSLT stylesheet, and will therefore be the XML file on which the transformation is run.

### 7.6.4 Variables

Using variables consists of two parts: (i) declaring the variable and (ii) using the variable.

**Note:** Variables are supported in Authentic View only in the Enterprise Editions of Altova products.

#### Declaring a variable

A variable can be declared on any template included in the design. It is given a name, a datatype, and a value. Additionally, you can specify whether it is to be editable in the Enterprise editions of Authentic View. The variable will then be in scope on this template and can be used within it. To declare a variable so that it is in scope for the entire document, declare the variable on the root template. A major advantage of declaring a variable only on the template where it is needed is that XPath expressions to locate a descendant node will be simpler.

Declare a variable as follows:

1. Right-click the node template on which the variable is to be created and select the command Define Variables.
2. In the Define Variables dialog that appears (screenshot below), click the Append Variable icon in the top left of the Variables pane, then enter a variable name. The value of the variable is given via an XPath expression. If you wish to enter a string as the value of the variable (as in the first variable in the screenshot below), then enclose the string in quotation marks. In the screenshot below, the value of the SelectGroup variable is the empty string. Otherwise, the text will be read as a node name or a function-call.
3. Setting a variable to Editable (by checking the **Editable** check box) enables the variable to be edited in **Authentic View**. In this case, you must also set the datatype value to the correct type, such as `xs:string`. When a variable is editable, the original value set by the SPS designer can be edited when the Authentic View user makes changes to the document in Authentic View. Such changes can be the explicit editing of the variable (such as when the variable value is created as editable contents or an editable text box and this is edited by the Authentic View user), or when a node or value used in the variable’s XPath expression is modified by the Authentic View user.

4. If the variable is set to Editable, then two more options relevant to Authentic View are enabled: **Undoable** and **Calc**. Checking the **Undoable** option generates an Undo step for every change made to the variable. The Authentic View user can therefore click through the Undo cycle to retrieve an earlier value of the variable. The **Calc** value can be either **Once** or **Auto**. If this option is set to **Once**, the variable value is calculated once, when the template containing the variable is evaluated. The value can only be changed when the user explicitly edits the variable (for example, if the variable is created as editable contents or an editable text box). On the other hand, if this option is set to **Auto**, the variable will be re-calculated each time a node or value used in the variable’s XPath expression is modified.

5. You can add as many variables as you like, but the name of a variable must not be the name of an already declared in-scope variable. To delete a variable click the **Delete** icon in the top right of the pane.

6. Click **OK** when done. The template tag will now have a $ icon to indicate that one or more variables have been declared on it.

In this way, variables can be created for each node template that is present in the design. Each of these variables will have a name and a value, and will be in scope within the template on which it was declared. To edit a variable subsequently, right-click the node template on which the variable was created and select the command **Define Variables** to access the Define Variables dialog.
Using a variable

For a variable to be used at any location, it must be in scope at that location. This means that a variable can only be used within the template on which it was defined. Variables can also be edited in Authentic View so that users can control the display. The edited value is discarded when the SPS is closed.

A variable can be used in any XPath expression, and is referenced in the XPath expression by prefixing its name with a $ symbol. For example, the XPath expression $VarName/Name selects the Name child element of the node selected by the variable named VarName.

When you enter an XPath expression in the Edit XPath Expression dialog, in-scope variables appear in a pop-up (see screenshot above). Selecting a variable in the pop-up and pressing Enter inserts the variable reference in the expression.

7.6.5 Editable Variables in Authentic

Variables that are in scope can be edited in Authentic View by the Authentic View user to control the display in Authentic View. For example, if a very large XML document containing, say the personnel data of several branches of a company, is being used, the Authentic View user can be given the option of selecting one particular company branch. The Authentic View display of the XML document could in this way be restricted to the branch selected by the Authentic View user.

How it works

Three steps are involved in setting up editable variables in Authentic View (also see screenshot below):

1. The required variable is defined on the template within which it will be used. This template delimits the scope of the variable. The variable can only be used within the template on which it is in scope.
2. A User-Defined Template is created with the name of the variable. The dynamic content of this User-Defined Template will contain the value of the variable. If the (contents) placeholder or an input field is inserted in the design as the content of the User-Defined Template, then the Authentic View user can enter any content as the value of the variable. The options available to the Authentic View user can however be restricted by inserting a form control, such as a combo box, as the content of the User-Defined Template.
3. The variable can be used in an XPath expression to control the Authentic View display. For example, the variable can be used in a condition. Depending on the value of each branch of the condition, a
different display can be specified. Another mechanism where a variable can be well used is in a template match expression or template filter.

**Note:** Note the following points:

- Since grouping and sorting are not supported in Authentic View, editable variables in Authentic View cannot be used in an SPS containing any of these features.
- Since the editable variables feature applies only to Authentic View, the design for Authentic View will need to be different than that for the other outputs. This can be designed easily using the **Output-Based Conditions** feature.

**Example file**

The file `AuthenticVariables.sps` in the (My) Documents folder shows how editable variables in Authentic View can be used. The XML file contains the results of matches in a tournament. The teams participating in the tournament are divided into two groups. The editable variable enables the Authentic View user to select the group to be viewed and restrict the display to that group.

The screenshot below displays the entire SPS design. One editable variable is created and the different steps required to set it up are labeled in the screenshot below. A description of the actual steps is given below the screenshot.

The key steps in setting up the editable variable were as follows:

- On the $XML template (the root template), an editable variable called `SelectGroup` is defined with a type of `xs:string`. This variable will be in scope for the entire template.
On the $XML template, a non-editable variable called Groups is defined with a type of <auto>. Its purpose is to dynamically collect the distinct values of all the results/group/@id attributes. These distinct values are planned to be displayed in the dropdown list of the combo box from which the Authentic View user will select the group he or she wishes to have displayed.

A User-Defined Template is created and given the name $SelectGroup (the name of the editable variable). The location of the User-Defined template does not matter as long as it is within the scope of the editable variable.

Within this User-Defined Template, a combo box is inserted. The combo box uses the XPath expression $Groups, 'All' to select the entry values of the dropdown list. This XPath expression returns the sequence of items contained in the variable $Groups (which dynamically collects all the available groups), and adds an item All to the sequence returned by $Groups. The All entry item of the combo box will be used to display all groups.

The User-Defined Template is enclosed in an output-based conditional template with the output set for Authentic View. This is because the editable variable can only be used in Authentic View.

The next step is to use the value of the editable variable that the Authentic View user selects. This will be used to filter the display down to the group that the Authentic View user selects. It is done by specifying a filter on the results/group template. The XPath expression of this filter is:

```
if ($SelectGroup != 'All') then @id=$SelectGroup else @id
```

This filter expression sets up a predicate step on the group element. If the $SelectGroup variable has a value not equal to All, then the predicate step will be [@id=X], where X is the value of the $SelectGroup variable (that the Authentic View user selected in the combo box). This filter has the effect of selecting the group that has an id attribute with the value the Authentic View user selected. If the $SelectGroup variable has a value of All, then the predicate expression will select groups with any id attribute value, that is, all groups.

The group template is enclosed within an output-based condition, each branch of which selects a different output. Only in the Authentic View branch does the group template have the filter applied.

The Authentic View output will look like this:

Notice the entries in the combo box, the combo box selection of Group B, and the display limited to Group B.
7.7 Table of Contents, Referencing, Bookmarks

The Table of Contents (TOC) and other referencing mechanisms work by creating anchors at the required points in the design document and then referring back to these references from TOCs, text references, auto-numbering sequences, and hyperlinks.

We will look briefly at the anchoring (or bookmarking) mechanism first and then look at the overall TOC mechanism. We do this because understanding the bookmarking mechanism first will provide a better understanding of the overall TOC mechanism.

The bookmarking mechanism

Two types of bookmarking mechanism are used: simple and complex. The complex bookmarking mechanism is the one used for creating TOCs.

- A simple bookmark is created at a point in the design document. The bookmark is given a unique name which is used as the target of links that point to it. This simple bookmarking mechanism is the mechanism used for the Bookmarks and Hyperlinks feature. (Note that hyperlinks can additionally point to URLs outside the document.)
- For more complex referencing, such as for TOCs and for the auto-numbering of document sections, building the bookmark involves two parts.

1. The design document is structured into a hierarchy of levels required for the TOC. These levels are known as TOC levels. The structuring is achieved by assigning TOC levels to different points in the document structure. TOC levels can be nested within other TOC levels so as to give the document a hierarchical TOC structure. (For example, a TOC level can be assigned to a book chapter, and another TOC level can be assigned within that level to the sections of the chapter.)
2. TOC bookmarks are created within the various TOC levels. These TOC bookmarks identify the document sections at various levels that are to go into the TOC. Additionally, each TOC bookmark must be defined to provide the text that will appear in the referencing component.

After the TOC levels and the TOC bookmarks’ reference texts have been defined, the TOC template containing the referencing components can be designed.

The overall TOC mechanism is broadly described below, under The TOC mechanism. The various referencing features are explained in detail in the rest of this section.

The TOC mechanism

If you have selected XSLT 2.0 or XSLT 3.0 (not XSLT 1.0) as the XSLT version of your SPS, you can create a table of contents (TOC)—essentially a template for the TOC—at any location in the design.

- It is recommended that the items from the design that are to be included in and linked to from the TOC are bookmarked in the design first. These items can be static content or dynamic content. In the bottom half of the screenshot below, yellow TOC bookmark tags within the header tag indicates that the header item has been bookmarked (for inclusion in the TOC template).
- A template is created for the TOC (highlighted in screenshot below). The TOC template contains the design of the TOC; it can be located anywhere in the design. In the example shown in the screenshot below, the TOC template is located near the top of the document.
Note: Either of these two parts can be created first, or both parts can be created concomitantly. We recommend, however, that the TOC bookmarks are created before the TOC template.

The TOC is displayed in Authentic View and in the HTML, Text, and RTF output. Also note that: (i) TOCs can be created with a flat or a hierarchical structure (with corresponding numbering), and (ii) multiple TOCs can be created within a design. As a result, a stylesheet designer can create a document with, say, one (hierarchical) TOC at the book level and others (also hierarchical) at the chapter level, plus (flat) lists of figures and tables.

Procedure for creating TOCs

Given below is one step-by-step way of creating a TOC. Items are first bookmarked for inclusion. The TOC template is constructed after that. (Alternatively, you can create the TOC template first, and then bookmark items for inclusion. Or you can create the TOC template and select items for inclusion in parallel.)

1. Make sure that XSLT 2.0 is the selected XSLT version.
2. **Structure the document in TOC levels**. If the TOC is to have multiple levels, structure the document design in a hierarchy of nested TOC levels. If the TOC is to have a flat structure (that is, one level only), then create at least one TOC level (in the document design) that will enclose the TOC bookmarks.

3. **Create one or more TOC bookmarks** within each level in the document design. The TOC bookmarks identify the components within each TOC level that are to appear in the TOC.

4. **Create a TOC template containing TOC level references (levelrefs)**. The TOC template should have the required number of TOC level references (levelrefs). In the case of a multi-level TOC, the levelrefs in the TOC template should be nested (see screenshot above).

5. **Create TOC references (TOCrefs) in the TOC template**. In the TOC template, set up a TOCref for each levelref. Each TOCref will reference, by name, the TOC bookmarks within the corresponding TOC level in the document. Alternatively, the TOCref can reference TOC bookmarks in other levels.

6. **Format the TOC items**. Each text item in the TOC output is generated by a TOCref in the TOC template. TOCref definitions can specify item numbering (including hierarchical), the TOC item text, a leader, and, for paged media, a page number. Each TOCref and its individual parts can be formatted separately as required. (Note that automatic numbering can also be defined within a TOC bookmark in the main body of the document. See the section, **Auto-Numbering**, for details.)

---

**Terminology**

The names of the main TOC-related components used in the interface are given in the table below. Components have been put in two different columns according to where they occur: in the **document body**, or in the **TOC template** (which is the template that specifies the design of the actual Table of Contents and typically occurs at the beginning of the document).

- The **TOC components in the document body** mark out items that will be used in the TOC template.
- The **TOC components in the TOC template** reference the marked items in the document body. Components in the TOC template have the word ‘reference’ in their names.

<table>
<thead>
<tr>
<th>Document body</th>
<th>TOC template</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TOC level</strong>: The TOC levels structure the document in a nested hierarchy.</td>
<td><strong>Level references (levelrefs)</strong>: Correspond to the TOC-level structure defined in the document body. Enables TOCrefs in a given level to target TOC bookmarks at the corresponding level.</td>
</tr>
<tr>
<td><strong>TOC bookmark</strong>: Has a name, with which it identifies a node in the document as a TOC item.</td>
<td><strong>TOC references (TOCrefs)</strong>: References a TOC bookmark by its name.</td>
</tr>
</tbody>
</table>
7.7.1 Bookmarking Items for TOC Inclusion

Bookmarking an item in the design for inclusion in a TOC consists of two steps, which can be done in any order:

1. **Structuring the design document in a hierarchy of nested TOC levels**. A TOC level can be created in the design either on a template or around a design component. In the screenshot below, a TOC level has been created on the **topic** template.

   ![Screenshot of TOC level creation](image)

   When a level is created on a template, this is indicated by the level icon inside the start tag of the template, for example, `<topic>`. When a level is created around a component it is indicated by TOC level tags `<TOC level>`. In the screenshot above, the `topics` template component is enclosed by a level. The difference between the two ways of marking levels is explained in the section **Structuring the Design in Levels**. When the TOC template is created, it must be structured in a hierarchy of levels, with the levels in the TOC template corresponding to the levels you have created in the design. Even for TOCs with a flat structure (one level), the design must have a corresponding level.

2. **Creating a TOC bookmark** in the design with a name and TOC-item text. The TOC bookmark can either enclose or not enclose a design component; in the latter case it is empty. In the screenshot below, the TOC bookmark does not enclose a design component.

   ![Screenshot of TOC bookmark creation](image)

   The TOC bookmark serves as an anchor in the document. In the screenshot above, the TOC bookmark (and anchor) is located at the start of `para` element instances. The TOC bookmark has two attributes: (i) a name that will be used to reference the TOC bookmark when creating the TOC item in the TOC template, and (ii) a text string that will be used as the text of the corresponding TOC item. How these two attributes are assigned is described in the section, **Creating TOC Bookmarks**.

---

How bookmarked items are referenced in the TOC template

The **TOC template** is structured in nested levels (called level references (levelrefs) to differentiate them from the levels created in the main body of the design template). Within each levelref, a TOC reference (TOCref) is inserted (see screenshot below). The TOCref within a levelref references TOC bookmarks using the TOC bookmark's name. Each TOC bookmark with that name and in the corresponding
level in the XML document will be created as a TOC item at this level in the TOC. For example, the TOCRef indicated with the tag \[\text{chapters}\] references all TOC bookmarks named chapters in the corresponding level in the XML document (when the scope of the TOCRef has been set to current). The text attribute of the respective instantiated TOC bookmarks will be output as the text of the TOC item.

In the screenshot above of a TOC template, there are three nested levelrefs, within each of which is a TOCRef that contains the template for the TOC item of that level. For example, in the first levelref, there is a TOCRef that references TOC bookmarks that have a name of MyTOC. As a result, all TOC bookmarks in the first level (as structured in the design) and named MyTOC will be accessed for output at this level in the TOC. The TOCRef within the second levelref also references TOC bookmarks having a name of MyTOC. As a result, all TOC bookmarks in the second level of the document and that are named MyTOC will be used for second-level items in the TOC. The third levelref works in the same way: TOC bookmarks named MyTOC that occur within the document’s third level are referenced for third-level items in the TOC.

In the sub-sections of this section, we describe: (i) how the design is structured into levels, and (ii) how bookmarks are created. How the TOC template is created is described in the section, Creating the TOC Template.

### 7.7.1.1 Structuring the Design in TOC Levels

The hierarchical structure you wish to design for the TOC is specified as a set of nested levels. As such it is a hierarchical structure which, although related to the XML document structure, is separate from it. This structure is specified in the SPS document design. The TOC template that you construct will use a structure corresponding to this hierarchical structure. In the case of a TOC with a flat structure (one level only), the design document must have at least one level. If more than one level exists in the document, a flat TOC can then be created for any of these levels or for multiple levels (aggregated together as one level).

In the design, levels can be created in the main template, in global templates, or in a combination of main template and global templates. The important thing to note is that, wherever created, these levels must together, in combination, define a clear hierarchical structure.

### Creating levels

Each level in the design is created separately. A level can be created on a template or around a component. In the screenshot below, one level has been created on the topic template (indicated by \[\text{topic}\]) and
another around the topics element (indicated by \texttt{TOC level}). The essential difference between these two ways of creating levels is that the enclose-within-a-level option enables levels to be created around components other than templates.

To create a level, do the following:

1. Select the component (template or other).
2. Right-click, and from the context menu select Template Serves As Level (enabled when a template is selected) or Enclose With | TOC Level. Both these options are also available in the Insert | Insert Table of Contents menu: TOC Level or Template Serves as Level.

Levels in global templates

Levels can also be set in global templates. In these cases, care must be taken to ensure that the levels created in various global templates, as well as those in the main template, together define a hierarchical structure when the SPS is executed. The screenshot below shows two levels, one in the main template (on the topic template) and one in the global template for topic (on the topic template).
In the content model represented by the screenshot above, topic is a recursive element, that is, a topic element can itself contain a descendant topic element. In the main template (the end of which is indicated by the $XML$ tag), a level has been set on the first level of topic. The rest-of-contents instruction in the main template specifies that templates will be applied for all child elements of topic/body except header. This means that the global template for topic children of topic/body will be processed.

In the global template for topic, a level has been set on the topic template (indicated by $topic$). This second level of the TOC hierarchy, which occurs on the second level of topic elements, is nested within the first level of the TOC hierarchy. Since this global template also has a rest-of-contents instruction, the global template for topic will be applied to all recursive topic elements, thus creating additional nested levels in the TOC hierarchy: third level, fourth level, and so on.

As a designer, you should be aware of the number of levels created in the design, because when the TOC template is constructed, you will need to explicitly specify how TOC items for each level will be selected and formatted.

**Levels in flat TOCs**

In a flat TOC hierarchy, TOC items will be output at a single level: for example, a simple list of the images in a document.

A flat hierarchy can be obtained in a number of ways.

- The design document can be structured with just a single TOC level. The TOC template will then have a single levelref with a single TOC reference (TOCref) within it.
- If the design document has more than one TOC level, then the TOC template could have a number of levelrefs equal to the sequential position of the TOC level being referenced. The levelref corresponding to the targeted TOC level will contain the single TOCref in the TOC template.
- If the design document has more than one TOC level, then the single TOCref in the TOC template must have a scope that covers all the targeted document levels, which, in effect, will be flattened into a single level.

Let us say that we wish to gather all the images in a document in a single flat-hierarchy TOC. The document design must therefore contain at least one level, and this level must contain all the required TOC bookmarks. In the TOC template, the images to be listed are referenced in the usual way: (i) by creating a corresponding number of levelrefs; and (ii) creating a TOCref within the levelref corresponding to the targeted TOC level. The TOCref will have the name of TOC bookmarks in the targeted TOC level.

In the TOC template shown below, there is one levelref containing a TOCref that references TOC bookmarks named images. The scope of the TOCref has been set to Current level and below. As a result, all TOC bookmarks named images in the first level and below (that is, in the whole document) will be referenced.
If the design contains more than one level, and a flat TOC is required, say, for items in the second level, then the TOC template could have two levelrefs with a TOCref only within the second level (no TOCref within the first level). Alternatively, the scope property of TOCrefs can be used to specify what level/s in the design document should be looked up for bookmarks of a given name.

7.7.1.2 Creating TOC Bookmarks

TOC bookmarks are created within a TOC level in the document design. They can be created in the main template and/or in global templates. A TOC bookmark serves two purposes:

- It marks a (static or dynamic) component in the design with a static name you assign. It can either enclose or not enclose a design component; in the latter case it is empty. In the output, the TOC bookmark is instantiated as an anchor identified by a name. This named anchor can be referenced by items in the TOC (template).
- A TOC bookmark also defines the text string that will be used as the text of a TOC item. This text string can be the content of child elements of the node where the marker is located, or it can be the output of an XPath expression.

You can create a TOC bookmark in two ways:

- By using the Create TOC Bookmark Wizard, which enables you to specify the TOC bookmark's name, its text entry, whether auto-numbering should be used, and the level within which it appears.
- By inserting an empty TOC bookmark, the properties of which will be defined subsequently.

Creating the TOC bookmark with the Create TOC Bookmark Wizard

To create a TOC bookmark using the TOC Bookmark Wizard, do the following:

1. Place the cursor at the point in the design where you wish to insert the TOC bookmark. Alternatively, select the design component around which you wish to insert the TOC bookmark.
2. From the context menu (obtained by right-clicking) or from the Insert menu, select Insert Table of Contents | TOC Bookmark (Wizard). If you are enclosing an a node with a TOC Bookmark, use the command Enclose with | TOC Bookmark (Wizard). This pops up the Create Marker Wizard (screenshot below).
3. In the wizard's first screen (screenshot above) you: (i) define the text for the TOC item; (ii) set the TOC bookmark name; and (iii) specify whether this TOC bookmark should be numbered in the output. For the text entry you can select whether the text of child elements should be used, or an XPath expression. For the name of the TOC bookmark, you can enter text directly or select from a dropdown list containing the names of already specified TOC bookmark names. When you are done, click Next.

4. In the wizard's second screen (screenshot below), you can create a TOC level on a template if you wish to do so. Ancestor templates of the insertion point location are shown in a tree. If a template has already been created as a TOC level, this is indicated with a symbol. In the screenshot below, the symbol next to the topic template indicates that it has already been created as a level. If you wish to create an additional level on any of the ancestor templates, select that template. Alternatively, you can choose to define the level later by checking the Define Level Later check box. When you have completed making your selection, click Finish. (Note that, if a TOC level already exists on a template, selecting such a template and clicking Finish will not create a new TOC level on that template.)
On clicking Finish, a TOC bookmark will be created at the insertion point and, if it was specified in the second screen of the wizard, a TOC level will be created on one template. The TOC bookmark that has been created will be in the TOC level that immediately contains it. For example, if that TOC level is the third TOC level in the TOC level hierarchy, then the inserted TOC bookmark will be in the third TOC level.

Creating a TOC bookmark
To create a TOC bookmark without attributes (TOC bookmark name, TOC item text, etc), do the following:

1. Place the cursor at the point in the design document where you wish to insert the TOC bookmark, or select the design component around which you wish to insert the TOC bookmark.
2. From the context menu (obtained by right-clicking) or from the Insert menu, select Insert Table of Contents | TOC Bookmark. A TOC bookmark is inserted. This TOC bookmark has neither a name nor a text entry. These can be defined subsequently using the Edit commands (see below).

Inserting hierarchical or sequential numbering for a component
Hierarchical or sequential numbering within the main body of the output document (not within the TOC) can be inserted within (but also outside) a TOC bookmark’s tags. Right-click at the location where you wish to insert the numbering, then select Insert Table Of Contents | Hierarchical Numbering / Sequential Numbering. For example, an auto-numbering TOC bookmark that is placed around the chapter heading template will generate numbering for all the chapter headings generated by the chapter heading template.

Note that numbering is based on the structure of TOC levels. So, for example, if a chapter heading element is in the first TOC level, then the fourth chapter heading will be numbered 4 because it is the fourth instance of a chapter heading within the first TOC level. If the sections of a chapter occur within the second TOC level, then the third section of the fourth chapter will be numbered 4.3. This is because, within the first (chapter) TOC level, it is the fourth instance of a chapter, and within the second (section) TOC level (of the fourth chapter), it is the third instance of a section.
Editing the name and text entry of a TOC bookmark

The name and text entry of the TOC bookmark can be edited in the Properties window (screenshot below). To edit these properties, select the TOC bookmark, and either directly edit the property in the Property window or right-click the TOC bookmark and select the property you wish to edit.

The TOC bookmark has the following properties: (i) the name of the TOC bookmark group (Group); (ii) a unique ID; (iii) an option to remove the bookmark if it is not referenced; and (iv) an option (Text From) to specify the text entry, which could come from the bookmark's content or from an XPath expression.

7.7.2 Creating the TOC Template

The TOC template is the template that produces the table of contents in the output. It can be created anywhere within the SPS design, and multiple TOC templates can be created in a single SPS design.

The steps to create a TOC template are as follows:

1. Place the cursor at the location where the TOC template is to be inserted.
2. Click the menu command Insert | Insert Table of Contents | Table of Contents. This pops up the Create TOC Page dialog (screenshot below). (Alternatively, this command can be accessed via the context menu, which appears when you right-click.)
3. Enter the information requested in the dialog: (i) The name of the generated TOC page is the (TOCref) name that will be used to reference the TOC bookmarks in the design document. If you select multiple levels for the TOC (level references, to be more accurate; next option), the same TOCref name will be used in all level references (though individual TOCref names can be edited subsequently). (ii) The number of TOC level references specifies how many level references the TOC is to have. (iii) For printed media, the option to output page references (i.e. page numbers) is available. (iv) The text entries in the TOC can be used as links to the TOC bookmarks.

4. Click OK to finish. The TOC template is created with the specified number of levelrefs (screenshot below; the formatting of the TOC template has been modified from that which is created initially).

Within each levelref is a TOCref having a name that identifies TOC bookmarks that are to be the TOC items for that levelref. Within each TOCref is a default template for the TOC item, which you can edit at any time.

**Editing the TOC template**

The following editing options are available:

- The TOC template can be dragged to another location in the SPS. Note, however, that a change of context node could affect XPath expressions within the TOC template.
- Levelrefs can be added to or deleted from the structure of the TOC template.
- The properties of individual TOC references (TOCrefs) can be edited. The name and scope of a TOCref can be changed, and you can choose whether the TOC item corresponding to the TOCref is created as a hyperlink or not.
7.7.2.1 Levelrefs in the TOC Template

The TOC template is structured in level references (or levelrefs); see screenshot below. These levels are initially created when the TOC template is created, and the number of levelrefs are the number you specify in the Create TOC Page dialog.

Notice that the levelrefs are nested. For the purposes of the TOC design there is a one-to-one correspondence between the levelrefs in the TOC template and the levels in the SPS design. Thus, the first levelref of the TOC template corresponds to the first level in the SPS design, the second levelref in the TOC template to the second level in the SPS design, and so on. The TOCrefs within a given levelref of the TOC template identify TOC bookmarks within a specified scope in the SPS design. For example, a TOCref can specify that the TOCref target TOC bookmarks in the corresponding document level, or target TOC bookmarks in all document levels, or those in the current document level and lower document levels.

Inserting and removing levelrefs

Levelrefs can be inserted in or deleted from the TOC template after the TOC template has been created.

To insert a levelref around content, select the content in the TOC template around which the levelref is to be created, then, from the context menu or via the menu bar, select the command Enclose With | TOC Level Reference. You can also insert an empty levelref at the cursor insertion point with the menu command Insert | Insert Table of Contents | TOC Level Reference (also available in the context menu).

To remove a levelref from the TOC template, select the levelref to be removed and either press the Delete key or select Remove from the context menu. Note that only the levelref will be removed—not its contents.
7.7.2.2 TOC References: Name, Scope, Hyperlink

TOC references (TOCrefs) occur within level references (levelrefs) and have four properties (see screenshot below):

- A **hyperlink** property which can be toggled between yes and no to specify whether the corresponding TOC items are created as hyperlinks or not.
- A **group** property, which is the name of the TOCref and identifies TOC bookmarks of the same name that occur within the specified scope (see below). The TOC bookmarks so identified provide the items to be included at that levelref of the TOC.
- An **id** to uniquely identify the TOCref.
- A **scope**, which specifies to which corresponding levels in the SPS design the TOCref applies. Three options are available: (i) global, (ii) current level, (iii) current level and descendant levels (see screenshot below).

To insert a TOCref, place the cursor within a levelref and, from the Insert menu or context menu, select Insert Table of Contents | TOC Reference.

To edit a TOCref property, right-click the TOCref tag in the TOC template and select the property you wish to edit (Create Hyperlink, Edit ID, Edit Group, or Edit Scope). This pops up the Properties window with the specified property selected for editing (screenshot below).

Alternatively, with the TOCref tag selected, go directly to the required property in the Properties window (TOC reference group of properties).

7.7.2.3 Formatting TOC Items

The TOC item can contain up to four standard components, plus optional user-specified content. The four standard components are (see also screenshot below):

- the text entry of the TOC item, indicated in the TOC template by (text ref)
the leader between the text entry and the page number (for paged media output), indicated by (......)

- the page reference of the TOC item (for paged media output), indicated by (page ref)
- hierarchical or sequential numbering, indicated by (num-lvl) and (num-seq), respectively

When the TOC template is initially created, the text entry is automatically inserted within TOCrefs. If the Include Page Reference option was selected, then the leader and page reference components are also included. Subsequently, components can be inserted and deleted from the TOC item. To insert a component, place the cursor at the desired insertion point within the TOC item, and in the context menu, select Insert Table Of Contents | TOC Reference | Entry Text / Leader / Page Reference or Insert Table Of Contents | Hierarchical Numbering / Sequential Numbering as required. (Hierarchical numbering should be inserted when the design is structured into nested levels, sequential numbering when there is no hierarchy, that is, just one flat TOC level. See the note below on flat TOCs) To delete a component, select it and press the Delete key.

Additionally, you can insert static content (e.g. text) and dynamic content (e.g. Auto-Calculations) within the TOC item.

Levels in flat TOCs
In a flat TOC hierarchy, TOC items will be output at a single level: for example, a simple list of the images in a document.

A flat hierarchy can be obtained in a number of ways.

- The design document can be structured with just a single TOC level. The TOC template will then have a single levelref with a single TOC reference (TOCref) within it.
- If the design document has more than one TOC level, then the TOC template could have a number of levelrefs equal to the sequential position of the TOC level being referenced. The levelref corresponding to the targeted TOC level will contain the single TOCref in the TOC template.
- If the design document has more than one TOC level, then the single TOCref in the TOC template must have a scope that covers all the targeted document levels, which, in effect, will be flattened into a single level.

Let us say that we wish to gather all the images in a document in a single flat-hierarchy TOC. The document design must therefore contain at least one level, and this level must contain all the required TOC bookmarks. In the TOC template, the images to be listed are referenced in the usual way: (i) by creating a corresponding number of levelrefs; and (ii) creating a TOCref within the levelref corresponding to the targeted TOC level. The TOCref will have the name of TOC bookmarks in the targeted TOC level.

In the TOC template shown below, there is one levelref containing a TOCref that references TOC bookmarks named images. The scope of the TOCref has been set to Current level and below. As a result, all TOC bookmarks named images in the first level and below (that is, in the whole document) will be referenced.
If the design contains more than one level, and a flat TOC is required, say, for items in the second level, then the TOC template could have two levelrefs with a TOCref only within the second level (no TOCref within the first level). Alternatively, the scope property of TOCrefs can be used to specify what level/s in the design document should be looked up for bookmarks of a given name.

### Formatting the TOC item

The TOC item can be formatted with CSS styles via the Styles sidebar. Individual TOC item components can be separately formatted by selecting the component and assigning it style properties in the Styles sidebar.

#### 7.7.3 Example: Simple TOC

An example SPS file to demonstrate the basic use of TOCs, called ChaptersSimple.sps, is in the (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\TOC. This SPS is based on a schema that defines the content model of a large chapter-based document. The schema structure is shown in the screenshot below and can be viewed in the Schema Tree window of StyleVision when you open ChaptersSimple.sps. (A more complex TOC example based on the same schema is described in the next section of this documentation, Example: Hierarchical and Sequential TOCs.)
The document element is `helpproject`, which contains a child `topics` element. The `topics` element can contain an unlimited number of `topic` elements, each of which can in turn contain descendant `topic` elements. The first level of `topic` elements can be considered to be the chapters of the document, while descendant `topic` elements are sections, sub-sections, and so on.

This SPS creates a TOC, located at the top of the document, which lists the names of each chapter (the first-level topics). Creating the TOC involves three steps:

1. **Structuring the design in TOC levels**: One or more levels are inserted in the design document to structure the (output) document hierarchically. This hierarchical structure will be the one that the TOC reflects. In our current example, to keep things simple, only one **TOC level** has been created—on the `Topic` template. Because there is only one level in the design, the **TOC template**—when it is created subsequently—can have only one level in its structure (i.e. one level reference).

2. **Creating TOC bookmarks**: A **TOC bookmark** is created within the TOC level that was created in Step 1 (in the design document). This enables TOC references in the TOC template (which will be created in the next step) to point back to this TOC bookmark. The TOC bookmark also specifies the text that will appear in the TOC item that points to it.

3. **Creating the TOC template**: This is the template that creates the TOC in the document. It is structured into **level references (levelrefs)**, which must correspond to the structure of TOC levels in the design document. For example if there are three nested levelrefs in the TOC template, then the design document must have at least three nested levels. In this example we have a single levelref to
correspond to the single TOC level in the design document. It is within the levelref that the TOC reference (TOCref) is placed. It is this TOCref that generates the TOC items for this level in the TOC.

SPS structure and levels
Look at the structure of the design in the SPS. Notice that the main template (with the green $XML tags) contains the TOC. The rest of the main template specifies, through the rest-of-contents instruction, that global and default templates are to be applied. The rest of the SPS design—outside the main template and after it—consists of global templates.

The TOC definitions (TOC levels and TOC bookmarks in the design) are in the global template for topic (screenshot below). In this global template a condition has been inserted to separate topic elements according to how many ancestor topic elements each has, thus providing separate processing (within different conditional branches) for chapters, sections, and sub-sections.

[Diagram of SPS structure and levels]

The screenshot above shows the contents of the first conditional branch, for first-level, chapter-type topic elements. Note that a TOC level has been created on the template start-tag of this topic element. In the other two conditional branches no TOC level has been created on the topic template. As a result, the document has been assigned only one TOC level, and this is at the level of the first-level (chapter-type) topic element.

Creating the TOC bookmark
A TOC bookmark (yellow tags in screenshot below) has been created within the header descendant element of topic (but outside the para element). This TOC bookmark serves as an anchor for every top-level, chapter-type topic element.

[Diagram of TOC bookmark]

The properties of the TOC bookmark can be edited in the Properties sidebar (screenshot below).
The Group property sets the TOC bookmark group (and is the name of the TOC bookmark). In our example, we have specified the value MyTOC for this property. The bookmark group will be referenced in the TOC when it is created, and it enables different TOC groups to be specified within the same level. The ID property enables unique IDs to be specified for the bookmark instances created. The Remove if not referenced property is an option to remove the bookmark if it is not referenced. The Text From property specifies the text entry that will be used as the text of the TOC item in the TOC. The text could come from the bookmark's content (the content between the start and end tags of the bookmark in the design) or from an XPath expression. In our example, an XPath expression is used which returns the header text, respectively, of each first-level topic element.

**TOC template**

Inside the TOC template (screenshot below), a single Level Reference (levelref) has been inserted. This levelref corresponds to the TOC Level assigned on the first-level, chapter-type topic element in the design (see 'SPS Structure and Levels' above).

Within this levelref, a TOC reference (TOCref) has been inserted. This TOCref has been set to select bookmarks (i) that are in the bookmark group named MyTOC (see 'Creating the TOC bookmark' above), and (ii) that are within the scope of the current level only. These settings can be made in the Properties sidebar when the TOCref is selected, or by right-clicking the TOCref in the design and selecting the relevant editing command from the context menu.

The appearance of the TOC item is specified within the TOCref tags of the TOC. The numbering format, the text, the leader, and the page reference can be inserted by right-clicking within the TOCref tags and selecting the component to insert from the context menu. Each of these components can be edited by selecting it in the design and modifying its properties in the Properties sidebar.
7.7.4 Example: Hierarchical and Sequential TOCs

An example SPS file to demonstrate the use of TOCs, called Chapters.sps, is in the (My) Documents folder. C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\TOC. This SPS is based on a schema that defines the content model of a large chapter-based document. The schema structure is shown in the screenshot below and can be viewed in the Schema Tree window of StyleVision when you open Chapters.sps.

The document element is helpproject, which contains a child topics element. The topics element can contain an unlimited number of topic elements, each of which can in turn contain descendant topic elements. The first level of topic elements can be considered to be the chapters of the document, while descendant topic elements are sections, sub-sections, and so on.

The SPS contains three TOCs, located at the top of the document, in the following order:

1. **Chapters at a glance**, which lists the names of each chapter (the first-level topics).
2. **Chapters and their sections**, which lists each chapter with its descendants sections (first-level topics, plus each topic’s hierarchy of sub-topics down to the lowest-level topic, which in the accompanying XML document, chapters.xml, is the third-level topic).
3. **List of images**, which is a flat list of all images in the document (except the first), listed by file name.

**SPS structure**

Before considering the TOCs in detail, take a look at the structure of the design. Notice that the main template (with the green $XML tags) contains the TOCs. The rest of the main template specifies, through the `rest-of-contents` instruction, that global and default templates are to be applied.

The TOC definitions are in the global templates for `topic` and `image`. In the global template for `topic` (*screenshot below*), a TOC level has been created on the `topic` element, and a TOC bookmark has been created within the `header` child element (but outside the `para` element).

Since the `topic` element is recursive, the TOC level and the TOC bookmark will also recurse. This means that, at the first recursion, a new hierarchically subordinate TOC level and a new TOC bookmark is created. This process continues for each descendant topic, thus creating a hierarchy of descendant TOC levels, each with a corresponding TOC bookmark. Since the formatting of the header (the topic title) for each TOC level is to be different, we have enclosed each level within a separate branch of a condition with three branches. Each branch tests for the TOC level at which a topic occurs: first, second, or third level.

Notice that hierarchical numbering `(num-lvl)` has been inserted within the level. This is done by right-clicking at the required location and selecting `Insert Table of Contents | Hierarchical Numbering`. The effect is to insert the correct hierarchical number before each topic title in the document's text flow, for example, 3.1 or 4.2.3.

**TOC descriptions**

Given below is a brief description of each TOC and the points to note about them.

*Chapters at a glance:* Select the TOC bookmark in the global template for `topic`. In the Properties sidebar (*screenshot below*), notice that the entry text has been set to be constructed using an XPath expression. When you click the Edit button in the value field of the `Text from` property, you will see that the XPath expression has been defined as `para`. This means that the contents of the `para` child of `header` (since the TOC bookmark has been inserted within the `header` element) will be used as the text of the TOC item.
The TOC template itself (screenshot below) contains one level reference (levelref) and the TOCref within that levelref has been set to select TOC bookmarks named MyTOC within the scope of the current level only—which is the first level. As a result, TOC items will be created only for first-level topics.

Notice also that the numbering has been defined as hierarchical numbering.

**Chapters and their sections:** In this TOC (screenshot below), notice that three nested levelrefs have been defined, each containing a TOCref for which the scope is the current level.

Since each TOC item is contained in a div block, formatting properties (including indentation) can be set for the block.

**List of images:** The list of images is a flat list. First of all, consider within which levels images will occur in the instantiated document. The image element is a child of the para element. Since levels have been created on
topic elements, image elements will occur within the first, second, and/or third levels of the document. There is therefore no need to create any level for the image element.

In the global template for image, the condition (see screenshot below) enables separate processing for (i) the first image (which is presented in this example), and (ii) the other images (which, for purposes of economy, are not presented in this example).

<table>
<thead>
<tr>
<th>image (simple)</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="src" alt="image" /></td>
</tr>
<tr>
<td><img src="src" alt="image intentionally omitted" /></td>
</tr>
</tbody>
</table>

Notice that the TOC bookmark is placed only within the second branch of the condition; this means that the images selected in the first branch are not bookmarked. Also, the sequential numbering (num-seq) of the images, inserted with Insert Table of Contents | Sequential Numbering, will start with the second image (because the first image is selected in the first branch of the condition). Another feature to note is that the numbering can be formatted, as has been done in this case. To see the formatting, right-click (num-seq), and select Edit Format. In the dialog box that pops up, you will see that the formatting has been set to 01, indicating that a 0 will be inserted in front of single-digit numbers.

In the TOC template for images (screenshot below), notice that there is a single TOCref identifying bookmarks named images, and that this TOCref is within a single levelref. The scope of the TOCref (editable in the Properties window when the TOCref is selected) has been set to: current level and below. The current level, determined by the levelref, is the first level. The levels below will be the second, third, and so on. In this way, all images from the first level downward are selected as items in the TOC.

Since the selected numbering is sequential, the images are numbered sequentially in a flat list.

### 7.7.5 Auto-Numbering in the Document Body

Repeating instances of a node can be numbered automatically in the main body of the document using the Auto-Numbering feature. For example, in a Book element that contains multiple Chapter elements, each Chapter element can be numbered automatically using the Auto-Numbering feature. This is an easy way to insert numbering based on the structure of the XML document.

**Note:** The Auto-Numbering feature refers to numbering within the main body of the document. It does not refer to numbering within tables of contents (TOCs), where numbering is considered to be a property of the TOC item.
Auto-Numbering can be either sequential (flat) or hierarchical. Sequential numbering provides ordinary numbering on a single level. Hierarchical numbering is based on the TOC-level hierarchy created in the document and creates numbering according to the element's position in the TOC-level hierarchy.

A wide variety of formatting is available for the numbers. In the case of hierarchical numbers, individual number tokens can be formatted separately. For example, a three-token number could be given the format: A.1.i., where each of the three tokens has a different number format. Number formatting is assigned differently for sequential and hierarchical numbering, and therefore have separate descriptions, each in their respective sections below.

Sequential numbering (num-seq)
Sequential (or flat) numbering can be inserted within a TOC Bookmark in the document design (see screenshot below). Create sequential numbering as follows:

1. Place the cursor within the node that has to be numbered and create the TOC bookmark (right-click, and select Insert Table of Contents | TOC Bookmark). The TOC bookmark will be created. In the screenshot below, we wish to number the topic element, so the TOC bookmark has been created within the topic element. The exact location within the topic element depends on where in the layout you want the numbering. (In the screenshot below, the numbering is placed immediately to the left of the chapter header (title).)

2. Place the cursor within the tags of the TOC bookmark, right-click, and select Insert Table of Contents | Sequential Numbering. This inserts the Auto-Numbering placeholder for sequential numbering, (num-seq) (highlighted within the TOC bookmark 'TopicHeader' in the screenshot below).

3. If the TOC bookmark is going to be referenced from within a TOC template, then you can enter TOC bookmark properties as required. However, if the TOC bookmark is going to be used only for sequential numbering, there is no need to name it. If you wish to name it, right-click it and select the Edit Group command.

In the example shown in the screenshot above, sequential numbering has been set on the topic node. The result is that each topic element receives a sequential number, as shown in the screenshot below. Note that the numbering is essentially the position of each topic element within the sequence of all sibling topic elements at that level of the XML document hierarchy.

1. Altova StyleVision 2007
2. About this Documentation
3. Introduction
4. User Interface
Note: If sequential numbering must be continued on another set of nodes, then use a TOC bookmark with the same name on both nodesets.

To format the sequential numbering, right-click the `num-seq` placeholder and select the Edit Format command. This pops up the Format Sequential Auto-Number dialog (screenshot below).

Select the format you want from the dropdown box of the Available numbering styles combo box (see screenshot above) and click OK to apply the selected format.

Hierarchical numbering (num-lvl)

Hierarchical numbering can be inserted within a TOC level in the design. To create hierarchical numbering in a document, you must therefore first structure the document in TOC levels. Do this as described in the section Structuring the Design in Levels. The following points should be borne in mind:

- Levels must be created either on the node to be numbered or within it.
- Levels must be nested according to the hierarchy of the numbering required (see screenshot below).
- The hierarchical numbering placeholder must be inserted within the corresponding level in the design (see screenshot below).

In the screenshot above, there are two levels. The `topic` element is recursive, and a level has been created on two `topic` elements (by right-clicking the node tag and selecting Template Serves as Level). One `topic` element (highlighted in the screenshot above) is nested within the other. As a result, the levels also are nested. Within each level, a hierarchical numbering placeholder (num-lvl) has been inserted (right-click within the level and select Insert Table of Contents | Hierarchical Numbering).
The result of the design shown in the screenshot above will look like this.

2: About this Documentation
3: Introduction
   3.1: What Is an SFS?
   3.2: Product Features
   3.3: Setting up StyleVision
4: User Interface
   4.1: Main Window
   4.2: Design Entry Helpers

The first level is shown in bold, the second in normal.

To format hierarchical numbering, right-click the num-lvl placeholder and select the Edit Format command. This pops up the Format Hierarchical Auto-Number dialog (screenshot below).

First select the number of tokens in the Token combo box. This number should be the same as the number of TOC levels in the document. Each token can then be separately formatted. In the lower of the two display boxes, select the token to be formatted. (In the screenshot above, the second token has been selected.) Next, in the Formatting combo box, select the formatting style you want. In the screenshot above, lowercase formatting has been selected for the second token, and this is reflected in the display box at the top of the dialog. Additionally, levels can be omitted by entering the required number of levels to be omitted in the Omit Levels box.

Note that formatting is defined on hierarchical numbering one level at a time. So the hierarchical numbering placeholder num-lvl at each level must be separately formatted.

Click OK when done.
7.7.6 Cross-referencing

A cross-reference is a reference to another part of the document. In an SPS a cross-reference is created in two parts: First, by setting the target of the cross-reference. Second, by defining the link to the target. Setting a target consists of creating a TOC bookmark within a TOC level. The link to the target is a Text Reference within a TOC reference (TOCref). The Text Reference generates the output text and serves as the link. Building a cross-reference therefore consists of the following three steps:

**Step 1: Levels**
The document is structured into TOC levels as described in the section Structuring the Design in Levels. TOC levels will be used during referencing to specify the scope of the referencing. Only those TOC bookmarks having the specified name and falling within the specified scope will be targeted. In the screenshot below, a level has been created on the n1:Office element.

**Step 2: Creating TOC bookmarks**
Within a level, a TOC bookmark is created by placing the cursor at the required location, right-clicking, and selecting Insert Table of Contents | TOC Bookmark. The TOC bookmark is given a name and an XPath expression that generates the output text. The XPath expression will typically identify a node in the document, the contents of which is the required text.

In the screenshot below, the TOC bookmark within the n1:Name element has a name of toc3 and an XPath expression that locates the current node. This means that the output text will be the contents of the n1:Name node.

When the XML document is processed, an anchor is created for every n1:Name element. This anchor will have a text reference (the text of the cross-reference) that is the value of the n1:Name element.

**Step 3: Creating TOC references**
A TOC reference (TOCref) is inserted (context menu, Insert Table of Contents | TOC Reference) to create a link to the anchors generated by a TOC Bookmark.

In the screenshot above, the TOCref named toc3 (screenshot above) is within the same TOC level as the TOC bookmark it references (the Office level). You must also specify the scope of the TOCref. The scope specifies what TOC levels must be searched for TOC bookmarks of the same name as the TOCref. In the example shown above, the scope is the current level. This means that TOC bookmarks within the current level that have a name of toc3 are targeted by this reference.
The screenshot above shows an n1:Office template. When an n1:Office node is processed, an anchor is created with output text that is the content of the n1:Name node. This is because the TOC bookmark specifies in an XPath expression (via the Text from property of the TOC bookmark) that the contents of this node will be the output text. The TOCref in the next line identifies the anchor with the name toc3, and the Text reference component generates the output text of the link to the anchor (purple text in the screenshot below). The output will look something like this:

In the example above, the scope was set to the current level. There are two other possibilities for the scope: (i) a global scope, (ii) scope for the current level and below. With these options, it is possible to also target TOC Bookmarks in other levels of the design.

7.7.7 Bookmarks and Hyperlinks

In the SPS document, bookmarks can be inserted anywhere within the design. These bookmarks are transformed into anchors in the output, which can be linked to from hyperlinks. Hyperlinks can not only link to bookmarks, but also to external resources like Web pages. StyleVision offers considerable flexibility in the way target URIs for hyperlinks can be built.

In this section, we describe:

- How bookmarks can be inserted in the SPS.
- How hyperlinks can be inserted in the SPS and how they link to the target pages.

Note: Links to external documents are supported in the FO spec but might not be supported by the FO processor you are using. You should check support for this feature if you are planning to use it.

7.7.7.1 Inserting Bookmarks

A bookmark (or anchor) can be inserted anywhere in the SPS, at a cursor insertion point or around an SPS component.

Bookmarks are created in the SPS via the Insert Bookmark dialog (screenshot below). In this dialog you define the name of the bookmark. The name can be a static name, or it can be a dynamic name that is (i) derived from XML document content, or (ii) generated arbitrarily with an XPath expression.

Creating a bookmark

To insert a bookmark, do the following:

1. Place the cursor at the location where you wish to create the bookmark.
2. Select the menu command **Insert | Insert Bookmark**, or right-click and select **Insert | Bookmark**.

3. In the Insert Bookmark dialog (screenshot below), select a tab according to whether the name of the bookmark should be static (Static tab), dynamically obtained from the XML document or arbitrarily generated from an XPath expression (Dynamic), or composed of both static and dynamic parts (Static and Dynamic). In the screenshot below a dynamic bookmark is created, which has a name that is a unique ID for each Name child of the context node.

![Insert Bookmark dialog](image)

4. Click **OK**. The bookmark is defined.

After a bookmark has been created, it can be linked to by a hyperlink.

**Note:** Bookmarks are created at the location specified in the design. If that location is within an element that repeats, a bookmark is created within each instance of that repeating element. If a static name is given, then each bookmark will have the same name. Therefore, it is better in such cases (of repeating elements) to give a dynamic name, which can be, for example, the name of a child element of the context node (the element within which the bookmark is created). If the node selected for the dynamic name might have the same content across multiple instances, then the uniqueness of the bookmark name can be ensured by using the `generate-id()` function to generate the name (see screenshot above). To reference such a bookmark, the same ID can be generated as the `href` value of a hyperlink. In this case make sure you use the fragment-identifier `#` in front of the `generate-id()` function. The XPath expression would be: `concat('#', generate-id(nodeXXX))`.

### Modifying a bookmark

After a bookmark has been created, its name can be modified via the Edit Bookmarks dialog. This dialog is accessed as follows:

1. Select the bookmark in the design.
2. In the Properties sidebar, click the **Edit** button of the **Bookmark Name** property (screenshot below) in the **Bookmark** group of properties. This pops up the Edit Bookmark dialog, which is identical to the Insert Bookmark dialog described above (see screenshot above).
3. In the Edit Bookmark dialog, edit the name of the bookmark in either the Static, Dynamic, or Static and Dynamic tab.

Deleting a bookmark
To delete a bookmark, select it in the design and press the Delete key.

### 7.7.7.2 Defining Hyperlinks

Hyperlinks can be created around SPS components such as text or images. The targets of hyperlinks can be: (i) bookmarks in the SPS design, or (ii) external resources, such as web pages or email messages. In this section, we first discuss the content of the hyperlink (text, image, etc) and then the target of the hyperlink.

Creating hyperlinks
A hyperlink can be created in the following ways:

- Around text (static or dynamic), nodes, images, conditional templates, Auto-Calculations, and blocks of content or nodes; it cannot be created around a data-entry device such as an input field or combo box—though it can be created around a node or conditional template in which that data-entry device is. This is the content of the link, which, when clicked, jumps to the target of the link. To create a hyperlink around a component in the SPS, select that component and use the Enclose With | Hyperlink menu command.
- A new hyperlink can be inserted via the Insert | Hyperlink menu command. The content of the link will need to be subsequently added within the tags of the newly created hyperlink.

Defining the target of the hyperlink
The target of the hyperlink is created in the Insert Hyperlink dialog (screenshot below), which is accessed via the Enclose With | Hyperlink or Insert | Hyperlink.
The target of a link can be either:

- A bookmark in the same SPS design (in which case the target URI must be a fragment identifier),
- Dynamically generated to match bookmark anchors (these URIs are also fragment identifiers),
- An external resource; the URI can be static (directly entered), dynamic (taken from a node in an XML document), a combination of static and dynamic parts, or the value of an unparsed entity.

How these targets are defined is explained below. After the URI has been defined in the Insert/Edit Hyperlink dialog, click OK to finish.

**Linking to bookmarks**

To link to a bookmark, do the following:

1. In the Static tab of the Insert Hyperlink dialog, click the **Bookmark** button. This pops up the Select Bookmark in Document dialog (screenshot below). The screenshot below shows two bookmarks: one static, one dynamic.
2. To select a static bookmark as the target URI, double-click the static bookmark and click OK. If you double-click a dynamic bookmark, you will be prompted to enter an XPath expression to match the selected dynamic bookmark (see screenshot below).

The dynamic bookmark is actually an XPath expression that generates the name of the bookmark; it is not itself the name of the bookmark. The Create Hyperlink to Dynamic Bookmark dialog, displays the XPath expression of the dynamic bookmark and enables you to construct an XPath expression that will generate a name to match that of the targeted bookmark. Click OK when done.
Linking to dynamically generated ID bookmarks

Bookmarks can have dynamically generated ID anchors. If one wishes to link back to such a bookmark, the problem then is this: Since the names of dynamically generated anchors are generated at runtime and therefore unknown at design time, how is one to set the href value of a hyperlink that targets such an anchor? The answer is to use the generate-id() function once again, this time within the href value of the hyperlink. The key to understanding why this works lies in a property of the generate-id() function. In a single transformation, each time the generate-id() function is evaluated for a specific node, it always generates the same ID. Because of this the IDs generated in the bookmark and the hyperlink will be the same.

Two points should be borne in mind:

- Since the generate-id() function must be evaluated as an XPath expression, use the Dynamic tab of the Insert Hyperlink dialog (see screenshot below) to set the target of the hyperlink.
- The evaluated value of the href attribute must start with # (the fragment identifier). Consequently the XPath expression will be: concat('#', generate-id(nodeXXX)). Alternatively, in the Static and Dynamic tab, enter # in the static part of the address and generate-id(nodeXXX) in the dynamic part.

Linking to external resources

URIs that locate external resources can be built in the following ways:

- By entering the URI directly in the Static tab of the Insert Hyperlink dialog. For example, a link to the Altova home page (http://www.altova.com) can be entered directly in the Address input field of the Static tab.
- By selecting a node in the XML document source in the Dynamic tab of the Insert Hyperlink dialog. The node in the XML source can provide a text string that is either: (i) the URI to be targeted, or (ii) the name of an unparsed entity which has the required URI as its value. For example, the Altova website address can be contained as a text string in a node.
- By building a URI that has both static and dynamic parts in the Static and Dynamic tab of the Insert Hyperlink dialog. This can be useful for adding static prefixes (e.g. a protocol) or suffixes (e.g. a domain name). For example, email addresses could be created by using a static part of mailto: and a dynamic part that takes the string content of the //Contact/@email node (the screenshot below creates a link on the contents placeholder of the //Contact/@email node, which is why the abbreviated self::node() selector has been used). The Edit XPath button opens the Edit XPath Expression dialog to help you build the dynamic part of the hyperlink.

How to use unparsed entities is described in the section Unparsed Entity URIs.
**Note:** While linking to external documents is supported in the FO specification, an FOP limitation could result in external links not working in PDF documents created with FOP.

Authentic View modification of parent node’s content
The [value of the parent node of a hyperlink can be selected by the Authentic View user](#). The SPS can be designed to modify presentation based on what the Authentic View user selects.

Editing hyperlink properties
To edit a hyperlink, right-click either the start or end hyperlink (\(\wedge\)) tag, and select **Edit URL** from the context menu. This pops up the Edit Hyperlink dialog ([screenshot above](#)). The Edit Hyperlink dialog can also be accessed via the **URL** property of the **Hyperlink** group of properties in the Properties window.

Removing and deleting hyperlinks
To delete a hyperlink, select the hyperlink (by clicking either the start or end hyperlink (\(\wedge\)) tag), and press the **Delete** key. The hyperlink and its contents are deleted.
7.8 Example: Multiple Languages

Very often, documents and Authentic Forms will need to contain content in multiple languages or will require the user to choose a preferred language. StyleVision offers a range of features that can be used to achieve these goals. Given below are some possibilities, all of which are demonstrated in the Multiple Language examples in the Examples project delivered with StyleVision. (The Examples project should load automatically by default when you first start StyleVision. It can also be loaded by selecting the menu command Project | Open, and then browsing for the Examples.svp file in the folder: C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples.)

Using variables and conditions

The user's preferred language is entered in an editable variable. A condition with multiple branches maps each language to the correct language content. The user's language choice is used to select the correct conditional branch.

In the screenshot above, notice that the user's choice is entered as the value of the editable variable. The conditions in the table have two branches for the two language choices and test for the value of the editable variable. The Authentic View output is as in the screenshot below.
The above strategy is well-suited for forms in which the user selects the required language. For details, see the file, `MultiLangByCondition.sps`, which is in the Examples project.

### Using parameters and Auto-Calculations

Another scenario would be one in which the same data is required to be output in different languages. A possible strategy for this requirement would be to use a parameter, the value of which triggers the required language output. The appropriate language output can be determined, for example, by means of an Auto-Calculation. The Auto-Calculation could output the appropriate content according to the value of the parameter.

In the screenshot above, the Auto-Calcs have XPath expressions of the form:

```
if ( $Language = 'E' ) then 'First' else
if ( $Language = 'G' ) then 'Vorname' else ''
```

The value of the `$Language` global parameter can be modified in the SPS design or can be supplied via the command line at runtime. Multiple transformation runs can be made to output the same data in multiple languages.

For details, see the file, `MultiLangByAutoCalcs.sps`, which is in the Examples project.
Example files
For more examples, open the Examples project file, Examples.svp, which is in the folder: C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples.
8 Presentation and Output

In the SPS design, a single set of styling features is defined for components. These styles are converted to the corresponding style markup in the respective outputs (Authentic View, HTML, RTF, PDF, Word 2007+ and Text in the Enterprise Edition; Authentic View, HTML, RTF, and Text in the Professional Edition; HTML in the Basic Edition). Some presentation effects, notably interactive Web presentation effects (such as combo boxes and JavaScript event handlers), will by their nature not be available in paged media output (RTF). In these cases, the paged media will use a suitable print rendition of the effect. For print output, however, StyleVision offers essential page definition options. These paged media options, such as page size, page layout, and headers and footers, are defined additionally to the styling of components, and will be used for RTF output alone.

Note: Since plain text cannot be formatted, text styling properties and page layouts in the design will be ignored when generating Text output.

Styling of SPS components

All styling of SPS components is done using CSS2 principles and syntax. Styles can be defined in external stylesheets, globally for the SPS, and locally on a component. The cascading order of CSS2 applies to the SPS, and provides considerable flexibility in designing styles. How to work with CSS styles is described in detail in the Working with CSS Styles sub-section of this section.

The values of style properties can be entered directly in the Styles or Properties sidebars, or they can be set via XPath expressions. The benefits of using XPath expressions are: (i) that the property value can taken from an XML file, and (ii) that a property value can be assigned conditionally according to a test contained in the XPath expression.

Additionally, in the SPS design, certain HTML elements are available as markup for SPS components. These predefined formats are passed to the HTML output. The formatting inherent in such markup is therefore also used to provide styling to SPS components. When CSS styles are applied to predefined formats, the CSS styles get priority over the inherent style of the predefined format. Predefined formats are described in the Predefined Formats sub-section of this section. Note that the inherent styles of predefined formats are converted to equivalent markup for RTF output.

Note: When defining CSS styles for an SPS component be aware that some styles may not, by their nature, be applicable to paged media output (RTF). Also, when HTML selectors are used (in external stylesheets and global style rules), these will not be applicable to paged media output (RTF). When such selectors are used, a comment is displayed next to the selector to the effect that the style will not be applied to Text, RTF output.

Designing for paged media output

For StyleVision's paged media support (RTF outputs and XSLT stylesheets for RTF), page definition and layout options are available. These options are used additionally to the component styling mechanism, and are described in the Designing Print Output sub-section of this section.
8.1 Predefined Formats

StyleVision provides a number of pre-defined formats, each of which corresponds to an HTML element (screenshot below). When you apply a Predefined Format to a component in the Design, that component is marked up as a component having the corresponding HTML semantics. This has two effects:

- Formatting inherent to the selected predefined format is applied.
- The component is contained in the component type, paragraph, which makes it available for local styling by component type.

Assigning Predefined Formats

Predefined formats can be assigned by clicking Insert | Special Paragraph, and then the required format, or by selecting the required format from the Format drop-down list in the Toolbar (shown below).

Inherent styles

The predefined formats used in StyleVision have either one or both of the following two styling components:

- a text-styling component
- a spacing component.

For example, the predefined para (p) format has a spacing component only; it puts vertical space before and after the selected component, and does not apply any text styling. On the other hand, the predefined Heading 1 (h1) format has both a text-styling component and a spacing component.

The following styling points about predefined formats should be noted:

- The spacing component of a predefined format applies for any type of SPS component, but the text styling only if it can be applied. For example, if you select an image and apply a predefined format of Heading 1 (h1) to it, then the spacing component will take effect, but the text-styling component will not.
- The text-styling component of predefined formats does not apply to data-entry devices.
- Only one predefined format applies to a component at any given time.
- The Preformatted predefined format (pre) applies formatting equivalent to that applied by the pre tab of HTML: linebreaks and spacing in the text are maintained and a monospaced font (such as Courier) is used for the display. In the case of run-on lines with no linebreaks, such as in a paragraph of text, the Preformatted (pre) predefined format will display lines of text without wrapping. If you wish to wrap the text, use the predefined format Preformatted, wrapping (pre-wrap).
Defining additional styling for a predefined format

Styles additional to the inherent styling can be defined for a predefined format by selecting it and applying a local style via the Styles sidebar.

The Return key and predefined formats

In Authentic View, when the Return key is pressed within the contents of an element having a predefined format, the current element instance and its block are terminated, and a new element instance and block are inserted at that point. This property is useful, for example, if you want the Authentic View user to be able to create a new element, say a paragraph-type element, by pressing the Return key.
8.2 Output Escaping

A character in a text string is said to be escaped when it is written as a character reference or entity reference. Both types of references (character and entity) are delimited by an ampersand at the start and a semicolon at the end. For example:

- the hexadecimal (or Unicode) character reference of the character A is \&#x41;
- the decimal character reference of the character A is \&#65;
- the HTML (and XML) entity reference of the character A is \&amp;
- the hexadecimal (or Unicode) character reference of the character & is \&#x26;
- the decimal character reference of the character & is \&#38;
- the HTML (and XML) entity reference of the character < is \&lt;

Output escaping

Output escaping refers to the way characters that are escaped in the input are represented in the output. A character is said to be output-escaped when it is represented in the output as a character or entity reference. Note that a character can only be output-escaped when it is escaped in the input (see table below for examples). In an SPS, output-escaping can be enabled or disabled for:

- Fragments of static text,
- The contents placeholder, and
- Auto-Calculations

This is done with the disable-output-escaping attribute of the Text group of properties. The default value of this property is no, which means that output-escaping will not be disabled. So characters that are escaped in the input will be escaped in the output by default (see table below for examples).

To disable output escaping, do the following:

1. Select the (i) static text, or (ii) fragment of static text, (iii) contents placeholder, or (iv) Auto-Calculation for which you wish to disable output escaping.
2. In the Properties sidebar, select the Text group of properties for the Text item, and set the disable-output-escaping attribute to yes for the various outputs individually or for all outputs. The available values are:

- For HTML (to set disable-output-escaping to yes for HTML output).
- For Authentic (to set disable-output-escaping to yes for Authentic output). Note that disabling output escaping for Authentic View is enabled only in Enterprise editions of Authentic View (that is, in the Enterprise editions of StyleVision, Authentic Desktop, Authentic Browser, and XMLSpy).
- For RTF (to set disable-output-escaping to yes for RTF output).
- For all (to set disable-output-escaping to yes for all outputs except Text).

Note: Output escaping does not apply to Text output. (It is neither enabled or disabled.)

When output escaping is disabled for a particular output format (for example, HTML output), the selected text will not be escaped in that output format, but will be escaped in the other output formats.

Given below are some examples of text with output escaping disabled and/or enabled.
Note: Disable-Output-Escaping is supported in Authentic View only in the Enterprise Editions of Altova products.

Using disabled output-escaping across output formats
If output-escaping is disabled, the text string can have significance in one output but no significance at all in another output. For example, consider the following input text, which has escaped characters (highlighted):

```xml
&lt;b&gt;This text is bold.&lt;/b&gt;
```

If output-escaping is disabled, this text will be output as:

```xml
&lt;b&gt;This text is bold.&lt;/b&gt;
```

If output-escaping is disabled for HTML output and this output is viewed in a browser (as opposed to a text editor), the markup will be significant for the HTML browser and the text will be displayed in bold, like this:

**This text is bold.**

However, if viewed in another output format, such as PDF, the markup that was significant in HTML will not necessarily be of significance in this other output format. In the particular case cited above, the unescaped text (output escaping disabled) will be output in PDF format as is, like this:

```xml
&lt;b&gt;This text is bold.&lt;/b&gt;
```

As the example above demonstrates, the output text obtained by disabling output-escaping might be interpretable as code in one output format but not in another. This should be clearly borne in mind when using the Disable-Output-Escaping property.
8.3 Value Formatting (Formatting Numeric Datatypes)

Value Formatting enables the contents of numeric XML Schema datatype nodes (see list below) to be displayed in a format other than the lexical representation of that datatype. (For example, the lexical representation of an xs:date datatype node is YYYY-MM-DD, with an optional timezone component, such as +02:00.) The Value Formatting is displayed in Authentic View and, depending on the formatting definition, may also be available for display in the HTML, Text, and RTF output. Value Formatting can also be used to format the result of an Auto-Calculation if the result of the Auto-Calculation is in the lexical format of one of the numeric datatypes (see list below) for which Value Formatting is available.

In the sub-sections of this section, we describe:

· how the Value Formatting mechanism works, and
· the syntax for defining the Value Formatting.

Note: Value Formatting does not change the format in which the data is stored in the XML document. In the valid XML document, the data is always stored in the lexical format appropriate to the datatype of the node. Value Formatting is applied to the display in Authentic View and, optionally (if available), to the display in the output.

### Numeric datatypes for which Value Formatting is available

Value Formatting is available for the following datatypes:

- xs:decimal; xs:integer; the 12 built-in types derived from xs:integer
- xs:double and xs:float when values are between and including 0.000001 and 1,000,000. Values outside this range are displayed in scientific notation (for example: 1.0E7), and cannot have Value Formatting applied to them.
- xs:date; xs:dateTime; xs:duration
- xs:gYear; xs:gYearMonth; xs:gMonth; xs:gMonthDay; xs:gDay

#### 8.3.1 The Value Formatting Mechanism

Value Formatting can be applied to:

- A numeric datatype node, such as xs:decimal or xs:date that is present in the SPS as contents or an input field.
- An Auto-Calculation that evaluates to a value which has the lexical format of a numeric datatype.

### Defining Value Formatting

To define Value Formatting for a node or Auto-Calculation in the SPS, do the following:

1. Select the contents placeholder or input field of the node, or the Auto-Calculation.
2. In the Properties sidebar, select the item, and then the Content group (or AutoCalc group) of properties. Now click the Edit button of the Value Formatting property. Alternatively, right-click...
and select **Edit Value Formatting** from the context menu. The Value Formatting dialog appears (screenshot below). It is different according to whether the selected component was a node or an Auto-Calculation. If the selected component was a node, then a dialog like the one below appears. The node represented in the screenshot below is of the `xs:date` datatype.

![Value Formatting dialog](image)

Note that the screenshot above contains the line: **Formats for type 'date'** and that the standard format for the `xs:date` datatype is given alongside the **Unformatted** check box. For a node of some other datatype, this information would be correspondingly different.

If the selected component was an Auto-Calculation, the following dialog appears.
3. You now specify whether the display of the component's value is to be unformatted or formatted. If you wish to leave the output unformatted, select the **Unformatted** radio button. Otherwise select the **Format as XML Schema Value** radio button. (If the value is unformatted, the output has the standard formatting for the datatype of the selected node or the datatype of the Auto-Calculation result. If you specify **Formatting as XML Schema Value** for an Auto-Calculation, you have to additionally select (from a dropdown list) the datatype of the expected Auto-calculation result.

4. Enter the Value Formatting definition. This definition can be entered in three ways: (i) by selecting from a dropdown list of available options for that datatype (see the 'Format in Output Documents' input field in the screenshots above); (ii) by entering the definition directly in the input field; and (iii) by using the **Insert Field** and **Field Options** buttons to build the definition correctly. See Value Formatting Syntax for a full description of the various formatting options.

Errors in syntax
If there is an error in syntax, the following happens:

- The definition is displayed in red.
- An error message, also in red, is displayed below the input field.
- The **OK** button in the Value Formatting dialog is disabled.
- The **Go to Error** button in the Value Formatting dialog is enabled. Clicking it causes the cursor to be placed at the point in the format definition where the syntax error is.

Mismatch of data and datatype formats
If the data entered in an XML node does not match the lexical format of that node's datatype, or if the result of an Auto-Calculation does not match the lexical format of the expected datatype, then the formatting will be undefined and will not be displayed correctly in the output.
Applying Value Formatting to the output

The Value Formatting that you define applies to Authentic View, which is supported in the Enterprise and Professional editions.

Some Value Formatting definitions—not all—can also, additionally, be applied to HTML, Text, RTF output. To do this, check the Apply Same Format to XSLT Output check box. If this option is not checked, or if it is not available, then only Authentic View will display the Value Formatting, while the output will display the value in the standard format for the datatype of the component (the lexical format).

8.3.2 Value Formatting Syntax

The syntax for Value Formatting is:

\[(\text{prefix character/s}]\text{field}[\text{suffix character/s}][\{\text{field-option1, field-option2, \ldots}\}]\]+

where

- prefix character/s and suffix character/s are optional specifiers used to control alignment and the display of positive/negative symbols;
- field can be any datatype-specific formatting or text; and
- \{\text{field-option(s)}\} is an optional qualifier, that enables additional formatting options.

Explanation of definition syntax

The Value Formatting definition is constructed as follows:

- The definition is composed of one or more fields. For example, the definition \text{DD Month YYYY} has three fields.
- Fields can be run together, or they can be separated by the following characters: space, hyphen, comma, colon, period, or by a text string in single or double quotes. For example, in the definition: \text{DD-Month' in the year 'YYYY}, the fields \text{DD} and \text{Month} are separated by a hyphen, and the fields \text{Month} and \text{YYYY} are separated by a text string enclosed in single quotes.
- A field can have optional prefix and/or suffix character/s. For example: \text{<+###,##0.00}.
- A field can have one or more optional field-options. The field-option/s for each field must be contained in a single set of curly braces, and must follow the field without any intervening space. Multiple field-options for a single field are separated by "," (comma). For example, in the definition: \text{DD Month(uc,ro) YYYY}, the curly-brace-enclosed \text{uc} and \text{ro} are field-options for the field \text{Month}.

Examples

Example of Value Formatting for an \text{xs:decimal} datatype:

"$"(##0.00)

Examples of the output would be:

- $ 25.00
- $ 25.42
- $267.56
Example of Value Formatting for an `xs:date` datatype:

```
DD Month(uc, ro) YYYY
```

where `uc` and `ro` are field-options for making the `Month` field uppercase and read-only, respectively

An example of the output would be:

```
24 SEPTEMBER 2003
```

Field types

A field type represents a component of the data and the way that component is to be formatted. The formatting inherent in the field type can be modified further by prefix and suffix modifiers as well as by field options. The following tables list the available field types. Note that, in the drop-down menu of the Value Formatting dialog, there are type-specific and field-only Value Formatting definitions. You can select one of these and modify them as required by adding prefix modifiers, suffix modifiers, and/or field options.

<table>
<thead>
<tr>

</tbody>
</table>
### Notes on field length and entry length

The following points relating to the length of data components should be noted:

**Length of date fields:** When fields such as MM, DD, HH, hh, mm, and ss are used, they must have a length of 2 in the definition. When the y or Y fields are used, the number of y or Y characters in the definition determines the length of the output. For example, if you specify YYYY, then the output for a value of 2006 would be 006; for a definition of YYYYY, it would be 002006. See also Base Year below.

**Extending field length:** The * (asterisk) symbol is used to extend the length of a non-semantic numeric field (integers, decimals, etc). In the case of decimals, it can be used on either or both sides of the decimal point. For example, the Value Formatting *0.00* ensures that a number will have zeroes as specified in the formatting if these digit locations are empty, as well as any number of digits on both sides of the decimal point.

**Entry lengths in Authentic View:** The display in Authentic View of the contents of a node is based on the Value Formatting definition for that node. Therefore, the Authentic View user will not be able to insert more characters than are allowed by the Value Formatting definition. This is a useful way to restrict input in Authentic View. Note, however, that if the length of a pre-existing value in the XML document exceeds the length specified in the formatting definition, then the entire value is displayed.

**Note:** If a field does not render any text, this might be because of your region setting in Windows. For example, Windows returns an empty string for the AM/PM field if the regional language setting is German.

### Prefix and suffix modifiers

Prefix and suffix modifiers are used to modify the textual alignment and positive/negative representations of fields. The following table lists the available prefix and suffix modifiers.

<table>
<thead>
<tr>
<th>Field Type</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weekday</td>
<td>Weekday (Sunday, Monday...)</td>
</tr>
<tr>

</tr>
<tr>
<td>^</td>
<td>^</td>
</tr>
<tr>
<td>th</td>
<td></td>
</tr>
<tr>
<td>TH</td>
<td></td>
</tr>
</tbody>
</table>

**Field options**

Field options enable advanced modifications to be made to fields. The following options are available:
Field options should be used to generate number formatting for European languages, which interchange the commas and periods of the English language system: for example, 123.456,75.

The Value Formatting to use to obtain the formatting above would be: ###,###.##\{dec=,,sep=.\}

Notice that the field retains the English formatting, while it is the field options `dec` and `sep` that specify the decimal symbol and digit separator. If the decimal symbol and digit separator are not specified, these characters will default to decimal symbol and digit separator of the regional settings of the Windows OS (Control Panel | All Items | Region | Format).

### Note on Base Year

When using short year formats (such as `yy` and `YY`), the base year specifies a cut-off for a century. For example, the base year field option could be used in the definition `DD-MM-YY\{base=1940\}`. If the user enters a value that is equal to or greater than the last two digits of the base year, which are considered together as a two-digit positive integer, then the century is the same as that of the base year. If the value entered by the user is less than the integer value of the last two digits, then the century is the century of the base year plus one. For example if you set `base=1940`, then if the Authentic View user enters 50, the value entered in the XML document will be 1950; if the user enters 23, the value entered in the XML document will be 2023.

Note the following points:

- Although two digits are commonly used as the short year format, one-digit and three-digit short year formats can also be used with a base year.
- Datatypes for which short year formats can be used are: `xs:date`, `xs:dateTime`, `xs:gYear`, and `xs:gYearMonth`.
- If the Value Formatting is being set for an Auto-Calculation component, make sure that the correct datatype is selected in the Value Formatting dialog. (The selected date datatype should be that of the result to which the Auto-Calculation evaluates.)
- If the \textit{yy} field type is used, the default base year is 1930. Explicitly setting a base year overrides the default.
- If the \textit{YY} field type is used without any base year being set, then the Authentic View user will be able to modify only the last two digits of the four-digit year value; the first two digits remain unchanged in the XML document.
8.4 Working with CSS Styles

The SPS design document is styled with CSS rules. Style rules can be specified:

- In external CSS stylesheets. External CSS stylesheets can be added via the Design Overview sidebar and via the Style Repository sidebar.
- In global styles for the SPS, which can be considered to be defined within the SPS and at its start. (In the HTML output these global styles are defined within the style child element of the head element.) Global styles are defined in the Style Repository sidebar.
- Locally, on individual components of the document. In the HTML output, such rules are defined in the style attribute of individual HTML elements. Local style rules are defined in the Styles sidebar.

Each of the above methods for creating styles is described in detail in the sub-sections of this section (links above).

Note: Since CSS styles cannot be applied to plain text, they will not be applied to Text output.

Terminology

A CSS stylesheet consists of one or more style rules. A rule looks like this:

```
H1 { color: blue }
```

or

```
H1 { color: blue;
     margin-top: 16px; }
```

Each rule has a selector (in the examples above, H1) and a declaration (color: blue). The declaration is a list of properties (for example, color) with values (blue). We will refer to each property-value pair as a style definition. In StyleVision, CSS styles can be defined in the Styles sidebar (local styles) and Style Repository sidebar (global styles).

Cascading order

The cascading order of CSS applies. This means that precedence of rules are evaluated on the basis of:

1. **Origin.** External stylesheets have lower precedence than global styles, and global styles have lower precedence than local styles. External stylesheets are considered to be imported, and the import order is significant, with the latter of two imported stylesheets having precedence.
2. **Specificity.** If two rules apply to the same element, the rule with the more specific selector has precedence.
3. **Order.** If two rules have the same origin and specificity, the rule that occurs later in the stylesheet has precedence. Imported stylesheets are considered to come before the rule set of the importing stylesheet.

CSS styles in modular SPSs

When an SPS module is added to another SPS, then the CSS styles in the referring SPS have priority over those in the added module. When multiple modules are added, then CSS styles in those modules located...
relatively lower in the module list have priority. For more information about modular SPSs, see the section, Modular SPSs.

CSS support in Internet Explorer

Versions of Internet Explorer (IE) prior to IE 6.0 interpret certain CSS rules differently than IE 6.0 and later. As a designer, it is important to know for which version of IE you will be designing. IE 6.0 and later offers support for both the older and newer interpretations, thus enabling you to use even the older interpretation in the newer versions (IE 6.0 and later). Which interpretation is used by IE 6.0 and later is determined by a switch in the HTML document code. In an SPS, you can specify whether the HTML and Authentic View output documents should be styled according to Internet Explorer's older or newer interpretation. You should then set CSS styles according to the selected interpretation. For more details, see Properties: CSS Support.

Note: For more information about the CSS specification, go to http://www.w3.org/TR/REC-CSS2/.

8.4.1 External Stylesheets

This section describes how external CSS stylesheets can be managed from within the StyleVision GUI. It consists of the following parts:

- Adding an external CSS stylesheet to the SPS
- Viewing the contents of an external CSS stylesheet and modifying the media applicability
- Changing the precedence
- Switching between the full CSS stylesheet set and a single CSS stylesheet

External CSS stylesheets can be managed from two sidebars: the Style Repository sidebar and the Design Overview sidebar. If an aspect of the external stylesheets is viewable in both sidebars (for example, the relative precedence of multiple stylesheets), then changes made in one sidebar will automatically be reflected in the other.

Adding an external CSS stylesheet to the SPS

To assign an external CSS stylesheet to the SPS, do the following:

1. In Design View, select the External item in the Style Repository window (screenshot below).

![Style Repository](image)

2. Click the Add button at the top left of the Style Repository toolbar (see screenshot above).
3. In the Open dialog that pops up, browse for and select the required CSS file, then click Open. The CSS file is added to the External item as part of its tree structure (see tree listing and screenshot below).
4. To add an additional external CSS stylesheet, repeat steps 1 to 3. The new CSS stylesheet will be added to the External tree, below all previously added external CSS stylesheets.
Note: You can also add an external CSS stylesheet via the Design Overview sidebar.

Viewing and modifying the tree of external CSS stylesheets

The tree of external CSS stylesheets is structured as follows *(also see screenshot below):*

- CSS-1.css (File location appears on mouseover)
  - Media (can be defined in Style Repository window)
  - Rules (non-editable; must be edited in CSS file)
  - Selector-1
    - Property-1
    - ...
    - Property-N
  - ...
  - Selector-N
  + ...
  + CSS-N.css

The media to which that particular stylesheet is applicable can be edited in the Style Repository window. Do this by clicking the down arrow to the right of the item and selecting the required media from the dropdown list. The rules defined in the external CSS stylesheet are displayed in the Style Repository window, but cannot be edited. The Stylesheet, Rules, and individual Selector items in the tree can be expanded and collapsed by clicking the + and – symbols to the left of each item *(see screenshot below).*

To delete an external stylesheet, select the stylesheet and click the **Reset** button in the Style Repository toolbar.
Changing the precedence of the external CSS stylesheets

The external CSS stylesheets that are assigned in the Style Repository window will be imported into the HTML output file using the `@import` instruction. In the HTML file, this would look something like this:

```html
<html>
  <head>
    <style>
      <!--
      @import url("ExternalCSS-1.css");
      @import url("ExternalCSS-2.css")screen;
      @import url("ExternalCSS-3.css")print;
      -->
    </style>
  </head>
  <body/>
</html>
```

The order in which the files are listed in the HTML file corresponds to the order in which they are listed in the External tree of the Style Repository and in the CSS Files tree of the Design Overview sidebar. To change the order of the CSS stylesheets in the Style Repository, select the stylesheet for which the precedence has to be changed. Then use the Move Up or Move Down buttons in the Style Repository toolbar to reposition that stylesheet relative to the other stylesheets in the tree. In the Design Overview sidebar, click the Edit button of a CSS stylesheet and select the Move Up or Move Down command as required.

**Important:** Note that it is the lowermost stylesheet that has the highest import precedence, and that the import precedence decreases with each stylesheet higher in the listing order. The order of import precedence in the listing shown above is: (i) `ExternalCSS-3.css`; (ii) `ExternalCSS-2.css`; (iii) `ExternalCSS-1.css`. When two CSS rules, each in a different stylesheet, use the same selector, the rule in the stylesheet with the higher import precedence applies.

Switching between all CSS files and a single CSS file

You can choose to either: (i) let rules in all CSS files apply with the cascading rules determining precedence, or (ii) let rules in a single selected CSS file apply. You can select the option you want in the Design Overview sidebar (see screenshot below). Click the Edit button of any of the listed CSS files and select either the Mix Styles command or Select One command. This option is also available in the Style Repository (on any of the external stylesheets).
If you click the **Select One CSS File with XPath** command, a dialog pops up in which you can enter the XPath expression *(screenshot below)*. The XPath expression must evaluate to the name of one of the CSS files in the SPS, exactly as these names are listed in the top pane of the dialog. If you enter the filename as a string, note that, like all strings in XPath expressions, the string must be entered within single quotes.

Note the following:

- **When a single CSS file is selected:** In the Authentic and HTML outputs, all rules from the selected CSS file are applied and these rules are supported on all design components. In the RTF output, only class selector rules from the selected CSS file are applied. Non-class rules are applied from all CSS files, with conflicts being resolved on the basis of the priority of the CSS file. In the RTF output, these
rules can be applied to the following design components: Auto-Calculations, the (contents) placeholder, paragraph (block) components, and table cells.

- When styles are mixed from all CSS files: In the Authentic and HTML outputs, all rules from all the CSS file are applied and are supported on all design components. Conflicts are resolved on the basis of the priority of the CSS file. In the RTF output, only non-class selector rules are applied, with conflicts being resolved on the basis of priority.

### 8.4.2 Global Styles

Global styles are defined for the entire SPS design in the Style Repository and are listed in the Style Repository under the Global heading. They are passed to Authentic View and the HTML output document as CSS rules. In the HTML document, these CSS rules are written within the `<html/head/style>` element.

In the Style Repository, a global style is a single CSS rule consisting of a selector and CSS properties for that selector. Creating a global style, therefore, consists of two parts:

- Adding a new style and declaring the CSS selector for it
- Defining CSS properties for the selector

**Supported selectors**

The following selectors are supported:

- Universal selector: written as `*`
- Type selectors: element names, such as `h1`
- Attribute selectors: for example, `[class=maindoc]`
- Class selectors: for example, `.maindoc`
- ID selectors: for example, `#header`

**Adding a global style**

To add a global style to the SPS design, do the following:

1. In Design View, select the Global item in the Style Repository window (screenshot below).

![Style Repository](image)

2. Click the Add button at the top left of the Style Repository toolbar (see screenshot above). A global style is inserted in the Global tree with a `*` selector (which selects all HTML elements); the universal selector is the default selector for each newly inserted global style.

3. To change the selector from the default universal selector, double-click the selector and edit it.
4. Now set the CSS property values for the selector. How to do this is explained in the section Setting Style Values.

5. To add another global style, repeat steps 1 to 4. The new global style will be added to the Global tree, below all previously added global styles.

Note:

- Global styles can also be inserted before a selected global style in the Global tree by clicking the Insert button in the Style Repository window. The Add and Insert buttons are also available via the context menu that appears when you right-click a global selector.
- A global style with a selector that is an HTML element can be inserted by right-clicking an item in the Global tree, then selecting Add Selector | HTML | HTMLElementName.

Editing and deleting global styles

Both a style's selector as well as its properties can be edited in the Style Repository window.

- To edit a selector, double-click the selector name, then place the cursor in the text field, and edit.
- For information about defining and editing a style's property values, see Setting Style Values. (The style properties can be displayed in three possible views. These views and how to switch between them are described in Views of Definitions.)

To delete a global style, select the style and click the Reset button in the Style Repository toolbar.

Changing the precedence of global styles

Global styles that are assigned in the Style Repository window are placed as CSS rules in the /html/head/style element. In the HTML file, they would look something like this:

```html
<html>
  <head>
    <style>
      <!--
      h1 { color:blue;
           font-size:16pt; }
      h2 { color:blue;
           font-size:14pt; }
      .red { color:red;}
      .green { color:green;}
      .green { color:lime;}
    -->
```
The order in which the global styles are listed in Authentic View and the HTML document corresponds to the order in which they are listed in the Global tree of the Style Repository. The order in Authentic View and the HTML document has significance. If two selectors select the same node, then the selector which occurs lower down the list of global styles has precedence. For example, in the HTML document having the partial listing given above, if there were an element `<h1 class="green">`, then three global styles match this element: that with the h1 selector and the two .green class selectors. The color property of the .green selector with the color lime will apply because it occurs after the .green selector with the color green and therefore has a higher precedence. (Class selectors always have a higher precedence than node selectors, so both .green selectors will have a higher precedence than the h1 selector regardless of their respective positions relevant to the h1 selector.) The font-size of the h1 style will, however, apply to the `<h1>` element because there is no selector with a higher precedence that matches the `<h1>` element and has a font-size property.

To change the precedence of a global style, select that style and use the Move Up and Move Down buttons in the Style Repository toolbar to reposition that global style relative to the other global styles in the tree. For example, if the .green global style were moved to a position before the .red style, then the color property of the .red style would have precedence over that of the .green style.

Note, however, that class selectors always have precedence over type selectors. So, if the selector order were changed to .red .green h1 h2, then h1 and h2 would still be green.

8.4.3 Local Styles

When styles are defined locally, the style rules are defined directly on the component. These local rules have precedence over both global style rules and style rules in external CSS stylesheets that select that component. Locally defined styles are CSS styles and are defined either via the Format toolbar or in the Styles sidebar. (This is as opposed to global styles, which are defined in the Style Repository sidebar.)

Local styles via the Format toolbar

You can select content in the design and apply local styles via the Format toolbar (screenshot below).

![Format toolbar screenshot](image)

You can apply predefined HTML formatting (such as div, h1, pre, etc), text styling, background color, text alignment, lists, and hyperlinks. See the section, Format toolbar, for details.

Local styles via the Styles sidebar

Defining a style locally via the Styles sidebar consists of three parts:

1. The component to be styled is selected in Design View. Any component in the design except node tags can be styled. The component selected in Design View then appears in the Styles-For column of
the Styles sidebar (see screenshot below). In the screenshot below, a content component was selected in Design View and consequently appears in the Styles-For column.

Very often, the component selected in Design View might contain other components. In this case all the components in the selection are displayed, organized by component-type, in the Styles-For column of the Styles sidebar. The screenshot below shows the different component-types contained in the Design View selection. To the left of each component-type is the number of instances of that component-type in the selection. For example, in the screenshot below, there are 16 text components and two Auto-Calculation components (among others) in the Design View selection. You can also select a range of components by keeping the Shift key pressed while selecting the second, end-of-range component.

2. After making the selection in Design View, you select, in the Styles-For column, the component-type you wish to style. If there is more than one instance of the component-type you select, then the styles you define will be applied to all these instances. So, for example, if you select the 16-texts item of the
screenshot above, then the styles you define (see Step 3 below) will be applied to all 16 text components. If you wish to style, say, four of these text components differently, then you must select and style each of the four components separately. If two components of the same component-type have been styled differently and both are selected in Design View, then the styles of both instances are displayed in the Style Definitions pane. In the screenshot above, for example, while one AutoCalculation has a normal font-weight, the other has a bold font-weight. When the 2-Autocals item is selected in the Styles-For pane, both font-weights are displayed.

3. After selecting, in the Styles-For column, the component-type to style, styles are defined in the Style Definitions pane. How to do this is described in the section Setting Style Values.

8.4.4 Setting Style Values

For the component-type selected in the Styles-For column, style properties are defined in the Style Definitions pane of the Styles sidebar (screenshot below). You can select more than one component-type in the Styles-For column if you like—by selecting additional component-types with the Ctrl-key pressed, or by selecting a range of component-types in the Styles-For column with the Shift-key pressed. When multiple component-types are selected, any style value you define in the Style-Definitions pane is applied to all instances of all the selected component-types.

Style property groups

The available style properties in the Style-Definitions column are organized into groups as shown in the screenshot below.
The display of properties can be modified using the List Non-Empty, Expand All, and Collapse All toolbar buttons. Each group of style properties can be expanded to access style properties or subgroups of style properties (see screenshot below).

**Entering style values**

Style property values (style values for short) can be entered in the following ways, all of which are show in the screenshot below:

- Entered directly in the Value column. To do this, select a property, double-click in its Value column, enter the value using the keyboard, and press Enter or click anywhere in the GUI.
- By selecting a value from the dropdown list of the combo box for that property. Click the down arrow of the combo box to drop down the list of style-value options. In the screenshot below, the options for the (background-)repeat property are displayed. Select the required value from the dropdown list.
- By using the icon on the right-hand side of the Value column for that style property. Two types of icon are available, and these are available only for properties to which they are relevant: (i) a color palette for selecting colors (in the screenshot below, see the (background-)color property), and (ii) a dialog for browsing for files (in the screenshot below, see the (background-)image property).
Values for styles can also be assigned via an XPath expression.

### Modifying or deleting a style value

If a style value is entered incorrectly or is invalid, it is displayed in red. To modify the value, use any of the applicable methods described in the previous section, Entering Property Values.

To delete a style value (or, in other words, to reset a style value), click the Reset button in the toolbar of the Styles sidebar. Alternatively, you can double-click in the Value column of the property, and delete the value using the Delete and/or Backspace key, and then pressing Enter.

### 8.4.5 Style Properties Via XPath

Styles can be assigned to design components via XPath expressions. This enables style property values to be taken from XML data or from the XPath expression itself. Also, by using the doc() function of XPath 2.0/3.0, nodes in any accessible XML document can be addressed. Not only can style definitions be pulled from XML data; this feature also enables style choices to be made that are conditional upon the structure or content of the XML data. For example, using the if...else statement of XPath 2.0/3.0, two different background colors can be selected depending on the position of an element in a sequence. Thus, when these elements are presented as rows in a table, the odd-numbered rows can be presented with one background color while the even-numbered rows are presented with another (see below for example). Also, depending on the content of a node, the presentation can be varied.

#### Style properties for which XPath expressions are enabled

XPath expressions can be entered for the following style properties:

- All properties available in the Styles sidebar
- The *Common, Event, and HTML* groups of properties in the Properties sidebar

### Static mode and dynamic (XPath) mode for property values

For those properties where XPath expressions are enabled, two modes are available:

- **Static mode**, where the value of the property is entered directly in the Value column of the sidebar. For example, for the background-color of a design component, the value `red` can be entered directly in the sidebar.
- **Dynamic, or XPath mode**, where an XPath expression is entered. The expression is evaluated at runtime, and the result is entered as the value of the property. For example, for the background color of a design component, the following XPath expression can be entered: `/root/colors/color1`. At runtime, the content of the node `/root/colors/color1` will be retrieved and entered as the value of the background-color property.

### Switching between static and dynamic (XPath) modes

For each property for which XPath expressions are enabled, static mode is selected by default. To switch a property to dynamic (XPath) mode, select that property and click the XPath icon in the toolbar of the sidebar (screen shot below).

If a static value was present for that property, it is now cleared and the mode is switched to dynamic. The *Edit XPath Expression dialog* appears. It is in this dialog that you enter the XPath expression for the property. Click **OK** when finished.

After you enter an XPath expression for the property, an *Edit XPath* expression button appears in the Value column for that property (screen shot above). Click this button to subsequently edit the XPath expression. If you wish to switch back to static mode, click the XPath icon in the toolbar. This will clear the XPath expression and switch the property to static mode.
Note: There are two important points to note. First, only one mode (static or dynamic), and the value/expression for that mode, is active at any time. Any value/expression that previously existed for the other mode is cleared; so switching to the other mode will present that mode with an empty entry field. (In order to go back to a previous value/expression, use the Undo command.) Second, if you reselect a property after further editing the SPS, then that property will be opened in the mode it was in previously.

Creating and editing the XPath definition

The XPath definition is created and edited in the Edit XPath Expression dialog. This dialog is accessed in two ways:

- Each time you switch to the dynamic mode of a property from static mode (by clicking the XPath icon in the toolbar of the sidebar), the Edit XPath Expression dialog appears. You can now create the XPath expression. (Note that clicking the toolbar icon when already in dynamic mode switches the mode to static mode; it does not pop up the Edit XPath Expression dialog.)
- The Edit XPath Expression dialog also pops up when you click the Edit XPath Expression button in the Value field of a property that already has an XPath expression defined for it. The dialog will contain the already defined XPath expression for that property, which you can now edit.

After you enter or edit the XPath expression in the entry field, click OK to finish.

Values returned by XPath expressions

The most important benefits of using XPath expressions to set a property value are that: (i) the property value can be taken from an XML file (instead of being directly entered); and/or (ii) an XPath expression can test some condition relating to the content or structure of the XML document being processed, and accordingly select a value. XPath expressions return values in the following two categories:

- **XML node content**
  The XPath expression can address nodes in: (i) the XML document being processed by the SPS, or (ii) any accessible XML document. For example the expression Format/@color would access the color attribute of the Format Child of the context node. The value of the color attribute will be set as the value of the property for which the XPath expression was defined. A node in some other XML document can be accessed using the doc() function of XPath 2.0. For example, the expression doc('Styles.xml')//colors/color-3 would retrieve the value of the element color-3 in the XML document Styles.xml and set this value as the value of the property for which the XPath expression was defined.

- **XPath expression**
  The value of the property can come from the XPath expression itself, not from the XML document. For example, the background color of an element that is being output as a row can be made to alternate depending on whether the position of the row is odd-numbered or even-numbered. This could be achieved using the XPath 2.0/3.0 expression: if (position() mod 2 = 0) then 'red' else 'green'. Note that the return value of this expression is either the string red or the string green, and it will be set as the value of the property for which the XPath expression was defined. In the example just cited, the property values were entered as string literals. Alternatively, they could come from an XML document, for example: if (position() mod 2 = 0) then doc('Styles.xml')//colors/color-1 else doc('Styles.xml')//colors/color-2. Conversely, the XPath expression could be a straightforward string, for example: 'green'. However, this is the same as entering the static value green for the property.
8.4.6 Composite Styles

A Composite Style is a group of CSS text-styling properties that have been associated with an attribute of an XML instance document node. Additionally, any group of CSS text-styling properties stored in the stylesheet is also considered to be a Composite Style. Composite Styles can then be specified on the following design components:

- Auto-Calculations
- The (contents) placeholder
- Paragraph (block) design elements
- Table cells

Advantages of Composite Styles

Composite Styles offer the following advantages:

- Styling properties are in the XML data and can therefore be edited by the user. In Authentic View, the RichEdit feature enables a toolbar-based, graphical editing of Composite Styles. See the section, Composite Styles in Authentic, for more information about setting up RichEdit for Composite Styles.
- The styling properties of the design components listed above can be a combination of properties stored in the XML data and properties assigned in the SPS.
- In the SPS design phase, the SPS designer can quickly switch between the multiple Composite Styles associated with an element.

Entering the Composite Style in the XML attribute

A Composite Style (composed of multiple styling properties) is entered as the attribute-value of an element in the source XML document. For example, the desc-style attribute in the XML source document listing below contains a default Composite Style:

```
<Desc desc-style="font-family:Verdana; font-size:12pt; color:blue">
```

You can also set more than one Composite Style on an element. In this case, each Composite Style must be entered in a separate attribute:

```
<Desc styleBlue="font-family:Verdana; font-size:12pt; color:blue"
      styleRed ="font-family:Verdana; font-size:12pt; color:red">
```

When multiple Composite Styles are available on an element, you can switch among Composite Styles when setting a value for the Composite Style property of a design component (see below).

Note: The attributes that will be used to access the Composite Styles must be defined in the source schema in order for the XML document to be valid.

Supported CSS text-styling properties

The following CSS styles can be used in Composite Styles:

- font-family
- font-size
- font-weight
- font-style
Setting an attribute as the Composite Style value

If you set the Composite Style of a design component to be an attribute, then the Authentic View user can edit this Composite Style. The Authentic View user can place the cursor anywhere within the text output of the design component and use the RichEdit toolbar of Authentic View to edit the Composite Style of that design component.

To set an attribute as the Composite Style of a design component, do the following:

1. In Design View, select the design component to which you wish to assign an attribute as Composite Style. In the screenshot below, the (contents) placeholder of the Desc element has been selected.

2. In the combo box of the Composite Style property of the Content component (see Properties sidebar at bottom right of screenshot above), the attributes of the context element are displayed. Select the attribute you wish to set as the Composite Style of the design component. (Note that there is also an empty entry in the combo box should you wish to apply no Composite Style. In this case, the RichEdit feature of Authentic View will not be enabled in the output of this design component.)

In Authentic View the user can now use the RichEdit toolbar to modify the Composite Style of this design component.

Setting an XPath expression as the Composite Style value

You can also enter an XPath expression as the value of the Composite Style property. In this case, however, since the Composite Style is stored in the SPS (not in the XML source document), the Authentic View will not be able to edit the Composite Style.
To set an XPath expression as the value of the Composite Style property, click the XPath icon in the toolbar of the Properties sidebar, and then enter the XPath expression in the XPath dialog that pops up. The XPath expression will be evaluated as an attribute value template; the returned value will be the value of an HTML style attribute (and its equivalent in non-HTML output formats).

For example, consider the following XPath expression created on the (contents) placeholder of the n1:Person element.

\[
\text{if (number(n1:Shares) gt 1000) then 'color:red' else 'color:green'}
\]

What this expression will do is this: If the n1:Person element has a child element n1:Shares with a number value greater than 1000, then the contents of the n1:Person element is output in red; otherwise, all n1:Person elements are output in green. The value returned by the XPath expression is passed to the output document as the value of an HTML style attribute (or its equivalent in non-HTML output formats).

In the XSLT stylesheet generated from the SPS, this XPath expression will be evaluated as an attribute value template, something like this:

\[
<\text{span style="}\{ \text{if (number(n1:Shares) gt 1000) then 'color:red' else 'color:green'} \}\}>\]

In the HTML output, one of the following lines would be generated depending on how the condition is evaluated:

\[
<\text{span style="color:red"}>
\]

or

\[
<\text{span style="color:green"}>
\]

Note: Attribute value templates are XSLT constructs that allow the value of an attribute to be read as an XPath expression. They are delimited by curly braces and allow the value of the attribute to be assigned dynamically.
8.5  Text-Styling Flexibility in Authentic

An SPS can be set up so that Authentic View users can also style text. They do this by selecting a text fragment in Authentic View and setting styling properties for the selected text. These styling properties can be pre-defined by you (the SPS designer) or they can be defined by the Authentic View user. In either case, the Authentic View user can be given the option of styling text in Authentic View.

The following text-styling options are available:

- **Composite Styles**: A set of CSS style properties (the Composite Style) is defined on the attribute of an element in the source XML document. By setting this attribute as the Composite Style property-value of a design component, the Composite Style becomes editable with the RichEdit feature of Authentic View. See the section Composite Styles for a description of how this mechanism works.
- **RichEdit**: If an element is created in the SPS design as a RichEdit component, then the Authentic View user can select text fragments within that element and style it using the RichEdit styling properties of Authentic View. RichEdit enables the Authentic View user to specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of text. See the section RichEdit for details.
- **Text State Icons**: You (the SPS designer) can create an Authentic View toolbar button and associate this button with an element name. We call such a toolbar button a Text State Icon. When the Authentic View user selects a text fragment in Authentic View and clicks a Text State Icon, the element associated with the Text State Icon is created around the highlighted text (a Text State Icon is enabled only if the schema allows it around the selected text). Consequently, the text formatting defined for this element (in a global template for this element) will be applied to the selected text fragment.

You can use a combination of all three text-styling options in your SPS.

You should note the following points:

- All three text-styling options depend on and require styling-related elements and/or attributes to be present in the XML document. Consequently, the schema on which the SPS is based must allow the required elements and/or attributes at the hierarchical levels on which they are required.
- Text styling applied by the Authentic View user will appear in both Authentic View as well as the output formats.

**Note**: The styling options listed above are derived from styling properties stored in the XML file and are additional to styling properties assigned in the SPS.

8.5.1  Composite Styles

The Composite Styles feature gives Authentic View users the ability to style the entire output of the following design components:

- Auto-Calculations
- The (contents) placeholder
- Paragraph (block) design elements
- Table cells
The mechanism for doing this is explained below.

**Note:** For a further more general description of Composite Styles, see the section Composite Styles. The description in this section describes how Composite Styles can be set up so that the Authentic View user can edit them.

### Entering the Composite Style in the XML attribute

A default Composite Style (composed of multiple styling properties) is entered as the attribute-value of an element in the source XML document. For example, the `desc-style` attribute in the XML source document listing below contains a default Composite Style:

```xml
<Desc desc-style="font-family:Verdana; font-size:12pt; color:blue"/>
```

You, the SPS designer, can now allow the Authentic View user to edit these styling properties. This gives the Authentic View user control over the styling of the design component's text output. You enable user-editing of a Composite Style by setting the Composite Style of the design component to be the attribute containing the default Composite Style (see below).

**Note:** The attributes that will be used to access the Composite Styles must be defined in the source schema in order for the XML document to be valid.

### Supported CSS text-styling properties

The following CSS styles can be used in Composite Styles:

<table>
<thead>
<tr>
<th>Property</th>
<th>Property</th>
<th>Property</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>font-family</td>
<td>font-size</td>
<td>font-weight</td>
<td>font-style</td>
</tr>
<tr>
<td>color</td>
<td>background-color</td>
<td>text-align</td>
<td>text-decoration</td>
</tr>
</tbody>
</table>

### Setting the attribute as the Composite Style of a design component

If you set the Composite Style of a design component to be an attribute, then the Authentic View user can edit this Composite Style. The Authentic View user can place the cursor anywhere within the text output of the design component and use the RichEdit toolbar of Authentic View to edit the Composite Style of that design component.

To set an attribute as the Composite Style of a design component, do the following:

1. In Design View, select the design component to which you wish to assign an attribute as Composite Style. In the screenshot below, the `(contents)` placeholder of the `Desc` element has been selected.
2. In the combo box of the Composite Style property of the Content component (see Properties sidebar at bottom right of screenshot above), the attributes of the context element are displayed. Select the attribute you wish to set as the Composite Style of the design component. (Note that there is also an empty entry in the combo box should you wish to apply no Composite Style. In this case, the RichEdit feature of Authentic View will not be enabled in the output of this design component.)

In Authentic View the user can now use the RichEdit toolbar to modify the Composite Style of this design component.

8.5.2 RichEdit

If an element is created in the SPS design as a RichEdit component, then the Authentic View user can mark text fragments within that element and style it using the RichEdit styling properties of Authentic View, as well as set paragraph-level formatting, such as text alignment.

RichEdit enables the Authentic View user to specify the following:

- **Character styles**: font, font-weight, font-style, font-decoration, font-size, color, background color.
- **Paragraph styles**: text alignment.

This description of the RichEdit feature given below is organized as follows:

- [The RichEdit mechanism](#)
- [Creating an element in the SPS design as a RichEdit component](#)
- [Using RichEdit in Authentic View](#)
The RichEdit mechanism

When an Authentic View user selects a text fragment in Authentic View and applies RichEdit styling to it, the RichEdit styling element and the attribute that holds the styling information is created around the selected text fragment. The RichEdit style properties that the Authentic View user selects are inserted as the value of this styling attribute.

So, if there is a text fragment in the source XML document like this:

```xml
<p> ... Altova StyleVision 2012 features a unique graphical design interface ... </p>
```

and a part of this text fragment is given a RichEdit style property of bold, then the text fragment in the source XML will look like this:

```xml
<p> ... <span style="font-weight: bold">Altova StyleVision 2012</span> features a unique graphical design interface ... </p>
```

The RichEdit styling element in the example above is `span` and its attribute that is to contain the RichEdit styling properties is `style`. They could be called anything. For example, instead of calling the styling element `span`, you could call it `Style`, and instead of calling the styling attribute `style`, you could call it `css`. In this case, the text fragment would then be marked up like this:

```xml
<p> ... <Style css="font-weight: bold">Altova StyleVision 2012</Style> features a unique graphical design interface ... </p>
```

The important thing is that whatever name you choose for the styling element and attribute, this styling element and attribute must be defined in the schema and must be allowed within every element containing the text that is to be styled.

When the text is processed with an XSLT stylesheet, the style properties are passed to the output as markup appropriate to the output format.

RichEdit also enables Authentic View users to apply block-level formatting (such as text-alignment). You can select the element and attribute that will contain the block-level formatting, similarly to how this is done for text fragments as described above. Certain block-level formatting properties, such as block-level text alignment, will then become available to the Authentic View user when the user edits an element that contains the element that has been defined for paragraph styles in the RichEdit Configuration dialog. As with character styles, the schema must be defined to allow the RichEdit paragraph-styling element inside any element in which you wish to make this paragraph styling available.

Creating an element as a RichEdit component

To create an element as a RichEdit component, do the following:

1. Drag the element from the Schema Tree and drop it at the desired location in the design.
2. From the menu that pops up, select **Create RichEdit**. The RichEdit Configuration dialog (screenshot below) pops up. (If a RichEdit character style has already been created for the document, you must right-click a RichEdit component in the design and select **Configure RichEdit Elements/Attributes** to pop up the RichEdit Configuration dialog.)
3. In the RichEdit Configuration dialog, and in the Character Styles pane, enter the name of the styling element and its attribute that is to contain the RichEdit styling properties for text fragments. You can also select the required element and attribute from the schema tree. Click the respective Select buttons to open the schema tree.

4. To enable block-level formatting (text alignment), do the following. In the Paragraph Styles pane, select the element and attribute that will contain the block-level formatting. In the Create Paragraph Type combo box, you can select the predefined format of the paragraph; this predefined format will be passed to the output.

5. When done, click OK. The element is created as a RichEdit component (see screenshot below), and an uneditable RichEdit global template for character styles that has the name of the styling element (Style in the screenshot below) is created in the design. If paragraph styles have also been specified, then an uneditable RichEdit global template for paragraph styles is also created.
Note the following:

- The uneditable RichEdit global template is created when the first RichEdit component is created in the SPS. No additional RichEdit global templates are created subsequently.
- When elements are created as RichEdit components subsequent to the creation of the first RichEdit component, the RichEdit Configuration dialog does not appear. All RichEdit components are indicated by having within them a RichEdit text box (see the overlook element in the screenshot above). This RichEdit text box appears instead of the usual contents placeholder.
- The RichEdit global template can be reconfigured in that the styling element and attribute for character styles and paragraph styles can be changed. Do this by right-clicking a RichEdit component, selecting Configure RichEdit Element/Attribute, and entering the desired element and attribute names. The new element names (for character styles and paragraph styles) will appear in the title bar of the RichEdit global templates.

All schema elements that have been created as RichEdit components can now be styled with RichEdit properties in Authentic View.

**Using RichEdit in Authentic View**

In Authentic View, when the cursor is placed inside an element that has been created as a RichEdit component, the buttons and controls in the RichEdit toolbar (screenshot below) become enabled. Otherwise they are grayed out.

To apply character styles, select the text to be styled. To apply paragraph styles, place the cursor within the paragraph to be styled. Then specify the required styling via the buttons and controls of the RichEdit toolbar. If the selected text is not already enclosed within the tags of the styling element, it will be enclosed now.
8.5.3 Text State Icons

A Text State Icon is an Authentic View toolbar button that is associated with an element name. In Authentic View, when a Text State Icon is clicked, the selected text fragment is enclosed by the element associated with the Text State Icon. The text formatting defined for this element (in the element’s global template) will therefore be applied to the selected text fragment. In this way, the Authentic View user can apply text styles using Text State Icons.

As the SPS designer, you will create the Text State Icons and define the styles of the elements associated with the Text State Icons.

Creating a Text State Icon

To create a Text State Icon for the Authentic toolbar, first select the command Authentic | Custom Toolbar Buttons, then click the Add button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select Add Text State Icon.

Text State Icons take the following parameters:

- **Element Name:** This is the element that will enclose the selected text fragment when the Text State Icon is clicked in Authentic View.
- **Bitmap:** The location of an image for the Text State Icon. The file path is relative to the SPS.
- **Text:** If no bitmap is available, the text entered in this field will be used as the button text of the Text State Icon.
- **Tooltip:** This is an optional guide for the Authentic View user on mouseover.
In the example above, we have used familiar bitmaps as the Text State Icons to mark up text with the bold and italic elements. If you wish, you could use any bitmap or button text that you think might be easier for the Authentic View user to relate to. For example, important text fragments could be associated with the bold element, while comments could be associated with the italic element. The Text State Icons could then be created as shown in the screenshot below.

![Authentic Custom Buttons](image)

In the above screenshot, note that the Comment Text State Icon is associated with the italic element. So, when text is selected in Authentic View and then the Comment Text State Icon is clicked, that text fragment will be enclosed by the italic element and will be processed in the way defined for the italic element (described in the next section).

**Defining a style rule for the element associated with a Text State Icon**

The style properties of an element associated with a Text State Icon can be defined in a global template (see screenshot below).

```plaintext
bold (simple)

/content/bold

italic (simple)

/content/italic
```
This screenshot shows the global templates of two elements (bold and italic), each of which has been associated with a Text State Icon. The styling has been done by selecting the (contents) component and defining the desired font style in the Styles sidebar.

Consequently, whenever the Authentic View user creates these elements around text fragments, the respective global template (with its text styles) is applied to that text fragment.
8.6 Designing Print Output

Properties for paged media output (PDF, RTF, and Word 2007+ in the Enterprise Edition; and RTF in the Professional Edition) can be defined in the Page Layout group of properties in the Properties sidebar. The following can be designed for print media:

- The document can be divided into sections, each of which can have separate page definitions. The properties that can be defined are listed below.
- Page dimensions (height and width) and a page orientation (portrait or landscape) can be defined.
- The margins for the body of the page and the available vertical space for headers and footers can be defined. Also, multiple pages can be defined to be facing (that is, with mirror margins) or to have the same left and right margins repeating for each page.
- Headers and footers can be defined for each section.
- Numbering styles and numbering starts can be defined for each section separately, or page numbering can run on from one section to the next.
- For each section, the number and width of columns on a page can be specified.

Note: Since page layouts cannot be applied to plain text output, the features for designing print output that are described in this section will not be applied to Text output.

Properties sidebar

Page properties can be defined individually for each section of the document in the Page Layout group of properties in the Properties sidebar (see screenshot below). These properties for a given section are accessed via the Edit Properties link of the Initial Section and Document Section items in the design (screenshot below).

| Document Section | Edit Properties... | Add Header/Footer... | Hide Headers/ Footers |

Clicking the Edit Properties link pops up the Properties window, with the Page Layout properties active within it (screenshot below).
How to set the values of these properties is discussed in the section, Page Properties.

8.6.1 Document Sections

An SPS can be designed to have multiple document sections, with each document section having its own page definition settings. For example, a report which contains tables of data and text that summarizes this data can be divided into two document sections: one document section can contain the descriptive text and have portrait orientation, while the other document section with the tables of data can have landscape orientation. For each document section, the whole range of page properties (see screenshot below) can be defined. Additionally, each document section can also have different headers and footers.
When an SPS is created, it is created with one document section, called the Initial Document Section. This document section is the first document section of the document (whether a single-sectioned or multiple-sectioned document) and cannot be deleted. Initial Document Section properties include properties and styles for the entire document; these are described in the subsection, *Initial Document Section*.

**Inserting document sections**

To add a new document section, do the following:

1. Place the cursor at the location in the document where you want the new document section to start.
2. In the context menu (right-click), select **Insert Page / Column / Document Section** | **New Document Section**. Alternatively, select this command from the **Insert** menu. A new document section will be inserted in the design and is indicated by a document section title bar (see screenshot below; the Hide/Show Headers/Footer hyperlink shown in the screenshot below appears after a Header or Footer has been added to a document section). In the output, a new document section will start on a new page.
3. The new document section will have the page layout properties that were assigned to the Initial Document Section at the time the new document section was created. These page layout properties for the document section can be edited via the Edit Properties hyperlink of the Document Section. If required, separate headers and footers can be added for the document section (via the Add Header/Footer hyperlink). How to define page layout properties and headers and footers are described in the respective subsections of this section. When a header or footer is added, it is shown in the design within that document section. The display of headers and footers in the design can be toggled on and off with the Hide/Show Headers/Footers hyperlink; this hyperlink appears after a Header or Footer has been added to a document section.

4. If you wish to create a new page for the section immediately after the Initial Document Section, go to the page layout definitions of the Initial Document Section and give the Render a Section Break property a value of Yes. This starts the first non Initial Document Section on a new page. Note the converse effect also, that is, when the property has a value of No. In this case, the first non Initial Document Section starts directly after the Initial Document Section, without rendering a page break. This is useful if the Initial Document Setting is blank—for example, if it contains only design processing templates that produce no output. A property value of No ensures that the first page of the print output document will not be blank (which would have been the case if a blank page with a break after it were to be rendered for the Initial Document Section).

Notes
Note the following points:

- In the RTF output generated by XSLT 1.0 SPSs, only document sections that are immediate children of the Main Template are allowed. This restriction does not apply to RTF output generated by XSLT 2.0 or XSLT 3.0 SPSs.
- In the output document, every document section starts on a new page.
- Page margin properties are also applied to the HTML page.
- When multiple document sections are present in a design, values of the mirror margins property and the associated margin-left and margin-right properties are taken from the initial document section. The values of these properties in subsequent document sections are ignored.

Deleting a document section
To delete a document section, in the title bar of the document section, right-click the words Document Section, and in the menu that pops up select the command Edit | Delete. The document section will be deleted, and this will be indicated by the deletion of the title bar. By deleting the document section you will be deleting the page layout properties and headers and footers created for the document section. The content of the document section, however, will not be deleted.

8.6.1.1 Initial Document Section
Whether the document has one document section or more, properties for the document as a whole are defined in those of the Initial Document Section (the first document section of the document, screenshot of title bar below). Cover pages are also created in Initial Document Sections.
To edit the properties of the document, click the *Edit Properties* hyperlink in the Initial Document Section title bar. This pops up the Properties dialog of the Initial Document Section (*screenshot below*). This dialog has three tabs, for: (i) basic page layout properties, (ii) (HTML) document properties, and (iii) document styles.

### Page layout properties

Page layout properties for the initial document section apply to the first document section of the document; in single-section documents, they apply to the entire document. When a new document section is created, it is created with the page layout properties of the Initial Document Section at that time. The properties of the new document section can be edited subsequently. If a property of the Initial Document Section is changed, this change will not be passed to other document sections that already exist. New document sections will be
created with the latest values of the Initial Document Section. The various page layout properties are described in the section **Page Layout Properties**. The **Watermarks** button brings up the Watermarks dialog in which you can **define a watermark** for the section's pages. A different watermark can be defined for each section.

**Document properties**

Properties of the output HTML document are specified in the Document Properties tab.

**Document styles**

The styles that are defined in the Document Styles tab apply to the entire document. If a document has more than one document section, design elements within each document section inherit style properties from the Initial Document Section. To over-ride inherited styles on a given design element, specify the required style values on the individual design elements. To do this click the design element, and, in the Styles sidebar, specify the desired styles.

**Cover pages**

If a cover page is required, it should be designed at the beginning of the Initial Document Section. To ensure that the rest of the document starts on a new page, insert a page break (**Insert | Insert Page | Column / Document Section | New Page**) below the cover page template. If the page layout properties of the cover page are to be different than those of the following pages, then the entire Initial Document Section should be used for the cover page. The following pages should then start with a new document section.

An example is shown below.

Click the Preview RTF tab to see the result in the preview window.
8.6.1.2 Page Layout Properties

Page properties are assigned individually for each document section of a document design, in the Page Layout group of properties of that document section. If a design has only one document section, then the page properties of that document section are the page properties of the entire document.

Note: Due to a limitation of FOP, Page Layout properties are available only for the Initial Document Section when FOP is used to generate output.

Accessing the page properties of a document section

To access the page properties of a document section, click the Edit Properties link of the Initial Document Section or Document Section item in the design (see screenshot below).

| Document Section | Edit Properties... | Add Header/Footer... | Hide Headers/Footers |

This pops up the Properties window, with the Page Layout properties active within it (screenshot below).
Alternatively, clicking the Document Section title bar makes the Page Layout group of properties of that document section active in the Properties window.

Page size

Three properties determine the size of pages of a document section: (i) page height, (ii) page width, and (iii) size. Page size can be set in one of two ways:

- You can select a predefined page size from the combo box in the Paper Format property field. In this case, values for the Page height and Page width fields are automatically filled in depending on what value has been selected in the combo box.
- You can specify your own values for the Page height and Page width properties. In this case, the Paper Format field will contain the value custom size.

Valid length dimensions (for the Page height and Page width properties) are inches (in), centimeters (cm), millimeters (mm), picas (pc), points (pt), pixels (px), and ems (em). Note that (i) a unit is mandatory; (ii)
there must be no space between the number and the unit; (iii) there is no default unit. Entering an invalid unit or no unit causes the property value to be displayed in red.

Page margins
The top, bottom, left and right margins of a page can be defined with the four margin properties, Margin body from page top, Margin body from page bottom, Margin body from page left, and Margin body from page right, respectively. To specify a margin, enter the required number in the relevant margin property field followed by any of the valid length units: inches (\textit{in}), centimeters (\textit{cm}), millimeters (\textit{mm}), picas (\textit{pc}), points (\textit{pt}), pixels (\textit{px}), and ems (\textit{em}). Note that (i) a unit is mandatory; (ii) there must not be a space between the number and the unit; (iii) there is no default unit. Entering an invalid unit or no unit causes the property value to be displayed in red.

The body area is defined by the page margins you set (see screenshot below).

Header and footer margins
The Margin header from page top and Margin footer from page bottom properties specify the distance from the top of the page to the top of the header and from the bottom of the page to the bottom of the footer, respectively (see screenshot below).

The vertical extents of headers and footers are determined by the actual content of the headers and footers. You should ensure that the vertical extent of a header plus the header margin does not exceed the Margin body from page top. Otherwise, the header will be too large to be contained in the space defined for it. Similarly, ensure that the sum of the vertical extent of the footer and footer margin does not exceed the value of the Margin body from page bottom.
If the actual header or footer is too large for the space assigned for it, then the value of the *Oversized Headers/Footers* property comes into play and can modify the treatment of headers and footers in RTF output. If the *Oversized Headers/Footers* property has been set to *Overlap Body Text*, then the oversized header or footer will superimpose, or be superimposed by, body text. If the option *Reduce Body Height* has been set, then the vertical extent of the body text is reduced so as to accommodate the oversized header or footer.

### The Multiple Pages setting

The Multiple Pages setting has two options:

- If you set *Multiple Pages* to *Normal*, then all pages in the output will have the same value for all left margins and the same value for all right margins (see screenshot below).
- If, on the other hand, you set *Multiple Pages* to *Mirror Margins*, then the document pages are treated as facing pages (see screenshot below). This means that for even-numbered pages (left-hand-side pages), the left margin (*Margin body left* property) is the outer margin while the right margin (*Margin body right* property) is the inner margin. For odd-numbered pages (right-hand-side pages), the left margin (*Margin body left* property) is the inner margin while the right margin (*Margin body right* property) is the outer margin.

The settings made for the *Margin body left* and *Margin body right* properties are applied by StyleVision to the odd-numbered pages; these margins will be reversed for even-numbered pages; the inner-margin value of odd-numbered pages becomes the outer-margin value of the even-numbered pages.

**Note:** If an SPS design has multiple document sections, then the value of the mirror margins setting is taken from the initial document section. The left and right margin values are also taken from the initial document section. The values of these properties in subsequent document sections will be ignored.

### Page orientation

Page orientation can be set to *portrait* or *landscape*.

### Columns

Columns and their widths are specified with two properties: *Column count* and *Column gap*, which specify, respectively, the number of columns and the space between two columns. The width of a column is thus the width of the page body minus the sum of the column gaps, divided by the number of columns.

Text will fill the columns on a page one by one. Only after all the columns have been filled will a new page be started. A column break can be forced by inserting a new column at the desired point in the design. To do this,
right-click at the location where the column break is required and select the context menu command **Insert Page / Column / Document Section | New Column**.

**Page numbering**
There are two relevant properties: *Numbering format* and *Numbering starts at*. These work as follows:

- The required page number format is set by selecting one of the pre-defined options from the drop-down menu for *Numbering format*. (The *Numbering format* selection also applies to the *page total*, if this is inserted.)
- The page numbering for a document section can be set to start with any positive integer. This integer is specified in the *Numbering starts at* property. If the numbering is to continue from the previous document section, then this field should be left blank or set to *auto*.

**Note:** Page numbers can be inserted in a document by inserting a page number placeholder (with the command **Insert Page / Column / Document Section | Page Number**). The total number of pages in the output document is inserted with the command **Insert Page / Column / Document Section | Page Total**.

**Note:** MS Word does not always update page numbers automatically. To manually update page numbers in MS Word, press **Ctrl+A** and **F9**.

**Page numbering in the RTF output**
In order to display page numbering in the RTF output in MS Word, you must select, in MS Word, the entire contents of the document (with *Edit | Select All* or **Ctrl+A**), and then press **F9**. This will cause the page numbering to be displayed—if you have inserted page numbering.

**Page totals**
To output the total number of pages at various locations in your document, use the *page total* feature.

**Page starts for document sections**
For each document section that is not the Initial Document Section, the *Section Starts On* property specifies whether the document section should start on the next page (irrespective of whether it is odd-numbered or even-numbered), or whether it should specifically start on an odd-numbered or even-numbered page. For example, if the previous document section ends on an odd-numbered page and the current document section is specified to start on an odd-numbered page, then the even-numbered page that occurs directly after the end of the previous document section will be left blank. Note that it is the underlying document page-numbering that determines whether a page is odd-numbered or even-numbered. The page numbering that the user specifies is irrelevant for determining the document section start-page.

**Page break after the Initial Document Section**
If you wish to start the section immediately after the Initial Document Section on a new page, give the *Render a Section Break* property (of the Initial Document Section's page layout properties) a value of Yes. This starts the second document section (that is the first section after the Initial Document Section) on a new page. Note that this property is available only for the Initial Document Section, not for any other section.

Note the converse effect also, that is, when the property has a value of No. In this case, the first non-Initial-Document-Section starts directly after the Initial Document Section—without rendering a page break. This is useful if the Initial Document Setting is blank—for example, if it contains a set of templates that produces no
output. A property value of No (for Render a Section Break) ensures that the first page of the print output document will not be blank (which would have been the case if a page break were to be rendered after an Initial Document Section that produced no output).

8.6.1.3 Headers and Footers: Part 1

Headers and footers can be added for each document section of the document, including the Initial Document Section.

Adding a header or footer for a document section

To add a header or footer for a document section, click the Add Header/Footer link of the Initial Document Section or the Document Section title bar (see screenshot below).

From the menu that pops up (screenshot below), select the required item. A header or footer can be added separately for odd or even pages, or a single header or footer can be added for all pages. Additionally, a separate header/footer template can be created for the first page (Add Header First, Add Footer First) and/or for the last page of a document section (Add Header Last, Add Footer Last, PDF output only). This is useful if the first and/or last page of a document section must have a different header/footer: for example, when the first page is a cover page (an empty header/footer template could be created in this case).

On clicking the required header or footer, a template for the header or footer is created within that document section in Design View. The Design View display of header/s and footer/s in a document section can be toggled on and off by clicking the Hide Headers/Footers link in the Initial Document Section or Document Section item (see screenshot above).

Note: Headers and footers for the last page are supported for PDF output only.
Designing the header/footer in Design View

The header/footer template is designed just like any other template. Components can be dragged from the schema tree or entered statically, and then styled. An example is shown below. When a header is added, the template will look something like this:

Change the header as required. Note that you can use both static and dynamic content, and even images.

Click the Preview RTF tab to see the results in the Preview windows. The illustration below shows Page 2 of the Organization Chart document in the PDF Preview window, with the header as defined above. To display page numbering in the RTF output, you must select Edit | Select All (or Ctrl+A) in MS Word, and then press F9. Also see displaying page-numbering in RTF output.

The following points should be noted:
• The vertical extent of the header and footer should not exceed the respective margin body (top or bottom) less the extent of the margin header or margin footer, respectively (see Page Layout Properties for details). The vertical extent of the header or footer, consequently, is determined by the top/bottom body margins and margin header/footer.
• You can define a header/footer either (i) for all pages in the document section, or for (ii) for even and odd pages in the document section separately. Additionally, separate first page and last page headers/footers can be inserted. (See Headers and Footers: Part 2 for more information.)
• Page numbering in a document section starts with the number you specify in the Page Layout Properties.

Deleting a header or footer
To delete a header or footer, right-click the header/footer title bar and, from the menu that pops up, click Edit | Remove.

8.6.1.4 Headers and Footers: Part 2
In this section, we describe how to create the following types of headers and footers:
- Different headers/footers for odd-numbered and even-numbered pages
- Different headers/footers for different document sections
- Simulating headers/footers inside a page
- Headers/footers with subtotals

Different headers/footers for odd-numbered and even-numbered pages
For each document section, odd-numbered and even-numbered pages can be assigned different headers/footers.

To create different headers for odd-numbered and even-numbered pages, click the Add Header/Footer link in the title bar of the respective document section, and select Add Header Odd and Add Header Even from the menu that pops up (screenshot below). This creates two header templates, one for odd-numbered pages, the other for even-numbered pages. Enter the content of the two headers in the templates.
Separate footers for odd-numbered and even-numbered pages can be created in a similar way to that described above for headers.

**Different headers/footers for different document sections**

Different headers/footers can be created for each document section of the document. To do this, click the Add Header/Footer link of the Initial Document Section or the Document Section title bar. This pops up the Add Header/Footer menu shown in the screenshot above. Note the following points:

- Headers/footers for odd-numbered and even-numbered pages can be added separately, or a common header/footer can be added for all pages in the document section.
- An additional first-page and/or last page header/footer can be added. These headers/footers will be used on the first and/or last page of the document section instead of other headers/footers that might be defined for that document section.
- Page numbering for the document section can either run on from the previous document section or start at a designated number.
- The Page Total is the page count of the entire document not that of the current document section.

**Simulating headers/footers inside a page**

Headers and footers can be designed manually inside a layout container. The approach would be to design a single page as a layout container. The header and footer are created within static tables located, respectively, at the top and bottom of the page. If more than one page is to be designed, then multiple layout containers can be used, each separated from the next by a page break.(Insert | Page / Column / Document Section | New Page).

**Headers/footers with subtotals and running totals**

When a document contains a list of numerical items that must be totalled and the list extends over multiple pages, subtotals of each page and/or running totals might be required to appear in the headers and/or footers of each page. The Subtotals.sps example, which is in the (My) Documents folder, demonstrates how running totals can be created and included in headers and footers.

The following strategy was used to design this SPS:

- Because the listing is in a table and because a table cannot be made to auto-fit a printed page, the number of rows that must be accommodated on a page must be specified. These numbers are given in two variables that have been defined on the top level template, that for the $XML template; they are named RowsOnFirstPage and RowsPerPage.
- The page count is derived by dividing the total number of list items by the number of rows per page (adjusted to take account of the different number of rows on the first page). The page count is stored in a variable called CountOfPages (defined on the $XML template).
- A user-defined template is created for the sequence 1 to $CountOfPages, and a static table is created within this template. Defined on this template are two variables that calculate the which row is to be the first row ($RowFrom) and the last row ($RowTill) on each page. The rows in the table are generated by a user-defined template, which selects the items in the XML file (file elements) on the basis of their position with respect to the $RowFrom and $RowTill values. If the position of the file element is an integer value that lies in the range delimited by values of the $RowFrom and $RowTill variables of the current page, then a row will be generated for the current file element.
• The running totals are generated with Auto-Calculations and inserted into rows at the top and bottom of the tables. Note that the XPath expressions to generate running totals at the top and bottom of pages are different from each other.
• Headers and footers are created in tables, respectively, above and below the main table on the page. The Auto-Calculations to generate the running totals are inserted in the header and footer templates.
• A page break is inserted at the end of each page.

8.6.2 Keeps and Breaks

In PDF documents (Enterprise edition only), keeps and breaks for pages and columns can be set in the XSL-FO group of styles (Styles sidebar, screenshot below). This group of styles enables you to specify whether the current design document block (the block within which the cursor is currently placed) should have a page/column break placed before or after it, or whether it should be kept with adjacent blocks. Whether table headers and footers are omitted (or repeated) at page breaks can also be set using the table-omit properties. For more information about these properties, see the XSL-FO specification.

For the printed version of HTML pages, settings for page breaks and widows/orphans (leading/trailing lines on a page) can be made via the relevant properties in the Paged Media group of styles (see screenshot above).

8.6.3 Footnotes

You can insert footnotes in a document by adding the Footnote component (Insert | Insert Footnote) at the location where you want the footnote number to be. Footnotes are available in paged media output (PDF, RTF, and Word 2007+ in the Enterprise Edition; and RTF in the Professional Edition).

Note the following points:

• The text of the footnote must be placed within the tags of the footnote component, and the footnote
text can be formatted.

- In the output, the footnote number appears at the location where the footnote was added. The footnote text appears at the bottom of the page, together with the corresponding footnote number.
- In the output, footnote text will be formatted according to the formatting of the text within the footnote component in the design.
- In the output, footnotes are numbered automatically through to the end of the document.
- In the case of multiple output documents, numbering is re-started for each output document.

In the screenshot below, two footnote components (Insert | Insert Footnote) have been inserted. The footnote text has been placed within the tags of the component, and the text has been formatted.

The screenshots below show the output. The screenshot at left shows the complete page, while the screenshots at right show closeups of the footnote numbers (top) and footnote texts (bottom).

Note: Formatting of footnote numbers is not supported.
8.6.4 Pixel Resolution

If you use pixels as a unit of length in your SPS, you should be aware that pixel-defined lengths are a function of screen resolution. The corresponding absolute lengths in print could be very different from what you see on screen. In this section, we do the following:

1. Discuss why pixel-defined sizes have two forms: (i) an abstract form, defined in pixels; (ii) an actual size, obtained by resolving the abstract form in terms of a specific screen resolution.
2. Explain StyleVision functionality to deal with this issue.

From pixels to points

A few key points are essential to understanding the factors that affect the abstract and actual dimensions of pixel-defined lengths:

- The pixel is a relative unit: its size depends on screen resolution. The higher the resolution, the smaller the pixel. Screen resolution is given with dpi (dots per inch). A dot in the case of screens is a pixel. So, if screen resolution is 72 dpi, then there are 72 pixels (dots) in one inch of a line of pixels. If screen resolution is 96 dpi, then there are 96 pixels in an inch. How many pixels there are in an inch of screen length depends on the screen resolution. The most commonly available screen resolutions today are 72 dpi, 96 dpi, and 120 dpi. The higher the dpi, the smaller will be the pixels.
- The length unit known as the point is an absolute unit of length, used most commonly in the printing industry: 72 points make up an inch.
- From the above it can be seen that only when screen resolution is 72 dpi will one pixel be equal to one point. For other screen resolutions, the absolute length can be calculated. The table below lists the absolute length (in points) of 100px at various screen resolutions.

<table>
<thead>
<tr>
<th>Resolution</th>
<th>Pixels</th>
<th>Points</th>
<th>Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>72 dpi</td>
<td>100</td>
<td>100</td>
<td>1.00</td>
</tr>
<tr>
<td>96 dpi</td>
<td>100</td>
<td>75</td>
<td>0.75</td>
</tr>
<tr>
<td>120 dpi</td>
<td>100</td>
<td>60</td>
<td>0.60</td>
</tr>
</tbody>
</table>

To convert pixels to points for each screen resolution, we can use a factor given by the ratio of points in one inch (72) to pixels in one inch (dpi), that is, 72 divided by dpi. The conversion factors for various resolutions are given in the table above. For example: 72 div 96 = 0.75 and 72 div 120 = 0.60.

Multiplying the length in pixels by the appropriate conversion factor gives the absolute length in points. So 100px on a 96 dpi screen is 75pt.

Since 72 points make an inch, you can obtain the length in inches by dividing the length in points by 72. For example, 100 points is equal to 100 div 72 inches = 1.389in.

Screen resolution and absolute length

In the previous section we have seen that only when the screen resolution is 72 dpi will the absolute length in points be the same as the number of pixels used to define that length. Screen resolutions on Windows systems, however, are typically not 72 dpi but 96 dpi. This means that the number of points of a pixel-defined length on such a screen will be 75% the number of pixels. For example, in the StyleVision Design View screenshot below, the two characters measure 100px and 75pt, respectively.
The reason they are the same height is that the screen resolution in which they appear is 96 dpi. At this resolution 100px is equal to 75pt in absolute terms.

The point to note is that when specifying pixels as a unit of length, be aware of your monitor's screen resolution (normally 96 dpi on Windows systems); it determines the absolute length of the pixel-defined length that you see on screen.

**Print output resolution**

When an SPS is transformed into a print format, such as PDF, RTF, or Word 2007+, non-absolute pixel lengths must be converted to absolute lengths, such as points or inches (because lengths on paper cannot be defined in terms of pixels). The question is: What factor (or screen resolution) should be used to convert from pixels to points?

In StyleVision, you can select the output dpi for each SPS individually. So, for example, if you select 96 dpi, then a 100px character will be rendered in print output as a 75pt character (see the table above). If you select 72 dpi, then the same character will be rendered in print output as a 100pt character. This system applies to all lengths defined in pixels.

**Note:** Conversion to an absolute measure is not carried out for HTML output. For HTML, the original pixel units are passed to the HTML file unchanged.

**Setting print output resolution of an SPS**

To set the print output resolution of an SPS, click **File | Properties**. In the Properties dialog that pops up, click the Resolution tab (**screenshot below**).
In the Resolution tab, select the required print resolution. The conversion factor for each listed dpi option is given in the conversion table above (in the section, From Pixels to Points). Multiplying the pixel count by the conversion factor gives the absolute length in points. Note that the conversion to absolute units is applied only to print output formats. The HTML output format will retain the original pixel definitions. Note also that this setting does not change the screen resolution of your monitor.

8.6.5 Watermarks

A watermark is an image or text that is displayed on the background of each page of a document section.

The following options are available:

- Watermarks must be defined separately for each document section. Each section can therefore have a different watermark.
- For each document section, you must define (with XPath) some condition to be fulfilled in order for that section's watermarks to be enabled. For example, the condition could be, say, that the drafts attribute of some element must have the value true. If the condition is not fulfilled, or if the condition evaluates to \texttt{false}(), that watermark is disabled.
- A watermark can be a text that you customize in StyleVision or it can be an image you select.
- In the design, you can specify the location and appearance of watermarks on the page.
Note: Watermarks are available only for print-output media, not for HTML or Authentic View.

Creating a watermark
A watermark can be created separately for each document section. To create (or to edit) a watermark, click the *Edit Properties* link of the Initial Section or Document Section items in the design (*screenshot below*).

![Document Section](image)

In the Properties dialog that pops up (*screenshot below*), click the **Watermark** button at the bottom of the dialog.

![Properties](image)

This pops up the Edit Watermark dialog (*screenshots below*), in which you specify the properties of the watermark/s of that document section. According to whether you wish to use an image or text as the watermark, select either the **Image** or **Text** tab. (If you wish to define both an image as well as a text as the watermarks of that section, enter the details of each type in their respective tabs. In this case, both types of watermark will be created in the output.)
Parameters for image watermarks

The Image tab (see screenshot above) contains the parameters for defining an image watermark for that section. An XPath expression specifies the condition for enabling the image watermark. If you do not wish to specify any condition, then enter `true()` in the Condition text box. This causes the condition to evaluate to `true()`. If the condition evaluates to `false()`, or if no condition is specified, then the image watermark is not enabled. Next, browse for the image, so that the filepath to the image is entered in the Image text box.

You can then set the transparency of the image and its size and position on the page. The Fill the entire page option expands the image till one dimension (height or width) is filled. Click OK when done.

Parameters for text watermarks

The Text tab (see screenshot below) contains the parameters for defining a text watermark for that section. An XPath expression specifies the condition for enabling the text watermark. If you do not wish to specify any condition, then enter `true()` in the Condition text box. This causes the condition to evaluate to `true()`. If the condition evaluates to `false()`, or if no condition is specified, then the text watermark is not enabled.
Next, enter the text you wish to use as the watermark, then specify its formatting (font family, font size, transparency, and color) and orientation. Note that the text will be stretched to extend across the page in all orientations. Click **OK** when done.

**Removing or disabling a watermark**

To remove or disable a watermark, in the Edit Watermark dialog (see screenshots above), either delete the condition or set the XPath expression of the condition to `false()`. Note that the **Image** tab and **Text** tab each have a separate condition, for their respective watermarks.
9 Additional Functionality

Additional to the content editing, structure, advanced, and presentation procedures described in this documentation, StyleVision provides a range of miscellaneous additional features. These are listed below and described in detail in the sub-sections of this section.

- **Global Resources**. Global resources provide flexibility in selecting resources. For example, multiple resources (such as files and databases), can be assigned to an alias. When an alias is used as a source (XML, XSD, etc) of an SPS, the resource can be switched among the multiple resources assigned to the alias.
- **Authentic Node Properties**. Individual nodes in the XML document have Authentic View-specific properties. Nodes can be defined to be non-editable, to be displayed with markup tags, to display user information on mouseover, etc.
- **Replace Parent Node OnClick With**. The value of the parent node of a button or hyperlink can be selected by the Authentic View user. The SPS can be designed to modify presentation based on what the Authentic View user selects.
- **Additional Validation**. A node can be tested using an XPath expression to return a Boolean value that determines whether user input for that node is valid. This test is in addition to document validation against a schema.
- **Working with Dates**. In Authentic View, a graphical date-picker ensures that dates are entered in the correct XML Schema format. Furthermore, dates can be manipulated and formatted as required.
- **Unparsed Entity URIs**. URIs can be stored in unparsed entities in the DTD on which an XML document is based. The Unparsed Entity URI feature enables images and hyperlinks to use these URIs as target URIs.
- **Using Scripts**. StyleVision contains a JavaScript Editor in which JavaScript functions can be defined. These functions are then available for use as event handlers anywhere within the SPS, and will take effect in the output HTML document.
- **HTML Import**. An HTML file can be imported into StyleVision and an XML, XSD, and SPS files can be created from it.
- **New from XSLT**. An SPS can be created from an XSLT-for-HTML or an XSLT-for-FO. Template structure and styling in the XSLT will be created in the SPS. You can then modify the SPS components and add content and formatting to the SPS.

9.1 Altova Global Resources

Altova Global Resources is a collection of aliases for file, folder, and database resources. Each alias can have multiple configurations, and each configuration maps to a single resource (see screenshot below). Therefore, when a global resource is used as an input, the global resource can be switched among its configurations. This is done easily via controls in the GUI that let you select the active configuration. For example, if an XSLT stylesheet for transforming an XML document is assigned via a global resource (an alias), then we can set up multiple configurations for the global resource, each of which points to a different XSLT file. After setting up the global resource in this way, switching the configuration would switch the XSLT file used for the transformation.

A global resource can not only be used to switch resources within an Altova application, but also to generate and use resources from other Altova applications. So, files can be generated on-the-fly in one Altova application for use in another Altova application. All of this tremendously eases and speeds up development and testing. For example, an XML file can be generated by an Altova MapForce mapping and used in StyleVision as an XML Working File in an SPS.

Using Altova Global Resources involves two processes:

- **Defining Global Resources**: Resources are defined and the definitions are stored in an XML file. These resources can be shared across multiple Altova applications.
- **Using Global Resources**: Within StyleVision, files can be located via a global resource instead of via a file path. The advantage is that the resource can be switched by changing the active configuration in StyleVision.

Global resources in other Altova products

Currently, global resources can be defined and used in the following individual Altova products: XMLSpy, StyleVision, MapForce, Authentic Desktop, MobileTogether Designer, and DatabaseSpy.

9.1.1 Defining Global Resources

Altova Global Resources are defined in the Manage Global Resources dialog, which can be accessed in two ways:

- Click the menu command Tools | Global Resources.
- Click the Manage Global Resources icon in the Global Resources toolbar (screenshot below).
The Global Resources Definitions file

Information about global resources is stored in an XML file called the Global Resources Definitions file. This file is created when the first global resource is defined in the Manage Global Resources dialog (screenshot below) and saved.

![Manage Global Resources Dialog](image)

When you open the Manage Global Resources dialog for the first time, the default location and name of the Global Resources Definitions file is specified in the Definitions File text box (see screenshot above):

```
C:\Users\<username>\My Documents\Altova\GlobalResources.xml
```

This file is set as the default Global Resources Definitions file for all Altova applications. So a global resource can be saved from any Altova application to this file and will be immediately available to all other Altova applications as a global resource. To define and save a global resource to the Global Resources Definitions file, add the global resource in the Manage Global Resources dialog and click OK to save.

To select an already existing Global Resources Definitions file to be the active definitions file of a particular Altova application, browse for it via theBrowse button of the Definitions File text box (see screenshot above).

**Note:** You can name the Global Resources Definitions file anything you like and save it to any location accessible to your Altova applications. All you need to do in each application, is specify this file as the Global Resources Definitions file for that application (in the Definitions File text box). The resources become global across Altova products when you use a single definitions file across all Altova products.

**Note:** You can also create multiple Global Resources Definitions files. However, only one of these can be active at any time in a given Altova application, and only the definitions contained in this file will be
available to the application. The availability of resources can therefore be restricted or made to overlap across products as required.

Managing global resources: adding, editing, deleting, saving

In the Manage Global Resources dialog (screenshot above), you can add a global resource to the selected Global Resources Definitions file, or edit or delete a selected global resource. The Global Resources Definitions file organizes the global resources you add into groups: of files, folders, and databases (see screenshot above).

To **add a global resource**, click the **Add** button and define the global resource in the appropriate Global Resource dialog that pops up (see the descriptions of files, folders, and databases in the sub-sections of this section). After you define a global resource and save it (by clicking **OK** in the Manage Global Resources dialog), the global resource is added to the library of global definitions in the selected Global Resources Definitions file. The global resource will be identified by an alias.

To **edit a global resource**, select it and click **Edit**. This pops up the relevant Global Resource dialog, in which you can make the necessary changes (see the descriptions of files, folders, and databases in the sub-sections of this section).

To **delete a global resource**, select it and click **Delete**.

After you finish adding, editing, or deleting, make sure to click **OK** in the Manage Global Resources dialog to **save your modifications** to the Global Resources Definitions file.

Relating global resources to alias names via configurations

Defining a global resource involves mapping an alias name to a resource (file, folder, or database). A single alias name can be mapped to multiple resources. Each mapping is called a configuration. A single alias name can therefore be associated with several resources via different configurations (screenshot below).

In an Altova application, you can then assign aliases instead of files. For each alias you can switch between the resources mapped to that alias simply by changing the application's active Global Resource configuration (active configuration). For example, in Altova's XMLSpy application, if you wish to run an XSLT transformation on the XML document MyXML.xml, you can assign the alias MyXSLT to it as the global resource to be used for XSLT transformations. In XMLSpy you can then change the active configuration to use different XSLT files. If Configuration-1 maps First.xslt to MyXSLT and Configuration-1 is selected as the active configuration, then First.xslt will be used for the transformation. In this way multiple configurations can be used to access multiple resources via a single alias. This mechanism can be useful when testing and comparing resources.
Furthermore, since global resources can be used across Altova products, resources can be tested and compared across multiple Altova products as well.

9.1.1.1 Files

The Global Resource dialog for Files (screenshot below) is accessed via the Add | File command in the Manage Global Resources dialog. In this dialog, you can define configurations of the alias that is named in the Resource Alias text box. After specifying the properties of the configurations as explained below, save the alias definition by clicking OK.

After saving an alias definition, you can add another alias by repeating the steps given above (starting with the Add | File command in the Manage Global Resources dialog).

Global Resource dialog
An alias is defined in the Global Resource dialog (screenshot below).
Global Resource dialog icons

- **Add Configuration**: Pops up the Add Configuration dialog in which you enter the name of the configuration to be added.
- **Add Configuration as Copy**: Pops up the Add Configuration dialog in which you can enter the name of the configuration to be created as a copy of the selected configuration.
- **Delete**: Deletes the selected configuration.
- **Open**: Browse for the file to be created as the global resource.

Defining the alias

Define the alias (its name and configurations) as follows:

1. **Give the alias a name**: Enter the alias name in the Resource Alias text box.
2. **Add configurations**: The Configurations pane will have, by default, a configuration named Default (see screenshot above), which cannot be deleted or renamed. You can add as many additional configurations as you like by: (i) clicking the Add Configuration or Add Configuration as Copy icons, and (ii) giving the configuration a name in the dialog that pops up. Each added configuration will be shown in the Configurations list. In the screenshot above, two additional configurations, named Long and Short, have been added to the Configurations list. The Add Configuration as Copy command enables you to copy the selected configuration and then modify it.
3. **Select a resource type for each configuration**: Select a configuration from the Configurations list, and, in the Settings for Configuration pane, specify a resource for the configuration: (i) File, (ii) Output of an Altova MapForce transformation, or (iii) Output of an Altova StyleVision transformation. Select the appropriate radio button. If a MapForce or StyleVision transformation option is selected, then a transformation is carried out by MapForce or StyleVision using, respectively, the .mfd or .sps file and the respective input file. The result of the transformation will be the resource.
4. **Select a file for the resource type**: If the resource is a directly selected file, browse for the file in the Resource File Selection text box. If the resource is the result of a transformation, in the File Selection text box, browse for the .mfd file (for MapForce transformations) or the .sps file (for StyleVision transformations). Where multiple inputs or outputs for the transformation are possible, a selection of the options will be presented. For example, the output options of a StyleVision transformation are displayed according to what edition of StyleVision is installed (the screenshot below shows the outputs for Enterprise Edition).

Select the radio button of the desired option (in the screenshot above, 'HTML output' is selected). If the resource is the result of a transformation, then the output can be saved as a file or itself as a global resource. Click the icon and select, respectively, Global Resource (for saving the output as a global resource) or Browse (for saving the output as a file). If neither of these two saving options is selected, the transformation result will be loaded as a temporary file when the global resource is invoked.
5. **Define multiple configurations if required:** You can add more configurations and specify a resource for each. Do this by repeating Steps 3 and 4 above for each configuration. You can add a new configuration to the alias definition at any time.

6. **Save the alias definition:** Click **OK** to save the alias and all its configurations as a global resource. The global resource will be listed under Files in the Manage Global Resources dialog.

**Result of MapForce transformation**

Altova MapForce maps one or more (existing) input document schemas to one or more (new) output document schemas. This mapping, which is created by a MapForce user, is known as a MapForce Design (MFD). XML files, text files, databases, etc, that correspond to the input schema/s can be used as data sources. MapForce generates output data files that correspond to the output document schema. This output document is the **Result of MapForce Transformation** file that will become a global resource.

If you wish to set a MapForce-generated data file as a global resource, the following must be specified in the Global Resource dialog (see screenshot below):

- **A `.mfd` (MapForce Design) file.** You must specify this file in the Resource will point to generated output of text box (see screenshot above).
- **One or more input data files.** After the MFD file has been specified, it is analyzed and, based on the input schema information in it, default data file/s are entered in the Inputs pane (see screenshot above). You can modify the default file selection for each input schema by specifying another file.
- **An output file.** If the MFD document has multiple output schemas, all these are listed in the Outputs pane (see screenshot above) and you must select one of them. If the output file location of an
individual output schema is specified in the MFD document, then this file location is entered for that output schema in the Outputs pane. From the screenshot above we can see that the MFD document specifies that the Customers output schema has a default XML data file (CustomersOut.xml), while the Text file output schema does not have a file association in the MFD file. You can use the default file location in the Outputs pane or specify one yourself. The result of the MapForce transformation will be saved to the file location of the selected output schema. This is the file that will be used as the global resource.

Note: The advantage of this option (Result of MapForce transformation) is that the transformation is carried out at the time the global resource is invoked. This means that the global resource will contain the most up-to-date data (from the input file/s).

Note: Since MapForce is used to run the transformation, you must have Altova MapForce installed for this functionality to work.

Result of StyleVision transformation

Altova StyleVision is used to create StyleVision Power Stylesheet (SPS) files. These SPS files generate XSLT stylesheets that are used to transform XML documents into output documents in various formats (HTML, PDF, RTF, Word 2007+, etc). If you select the option Result of StyleVision Transformation, the output document created by StyleVision will be the global resource associated with the selected configuration.

For the StyleVision Transformation option in the Global Resource dialog (see screenshot below), the following files must be specified.
• **A .sps (SPS) file.** You must specify this file in the Resource will point to generated output of text box (see screenshot above).

• **Input file/s.** The input file might already be specified in the SPS file. If it is, it will appear automatically in the Inputs pane once the SPS file is selected. You can change this entry. If there is no entry, you must add one.

• **Output file/s.** Select the output format in the Outputs pane, and specify an output file location for that format.

**Note:** The advantage of this option (Result of StyleVision transformation) is that the transformation is carried out when the global resource is invoked. This means that the global resource will contain the most up-to-date data (from the input file/s).

**Note:** Since StyleVision is used to run the transformation, you must have Altova StyleVision installed for this functionality to work.
9.1.1.2 Folders

In the Global Resource dialog for Folders (screenshot below), add a folder resource as described below.

Global Resource dialog icons

- **Add Configuration**: Pops up the Add Configuration dialog in which you enter the name of the configuration to be added.
- **Add Configuration as Copy**: Pops up the Add Configuration dialog in which you can enter the name of the configuration to be created as a copy of the selected configuration.
- **Delete**: Deletes the selected configuration.
- **Open**: Browse for the folder to be created as the global resource.

Defining the alias

Define the alias (its name and configurations) as follows:

1. **Give the alias a name**: Enter the alias name in the Resource Alias text box.
2. **Add configurations**: The Configurations pane will have a configuration named Default (see screenshot above). This Default configuration cannot be deleted nor have its name changed. You can enter as many additional configurations for the selected alias as you like. Add a configuration by clicking the Add Configuration or Add Configuration as Copy icons. In the dialog which pops up, enter the
configuration name. Click OK. The new configuration will be listed in the Configurations pane. Repeat for as many configurations as you want.

3. **Select a folder as the resource of a configuration:** Select one of the configurations in the Configurations pane and browse for the folder you wish to create as a global resource. If security credentials are required to access a folder, then specify these in the **Username** and **Password** fields.

4. **Define multiple configurations if required:** Specify a folder resource for each configuration you have created (that is, repeat Step 3 above for the various configurations you have created). You can add a new configuration to the alias definition at any time.

5. **Save the alias definition:** Click OK in the Global Resource dialog to save the alias and all its configurations as a global resource. The global resource will be listed under **Folders** in the Manage Global Resources dialog.

### 9.1.1.3 Databases

In the Global Resource dialog for Databases *(screenshot below)*, you can add a database resource as follows:

![Global Resource dialog for Databases](screenshot)
Global Resource dialog icons

- **Add Configuration**: Pops up the Add Configuration dialog in which you enter the name of the configuration to be added.
- **Add Configuration as Copy**: Pops up the Add Configuration dialog in which you can enter the name of the configuration to be created as a copy of the selected configuration.
- **Delete**: Deletes the selected configuration.

Defining the alias

Define the alias (its name and configurations) as follows:

1. **Give the alias a name**: Enter the alias name in the Resource Alias text box.
2. **Add configurations**: The Configurations pane will have a configuration named Default (see screenshot above). This Default configuration cannot be deleted nor have its name changed. You can enter as many additional configurations for the selected alias as you like. Add a configuration by clicking the Add Configuration or Add Configuration as Copy icons. In the dialog which pops up, enter the configuration name. Click OK. The new configuration will be listed in the Configurations pane. Repeat for as many configurations as you want.
3. **Start selection of a database as the resource of a configuration**: Select one of the configurations in the Configurations pane and click the Choose Database icon. This pops up the Create Global Resources Connection dialog.
4. **Connect to the database**: Select whether you wish to create a connection to the database using the Connection Wizard, an existing connection, an ADO Connection, an ODBC Connection, or JDBC Connection. Complete the definition of the connection method as described in the section Connecting to a Database. If a connection has already been made to a database from StyleVision, you can click the Existing Connections icon and select the DB from the list of connections that is displayed.
5. **Select the root object**: If you connect to a database server where a root object can be selected, you will be prompted, in the Choose Root Object dialog (screenshot below), to select a root object on the server. Select the root object and click Set Root Object. The root object you select will be the root object that is loaded when this configuration is used.

![Choose Root Object](image)

If you choose not to select a root object (by clicking the Skip button), then you can select the root object at the time the global resource is loaded.
6. **Define multiple configurations if required:** Specify a database resource for any other configuration you have created (that is, repeat Steps 3 to 5 above for the various configurations you have created). You can add a new configuration to the alias definition at any time.

7. **Save the alias definition:** Click **OK** in the Global Resource dialog to save the alias and all its configurations as a global resource. The global resource will be listed under databases in the Manage Global Resources dialog.

### 9.1.2 Using Global Resources

There are several types of global resources (file-type, folder-type, and database-type). Particular scenarios in StyleVision allow the use of particular types of global resources. For example, you can use file-type or folder-type global resources for a Working XML File or a CSS file. Or you can use a database-type resource to create a new DB-based SPS. Some scenarios in which you can use global resources in StyleVision are listed here: [Files and Folders](#) and [Databases](#).

**Selections that determine which resource is used**

There are two application-wide selections that determine what global resources can be used and which global resources are actually used at any given time:

- **The active Global Resources XML File** is selected in the [Global Resource dialog](#). The global-resource definitions that are present in the active Global Resources XML File are available to all files that are open in the application. Only the definitions in the active Global Resources XML File are available. The active Global Resources XML File can be changed at any time, and the global-resource definitions in the new active file will immediately replace those of the previously active file. The active Global Resources XML File therefore determines: (i) what global resources can be assigned, and (ii) what global resources are available for look-up (for example, if a global resource in one Global Resource XML File is assigned but there is no global resource of that name in the currently active Global Resources XML File, then the assigned global resource (alias) cannot be looked up).

- **The active configuration** is selected via the menu item **Tools | Active Configuration** or via the [Global Resources toolbar](#). Clicking this command (or drop-down list in the toolbar) pops up a list of configurations across all aliases. Selecting a configuration makes that configuration active application-wide. This means that wherever a global resource (or alias) is used, the resource corresponding to the active configuration of each used alias will be loaded. The active configuration is applied to all used aliases. If an alias does not have a configuration with the name of the active configuration, then the default configuration of that alias will be used. The active configuration is not relevant when assigning resources; it is significant only when the resources are actually used.

### 9.1.2.1 Assigning Files and Folders

File-type and folder-type global resources are assigned differently. In any one of the [usage scenarios](#) below, clicking the **Switch to Global Resources** button displays the Open Global Resource dialog ([screenshot below](#)).
Manage Global Resources: Displays the Manage Global Resources dialog.

Selecting a file-type global resource assigns the file. Selecting a folder-type global resource causes an Open dialog to open, in which you can browse for the required file. The path to the selected file is entered relative to the folder resource. So if a folder-type global resource were to have two configurations, each pointing to different folders, files having the same name but in different folders could be targeted via the two configurations. This could be useful for testing purposes.

You can switch to the file dialog or the URL dialog by clicking the respective button at the bottom of the dialog. The Manage Global Resources icon in the top right-hand corner pops up the Manage Global Resources dialog.

Usage scenarios
File-type and folder-type global resources can be used in the following scenarios:

- Adding and modifying schema sources and Working XML Files and Template XML Files
- Saving as Global Resource
- Adding modules and CSS files
- Adding global resources to a project

Schema, Working XML File, Template XML File
In the Design Overview sidebar (screenshot below), the context menus for the Schema, Working XML File, Template XML File contains an entry that pops up the Open dialog in which you can assign the schema or Working XML File via a global resource. Clicking the Switch to Global Resources button pops up a dialog with a list of all file-type global resources that are defined in the Global Resources XML File currently active in
StyleVision. (How to set the currently active Global Resources XML File is described in the section Defining Global Resources.)

If a global resource has been selected as the file source, it is displayed in the relevant entry in the Design Overview sidebar (screenshot below).

![Design Overview Sidebar](image)

Adding modules and CSS files from a global resource

In the Design Overview sidebar, the Add New Module and Add New CSS File commands pop up the Open dialog, in which you can click Switch to Global Resources to select a Global Resource to be used. Modules and CSS files can then be changed by changing the configuration.

Saving as global resource

A newly created file can be saved as a global resource. Also, an already existing file can be opened and then saved as a global resource. When you click the File | Save or File | Save As commands, the Save dialog appears. Click the Switch to Global Resource button to access the available global resources (screenshot below), which are the aliases defined in the current Global Resources XML File.
Select an alias and then click **Save**. If the alias is a **file alias**, the file will be saved directly. If the alias is a **folder alias**, a dialog will appear that prompts for the name of the file under which the file is to be saved. In either case the file will be saved to the location that was defined for the **currently active configuration**.

**Note:** Each configuration points to a specific file location, which is specified in the definition of that configuration. If the file you are saving as a global resource does not have the same filetype extension as the file at the current file location of the configuration, then there might be editing and validation errors when this global resource is opened in StyleVision. This is because StyleVision will open the file assuming the filetype specified in the definition of the configuration.

### Global Resources in projects

Global resources can also be added to the currently active project via the **Project | Add Global Resource to Project** command. This pops up a dialog listing the file-type global resources in the currently active **Global Resources XML File**. Select a global resource and click **OK** to add it to the project. The global resource appears in the Project sidebar and can be used like any other file.

### 9.1.2.2 Assigning Databases

When an SPS is created from a database (DB) with the **File | New from DB** command, you can select the option to use a global resource (**screenshot below**). Other commands where a database-type global resource can be used are database-related commands in the menu.
In the Connection dialog (screenshot above), all the database-type global resources that have been defined in the currently active Global Resources XML File are displayed. Select the required global resource and click **Connect**. If the selected global resource has more than one configuration, then the database resource for the currently active configuration is used (check **Tools | Active Configuration** or the Global Resources toolbar), and the connection is made.

### 9.1.2.3 Changing the Active Configuration

One configuration of a global resource can be active at any time. This configuration is called the active configuration, and it is active application-wide. This means that the active configuration is active for all global resources aliases in all currently open files and data source connections. If an alias does not have a configuration with the name of the active configuration, then the default configuration of that alias will be used. As an example of how to change configurations, consider the case in which a file has been assigned via a global resource with multiple configurations. Each configuration maps to a different file. So, which file is selected depends on which configuration is selected as the application's active configuration.

Switching the active configuration can be done in the following ways:
- Via the menu command **Tools | Active Configuration**. Select the configuration from the command's submenu.
- In the combo box of the Global Resources toolbar (*screenshot below*), select the required configuration.

In this way, by changing the active configuration, you can change source files that are assigned via a global resource.
9.2 **Authentic Node Properties**

Authentic node properties are properties you set for the display of a node in **Authentic View**. For example, a node can be displayed with XML markup tags, be defined to be non-editable, and/or to have user information displayed when the cursor is placed over the node. Authentic node properties can be set on various SPS components. What properties are available for a component depends upon the type of component it is.

To assign Authentic node properties, select the required component in the design. Then, in the **Authentic** group of properties in the Properties sidebar (screenshot below), specify the required Authentic node settings. Alternatively, you can right-click the node-template and select **Edit Authentic Properties**.

![Properties](image)

**Defining Authentic Properties**

The following node settings can be made to control the behavior of individual nodes in the Authentic View display.

**Add children**

This setting is available when the selected node is an element. It allows you to define what child elements of the selected element are inserted when the selected element is added. The options are: all child elements, mandatory child elements, and no child element.

**Additional validation**

In addition to validation of the XML document against a schema, additional validation can be specified for individual nodes and Auto-Calculations. You can set an XPath expression to define the validity range of the XML content of the node or Auto-Calculation. If the XML value of the node is invalid, this is made known to the Authentic View user by means of an error message when the XML document is validated (F8). See [Additional Validation](#) for details.

**DB rows displayed and fetched**

The **DB Rows Displayed** and **DB Rows Fetched** properties define, respectively, how many DB rows will be displayed in Authentic View and how many DB records are originally loaded. The **DB Records Fetched** property thus enables you to speed up the loading and display time.
Content is editable
Defines whether the node is editable or not. By default the node is editable. This setting is available when the selected node is an element, attribute, or contents. Auto-Calculation results cannot be edited because the value is computed with the XPath expression you enter for the Auto-Calculation; this option is therefore not available for Auto-Calculations.

Mixed markup
This setting is available when the selected node is an element or attribute, and enables you to specify how individual nodes will be marked up in the mixed markup mode of Authentic View. The following options exist: large markup (tags with node names); small markup (tags without node names); and no markup.

Show "add Name" when XML Element is missing
Determines whether a prompt ("Add [element/attribute name]") will appear in Authentic View when the selected element or attribute is missing. By default, the prompt will be displayed. This setting is available when the selected node is an element or an attribute.

User info
Text entered in this text box appears as a tooltip when the mouse pointer is placed over the node. It is available when the selected node is an element, attribute, contents, or an Auto-Calculation. If both the element/attribute node as well as the contents node has User Info, then the User Info for the contents node is displayed as the tooltip when the mouse is placed over the node.
9.3 Replace Parent Node OnClick With

With the Replace Parent Node OnClick With property (in the Authentic group of properties, assignable in the Properties sidebar, see screenshot below), you can specify text content of the parent node of a button or hyperlink.

When the Authentic View user clicks the design component (a button or hyperlink), the text you, the SPS designer, have specified will be inserted as the XML content of the design component's parent node. This enables you to allow the Authentic View user to make certain selections (by clicking a button or hyperlink) that will alter the presentation of the XML document in Authentic View.

Usage mechanism
This feature can be used as follows:

1. In the design, insert the design component (button or hyperlink) within the node for which you wish to insert text content.
2. Select the design component in the design, and, in the Properties sidebar, select that design component (in the Properties For column), and enter a value for the Replace Parent Node OnClick With property (which is in the Authentic group of properties; see screenshot above). This value can be entered as a text value directly or via an XPath expression. (Click the XPath icon in the toolbar of the Properties sidebar to enter the value as an XPath expression). In the screenshot above, the value is an XPath string expression 'default'. Now, if the Authentic View user clicks the design component in Authentic View, the text default will be entered as the text content of the parent node of the design component. This result can also be obtained if you enter a text value (not an XPath expression) of default directly as the value of the Replace Parent Node OnClick With property.
3. Now that you know what content the parent node will have when the Authentic View user clicks the design component, you can set up processing based on the text content of the parent node. For example, using a condition, you can specify that when the content of the parent node is default, then some default formatting is applied; or, when the content is hide, the text of a node is hidden. In this way you can use this feature to achieve powerful effects that might otherwise have required the deployment of scripts.

Note: For this feature to work correctly, in the schema, the parent node must be defined to allow text content.
Usage with variables

The parent node can also be a variable that has been defined on an ancestor node. The value of the variable can then be set up by the SPS designer using the Replace Parent Node OnClick With property. When the Authentic View user clicks the design component (button or hyperlink), the value defined for the Replace Parent Node OnClick With property of the design component is assigned to the variable. You can now set up alternative processing options based on the value of the variable.

A simple example is shown below. When the value of the variable \texttt{Var2} is set to Boolean \texttt{true()}, a button enabling the value to be changed to Boolean \texttt{false()} is displayed (see screenshot below). This processing is specified in the first branch of a condition.

The Otherwise branch of the condition specifies processing that displays a button enabling the value of the variable to be changed to Boolean \texttt{true()} (screenshot below). You can define additional processing according to the value of the variable \texttt{Var2} (true() or false()).
In this way you, the SPS designer, can allow Authentic View users to select from a range of options that then produce specific and corresponding processing of the document.
9.4 Additional Validation

The Additional Validation setting is available when the selected component is an element or attribute node, contents (contents placeholder), a data-entry device, or an Auto-Calculation. You can set an XPath expression to define the validity range of the XML content of the node or Auto-Calculation. An XML value that falls outside this defined range is invalid. If the XML value of the node is invalid, this is made known to the Authentic View user by means of an error message when the XML document is validated (F8). The error message that is displayed is the text you enter into the Error message field of the Additional Validation setting.

Setting Additional Validation
To set additional validation, do the following:

1. Select the component for which additional validation is required.
2. In the Properties sidebar, select the Authentic group of properties, and click the Edit button of the Additional Validation property (screenshot below). This pops up the Additional Validation dialog.

3. In the Additional Validation dialog (screenshot below), add a row for an Additional Validation entry by clicking the Add button near the top left of the pane.
4. In the XPath expression column, enter an XPath expression to define the validity range of the XML data in that component.
5. Enter an error message to display when the data is invalid.
6. Click **OK** to finish.
9.5 Unparsed Entity URIs

If you are using a DTD and have declared an unparsed entity in it, you can use the URI associated with that entity for image and hyperlink targets in the SPS. This is useful if you wish to use the same URI multiple times in the SPS. This feature makes use of the XSLT function unparsed-entity-uri to pass the URI of the unparsed entity from the DTD to the output, and is therefore only available in the outputs (HTML, RTF); not in Authentic View. Note that unparsed entity URIs are not processed for Text output.

Using this feature requires that the DTD, XML document, and SPS documents be appropriately edited, as follows:

1. In the DTD, the unparsed entities must be declared, with (i) the URI, and (ii) the notation (which indicates to StyleVision the resource type of the entity).
2. In the XML document, the unparsed entity must be referenced. This is done by giving the names of the required unparsed entities.
3. In the SPS, unparsed entities can be used to target images and hyperlinks by correctly accessing the relevant dynamic node values as unparsed entities.

Declaring and referencing unparsed entities

Given below is a cut-down listing of an XML document. It has an internal DTD subset which declares two unparsed entities, one with a GIF notation (indicating a GIF image) and the other with an LNK notation (indicating a hyperlink). The img/@src and link/@href nodes in the XML code reference the unparsed entities by giving their names.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE document SYSTEM "UEURIDoc.dtd" [ الناون pic SYSTEM "nanonull.gif" NDATA GIF
<!ENTITY AltovaURI SYSTEM "http://www.altova.com" NDATA LNK>
]
<document>
  <header>Example of How to Use Unparsed Entity URIs</header>
  <para>...</para>
  <img src="Picture" />
  <link href="AltovaURI">Link to the Altova Website.</link>
</document>
```

SPS images and hyperlinks that use unparsed entities

Images and hyperlinks in the SPS that reference unparsed entity URIs are used as follows:

1. Insert the image or hyperlink via the Insert menu.
2. In the object’s Edit dialog, select the Dynamic tab properties (screenshot below), and enter an XPath expression that selects the node containing the name of the unparsed entity. In the XML document example given above, these nodes would be, respectively, the //img/@src and //link/@href nodes.
3. Then check the Treat as Unparsed Entity check box at the bottom of the dialog. This causes the
text of the selected node to be read as an unparsed entity. If an unparsed entity of that name is
declared, the URI associated with that unparsed entity is used to locate the resource (image or
hyperlink).

When the stylesheet is processed, the URI associated with the entity name is substituted for the entity name.

**Note:** If the URI is a relative URI, then the XSLT processor expands it to an absolute URI applying the base
URI of the DTD. For example, if the unparsed entity is associated with the relative URI
"nanonull.gif", then this URI will be expanded to file:///c:/someFolder/nanonull.gif, where
the DTD is in the folder someFolder.
9.6 New from XSLT, XSL-FO or FO File

An SPS design can be based on existing XSLT files that were designed for HTML output or XSLT files with XSL-FO commands for output in PDF or FO files. This means that SPS files do not have to be designed from scratch, but can take an already existing XSLT file as a starting point.

Steps for creating an SPS from XSLT

The steps for creating an SPS file from an XSLT, XSLT-for-FO, or FO file are as follows.

1. Select the command File | New | New from XSLT, XSL-FO or FO File.
2. In the Open dialog that appears, browse for the file you want.
3. In the next dialog you will be prompted to select a schema on which the SPS is to be based. Select the schema you want.
4. An SPS based on the structure and formatting in the XSLT or FO file will be created and displayed in Design View.
5. You can now modify the SPS in the usual way. For example, you could drag in nodes from the Schema Tree, modify the styling and presentation or add additional styling, and use StyleVision functionality such as Auto-Calculations and Conditional Templates.
6. You can save the SPS and use a Working XML File to preview various output formats. Subsequently you can generate stylesheets and output files using the Save Generated Files command.

Example

The example discussed below is located in the (My) Documents folder, C:\Documents and Settings\<username>\My Documents\Altova\StyleVision2022\StyleVisionExamples\Tutorial\NewFromXSLT. This folder contains the files: SimpleExample.xslt, SimpleExample.xsd, and SimpleExample.xml.

The XML file is shown below.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<Data xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="YearlySales.xsd">
  <ChartType>Pie Chart 2D</ChartType>
  <Region id="Americas">
    <Year id="2005">30000</Year>
    <Year id="2006">90000</Year>
    <Year id="2007">120000</Year>
    <Year id="2008">180000</Year>
    <Year id="2009">140000</Year>
    <Year id="2010">100000</Year>
  </Region>
  <Region id="Europe">
    <Year id="2005">50000</Year>
    <Year id="2006">60000</Year>
    <Year id="2007">80000</Year>
    <Year id="2008">100000</Year>
    <Year id="2009">95000</Year>
  </Region>
</Data>
```
The XSLT file is as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:fn="http://www.w3.org/2005/xpath-functions">
  <xsl:output method="xml" version="1.0" encoding="UTF-8" indent="yes"/>
  <xsl:template match="/">
    <html>
      <head>
        <title>Simple Example for New From XSLT</title>
      </head>
      <body>
        <xsl:apply-templates/>
      </body>
    </html>
  </xsl:template>
  <xsl:template match="Data">
    <xsl:for-each select="Region">
      <h1 style="color:red">Region</h1>
      <xsl:apply-templates select="@id"/>
    </h1>
  </xsl:for-each>
</xsl:template>
</xsl:stylesheet>
```

Follow the steps 1 to 4 listed above to obtain the SPS in Design View. The SPS will look something like this:
Notice that the two templates in the XSLT have been created in the SPS. Now switch to the HTML Preview (screenshot below), and notice that the \texttt{h1} element's styling (\texttt{color:red}) has been also passed to the SPS.

In Design View select the \texttt{h1} element and change its color to black (in the Styles sidebar, in the \texttt{Color} group of properties). Then, from the Schema Tree, drag the \texttt{Year} element and create it as a table at the location shown in the screenshot below. Reverse the contents of the two columns so that the Year ID is in the first column.
You can make additional changes in the content, structure, and presentation properties of the document, then preview the output and save files using the `Save Generated Files` command.
9.7 User-Defined XPath Functions

The SPS designer can define customized XPath 2.0/3.0 functions. A user-defined XPath function can be reused in any design component that accepts an XPath expression, for example, in Auto-Calculations, conditions, and combo boxes.

Defining and editing user-defined XPath functions

User-defined XPath functions are created (and subsequently accessed for editing) in either the Schema Tree sidebar or the Design Tree sidebar (see screenshot below). All the user-defined XPath functions in an SPS are listed under the XPath Functions item in both the Schema Tree and Design Tree sidebars and can be accessed via either sidebar.

To create a user-defined XPath function, click the icon of the XPath Functions item. This pops up the XPath Functions dialog (screenshot below). If you wish to edit a function that has already been created, double-click its entry in the list of XPath functions. The XPath Functions dialog (screenshot below) will appear and the function definition can be edited.
After a user-defined XPath function is created, it is available for use anywhere in the design.

**Namespace of user-defined XPath functions**

User-defined XPath functions are created in the namespace: `http://www.altova.com/StyleVision/user-xpath-functions`. This namespace is bound to the prefix `sps:`, so user-defined XPath functions must be called using this namespace prefix. For example, `sps:MyFunction()`.

**Enabling and disabling user-defined XPath functions**

Each user-defined XPath function can be enabled or disabled by, respectively, checking or unchecking the check box to the left of the function's entry in the list of user-defined XPath functions (see screenshot below).
This feature is useful if two functions have the same name. Such a situation could arise, for example, when an imported SPS module contains a function having the same name.

**Calling a user-defined XPath function**

A user-defined XPath function can be called in an XPath expression at any location in the design. For example, the user-defined XPath function `sps:MyFunction` defined above can be called, for example, with the following XPath expression in an Auto-Calculation:

```
sps:MyFunction()/@name.
```

This XPath expression would be evaluated as follows:

1. The `sps:MyFunction()` function is evaluated. Let's say the function is defined as follows: `$XML/Trades/Stock[@name=$XML/Trades/Selection/Stock]`. When the function is evaluated it returns the `/Trades/Stock` element that has a `name` attribute with a value that matches the content of the `/Trades/Selection/Stock` element.
2. The result of Step 1 is returned to the XPath expression in the function call. Now the value of the `name` attribute of this `/Trades/Stock` element is returned as the value of the Auto-Calculation.

**Deleting a function**

To delete a function, select it in the XPath Functions list in the Schema Tree or Design Tree sidebar and then click the **Remove Item** icon in the toolbar of the sidebar. Alternatively, you can right-click the XPath function and select **Remove Item** from the context menu.

### 9.7.1 Defining an XPath Function

A user-defined XPath function requires: (i) a name (a text string), and (ii) a definition (an XPath expression).
Additionally, you can specify one or more parameters for the function. A user-defined XPath function can also have an optional return type (specified by selecting a type from the dropdown list of the Return Type combo box). A return type is useful if you wish to check that the datatype of the returned value conforms to the selected datatype. Note that the return value is not converted to the selected datatype. If there is a type mismatch, an error is returned. If no return type is specified, no datatype check is carried out.

After a user-defined XPath function is created, it is available for use anywhere in the design. In the XSLT stylesheet, it is created as an xsl:function element that is a child of the xsl:stylesheet element, as shown in the listing below.

```xml
<xsl:stylesheet>
  ...
  <xsl:function name="sps:Stock">
    <xsl:sequence select="$XML/Trades/Stock[@name=$XML/Trades/Selection/Stock]"/>
  </xsl:function>
  <xsl:function name="sps:Average" as="xs:decimal">
    <xsl:param name="a" as="xs:integer"/>
    <xsl:param name="b" as="xs:integer"/>
    <xsl:param name="c" as="xs:integer"/>
    <xsl:sequence select="avg( ($a, $b, $c) )"/>
  </xsl:function>
</xsl:stylesheet>
```

The `sps:Stock` function shown in the screenshot below and listed above returns the `/Trades/Stock` element that has a `name` attribute with a value that matches the content of the `/Trades/Selection/Stock` element. The `sps:Average` function listed above returns the average of three input parameter-values. The function definition uses the `avg()` function of XPath 2.0/3.0. The return datatype is specified to be of the `xs:decimal` type, which is the datatype returned by the `avg()` function when evaluating input values of datatype `xs:integer`. If the return type is specified, then the datatype of the return value is checked to see if it conforms with the specified type. If it doesn't, an error is returned.
Defining the function

To define a function, click the icon of the XPath Functions item in the Schema Tree or Design Tree. This pops up the XPath Functions dialog (screenshot above). If you wish to edit a function that has already been created, double-click its entry in the list of XPath functions. Then enter a name for the function and a definition in the Function Body pane. Parameter definitions can be entered if required (see the next two sections, Parameters and Sequences and Parameters and Nodes, for details). A return type for the function can also be specified (see above).

The most important point to bear in mind when writing the XPath expression that defines XPath function is that there is no context node for the XPath expression. If the XPath expression must locate a node then the context node for the expression can be provided in one of the following ways:

1. The XPath expression starts with the document root. The document root is specified in the first location step of the XPath expression as $XML. For example, the XPath expression $XML/Trades/Stock[1] locates the first Stock child element of the /Trades element. The variable $XML (which locates the document root of the main schema) is defined globally by StyleVision in all SPS designs.
2. The context node can be passed as a parameter. See the section Parameters and Nodes below for an explanation.

In the following cases, errors are returned:

- If a parameter is defined but is not used in the body of the definition.
If the datatype of the value returned by the function does not match the return type defined for the function.

If any function in the SPS contains an error, an XSLT error is generated for the whole design, even if the function containing the error is not called. Note, however, that a function can be disabled by unchecking its check box in the list of user-defined XPath functions. When disabled in the design, the function is not included in the XSLT document generated from the design. In this way, an XPath expression containing an error can be excluded from the XSLT and no XSLT error will be generated.

### 9.7.2 Reusing Functions to Locate Nodes

In the previous section we saw how an XPath function can be built to locate a node. The `sps:Stock` function which is defined as shown in the screenshot below returns the `/Trades/Stock` element that has a name attribute with a value that matches the content of the `/Trades/Selection/Stock` element.

We could modularize the location steps of the XPath expression

$\text{XML/Trades/Stock[@name=$\text{XML/Trades/Selection/Stock]}$ into separate XPath functions. For example as follows:

- **The function** `sps:stocks()`, with the definition: $\text{XML/Trades/Stock}$
- **The function** `sps:SelectedStock()`, with the definition: $\text{XML/Trades/Selection/Stock}$
The whole XPath expression can then be written in another XPath expression as:

```
sps:Stocks()[@name=sps:SelectedStock()]
```

When XPath functions are created in this way to locate a node or nodeset, these functions can be re-used in other XPath expressions across the SPS design, thus considerably simplifying the writing of complex XPath expressions.

### 9.7.3 Parameters in XPath Functions

A user-defined XPath function can be assigned any number of parameters. The function's parameters are defined in the **Parameters** pane of the XPath Functions dialog (see screenshot below). These parameters can then be used in the definition of the user-defined XPath function (in the **Function Body** pane).

**User-defined XPath function mechanism**

The steps below explain how an XPath function works.

1. In a function call (for example, in an Auto-Calculation), the number of arguments in the function call must match the number of parameters defined for the user-defined function (as defined in the **Parameters** pane of the user-defined function; see screenshot below). Additionally, the number of items submitted by each argument (in the function call) must match the **Occurrence** definition of the corresponding parameter. If a datatype restriction has been specified for a parameter (in the **Type** column of the **Parameters** pane), the value/s submitted by the argument must match this datatype.

2. The arguments passed to the function's parameters are then used in the XPath function (as defined in the **Function Body** pane; see screenshot below). The result obtained by evaluating the XPath expression is then checked against the optional **Return Type** definition (see screenshot below). If the datatype is as expected, the result is used in the XPath expression from which the function was called.

**Order of parameters**

The order of the user-defined function's parameters is important because, when the function is called, the arguments submitted in the function call will be assigned to the parameters according to the order in which they are defined in the **Parameters** pane (see screenshot below).
So if the `sps:Stock` user-defined XPath function is defined as in the screenshot above and if it is called with the following XPath expression:

```
<sps:Stock($XML, Node1, Node2)
```

then these three arguments—$XML, Node1, Node2—will be assigned, in that order, respectively, to the parameters $ContextStock, $Selection, and $StockInfo.

Note that each argument in the function call is separated from the next by a comma. So, each argument, as delimited by the commas in the function call, will be passed to the corresponding parameter (as ordered in the Parameters pane; see screenshot above).

The order of parameters in the Parameters pane can be controlled with the Append, Insert, and Delete icons of the Parameters pane.

**Datatype of parameters**

Optionally, the datatypes of parameters of the user-defined function can be defined. If a datatype is specified, then the datatype of the incoming argument will be checked against the parameter's datatype, and an error will be returned if the types do not match. This feature enables the input data (from the function call's arguments) to be checked.
Occurrence

Each parameter of the user-defined X Path function can be considered to be a sequence. The Occurrence property of a parameter specifies how many items must be submitted for that parameter by the corresponding argument of the function-call.

In both function definitions and in function calls, commas are used to separate one parameter or argument from another as well as to separate items within a sequence. It is important, therefore, to note the context in which a comma is used: to separate parameters/arguments or to separate sequence items.

- In parameters/arguments, if required, parentheses are used to delimit sequences—in the function definition (parameters) or in the function call (arguments).
- In sequences, parentheses are ignored.

In this context, the following examples and points should be noted:

- **Parentheses in parameters/arguments:** Several X Path functions take a single sequence as an argument, for example, the `avg()` and `count()` functions. If this sequence is enumerated using comma separators or range operators, the sequence must be enclosed in parentheses to unambiguously show that it is a single sequence—and not multiple comma-separated sequences. For example, in the function `avg((count($a), $b, $c))`, the XPath 2.0 `avg()` function takes the single sequence `(count($a), $b, $c)` as its argument. Since the items of the sequence are enumerated, making up a sequence of three items, the sequence must be enclosed in parentheses and submitted as a single argument to the `avg()` function: `avg((count($a), $b, $c))`. Without the inner pair of parentheses, the definition of the `avg()` function would have three parameters, and that would be an error (since the `avg()` function expects one argument consisting of a single sequence).

- **No parentheses in parameters/arguments:** Similarly, the `count()` function also takes a single sequence as its one-parameter argument. However, since in our example `count($a)` the single sequence is not a comma-separated enumerated list, but is fetched instead by the variable/parameter `$a`, the argument does not need to be enclosed by an inner set of parentheses: So the expression `count($a)` is correct.

- **Parentheses and commas in function calls:** In a function call, parentheses must be correctly used so that each argument corresponds to a parameter (as defined in the Parameters pane of the XPath Functions dialog). For example, if a user-defined XPath function named `MyAverage()` is defined with the XPath 2.0 expression: `avg((count($a), $b, $c))`, then the following function call would be valid: `MyAverage((1,2,3),4,5)`. The values corresponding to the three parameters `$a`, `$b`, and `$c` would be, respectively, the sequence `(1,2,3)`, the singleton-sequence `4`, and the singleton sequence `5`. Singleton-sequences can, optionally, be enclosed in parentheses. The value returned by `MyAverage()` in this case would be `4`.

9.7.3.1 Parameters and Sequences

It is important to note the relationship between parameters and sequences, and how parameters and sequences are used in XPath expressions. We use the following definitions to make these relationships clearer:

- A **sequence** consists of items that are either atomic values or nodes. A comma can be used to construct a sequence, by placing it between the items of a sequence and so allowing the sequence to be built.
An XPath function can be defined to take **parameters**. For example, in the XPath 2.0 expression `count($a)`, the part within the function's parentheses is the parameter of the function and it must be a sequence of items.

An **argument** consists of one or more items in a function call. For example, the function `count(//Person)` has one argument: `//Person`. This argument is valid because it returns one sequence of nodes, which corresponds to the signature of the `count()` function. (The signature of a function specifies the number of parameters and the expected datatype of each parameter. It also specifies what the function will return and the datatype of the returned object).

The function `substring('StyleVisionExamples', 6, 6)`—which returns the string Vision—has three arguments. This is valid according to the signature of the `substring()` function, and is specified by it. When a function call has multiple arguments, these are separated by commas.

### Parentheses as sequence delimiters

A key point to note when constructing XPath expressions is this: Parentheses are used to delimit sequences that use the comma separator or range operator to enumerate sequences. As a result, each parentheses-delimited sequence is read as one parameter (in function definitions) or one argument (in function calls).

Parentheses are not necessary around a path (or locator) expression (example of a path expression: `//Person/@salary`), because a path expression can be read unambiguously as one parameter or one argument. It is in fact a one-sequence parameter/argument.

Here are some examples to illustrate the points made above:

- `avg((10, 20, 30))` The `avg` function of XPath 2.0 takes one sequence of items as its single argument. Since this sequence is a comma-separated enumeration, the inner pair of parentheses are necessary in order to delimit the mandatory single sequence. Without the inner parentheses, the argument would have three arguments and therefore be invalid. (The outer pair of parentheses are the parentheses of the function.)
- `avg(//Person/@salary)` This path expression selects the `salary` attribute nodes of all `Person` elements and returns their attribute-values as the sequence to be evaluated (that is, to be averaged). No parentheses are required because the sequence is not enumerated before the argument is read. The argument is the single path (or locator) expression. The path expression is evaluated and the returned values are submitted to the function as the items of a sequence.
- `count((10 to 34))` This is an enumeration via the range operator. The range operator 'to' generates a sequence of comma-separated items (the integers from 10 to 34) before the argument is read. As a result, the `count()` function has within its argument a comma-separated sequence of 25 items. To read this as one single-sequence argument, delimiting parentheses are required. Without such parentheses, the function call would have 25 arguments instead of one—thus invalidating the function call, since the `count()` function must, according to its signature, have only one argument.
- `count((10 to 34, 37))` The inner parentheses indicate that everything within them is the one argument of the function call—a single sequence consisting of 26 items.
- `count(//Person)` No sequence-delimiter parentheses are required around the single argument. The argument is a path expression that collects the `//Person` nodes in the XML document and returns these nodes as the items of the sequence to be counted.

### Using XPath parameters in XPath functions

When parameters are used in the definition of a user-defined XPath function, ensure (i) that the number of arguments in a function call to this user-defined XPath function is correct, and (ii) that the arguments evaluate correctly to the expected type and occurrence.
The screenshot above defines three parameters (in the Parameters pane) and then uses these parameters (in the Function Body pane) to define an XPath function.

Each parameter that is defined in the Parameters can be considered to be a single sequence. The number of items allowed within the single sequence is specified with the Occurrence property. In the definition above, each parameter is defined (in its Occurrence property) as a singleton-sequence (that is, a sequence of exactly one item). Each argument of the function call must therefore be a sequence of one item. The Type property specifies the datatype of the items of the sequence.

In the definition of our example XPath function (in the Function Body pane), each parameter provides one item of the sequence that is to be averaged. Since the XPath parameters together constitute a sequence, the sequence must be enclosed in parentheses to ensure that the entire sequence is read as the one parameter of the avg() function. If, at runtime, any of the arguments in the function call (corresponding to the three parameters) is not a singleton-sequence, an error is returned.

Given below are examples of XPath parameter usage in calls to the XPath function ThreeAverage() shown in the screenshot above. In Design View, you can insert an Auto-Calculation and give it the XPath expressions listed below to see the results. The function has been defined to take a sequence of three integers and average them.

- `sps:ThreeAverage(10,20,30)` returns 20. There are three valid arguments in the function call, corresponding to the three XPath parameters.
• \( \text{sps:ThreeAverage( (10),(20),(30) )} \) returns 20. There are three valid input arguments, corresponding to the three XPath parameters. Each input argument has been enclosed with parentheses (which are redundant, since each sequence is a singleton-sequence; however, this redundancy is not an error).

• \( \text{sps:ThreeAverage( (10),20,30 )} \) returns 20. There are three valid input arguments, corresponding to the three XPath parameters. The first argument has been enclosed with parentheses (redundant, but not an error).

• \( \text{sps:ThreeAverage( (10,20),(30),(40) )} \) returns an error because the first argument is not valid. It is not a singleton-sequence, as required by the property definition of the first \$a\) parameter (‘Exactly one’).

• \( \text{sps:ThreeAverage( (10,20,30) )} \) returns an error because only one input argument is submitted, inside the parentheses. Additionally, the argument is invalid because the sequence is not a singleton-sequence.

If the \textit{Occurrence} property of a parameter is set to \textit{At-least-one} (\textit{as in the definition shown in the screenshot below}), then that parameter is defined as a sequence of one-or-more items.

In the definition above, the first parameter has been defined as a sequence of one or more items, the next two parameters as singleton-sequences. The function has been defined to count the number of items submitted by the first parameter, add the result to the sum of the two integers submitted by the other two parameters, and then divide the result by three to obtain the average. Notice the following:
- The sequence that is the parameter of the `avg()` function is enclosed in parentheses. This is to specify that the `avg()` function takes a single sequence consisting of three items as its parameter. The single sequence consists of three integers: the first submitted by the `count()` function; the second and third are the two parameters \( b \) and \( c \).

- The argument of the `count()` function is not enclosed in sequence-delimiter parentheses because the argument is unambiguously a single sequence.

Here are examples of parameter usage in calls to the XPath function `Average()` shown in the screenshot above.

- \( \text{sps:Average}((1,2),3,4) \) returns 3. There are three valid input arguments, corresponding to the three parameters. The first argument is enclosed in parentheses to delimit it. When the `count()` function operates on it, the function will return the value 2, which will be the first item of the sequence submitted to the `avg()` function.

- \( \text{sps:Average}(4,4,4) \) returns 3. There are three valid input arguments. The first argument is allowed to be a sequence of one item (see the `Occurrence` property of its corresponding parameter). No parentheses are required to indicate separate arguments.

Additional points of interest

The following additional points should be noted:

- If an parameter is defined as having `At-least-one` occurrence, then a function such as `MyAverage()` could be defined with an XPath expression such as `avg(($a))`. This function would accept an argument that is a single sequence of one-or-more items. The function could be called as follows: \( \text{sps:MyAverage}((2,3,4)) \), and it would return the value 3. The input argument must be enclosed in parentheses to ensure that the input is being read as a single sequence rather than as three singleton-sequences (which would be the case if there were no enclosing parentheses).

- If an XPath parameter \( $a \) is defined as having `None-or-one` occurrence, then a function such as `MyAverage()` could be defined with an XPath expression such as `avg(($a, $b, $c))`. This function would accept as its argument three sequences, with the possibility of the first sequence being empty. If the first sequence is to be empty, then an empty sequence must be explicitly submitted as the first input argument. Otherwise an error is reported. If the function were called as follows: \( \text{sps:MyAverage}(30,20,10) \), it would return the value 20. The function could also be called with: \( \text{sps:MyAverage}(),20,10 \), returning 15 (note that the empty sequence does `count`: as an input value of empty; for a return value of 10, the first item would have to be 0). The following, however, would generate an error: \( \text{sps:MyAverage}(20,10) \), because no first empty sequence is supplied and, as a consequence, the third input argument is considered to be absent.

Complex examples

Besides providing the benefit of being able to re-use an XPath expression, user-defined XPath functions also enable the construction of complex customized XPath functions that are not available in the XPath 2.0 function set. For example, a factorial function could easily be constructed with an XPath expression that takes a singleton-sequence as its single parameter. If the parameter \( $num \) is the number to be factorialized, then the XPath expression to create the function would be:

\[
\text{if ($num < 2) then 1 else $num * sps:Factorial($num - 1)}
\]

If this function were called \( \text{Factorial()} \), then the factorial of, say 6, could be obtained by calling the function with: \( \text{sps:Factorial}(6) \).
9.7.3.2 Parameters and Nodes

When using parameters in XPath functions that locate nodes, it is important to bear in mind that the function has no context node, no matter from where in the design it is called. The context node can be supplied either in the XPath expression that is used to define the function (that is, in the Function Body pane) or in the XPath expression that is used to call the XPath function. In the latter case, the context can be supplied via arguments in the function call.

Consider the user-defined XPath function `Stock()`, which is defined with three parameters as shown in the screenshot below.

![XPath Functions](image)

The definition in the function body is `$ContextStock[@name=$Selection]/$StockInfo`, which uses the three parameters but contains no context node information. The context node information can be supplied in the XPath expression that calls the function, for example in this way:

```
sps:Stock( $XML/Trades/Stock, $XML/Trades/Selection/Stock, @name )
```

The function call has three arguments, the value of each of which supplies either context or node-locator information. Alternatively, the following XPath expressions can be used as the function-call and give the same results:

```
sps:Stock( /Trades/Stock, /Trades/Selection/Stock, @name )
```
sps:Stock( /Trades/Stock, //Selection/Stock, @name )

The $XML variable, which returns the document root, can be left out in function calls from design components because in the XPath expressions of design components the context node is known.

Notice that in the function-call listed above there are three input arguments corresponding respectively to the three parameters defined for the user-defined XPath function:

- $ContextStock = $XML/Trades/Stock (the /Trades/Stock element)
- $Selection = $XML/Trades/Selection/Stock (the /Trades/Selection/Stock element)
- $StockInfo = @name

The XPath expression in the function definition is:

$ContextStock[@name=$Selection]/$StockInfo

When the input arguments are substituted, the XPath expression in the function definition becomes:

$XML/Trades/Stock[@name=$XML/Trades/Selection/Stock]/@name

It is important to note that it is the nodesets that are passed to the function, not the text strings.

It is in this way that the context node and location steps are passed to the function via parameters. The function can then be evaluated to locate and return the required nodes.
9.8 Working with Dates

If the source document contains nodes that take date values, using the `xs:date` or `xs:dateTime` datatypes in the underlying XML Schema makes available the powerful date and time manipulation features of XPath 2.0/3.0 (see examples below). StyleVision supports the `xs:date` or `xs:dateTime` datatypes by providing:

1. A graphical date picker to help Authentic View users enter dates in the correct lexical format of the datatype for that node. The date picker, since it is intended for data input, is available only in Authentic View.
2. A wide range of date formatting possibilities via the Input Formatting feature.

These StyleVision features are described in the sub-sections of this section: Using the Date-Picker and Formatting Dates. In the rest of the introduction to this section, we show how XPath 2.0 can be used to make calculations that involve dates.

Note: Date and time data cannot be manipulated with XPath 1.0. However, with XPath 1.0 you can still use the Date Picker to maintain data integrity and use Input Formatting to provide date formatting.

Date calculations with XPath 2.0

Data involving dates can be manipulated with XPath 2.0 expressions in Auto-Calculations. Given below are a few examples of what can be achieved with XPath 2.0 expressions.

- The XPath 2.0 functions `current-date()` and `current-dateTime()` can be used to obtain the current date and date-time, respectively.
- Dates can be subtracted. For example: `current-date() - DueDate` would return an `xdt:dayTimeDuration` value; for example, something like `P24D`, which indicates a positive difference of 24 days.
- Time units can be extracted from durations using XPath 2.0 functions. For example: `days-from-duration(xdt:dayTimeDuration('P24D'))` would return the integer 24.

Here is an XPath 2.0 expression in an Auto-Calculation. It calculates a 4% annual interest on an overdue amount on a per-day basis and returns the sum of the principal amount and the accumulated interest:

```xml
if (current-date() gt DueDate)
then (round-half-to-even(InvoiceAmount +
   (InvoiceAmount*0.04 div 360 *
    days-from-duration((current-date() - DueDate)), 2))
else InvoiceAmount
```

Such a calculation would be possible with XPath 2.0 only if the `DueDate` element were defined to be of a date type such as `xs:date` and the content of the element is entered in its lexically correct form, that is, `YYYY-MM-DD[±HH:MM]`, where the timezone component (prefixed by ±) is optional. Using the Date Picker ensures that the date is entered in the correct lexical form.
9.8.1 Using the Date-Picker

The Date Picker (screenshot below) is a graphical calendar in Authentic View for entering dates in the correct lexical format for nodes of `xs:date` and `xs:dateTime` datatype.

![Date Picker Calendar](image)

The lexical format is entered appropriately according to the datatype.

- For `xs:date`, the format of the entry is `YYYY-MM-DD[±HH:MM]`, where the timezone component (prefixed by ±) is optional according to the XML Schema specification. A value for the timezone component can be selected in the Date Picker.
- For `xs:dateTime`, the format of the entry is `YYYY-MM-DDTHH:MM:SS[±HH:MM]`. The timezone component (prefixed by ±) is optional according to the XML Schema specification. A value for the timezone component can be selected by the user.

Inserting and deleting a Date Picker in the design

A Date Picker can be inserted in the SPS design: (i) for any node that is of datatype `xs:date` or `xs:dateTime`, and (ii) when that node is created either as contents or as an input field. A Date Picker can be inserted in one of two ways:

- By default when a node of datatype `xs:date` or `xs:dateTime` is created in the SPS. To set this default, toggle the Auto-Add Date Picker feature ON. Do this by selecting/de-selecting the command `Authentic | Auto-add Date Picker`. When the Auto-Addition of the Date Picker is switched on, the Date Picker is inserted when any element of datatype `xs:date` or `xs:dateTime` is created as either contents or an input field, or changed to either of these two components.
- By clicking the menu command `Insert | Date Picker` when the cursor is at the desired location within the `xs:date` or `xs:dateTime` node in the SPS. This command can be accessed via the Insert menu, or via the context menu when the cursor is within the `xs:date` or `xs:dateTime` node.

When the Date Picker is inserted, the Date Picker icon appears at that location. To delete a Date Picker, use the Delete or Backspace buttons.

Using the Date Picker in Authentic View

In Authentic View, the Date Picker appears as an icon (screenshot below).
To modify the date, click the icon. This pops up the Date Picker (screenshot below). To enter a new date, select the required date in the Date Picker. The date will be entered in the correct lexical format according to that node's datatype.

To enter a timezone, click the Timezone button, which is set to a default of No Timezone. The timezone will be entered in the lexical format appropriate to the node's datatype (screenshot below).

9.8.2 Formatting Dates

A date in an XML document is saved in the format specific to the datatype of its node. For example, the value of an xs:date node will have the format YYYY-MM-DD[±HH:MM], while the value of an xs:dateTime node will
have the format `YYYY-MM-DDTHH:MM:SS±HH:MM`. These formats are said to be the lexical representations of that data. By default, it is the lexical representation of the data that is displayed in Authentic View and the output. However, in the SPS, the Value Formatting feature can be used to display dates in alternative formats in Authentic View and, in some cases, optionally in the output.

Value Formatting for dates can be used to define custom formats for nodes and Auto-Calculations of the following datatypes:

- `xs:date`
- `xs:dateTime`
- `xs:duration`
- `xs:gYear`
- `xs:gYearMonth`
- `xs:gMonth`
- `xs:gMonthDay`
- `xs:gDay`

**Using Value Formatting to format date nodes**

To format dates alternatively to the lexical format of the date node, do the following:

1. Select the contents placeholder or input field of the node. Note that value formatting can only be applied to nodes created as contents or an input field.
2. In the Properties sidebar, select the `autocalc` item, and then the `AutoCalc` group of properties. Now click the Edit button of the `Value Formatting` property. This displays the Value Formatting dialog (screenshot below).

![Value Formatting dialog](image)
By default, the Unformatted radio button (the standard lexical format for the node's datatype) is selected.

3. To define an alternative format, select the Format radio button.
4. You can now select a predefined date format from the drop-down list of the combo box (screenshot below), or define your own format in the input field of the combo box. See Value Formatting Syntax for details about the syntax to use when defining your own format.

Using Value Formatting to format Auto-Calculations

When Auto-Calculations evaluate to a value that is a lexical date format, Value Formatting can be used to format the display of the result. Do this as follows:

1. Select the Auto-Calculation in the design.
2. In the Properties sidebar, select the content item, and then the AutoCalc group of properties. Now click the Edit button of the Value Formatting property. This pops up the Value Formatting dialog (screenshot below).

   By default, the Unformatted radio button is selected.
3. To define an alternative format, select the Format radio button.
4. In the Options for XML Schema value pane, in the Datatype combo box, select the date datatype to which the Auto-Calculation will evaluate. In the Format combo box, you can then select a predefined date format from the drop-down list (available options depend on the selected datatype), or define your own format in the input field of the combo box. See Value Formatting Syntax for details about the syntax to use when defining your own format.
Applying Value Formatting to the output
The Value Formatting that you define applies to Authentic View. Additionally, some Value Formatting definitions—not all—can also be applied to HTML, Text, and RTF output. To do this, check the Apply Same Format to XSLT Output check box. If this option is not checked or if it is not available, then only Authentic View will display the Value Formatting; the output will display the value in its lexical format (for nodes) or, in the case of Auto-Calculations, in the format to which the Auto-Calculation evaluates.
9.9 Using Scripts

In StyleVision, you can define JavaScript functions for each SPS in a JavaScript editor (available as a tab in the Design View). The function definitions created in this way are stored in the header of the HTML document and can be called from within the body of the HTML document. Such functions are useful when:

- You wish to achieve a complex result using multiple script statements. In this case it is convenient to write all the required scripts, as separate functions, in one location (the header) and refer to the functions subsequently in the design document.
- You wish to use a particular script at multiple locations in the design document.

How to define functions in the JavaScript Editor is described in the sub-section Defining JavaScript Functions.

In the GUI, all JavaScript functions which are defined for a given SPS in the JavaScript Editor are listed in the Design Tree window under the Scripts entry (screenshot below). The screenshot below indicates that four JavaScript functions, Average, ImageOut, ImageOver, and Buttons, are currently defined in the active SPS.

The functions defined in the JavaScript Editor are available as event handler calls within the GUI. When a component in the design document is selected, any of the defined functions can be assigned to an event handler property in the Event property group in the Properties sidebar (screenshot below). How to assign a JavaScript function to an event handler is described in the section Assigning Function to Event Handlers.
9.9.1 Defining JavaScript Functions

To define JavaScript functions, do the following:

1. In Design View, switch to the JavaScript Editor by clicking the Design View tab and selecting JavaScript (screenshot below).

2. In the JavaScript Editor, type in the function definitions (see screenshot below).
The screenshot above shows the definitions of two JavaScript functions: `DisplayTime` and `ClearStatus`. These have been described for the active SPS. They will be entered in the header of the HTML file as follows:

```html
<script language="javascript">
<!--
  function DisplayTime()
  {
    now = new Date();
    hours = now.getHours();
    mins = now.getMinutes();
    secs = now.getSeconds();
    result = hours + ":" + mins + ":" + secs;
    alert(result);
  }

  function ClearStatus()
  {
    window.status="";
  }
-->

function ClearStatus()
{
  window.status="";
}

</script>
```

These functions can now be called from anywhere in the HTML document. In StyleVision, all the defined functions are available as options that can be assigned to an event handler property in the `Event` property group in the Properties sidebar. See Assigning Function to Event Handlers for details.

### 9.9.2 Assigning Functions as Event Handlers

In the StyleVision GUI, you can assign JavaScript functions as event handlers for events that occur on the HTML renditions of SPS components. These event handlers will be used in the HTML output. The event handler for an available event—such as `onclick`—is set by assigning a global function as the event handler. In the Properties sidebar, global functions defined in the JavaScript Editor are available as event handlers in the dropdown boxes of each event in the `Events` property group for the selected component (screenshot below).
To assign a function to an event handler, do the following:

1. Select the component in the SPS for which the event handler is to be defined. The component can be a node or content of any kind, dynamic or static.
2. In the Properties sidebar select the Event group. This results in the available events being displayed in the Attribute column (screenshot above).
3. In the Value column of the required event, click the down arrow of the combo box. This drops down a list of all the functions defined in the JavaScript Editor.
4. From the dropdown list, select the required function as the event handler for that event.

In the HTML output, when that event is triggered on the component for which the event handler is defined, the JavaScript function is executed.

9.9.3 External JavaScript Files

An SPS can access external JavaScript files in two ways:

1. **By creating a User-Defined Element or User-Defined XML Block**. These design objects can contain a SCRIPT element that accesses the external JavaScript file. Note that location of the User-Defined Element or User-Defined XML Block is within the BODY element of the design (and therefore within the BODY element of the HTML output, not within the HEAD element).
2. **By adding a script in the Javascript Editor** that accesses the external file. A script that is added in this way will be located in the HEAD element of the HTML output.

User-Defined Elements and User-Defined XML Blocks

External JavaScript files can be accessed by means of User-Defined Elements and User-Defined XML Blocks. Using these mechanisms, a SCRIPT element that accesses the external JavaScript file can be inserted at any location within the BODY element of the output HTML document.

A User-Defined Element could be inserted as follows:
1. Place the cursor at the location in the design where the `<script>` element that accesses the JavaScript file is to be inserted.
2. From the Insert menu or context menu, select the command for inserting a User-Defined Element.

3. In the dialog that pops up (see screenshot above), enter the `<script>` element as shown above, giving the URL of the JavaScript file as the value of the `src` attribute of the `<script>` element: for example, `script type="text/javascript" src="file:///c:/Users/mam/Desktop/test.js"`

4. Click OK to finish.

You can also use a User-Defined XML Block to achieve the same result. To do this use the same procedure as described above for User-Defined Elements, with the only differences being (i) that a User-Defined XML Block is inserted instead of a User-Defined Element, and (ii) that the `<script>` element is inserted as a complete XML block, that is, with start and end tags.

JavaScript Editor

The JavaScript Editor enables you to insert an external script in the `<head>` element of the HTML output. Do this by entering, in the JavaScript Editor, the following script fragment, outside any other function definitions that you create.

```javascript
var script = document.createElement('script');
script.type = 'text/javascript';
script.src = 'file:///c:/Users/Desktop/test.js';
var head = document.getElementsByTagName('head')[0];
head.appendChild(script);
```

The external JavaScript file that is located by the URL in `script.src` is accessed from within the `<head>` element of the output HTML document.
9.10 HTML Import

In StyleVision you can import an HTML file and create the following documents based on it:

- An SPS document based on the design and structure of the imported HTML file.
- An XML Schema, in which HTML document components are created as schema elements or attributes. Optionally, additional elements and attributes that are not related to the HTML document can be created in the user-defined schema.
- An XML document with: (i) a structure based on the XML Schema you have created, and (ii) content from the HTML file.
- XSLT stylesheets based on the design in Design View.

HTML-to-XML: step-by-step

The HTML Import mechanism, which enables the creation of XML files based on the imported HTML file, consists of the following steps:

1. Creating New SPS via HTML Import

   When an HTML file is imported into StyleVision, a new SPS document is created. The HTML document is displayed in Design View with HTML markup tags. A user-defined XML Schema with a document element called `UserRoot` is created in the Schema Tree window. This is the schema on which the SPS is based. The HTML document content and markup that is displayed in Design View at this point is included in the SPS as static content.

2. Creating the Schema and SPS Design

   Create the schema by (i) dragging components from the HTML document to the required location in the schema tree (in the Schema Tree window); and, optionally, (ii) adding your own nodes to the schema tree. In the Design Window, HTML content that has been used to build nodes in the schema tree will now be displayed with schema node tags around the content. HTML content that has no corresponding schema node will continue to be displayed without schema node tags.

3. In the Design Document, assign formatting to nodes, refine processing rules, or add static content as required. These modifications will have an effect only on the SPS and the generated XSLT. It will not have an effect on either the generated schema or XML file.

4. After you have completed the schema tree and the design of the SPS, you can generate and save the following:
   - an XML Schema corresponding to the schema tree you have created;
   - an XML data file with a structure based on the schema and content for schema nodes that are created with the (content) placeholder in the SPS design;
   - a SPS (.sps file) and/or XSLT stylesheet based on your design.

9.10.1 Creating New SPS via HTML Import

To create a new SPS file from an HTML document, do the following:

1. Select the menu command File | New | New from HTML File.
2. In the Open dialog that pops up, browse for the HTML file you wish to import. Select it and click Open.
3. You will be asked whether relative paths should be converted to absolute paths. Make your choice by clicking either Yes or No.
A new SPS document is created. The document is displayed in Design View and is marked up with the predefined HTML formats available in StyleVision (screenshot below).

### A Sample Article

This is a simple article, marked up in HTML. It is the example HTML document used to demonstrate how STYLEVISION can generate schema files, XML files, and stylesheets from an HTML document. It contains headlines, paragraphs, two lists, a table, an image, a hyperlink, horizontal rules, and inline italics. A number of these elements have attributes.

It is important to note that the HTML-to-XML conversion involves two parallel processes:

- Creation of a schema tree
- Design of a STYLEVISION Power StyleSheet (SPS)

Note that the HTML document is displayed within the main template. There is no global template.

In the Schema Tree sidebar, a user-defined schema is created (screenshot below) with a root element (document element) called **UserRoot**.

---

**SPS structure and design**

The SPS contains a single template—the main template—which is applied to the document node of a temporary internal XML document. This XML document has the structure of the user-defined schema which was created in the Schema Tree window. In Design View, **at this point**, the HTML document components within the main template are included in the SPS as static components. The representation of these HTML components
in Authentic View will be as non-editable, non-XML content. The XSLT stylesheets will contain these HTML components as literal result elements. The schema, at this point, has only the document element Root; consequently, the temporary internal XML document contains only the document element Root with no child node.

When you create HTML selections as elements and attributes in the user-defined schema, you can do this in either of two ways:

1. By converting the selection to an element or attribute. In the design, the node tags are inserted with a (content) placeholder within the tag. In the schema, an element or attribute is created. In the XML document, the selection is converted to the text content of the schema node which is created in the XML document. The contents of the node created in the XML document will be inserted dynamically into the output obtained via the SPS.

2. By surrounding the selection with an element or attribute. In the design, the selection is surrounded by the node tags; no (content) placeholder is inserted. This means that the selection is present in the SPS design as static content. In the schema, an element or attribute is created. In the XML document, the node is created, but is empty. The static text which is within the schema node tags in the design will be output; no dynamic content will be output for this node unless a (content) placeholder for this node is explicitly inserted in the design.

The significance of the (content) placeholder is that it indicates locations in the design where data from the XML document will be displayed (in the output) and can be edited (in Authentic View).

9.10.2 Creating the Schema and SPS Design

The schema is created by dragging selections from Design View into the user-defined schema. You do this one selection at a time. The selection is dropped on a node in the schema tree (relative to which the new node will be created, either as a child or sibling). You select the type of the node to be created (element or attribute) and whether the selection is to be converted to the new node or surrounded by it.

The selection

The selection in Design View can be any of the following:

- A node in the HTML document.
- A text string within a node.
- Adjacent text strings across nodes.
- An image.
- A link.
- A table.
- A list.
- A combination of any of the above.

In this section we explain the process in general for any selection. The special cases of tables and lists are discussed in more detail in the section Creating Tables and Lists as Elements/Attributes.

To make a selection, click an HTML document component or highlight the required text string. If multiple components are to be selected, click and drag over the desired components to highlight the selection. Note that StyleVision extends the selection at the beginning and end of the selection to select higher-level elements till the first and last selected elements belong to the same parent.
The location in the schema tree

On dragging the selection over the desired schema tree node, the mouse pointer will be changed to one of the following symbols.

- Dropping the node when the Create as Sibling symbol \(\downarrow\) appears, creates the selection as a sibling node of the node on which the selection is dropped.
- Dropping the node when the Create as Child symbol \(\rightarrow\) appears, creates the selection as a child node of the node on which the selection is dropped.

You should select the node on which the selection is to be dropped according to whether the selection is to be created as a sibling or child of that node.

Selecting how the node is created

When you drop the selection (see previous section), a context menu pops up (screenshot below) in which you make two choices: (i) whether the node is to be created as an element or attribute; (ii) whether the selection is to be converted to the node or whether the node is to simply surround the selection.

The following points should be noted:

- When a selection is converted to a node (element or attribute), the node tags, together with a contained (content) placeholder, replace the selection in the design. In the design and the output the text content of the selection is removed from the static content. In the output, the text of the selection appears as dynamic content of the node in the XML document.
- If an HTML node is converted to an XML node, the XML node tags are inserted within the HTML node tags.
- When a selection (including HTML node selections) is surrounded by an XML node, the XML node tags are inserted before and after the selection. In the design and the output, the text content of the selection is retained as static text.
- The inserted node tags are inserted with the necessary path (that is, with ancestor node tags that establish a path relative to the containing node). The path will be absolute or relative depending on the context of the node in the design.
- How to create nodes from table and list selections are described in Creating Tables and Lists as Elements/Attributes.
Adding and deleting nodes in the schema
You can add additional nodes (which are not based on an HTML selection) to the user-defined schema. Do this by right-clicking on a node and selecting the required command from the context menu. Alternatively, you can use the toolbar icons of the Schema Tree sidebar.

To delete a node, select the node and then use either the context menu or the toolbar icon. Note, however, that when a node is deleted, some paths in the design could be invalidated.

Modifying the design
You can modify the structure of the design by dragging components around and by inserting static and dynamic components. Styles can also be modified using the various styling capabilities of StyleVision.

9.10.3 Creating Tables and Lists as Elements/Attributes
Tables and lists in the HTML document can be converted to element or attribute nodes in the XML Schema so that they retain the table or list structure in the schema.

Converting a table to elements/attributes
To convert a table to schema nodes, do the following:

1. Select the HTML table by highlighting some text in it.
2. Drag it to the node in the schema tree as a sibling or child of which you want to create it.
3. Drop the node when the Create as Sibling symbol or Create as Child symbol appears.
4. In the context menu that now pops up, select the command Convert selected table/list to elements or Convert selected table/list to attributes according to whether you wish to create the contents of table cells as elements or attributes, respectively.

5. In the Convert Table dialog that pops up, select whether the table created in the SPS should be a static table or dynamic table.
If the **static table** option is selected, then for each cell in the table, a schema node is created. In the design, each node is inserted with the `(content)` placeholder. The data in the table cells is copied to the temporary internal XML document (and to the generated XML document). The **dynamic table** option is available when the structure of all rows in the table are identical. When created in the SPS, the rows of the dynamic table are represented by a single row in the design (because each row has the same structure). The table data will be copied to the XML file. The dynamic table can grow top/down (rows are arranged vertically relative to each other) or left/right (rows become columns and extend from left to right). If you indicate that the first row/column is a header, then (i) a header row containing the column headers as static text is included in the design; and (ii) the schema element/attribute nodes take the header texts as their names. If the first row/column is not indicated as a header, then no header row is included in the design.

6. After you have selected the required option/s, click **Convert** to finish.

### Converting a list to elements/attributes

To convert a list to schema nodes, do the following:

1. Select the HTML list by highlighting some text in it.
2. Drag it to the node in the schema tree as a sibling or child of which you want to create it.
3. Drop the node when the Create as Sibling symbol 👈 or Create as Child symbol 👉 appears.
4. In the context menu that now pops up *(screenshot below)*, select the command **Convert selected table/list to elements** or **Convert selected table/list to attributes** according to whether you wish to create the contents of table cells as elements or attributes, respectively.

<table>
<thead>
<tr>
<th>Convert selection to elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Convert selection to attributes</td>
</tr>
<tr>
<td>Surround selection with element</td>
</tr>
<tr>
<td>Convert selected table/list to elements</td>
</tr>
<tr>
<td>Convert selected table/list to attributes</td>
</tr>
</tbody>
</table>

5. In the Convert List dialog that pops up *(screenshot below)*, select whether the list created in the SPS should be a static list or dynamic list.
If the **static list** option is selected, then for each list item, a schema node is created. In the design, each node is inserted with the text of the HTML list item included as static content of the list item. If the **dynamic list** option is selected, then each list item is represented by a single list item node in the design. In the design, the list item element is inserted with the \((content)\) placeholder.

6. After you have selected the required option, click **Convert** to finish.

### 9.10.4 Generating Output

After completing the SPS, you can generate the following output using the **File | Save Generated Files** command:

- Generated user-defined schema, which is the schema you have created in the Schema Tree sidebar.
- Generated user-defined XML data, which is an XML document based on the schema you have created and containing data imported from the HTML file.
- XSLT stylesheets for HTML, Text, and RTF output.
- HTML, Text, and RTF output.
9.11 ASPX Interface for Web Applications

If an HTML report of DB or XML data for the Internet is to be created with an SPS, then the usual procedure for creating the report with StyleVision would be as follows:

1. If the source data is in a DB, then, with the finished SPS active in StyleVision, generate an XML file from the DB. (If the source data is in an XML file, then this step is not required.)
2. Also from the SPS, generate the XSLT-for-HTML file.
3. Transform the XML file using the generated XSLT-for-HTML file.
4. Place the resulting HTML file on the server.

For a web application, the HTML file could become outdated if the source (DB or XML) data is modified. Updating the HTML file on the Web server with the new data would require: (i) for DB-based data, the regeneration of the XML file, (ii) transforming the new XML file using the XSLT-for-HTML, and (iii) placing the result HTML file on the server.

StyleVision provides a solution to quickly update HTML web pages. This is a feature for automatically generating an ASPX application. All the required ASPX application files (the .aspx file, XSLT file, and the code files) are generated by StyleVision. These files can then be placed on the server together with the source DB file or XML file and the XSLT-for-HTML file. Each time the .aspx file—which is the web interface file—is refreshed, the following happens: (i) for DB-based data, a new XML file is generated from the DB; for XML-based data, this step is not required; (ii) the XML file is transformed using the XSLT-for-HTML file that is on the server; and (iii) the output of the transformation is displayed in the web interface page. In this way, the web interface page will quickly display the latest and up-to-date DB or XML data.

Generating files for an ASPX solution

After creating the DB-based SPS or XML-based SPS, do the following to create an ASPX solution:

1. With the SPS active in StyleVision, generate the ASPX files by clicking the command, File | Web Design | Generate ASPX Web Application. The ASPX application files will be created in the folder location you specify. The folder in which you generate the ASPX application will contain the following files among others:
   - Readme.doc
   - SPSFilename.aspx
   - SPSFilename.xslt
   - SPSFilename.cs

2. Place the DB file or XML file on the server, in the same folder as the ASPX application. The .aspx file is the entry point of the application. Refreshing this file will cause the DB or XML data that is displayed in it to be updated.

Note: You will need to have Altova's RaptorXML application installed in order for the XSLT transformation to run correctly. If you have problems with the transformation, see the ReadMe.doc file for details about setting up RaptorXML.

How it works

The folder in which you generate the ASPX application will contain the following files among others:
SPSFilename.aspx is the URL of the output document. SPSFilename.aspx executes C# code stored in the file SPSFilename.cs. This C# code reads the XML content (from files or a database as required) and passes it to RaptorXML, together with the SPSFilename.xslt file. (RaptorXML contains Altova’s XSLT transformation engine. It can be downloaded from the Altova website.) RaptorXML performs a transformation of the XML content, using the provided XSLT file. The result is an HTML document, which the web application then displays in the browser. When the XML content changes, for example because of changes made to the database, browsing to SPSFilename.aspx (or refreshing the page in the browser) will automatically fetch the most recent data from the database or XML file and render an updated document.

9.11.1 Example: Localhost on Windows 7

The procedure outlined below sets up your local host to serve an ASPX application. For more information, see the file Readme.doc in the ASPX application folder. This folder and file are generated when you select the command File | Web Design | Generate ASPX Web Application with an SPS file active.

Install RaptorXML

Make sure that the latest version of RaptorXML is installed. RaptorXML contains Altova’s transformation engine. It will be used to transform the (DB-generated) XML file.

Activate Internet Information Services (Microsoft’s web server)

If Internet Information Services (IIS) is not activated, carry out the steps below to activate it. Step 5 shows how to test whether IIS has been activated.

1. Go to Control Panel | Programs and Features | Turn Windows features on or off.
2. Set the Internet Information Services checkbox. The tri-state checkbox will change to Partly checked.
3. Additionally, set the Internet Information Services | World Wide Web Services | Application Development Features | ASP.NET checkbox.
4. Click OK. When the process is complete, you will have a folder named C:/inetpub/wwwroot. This is the web server’s root folder.
5. As a test, go to localhost in a browser. This will display the IIS welcome screen

In StyleVision, generate the ASPX application

Generate the ASPX application as follows:

1. It is recommended that the database and the SPS file be in the same folder.
2. After the SPS file has been completed, issue the command Files | Web Design | Generate ASPX Web Application.
3. In the dialog that opens, create a folder below C:/inetpub/wwwroot and select that folder, for example: C:/inetpub/wwwroot/Test1.
4. On confirming your folder selection, StyleVision will generate the following files in it: `<FileName>.aspx`, `<FileName>_AltovaDataBaseExtractor.cs`, `Web.config`, and a folder `App_Code` containing the various files.

Note: In order to save files to `C:/inetpub/wwwroot` you will need to run StyleVision as an administrator. Do this by restarting StyleVision. Right-click the StyleVision executable file or a shortcut to it and select Run as Administrator.

Make ASPX aware of the generated application

Carry out the following steps to make ASPX aware of the application you have generated with StyleVision:

1. Go to Control Panel | Administrative Tools | Internet Information Services (IIS) Manager.
2. In the Connections panel, expand the tree to display the folder (for example, Test1). The folder’s icon will be a standard yellow folder at this point.
3. In the folder’s context menu, issue the command Convert to Application, then click OK in the dialog. The folder’s icon will now be a globe.
4. In the Connections panel, expand the tree to display Application Pool and select this.
5. In the context menu for DefaultAppPool (available in the main pane when you select the Application Pools item in the Connections pane), select the command Advanced Settings.
6. For the Identity property, select Custom account and enter your Windows user name and password.
7. For the Enable 32-Bit Applications property, enter True. (This is so the database drivers have access). This step applies only to 64-bit versions of Windows 7.

Run the application

In the browser, go to localhost/Test1/<FileName>.aspx (assuming Test1 is the name of the folder in which the ASPX application has been saved). The transformed HTML will be displayed in the browser. Refreshing this ASPX page will cause the latest data from the database or XML file to be displayed.

Note: If the browser hangs at this point, make sure that the RaptorXML is correctly licensed.
# PXF File: Container for SPS and Related Files

An SPS design that uses XSLT 2.0 or 3.0 can be saved as a Portable XML Form (PXF) file. The PXF file format has been specially developed by Altova to package the SPS design with related files (such as the schema file, source XML file, image files used in the design, and XSLT files for transformation of the source XML to an output format). The benefit of the PXF file format is that all the files required for Authentic View editing and for the generation of output from Authentic View can be conveniently distributed in a single file.

This section describing the use of PXF files is organized in two parts:

- [Creating a PXF file](#)
- [Editing a PXF File](#)
- [Deploying a PXF file](#)

**Note:** PXF files can be created only from SPSs designed with XSLT 2.0 or 3.0.

## 9.12.1 Creating a PXF File

To create a PXF file that will contain an SPS design plus related files, open the SPS design in StyleVision and select the command `File | Save As`. This pops up the Save Design dialog (screenshot below).

![Save Design Dialog](image)

The SPS format is the standard Altova format for StyleVision designs. In this section we are concerned with the PXF format and so will not consider the SPS format here. Saving a file as an SPS is described in detail in the [User Reference section](#).

**Save as PXF**

Selecting the PXF option causes the familiar Save As dialog of Windows systems to pop up. Saving works exactly as described for the `Save Design` command—with the additional step of selecting the files you wish to include in the PXF file. After you specify the PXF filename, the Configure PXF dialog (screenshot below) will appear, in which you can select/deselect the files you wish to embed.
In the Global Configuration pane of the Design-time Files tab, you can select/deselect the design-related source files to be embedded/omitted. You can additionally choose to embed XSLT files generated from the design. In the XSLT files pane, select the output formats for which you wish to generate and embed XSLT files. If an XSLT file is included in the PXF file and the PXF file is opened in the Authentic View of an Altova product, then the toolbar button to generate and view that output format is enabled in Authentic View (screenshot below).

**Note:** If XSLT files for outputs supported only in a higher edition of StyleVision (high to low: Enterprise, Professional, Basic) were created in a PXF file and if that PXF file is then opened in a lower edition, then on saving the PXF file the XSLT files for outputs not supported in the lower edition will not be saved. A prompt appears, asking whether you wish to continue saving the PXF file. You can then save
without the unsupported formats, or abort the save and retain the unsupported formats.

In the Additional Files tab (screenshot below), you can specify any additional files you wish to include that are not design-time files. These could be, for example, image files referenced in the design by a URL generated with an XPath expression. In the screenshot below, the image file NewsItems.bmp located in the Images folder is selected for inclusion in the PXF file.

To include an additional file in the PXF file, click the Add Document button and then browse for the file you want. The Open dialog (in which you browse for the required file) opens the folder in which the SPS is located. Files from this folder or any descendant folder may be selected. After an additional file has been added to the PXF file, it and the folder structure leading to it are displayed. The screenshot above indicates that the additional file NewsItems.bmp is in a folder named Images, which is itself contained in the folder in which the SPS file is located.

If a file is selected from a folder located in any level above the folder containing the SPS file, an error is reported.
In the SPS design, any reference to an additional file must be made with a relative path and must use the folder structure shown in the Additional Files pane. For example, NewsItems.bmp in the screenshot above must be referenced with the relative path: Images/NewsItems.bmp.

Note: In order to save PXF files, the option Embed Images for RTF and Word 2007+ (File | Properties | Images) must be selected.

9.12.2 Editing a PXF File

A PXF file can be opened in StyleVision via the File | Open command and edited. These edits can be of two types:

- The configuration of the PXF file can be edited
- The content of individual component files such as the SPS and Authentic XML can be edited in StyleVision, while other component files (such as image and CSS files) can be edited in external applications. All component files must however be explicitly updated in StyleVision.

Entry point for PXF editing

The entry point for editing the PXF configuration and for updating the PXF file is the PXF item in the Design Overview sidebar (screenshot below).

Configure embedded files

Clicking the Configure Embedded Files link in Design Overview (see screenshot above) opens the Configure Portable XML Form (PXF) dialog. The configuration options are exactly the same as described in the section, Creating a PXF File.

Updating embedded files

Clicking the Update Embedded Files link in Design Overview (see screenshot above) opens the Portable XML Form (PXF) Update dialog (screenshot below).
First, select whether the source files should be retrieved relative to their current PXF locations or from their original locations. Then check the files you wish to update and click **Update**. A new PXF file will be created and will overwrite the existing PXF file. Therefore, before you update, it is highly recommended that you back up the original PXF file.

### 9.12.3 Deploying a PXF File

After a PXF file has been created, it can be transported, downloaded, copied, and saved like any other data file. Since the PXF file can contain all the files required to edit an XML file in Authentic View and to generate output reports, it is the only file an Authentic user needs in order to get started and to generate output.

A PXF file can be opened in the Authentic View of Altova products. To give you an idea of how a PXF file may be used, here is a list of some usage scenarios in XMLSpy:

- The PXF file is opened via the **File | Open** command. The embedded XML file will be displayed in Authentic View using the embedded SPS, and can be edited in Authentic View. The **File | Save** command saves changes to the PXF (the embedded XML is modified).

- The PXF file contains no embedded XML file and is opened via the **File | Open** command. If no XML file is included, then a Template XML file based on the SPS design is opened in Authentic View. The **File | Save** command will save this XML file as an embedded file in the PXF file.
In the Altova product, XMLSpy, an XML file can be associated with a PXF file so that the embedded SPS of the PXF file is used for Authentic View editing. The association is done via the menu command Authentic | Assign a StyleVision Stylesheet. When changes are saved, they will be saved to the XML file; the PXF file will be unchanged.

If an XSLT stylesheet for one of the output formats has been embedded in the PXF file, then the Authentic View user will be able to generate output in that format. This is done with the appropriate output-generation toolbar button (screenshot below). In Authentic View, individual output-generation toolbar buttons will be enabled only if the PXF file was configured to contain the XSLT stylesheet for that output. For example, if the PXF file was configured to contain the XSLT stylesheets for HTML and PDF, then only the toolbar buttons for HTML and PDF output will be enabled while those for RTF and DocX (Word 2007+) output will be disabled.

Note: If a PXF file is located on a web server and will be used with the Authentic Browser Plug-in, you must ensure that the server does not block the file. You can do this by adding (via the IIS administration panel, for example) the following MIME type for PXF (.pxf) file extensions: application/x- zipfile-compressed.
10 Databases

When a DB is used as the basis of an SPS—that is, as the main schema of an SPS—the SPS can be used in the following ways:

- To edit the DB in Authentic View.
- To generate an XML Schema having a structure based on the DB (if the DB does not contain a schema; only XML DBs, such as IBM DB2 version 9 upwards, contain schemas).
- To generate an XML file with data from the DB (if the required DB data is not already in XML format).
- To design and generate XSLT stylesheets for HTML, Text, and RTF output.
- To generate DB reports (based on the SPS design) in HTML, Text, and RTF format. These reports can be previewed in StyleVision.

When a DB is the source of a subsidiary schema in an SPS, then data from the DB can be included in the design document, but the DB itself cannot be edited in Authentic View. It is the XML document or DB associated with the main schema that can be edited.

General procedure

This section describes the procedure for working with DBs in StyleVision. After an introductory sub-section, which provides an overview of how DBs work in StyleVision, the sub-sections of this section describe the various steps in the work procedure. Note that we distinguish between two broad types of DBs: non-XML DBs and XML DBs. The term DB is used in two senses: generically, it refers to all DBs; specifically, to non-XML DBs. XML DBs are always referred to as XML DBs. The distinction should be borne in mind because the method of selecting the DB data that provides the schema and XML data for the SPS is different for these two types of DB.

- Connecting to a DB: Describes how to connect to non-XML DBs, including IBM DB2 versions below 9.
- DB Data Selection: Describes how the schema and XML data for the SPS is selected from the DB's table structure, for non-XML and XML DBs separately.
- The DB Schema and DB XML file: When DB tables (from non-XML DBs) are loaded, StyleVision generates and works with temporary XML Schema and XML data files based, respectively, on the DB structure and data. For XML DBs, the schema and XML files are not generated by StyleVision but referenced directly from the DB or, in the case of schemas, from another file location.
- DB Filters: Filtering DB Data: DB data that is loaded into the temporary XML file can be filtered.
- SPS Design Features for DB: In the SPS, special DB functionality, such as DB controls and DB Queries, are available.
- Generating Output Files: A wide range of DB report-related files can be generated by StyleVision.

Supported databases

The following databases are supported. While Altova endeavors to support other databases, successful connection and data processing have only been tested with the databases listed below. If your Altova application is a 64-bit version, ensure that you have access to the 64-bit database drivers needed for the specific database you are connecting to.

<table>

10.1 DBs and StyleVision

In StyleVision, you can create DB-based SPSs. These stylesheets enable you to do two things:

- Edit DBs in Authentic View, and
- Generate reports from DBs.

After you have created the SPS, you can view reports in StyleVision and generate report files in HTML and RTF format. You can also save the following DB-related XML files that StyleVision generates:

- XML Schema based on DB structure (not applicable for XML DBs, where a schema is already available)
- XML file having structure defined in the generated schema and content from the DB (not applicable for XML DBs, where the data is already available in XML format)
- SPS that you design, and which is based on the generated schema
- XSLT stylesheet for HTML output (based on design of SPS)
- XSLT stylesheet for Text output (based on design of SPS)
- XSLT stylesheet for RTF output (based on design of SPS)
- HTML output
- Text output
- RTF output

The saved XML file can then be processed with the required XSLT stylesheet/s. This provides more flexible report-generating capabilities.

**Note:** The XML Schema and XML files are generated from non-XML DBs by StyleVision, and you cannot alter their structure or content for use in Authentic View. This is because the structure of these files is related to the structure of the non-XML DB. Editing the DB and creating reports from the DB depend on the unique XML structure generated by StyleVision from the DB.
Broad mechanism for working with DB-based SPSs

Given below are the steps involved in creating and using DB-based SPSs. These steps cover the two uses of DB-based StyleVision Power Stylesheets: editing the DB and creating HTML, Text, and RTF reports from the DB.

- **Connect to the DB** with StyleVision. During the connection process you can specify what data tables in the DB should be filtered out from the XML Schema.
- When the connection is made, a temporary XML Schema is generated based on the structure of the DB and that schema is displayed in the Schema Window of StyleVision in tree form. In the case of XML DBs, a pre-existing schema (either in the DB or at a file location) is referenced.
- Temporary StyleVision-internal XML files are also created. One is non-editable (see diagram above) and is used for the previews and as the source of the generated XML data file. The other is an editable XML file, which is displayed in Authentic View (see screenshot above). When changes made to this file in Authentic View are saved (with the File | Save Authentic XML Data command), the modifications are written back to the DB. The non-editable XML file is updated if necessary each time an output view is newly accessed or when the XML data is saved.
- In StyleVision, you can define top-level filters to restrict the data imported into the non-editable XML File, i.e. for the output views and the reports.
- A DB Query is used within Authentic View to restrict the list of records displayed in Authentic View. It is used only during editing.
- If editing changes have been saved to the DB, then the next time an output view window is accessed, the non-editable XML file is updated with the modified contents of the DB and the refreshed file is displayed in the preview.
- A DB-based SPS is created in the same way as the standard schema-based SPS: by dragging-and-dropping nodes into the Design Window, inserting static stylesheet components, assigning display properties, etc. These mechanisms are described in this documentation.
10.2 Connecting to a Data Source

In the most simple case, a database can be a local file such as a Microsoft Access or SQLite database file. In a more advanced scenario, a database may reside on a remote or network database server which does not necessarily use the same operating system as the application that connects to it and consumes data. For example, while StyleVision runs on a Windows operating system, the database from which you want to access data (for example, MySQL) might run on a Linux machine.

To interact with various database types, both remote and local, StyleVision relies on the data connection interfaces and database drivers that are already available on your operating system or released periodically by the major database vendors. In the constantly evolving landscape of database technologies, this approach caters for better cross-platform flexibility and interoperability.

The following diagram illustrates, in a simplified way, data connectivity options available between StyleVision (illustrated as a generic client application) and a data store (which may be a database server or database file).

* Direct native connections are supported for SQLite, PostgreSQL, CouchDB and MongoDB databases. To connect to such databases, no additional drivers are required to be installed on your system.

As shown in the diagram above, StyleVision can access any of the major database types through the following data access technologies:

- ADO (Microsoft® ActiveX® Data Objects), which, in its turn, uses an underlying OLE DB (Object Linking and Embedding, Database) provider
- ADO.NET (A set of libraries available in the Microsoft .NET Framework that enable interaction with data)
About data access technologies

The data connection interface you should choose largely depends on your existing software infrastructure. You will typically choose the data access technology and the database driver which integrates tighter with the database system to which you want to connect. For example, to connect to a Microsoft Access 2013 database, you would build an ADO connection string that uses a native provider such as the Microsoft Office Access Database Engine OLE DB Provider. To connect to Oracle, on the other hand, you may want to download and install the latest JDBC, ODBC, or ADO.NET interfaces from the Oracle website.

While drivers for Windows products (such as Microsoft Access or SQL Server) may already be available on your Windows operating system, they may not be available for other database types. Major database vendors routinely release publicly available database client software and drivers which provide cross-platform access to the respective database through any combination of ADO, ADO.NET, ODBC, or JDBC. In addition to this, several third party drivers may be available for any of the above technologies. In most cases, there is more than one way to connect to the required database from your operating system, and, consequently, from StyleVision. The available features, performance parameters, and the known issues will typically vary based on the data access technology or drivers used.

10.2.1 Start Database Connection Wizard

StyleVision provides a Database Connection Wizard that guides you through the steps required to set up a connection to a data source. Before you go through the wizard steps, be aware that for some database types it is necessary to install and separately configure several database prerequisites, such as a database driver or database client software. These are normally provided by the respective database vendors, and include documentation tailored to your specific Windows version. For a list of database drivers grouped by database type, see Database Drivers Overview.

To start the Database Connection Wizard (see screenshot below), do the following:

- On the File menu, click New, and then click New From DB.

The Database Connection Wizard (screenshot below) is started. On the left hand side of the window, you can select the most suitable from the following ways to connect to your database:

- Connection Wizard, which prompts you to choose your database type and then guides you through the steps for connecting to a database of that type
- Select a data access technology: ADO, ADO.NET, ODBC, or JDBC
- Use an Altova global resource in which database connection is stored
- A native PostgreSQL connection

In the Connection Wizard pane (see screenshot below) databases can be sorted alphabetically by the name of the database type or by recent usage. Select the option you want in the Sort By combo box. After you have selected the database type to which you want to connect, click Next.
The wizard will take you through the next steps according to the database type, connection technology (ADO, ADO.NET, ODBC, JDBC), and driver that will be used. For examples applicable to each database type, see Database Connection Examples.

Alternatively to using Connection Wizard, you can use one of the following database access technologies:

- Setting up an ADO Connection
- Setting up an ADO.NET Connection
- Setting up an ODBC Connection
- Setting up a JDBC Connection
10.2.2 Database Drivers Overview

The following table lists common database drivers you can use to connect to a particular database through a particular data access technology. Note that this list does not aim to be either exhaustive or prescriptive; you can use other native or third party alternatives in addition to the drivers shown below.

Even though a number of database drivers might be already available on your Windows operating system, you may still need to download an alternative driver. For some databases, the latest driver supplied by the database vendor is likely to perform better than the driver that shipped with the operating system.

Database vendors may provide drivers either as separate downloadable packages, or bundled with database client software. In the latter case, the database client software normally includes any required database drivers, or provides you with an option during installation to select the drivers and components you wish to install. Database client software typically consists of administration and configuration utilities used to simplify database administration and connectivity, as well as documentation on how to install and configure the database client and any of its components.

Configuring the database client correctly is crucial for establishing a successful connection to the database. Before installing and using the database client software, it is strongly recommended to read carefully the installation and configuration instructions of the database client; these may vary for each database version and for each Windows version.

To understand the capabilities and limitations of each data access technology with respect to each database type, refer to the documentation of that particular database product and also test the connection against your specific environment. To avoid common connectivity issues, note the following:

- Some ADO.NET providers are not supported or have limited support. See ADO.NET Support Notes.
- When installing a database driver, it is recommended that it has the same platform as the Altova application (32-bit or 64-bit). For example, if you are using a 32-bit Altova application on a 64-bit operating system, install the 32-bit driver, and set up your database connection using the 32-bit driver, see also Viewing the Available ODBC Drivers.
- When setting up an ODBC data source, it is recommended to create the data source name (DSN) as System DSN instead of User DSN. For more information, see Setting up an ODBC Connection.
- When setting up a JDBC data source, ensure that JRE (Java Runtime Environment) or Java Development Kit (JDK) is installed and that the CLASSPATH environment variable of the operating system is configured. For more information, see Setting up a JDBC Connection.
- For the installation instructions and support details of any drivers or database client software that you install from a database vendor, check the documentation provided with the installation package.

### 10.2.3 ADO Connection

Microsoft ActiveX Data Objects (ADO) is a data access technology that enables you to connect to a variety of data sources through OLE DB. OLE DB is an alternative interface to ODBC or JDBC; it provides uniform access to data in a COM (Component Object Model) environment. ADO is a precursor of the newer...
ADO.NET™ and is still one of the possible ways to connect to Microsoft native databases such as Microsoft Access or SQL Server, although you can also use it for other data sources.

Importantly, you can choose between multiple ADO providers, and some of them must be downloaded and installed on your workstation before you can use them. For example, for connecting to SQL Server, the following ADO providers are available:

- Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL)
- Microsoft OLE DB Provider for SQL Server (SQLOLEDB)
- SQL Server Native Client (SQLNCLI)

From the providers listed above, the recommended one is MSOLEDBSQL; you can download it from https://docs.microsoft.com/en-us/sql/connect/oledb/download-oledb-driver-for-sql-server?view=sql-server-ver15. Note that it must match the platform of StyleVision (32-bit or 64-bit). The SQLOLEDB and SQLNCLI providers are considered deprecated and thus are not recommended.

The Microsoft OLE DB Provider for SQL Server (SQLOLEDB) is known to have issues with parameter binding of complex queries like Common Table Expressions (CTE) and nested SELECT statements.

To set up an ADO connection:

1. Start the database connection wizard.
2. Click ADO Connections.
3. Click Build.
4. Select the data provider through which you want to connect. The table below lists a few common scenarios.

<table>
<thead>
<tr>
<th>To connect to this database...</th>
<th>Use this provider...</th>
</tr>
</thead>
</table>
| Microsoft Access              | • Microsoft Office Access Database Engine OLE DB Provider (recommended)  
                                  • Microsoft Jet OLE DB Provider  
                                  If the Microsoft Office Access Database Engine OLE DB Provider is not available in the list, make sure that you have installed either Microsoft Access or the Microsoft Access Database Engine Redistributable (https://www.microsoft.com/en-us/download/details.aspx?id=54920) on your computer. |
| SQL Server                    | • Microsoft OLE DB Driver for SQL Server (MSOLEDBSQL) - this is the recommended OLE DB provider. In order for this provider to appear in the list, it must be downloaded from https://docs.microsoft.com/en-us/sql/connect/odbc/download-odbc-driver-for-sql-server?view=sql-server-ver15 and installed.  
                                  • Microsoft OLE DB Provider for SQL Server (OLEDBSQL)  
                                  • SQL Server Native Client (SQLNCLI) |
| Other database                | Select the provider applicable to your database. |
### Connecting to a Data Source

<table>
<thead>
<tr>
<th>To connect to this database...</th>
<th>Use this provider...</th>
</tr>
</thead>
<tbody>
<tr>
<td>If an OLE DB provider to your database is not available, install the required driver from the database vendor (see Database Drivers Overview). Alternatively, set up an ADO.NET, ODBC, or JDBC connection.</td>
<td>If the operating system has an ODBC driver to the required database, you could also use the Microsoft OLE DB Provider for ODBC Drivers, or preferably opt for an ODBC connection.</td>
</tr>
</tbody>
</table>

5. Having selected the provider of choice, click **Next** and complete the wizard.

The subsequent wizard steps are specific to the provider you chose. For SQL Server, you will need to provide or select the host name of the database server, the authentication method, the database name, as well as the database username and password. For an example, see Connecting to Microsoft SQL Server (ADO). For Microsoft Access, you will be asked to browse for or provide the path to the database file. For an example, see Connecting to Microsoft Access (ADO).

The complete list of initialization properties (connection parameters) is available in the **All** tab of the connection dialog box—these properties vary depending on the chosen provider and may need to be set explicitly in order for the connection to be possible. The following sections provide guidance on configuring the basic initialization properties for Microsoft Access and SQL Server databases:

- Setting up the SQL Server Data Link Properties
- Setting up the Microsoft Access Data Link Properties

### 10.2.3.1 Connecting to an Existing Microsoft Access Database

This approach is suitable when you want to connect to a Microsoft Access database which is not password-protected. If the database is password-protected, set up the database password as shown in Connecting to Microsoft Access (ADO).

#### To connect to an existing Microsoft Access database:

1. Run the database connection wizard (see Starting the Database Connection Wizard).
2. Select **Microsoft Access (ADO)**, and then click **Next**.
3. Browse for the database file, or enter the path to it (either relative or absolute).
4. Click **Connect**.

### 10.2.3.2 Setting up the SQL Server Data Link Properties

When you connect to a Microsoft SQL Server database through ADO, you may need to set the following connection properties in the **All** tab of the Data Link Properties dialog box.
**Data Link Properties dialog box**

<table>
<thead>
<tr>
<th>Property</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Integrated Security</strong></td>
<td>If you selected the <strong>SQL Server Native Client</strong> data provider on the <strong>Provider</strong> tab, set this property to a space character.</td>
</tr>
<tr>
<td><strong>Persist Security Info</strong></td>
<td>Set this property to <strong>True</strong>.</td>
</tr>
</tbody>
</table>

### 10.2.3.3 Setting up the Microsoft Access Data Link Properties

When you connect to a Microsoft Access database through **ADO**, you may need to set the following connection properties in the **All** tab of the Data Link Properties dialog box.
## Databases Connecting to a Data Source

The Data Link Properties dialog box is used to configure the connection to a Microsoft Access database. Here's how to properly set the properties:

### Property Notes

<table>
<thead>
<tr>
<th>Property</th>
<th>Notes</th>
</tr>
</thead>
</table>
| **Data Source**                 | This property stores the path to the Microsoft Access database file. To avoid database connectivity issues, it is recommended to use the UNC (Universal Naming Convention) path format, for example:  
  \anyserver\share$\filepath |
| **Jet OLEDB:System Database**   | This property stores the path to the workgroup information file. You may need to explicitly set the value of this property before you can connect to a Microsoft Access database.  
  If you cannot connect due to a "workgroup information file" error, locate the workgroup information file (System.MDW) applicable to your user profile, and set the property value to the path of the System.MDW file. |
Connecting to a Data Source

10.2.4 ADO.NET Connection

ADO.NET is a set of Microsoft .NET Framework libraries designed to interact with data, including data from databases. To connect to a database from StyleVision through ADO.NET, Microsoft .NET Framework 4 or later is required. As shown below, you connect to a database through ADO.NET by selecting a .NET provider and supplying a connection string.

A .NET data provider is a collection of classes that enables connecting to a particular type of data source (for example, a SQL Server, or an Oracle database), executing commands against it, and fetching data from it. In other words, with ADO.NET, an application such as StyleVision interacts with a database through a data provider. Each data provider is optimized to work with the specific type of data source that it is designed for. There are two types of .NET providers:

1. Supplied by default with Microsoft .NET Framework.
2. Supplied by major database vendors, as an extension to the .NET Framework. Such ADO.NET providers must be installed separately and can typically be downloaded from the website of the respective database vendor.

**Note:** Certain ADO.NET providers are not supported or have limited support. See ADO.NET Support Notes.

---

<table>
<thead>
<tr>
<th>Property</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jet OLEDB:Database Password</td>
<td>If the database is password-protected, set the value of this property to the database password.</td>
</tr>
</tbody>
</table>

**Property Description**

Jet OLEDB: System database

**Property Value**

C:\Users\john.doe\AppData\Roaming\Microsoft\Access

[Reset Value] [OK] [Cancel]
To set up an ADO.NET connection:

1. Start the database connection wizard.
2. Click ADO.NET Connections.
3. Select a .NET data provider from the list.

The list of providers available by default with the .NET Framework appears in the "Provider" list. Vendor-specific .NET data providers are available in the list only if they are already installed on your system. To become available, vendor-specific .NET providers must be installed into the GAC (Global Assembly Cache), by running the .msi or .exe file supplied by the database vendor.

4. Enter a database connection string. A connection string defines the database connection information, as semicolon-delimited key/value pairs of connection parameters. For example, a connection string such as `Data Source=DBSQLSERV;Initial Catalog=ProductsDB;UserID=dbuser;Password=dbpass` connects to the SQL Server database `ProductsDB` on server `DBSQLSERV`, with the user name `dbuser` and password `dbpass`. You can create a connection string by typing the key/value pairs directly into the "Connection String" dialog box. Another option is to create it with Visual Studio (see Creating a Connection String in Visual Studio).

The syntax of the connection string depends on the provider selected from the "Provider" list. For examples, see Sample ADO.NET Connection Strings.
5. Click **Connect**.

10.2.4.1 Creating a Connection String in Visual Studio

In order to connect to a data source using ADO.NET, a valid database connection string is required. The following instructions show you how to create a connection string from Visual Studio.

**To create a connection string in Visual Studio:**

1. On the **Tools** menu, click **Connect to Database**.
2. Select a data source from the list (in this example, Microsoft SQL Server). The Data Provider is filled automatically based on your choice.
3. **Click Continue.**
4. Enter the server host name and the user name and password to the database. In this example, we are connecting to the database ProductsDB on server DBSQLSERV, using SQL Server authentication.

5. Click OK.

If the database connection is successful, it appears in the Server Explorer window. You can display the Server Explorer window using the menu command View | Server Explorer. To obtain the database connection string, right-click the connection in the Server Explorer window, and select Properties. The connection string is now displayed in the Properties window of Visual Studio. Note that, before pasting the string into the "Connection String" box of StyleVision, you will need to replace the asterisk ( * ) characters with the actual password.
10.2.4.2 Sample ADO.NET Connection Strings

To set up an ADO.NET connection, you need to select an ADO.NET provider from the database connection dialog box and enter a connection string (see also Setting up an ADO.NET Connection). Sample ADO.NET connection strings for various databases are listed below under the .NET provider where they apply.

.NET Data Provider for Teradata
This provider can be downloaded from Teradata website (https://downloads.teradata.com/download/connectivity/net-data-provider-for-teradata). A sample connection string looks as follows:

```
Data Source=ServerAddress;UserId=user;Password=password;
```

.NET Framework Data Provider for IBM i
This provider is installed as part of IBM i Access Client Solutions - Windows Application Package. A sample connection string looks as follows:

```
DataSource=ServerAddress;UserID=user;Password=password;DataCompression=True;
```

For more information, see the ".NET Provider Technical Reference" help file included in the installation package above.

.NET Framework Data Provider for MySQL
This provider can be downloaded from MySQL website (https://dev.mysql.com/downloads/connector/net/). A sample connection string looks as follows:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

.NET Framework Data Provider for SQL Server
A sample connection string looks as follows:

```
Data Source=DBSQLSERV;Initial Catalog=ProductsDB;UserId=dbuser;Password=dbpass
```

See also: https://msdn.microsoft.com/en-us/library/ms254500(v=vs.110).aspx

IBM DB2 Data Provider 10.1.2 for .NET Framework 4.0

```
Database=PRODUCTS;UID=user;Password=password;Server=localhost:50000;
```
Note: This provider is typically installed with the IBM DB2 Data Server Client package. If the provider is missing from the list of ADO.NET providers after installing IBM DB2 Data Server Client package, refer to the following technical note: https://www-01.ibm.com/support/docview.wss?uid=swg21429586.

Oracle Data Provider for .NET (ODP.NET)
The installation package which includes the ODP.NET provider can be downloaded from the Oracle website (see http://www.oracle.com/technetwork/topics/dotnet/downloads/index.html). A sample connection string looks as follows:

```
Data Source=DSORCL;User Id=user;Password=password;
```

Where DSORCL is the name of the data source which points to an Oracle service name defined in the tnsnames.ora file, as described in Connecting to Oracle (ODBC).

To connect without configuring a service name in the tnsnames.ora file, use a string such as:

```
Data Source=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=host)(PORT=port)))
(CONNECT_DATA=(SERVER=DEDICATED)(SERVICE_NAME=MyOracleSID)));User Id=user;Password=password;
```

See also: https://docs.oracle.com/cd/B28359_01/win.111/b28375/featConnecting.htm

### 10.2.4.3 ADO.NET Support Notes

The following table lists known ADO.NET database drivers that are currently not supported or have limited support in StyleVision.

<table>
<thead>
<tr>
<th>Database</th>
<th>Driver</th>
<th>Support notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>All databases</td>
<td>.Net Framework Data Provider for ODBC</td>
<td>Limited support. Known issues exist with Microsoft Access connections. It is recommended to use ODBC direct connections instead.</td>
</tr>
<tr>
<td></td>
<td>.Net Framework Data Provider for OleDb</td>
<td>Limited support. Known issues exist with Microsoft Access connections. It is recommended to use ADO direct connections instead.</td>
</tr>
<tr>
<td>Firebird</td>
<td>Firebird ADO.NET Data Provider</td>
<td>Limited support. It is recommended to use ODBC or JDBC instead.</td>
</tr>
<tr>
<td>Informix</td>
<td>IBM Informix Data Provider for</td>
<td>Not supported. Use DB2 Data Server</td>
</tr>
</tbody>
</table>
10.2.5 ODBC Connection

ODBC (Open Database Connectivity) is a widely used data access technology that enables you to connect to a database from StyleVision. It can be used either as primary means to connect to a database, or as an alternative to native, OLE DB, or JDBC-driven connections.

To connect to a database through ODBC, first you need to create an ODBC data source name (DSN) on the operating system. This step is not required if the DSN has already been created, perhaps by another user of the operating system. The DSN represents a uniform way to describe the database connection to any ODBC-aware client application on the operating system, including StyleVision. DSNs can be of the following types:

- System DSN
- User DSN
- File DSN

A System data source is accessible by all users with privileges on the operating system. A User data source is available to the user who created it. Finally, if you create a File DSN, the data source will be created as a file with the .dsn extension which you can share with other users, provided that they have installed the drivers used by the data source.

Any DSNs already available on your machine are listed by the database connection dialog box when you click ODBC connections on the ODBC connections dialog box.
If a DSN to the required database is not available, the StyleVision database connection wizard will assist you to create it; however, you can also create it directly on your Windows operating system. In either case, before you proceed, ensure that the ODBC driver applicable for your database is in the list of ODBC drivers available to the operating system (see Viewing the Available ODBC Drivers).

To connect by using a new DSN:

1. Start the database connection wizard.
2. On the database connection dialog box, click ODBC Connections.
3. Select a data source type (User DSN, System DSN, File DSN).
4. Click Add.
5. Select a driver, and then click User DSN or System DSN (depending on the type of the DSN you want to create). If the driver applicable to your database is not listed, download it from the database vendor and install it (see Database Drivers Overview).
6. On the dialog box that pops up, fill in any driver specific connection information to complete the setup.

For the connection to be successful, you will need to provide the host name (or IP address) of the database server, as well as the database username and password. There may be other optional connection parameters—these parameters vary between database providers. For detailed information about the parameters specific to
each connection method, consult the documentation of the driver provider. Once created, the DSN becomes available in the list of data source names. This enables you to reuse the database connection details any time you want to connect to the database. Note that User DSNs are added to the list of User DSNs whereas System DSNs are added to the list of System DSNs.

To connect by using an existing DSN:

1. Start the database connection wizard.
2. Click ODBC Connections.
3. Choose the type of the existing data source (User DSN, System DSN, File DSN).
4. Click the existing DSN record, and then click Connect.

To build a connection string based on an existing .dsn file:

1. Start the database connection wizard.
2. Click ODBC Connections.
3. Select Build a connection string, and then click Build.
4. If you want to build the connection string using a File DSN, click the File Data Source tab. Otherwise, click the Machine Data Source tab. (System DSNs and User DSNs are known as "Machine" data sources.)
5. Select the required .dsn file, and then click OK.

To connect by using a prepared connection string:

1. Start the database connection wizard.
2. Click ODBC Connections.
3. Select Build a connection string.
4. Paste the connection string into the provided box, and then click Connect.

10.2.5.1 Available ODBC Drivers

You can view the ODBC drivers available on your operating system in the ODBC Data Source Administrator. You can access the ODBC Data Source Administrator (Odbcad32.exe) from the Windows Control Panel, under Administrative Tools. On 64-bit operating systems, there are two versions of this executable:

- The 32-bit version of the Odbcad32.exe file is located in the C:\Windows\SysWoW64 directory (assuming that C: is your system drive).
- The 64-bit version of the Odbcad32.exe file is located in the C:\Windows\System32 directory.

Any installed 32-bit database drivers are visible in the 32-bit version of ODBC Data Source Administrator, while 64-bit drivers—in the 64-bit version. Therefore, ensure that you check the database drivers from the relevant version of ODBC Data Source Administrator.
If the driver to your target database does not exist in the list, or if you want to add an alternative driver, you will need to download it from the database vendor (see Database Drivers Overview). Once the ODBC driver is available on your system, you are ready to create ODBC connections with it (see Setting up an ODBC Connection).

### 10.2.6 JDBC Connection

JDBC (Java Database Connectivity) is a database access interface which is part of the Java software platform from Oracle. JDBC connections are generally more resource-intensive than ODBC connections but may provide features not available through ODBC.

**Prerequisites**

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application Options; b) The JVM path found in the Windows registry; c) The `JAVA_HOME` environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC drivers from the database vendor must be installed. These may be JDBC drivers installed as part of a database client installation, or JDBC libraries (.jar files) downloaded separately, if available and supported by the database, see also Database Connection Examples.
- The **CLASSPATH** environment variable must include the path to the JDBC driver (one or several .jar files) on your Windows operating system. When you install some database clients, the installer may configure this variable automatically. See also Configuring the **CLASSPATH**.

Connecting to SQL Server via JDBC with Windows credentials

If you connect to SQL Server through JDBC with Windows credentials (integrated security), note the following:

- The **sqljdbc_auth.dll** file included in the JDBC driver package must be copied to a directory that is on the system PATH environment variable. There are two such files, one for the x86 and one for x64 platform. Make sure that you add to the PATH the one that corresponds to your JDK platform.
- The JDBC connection string must include the property `integratedSecurity=true`.

Setting up a JDBC connection

1. Start the database connection wizard.
2. Click **JDBC Connections**.
3. Optionally, enter a semicolon-separated list of .jar file paths in the "Classpaths" text box. The .jar libraries entered here will be loaded into the environment in addition to those already defined in the **CLASSPATH** environment variable. When you finish editing the "Classpaths" text box, any JDBC drivers found in the source .jar libraries are automatically added to the "Driver" list (see the next step).

![JDBC Connection Setup](image-url)
4. Next to "Driver", select a JDBC driver from the list, or enter a Java class name. Note that this list contains any JDBC drivers configured through the CLASSPATH environment variable (see Configuring the CLASSPATH), as well as those found in the "Classpaths" text box.

   The JDBC driver paths defined in the CLASSPATH variable, as well as any .jar file paths entered directly in the database connection dialog box are all supplied to the Java Virtual Machine (JVM). The JVM then decides which drivers to use in order to establish a connection. It is recommended to keep track of Java classes loaded into the JVM so as not to create potential JDBC driver conflicts and avoid unexpected results when connecting to the database.

5. Enter the username and password to the database in the corresponding boxes.

6. In the Database URL text box, enter the JDBC connection URL (string) in the format specific to your database type. The following table describes the syntax of JDBC connection URLs (strings) for common database types.

<table>
<thead>
<tr>
<th>Database</th>
<th>JDBC Connection URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firebird</td>
<td>jdbc:firebirdsql://&lt;host&gt;[:&lt;port&gt;]/&lt;database path or alias&gt;</td>
</tr>
<tr>
<td>IBM DB2</td>
<td>jdbc:db2://&lt;hostName&gt;:&lt;port&gt;/&lt;databaseName&gt;</td>
</tr>
<tr>
<td>IBM DB2 for i</td>
<td>jdbc:as400://[host]</td>
</tr>
<tr>
<td>IBM Informix</td>
<td>jdbc:informix-sqli://&lt;hostName&gt;:&lt;port&gt;/&lt;databaseName&gt;:INFORMIXSERVER=myserver</td>
</tr>
<tr>
<td>MariaDB</td>
<td>jdbc:mariadb://&lt;hostName&gt;:&lt;port&gt;/&lt;databaseName&gt;</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>jdbc:sqlserver://&lt;hostName&gt;:&lt;port&gt;/&lt;databaseName&gt;=name</td>
</tr>
<tr>
<td>MySQL</td>
<td>jdbc:mysql://&lt;hostName&gt;:&lt;port&gt;/&lt;databaseName&gt;</td>
</tr>
<tr>
<td>Oracle</td>
<td>jdbc:oracle:thin:@&lt;hostName&gt;:&lt;port&gt;:SID</td>
</tr>
<tr>
<td></td>
<td>jdbc:oracle:thin:@&lt;hostName&gt;:&lt;port&gt;/service</td>
</tr>
<tr>
<td>Oracle XML DB</td>
<td>jdbc:oracle:oci:@&lt;hostName&gt;:&lt;port&gt;/service</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>jdbc:postgresql://&lt;hostName&gt;:&lt;port&gt;/&lt;databaseName&gt;</td>
</tr>
<tr>
<td>Progress OpenEdge</td>
<td>jdbc:datadirect:openedge://&lt;host&gt;:&lt;port&gt;/databaseName=db_name</td>
</tr>
<tr>
<td>Sybase</td>
<td>jdbc:sybase:Tds:&lt;hostName&gt;:&lt;port&gt;/&lt;databaseName&gt;</td>
</tr>
<tr>
<td>Teradata</td>
<td>jdbc:teradata://databaseServerName</td>
</tr>
</tbody>
</table>

**Note:** Syntax variations to the formats listed above are also possible (for example, the database URL may exclude the port or may include the username and password to the database). Check the documentation of the database vendor for further details.

7. Click **Connect**.
### 10.2.6.1 Configuring the CLASSPATH

The **CLASSPATH** environment variable is used by the Java Runtime Environment (JRE) or the Java Development Kit (JDK) to locate Java classes and other resource files on your operating system. When you connect to a database through JDBC, this variable must be configured to include the path to the JDBC driver on your operating system, and, in some cases, the path to additional library files specific to the database type you are using.

The following table lists sample file paths that must be typically included in the **CLASSPATH** variable. Importantly, you may need to adjust this information based on the location of the JDBC driver on your system, the JDBC driver name, as well as the JRE/JDK version present on your operating system. To avoid connectivity problems, check the installation instructions and any pre-installation or post-installation configuration steps applicable to the JDBC driver installed on your operating system.

<table>
<thead>
<tr>
<th>Database</th>
<th>Sample CLASSPATH entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firebird</td>
<td>C:\Program Files\Firebird\Jaybird-2.2.8-JDK_1.8\jaybird-full-2.2.8.jar</td>
</tr>
<tr>
<td>IBM DB2</td>
<td>C:\Program Files (x86)\IBM\SQLLIB\java\db2jcc.jar;C:\Program Files (x86)\IBM\SQLLIB\java\db2jcc_license_cu.jar;</td>
</tr>
<tr>
<td>IBM DB2 for i</td>
<td>C:\jt400\jt400.jar;</td>
</tr>
<tr>
<td>IBM Informix</td>
<td>C:\Informix_JDBC_Driver\lib\ifxjdbc.jar;</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>C:\Program Files\Microsoft JDBC Driver 4.0 for SQL Server\sqljdbc_4.0\enu\sqljdbc.jar</td>
</tr>
<tr>
<td>MariaDB</td>
<td>&lt;installation directory&gt;\mariadb-java-client-2.2.0.jar</td>
</tr>
<tr>
<td>MySQL</td>
<td>&lt;installation directory&gt;\mysql-connector-java-&lt;version&gt;-bin.jar;</td>
</tr>
<tr>
<td>Oracle</td>
<td>ORACLE_HOME\jdbc\lib\ojdbc6.jar;</td>
</tr>
<tr>
<td>Oracle (with XML DB)</td>
<td>ORACLE_HOME\jdbc\lib\ojdbc6.jar;ORACLE_HOME\LIB\xmlparserv2.jar;ORACLE_HOME\RDBMS\jlib\xdb.jar;</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>&lt;installation directory&gt;\postgresql.jar</td>
</tr>
<tr>
<td>Progress OpenEdge</td>
<td>%DLC%\java\openedge.jar;%DLC%\java\pool.jar;</td>
</tr>
<tr>
<td></td>
<td>Note: Assuming the Progress OpenEdge SDK is installed on the machine, % DLC% is the directory where OpenEdge is installed.</td>
</tr>
<tr>
<td>Sybase</td>
<td>C:\sybase\jConnect-7_0\classes\jconn4.jar</td>
</tr>
<tr>
<td>Teradata</td>
<td>&lt;installation directory&gt;\tdgssconfig.jar;&lt;installation directory&gt;\terajdbc4.jar</td>
</tr>
</tbody>
</table>
• Changing the CLASSPATH variable may affect the behavior of Java applications on your machine. To understand possible implications before you proceed, refer to the Java documentation.
• Environment variables can be user or system. To change system environment variables, you need administrative rights on the operating system.
• After you change the environment variable, restart any running programs for settings to take effect. Alternatively, log off or restart your operating system.

To configure the CLASSPATH on Windows 7:

1. Open the Start menu and right-click Computer.
2. Click Properties.
3. Click Advanced system settings.
4. In the Advanced tab, click Environment Variables.
5. Locate the CLASSPATH variable under user or system environment variables, and then click Edit. If the CLASSPATH variable does not exist, click New to create it.
6. Edit the variable value to include the path on your operating system where the JDBC driver is located. To separate the JDBC driver path from other paths that may already be in the CLASSPATH variable, use the semi-colon separator ( ; ).

To configure the CLASSPATH on Windows 10:

1. Press the Windows key and start typing "environment variables".
2. Click the suggestion Edit the system environment variables.
3. Click Environment Variables.
4. Locate the CLASSPATH variable under user or system environment variables, and then click Edit. If the CLASSPATH variable does not exist, click New to create it.
5. Edit the variable value to include the path on your operating system where the JDBC driver is located. To separate the JDBC driver path from other paths that may already be in the CLASSPATH variable, use the semi-colon separator ( ; ).

10.2.7 PostgreSQL Connection

Connections to PostgreSQL databases can be set up either as native connections, or connections via ODBC, JDBC, and other drivers. The advantage of setting up a native connection is that no drivers are required to be installed on your system. Also, if you intend to deploy files for execution on a Linux or macOS server, no drivers are required to be installed on the target server as well.

If you prefer to establish a connection by means of a non-native driver, see the following topics:

• Setting up a JDBC Connection
• Connecting to PostgreSQL (ODBC)

Otherwise, if you want to set up a native connection to PostgreSQL, follow the steps below. To proceed, you need the following prerequisites: host name, port, database name, username, and password.
To set up a native PostgreSQL connection:

1. Start the database connection wizard.
2. Click PostgreSQL Connections.
3. Enter the host (localhost, if PostgreSQL runs on the same machine), port (typically 5432, this is optional), the database name, username, and password in the corresponding boxes.
4. Click Connect.

If the PostgreSQL database server is on a different machine, note the following:

- The PostgreSQL database server must be configured to accept connections from clients. Specifically, the pg_hba.conf file must be configured to allow non-local connections. Secondly, the postgresql.conf file must be configured to listen on specified IP address(es) and port. For more information, check the PostgreSQL documentation (https://www.postgresql.org/docs/9.5/static/client-authentication-problems.html).
The server machine must be configured to accept connections on the designated port (typically, 5432) through the firewall. For example, on a database server running on Windows, a rule may need to be created to allow connections on port 5432 through the firewall, from Control Panel > Windows Firewall > Advanced Settings > Inbound Rules.

10.2.8 SQLite Connection

SQLite (https://www.sqlite.org/index.html) is a file-based, self-contained database type, which makes it ideal in scenarios where portability and ease of configuration is important. Since SQLite databases are natively supported by StyleVision, you do not need to install any drivers to connect to them.

10.2.8.1 Connect to an Existing SQLite Database

To connect to an existing SQLite database:

1. Run the database connection wizard (see Starting the Database Connection Wizard).
2. Select SQLite, and then click Next.
3. Browse for the SQLite database file, or enter the path (either relative or absolute) to the database. The Connect button becomes enabled once you enter the path to a SQLite database file.
4. Optionally, select the Disable Foreign Keys check box, see Foreign Key Constraints.
5. Click Connect.

10.2.8.2 Foreign Key Constraints

When you connect to an existing SQLite database from StyleVision, foreign key constraints are enabled by default. Foreign key constraints help preserve the integrity of data in your database. For example, when foreign keys are enabled, it is not possible to delete a record from a table if it has dependencies in another table.
In certain cases, you may want to temporarily override this behavior and disable foreign keys, perhaps, in order to update or insert multiple rows of data without getting data validation errors. To explicitly disable foreign keys before connecting to the SQLite database, select the **Disable Foreign Keys** option available on the database connection wizard.

!["Connect to SQLite" wizard page](image)

When foreign keys are disabled, you will be able to perform operations against data that would otherwise not be possible due to validation checks. At the same time, however, there is also the risk of introducing incorrect data into the database, or creating "orphaned" rows. (An example of an "orphaned" row would be an address in the "addresses" table not linked to any person in the "person" table, because the person was deleted but its associated address was not.)

### 10.2.9 MongoDB Connection

To connect to an existing MongoDB, do the following.

1. Start the database connection wizard (see *Starting the Connection Wizard*).
2. Select MongoDB, and then click **Next**.
3. In the *Connect to MongoDB* screen that appears (screenshot below), enter the connection details of the MongoDB.
4. Click **Connect**.
5. The connection will be made and the **Insert Database Objects** screen appears, in which the document (record) collections of the selected database will be listed.
6. Select the collection/s that you want and click **OK**.

### 10.2.10 CouchDB Connection

To connect to an existing CouchDB, do the following.

1. Start the database connection wizard (see [Starting the Connection Wizard](#)).
2. Select **CouchDB**, and then click **Next**.
3. In the **Connect to CouchDB** screen that appears (screenshot below), enter the connection details of the CouchDB.
4. Click **Connect**.
5. The connection will be made and the *Insert Database Objects* screen appears, in which the tables of the database will be listed.
6. Select the table/s that you want and click **OK**.

### 10.2.11 Global Resources

After you have created a database as a global resource, its connection details are stored and can be used across all Altova products installed on your machine.

#### Create a database as a global resource

To create a database as a global resource, do the following:

1. On the **Tools** menu of StyleVision, click **Global Resources**.
2. Click **Add**, and then click Database.
3. Type in a name for the global resource in the *Resource Alias* field.
4. Click **Choose Database**. The *Connection Wizard* appears.
5. Use the Connection Wizard to add a database connection as described above.

#### Use a global-resource database

To use a database that has been created as a global resource (*see above*), do the following:

1. Start the Connection Wizard as described above.
2. Select Global Resources. All the databases that have been created as global resources will be listed by their names in the Global Resources pane (*see screenshot below*).
3. Select the global resource that you want. Tip: Move the mouse cursor over a global resource in the list to see information about the database.

10.2.12 Database Connection Examples

This section includes examples for connecting to a database from StyleVision through ADO, ODBC, or JDBC. The ADO.NET connection examples are listed separately, see Sample ADO.NET Connection Strings. For instructions about establishing a native connection to PostgreSQL and SQLite, see Setting up a PostgreSQL Connection and Setting up a SQLite Connection, respectively.

Note the following:

- The instructions may differ if your Windows configuration, network environment and the database client or server software are not the same as the ones described in each example.
- For most database types, it is possible to connect using more than one data access technology (ADO, ADO.NET, ODBC, JDBC) or driver. The performance of the database connection, as well as its features and limitations will depend on the selected driver, database client software (if applicable), and any additional connectivity parameters that you may have configured outside StyleVision.

10.2.12.1 Firebird (JDBC)

This example illustrates how to connect to a Firebird database server through JDBC.

Prerequisites:

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application Options; b) The JVM path found in the Windows registry; c) The JAVA_HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The Firebird JDBC driver must be available on your operating system (it takes the form of a .jar file which provides connectivity to the database). The driver can be downloaded from the Firebird website (https://www.firebirdsql.org/). This example uses Jaybird 2.2.8.
- You have the following database connection details: host, database path or alias, username, and password.

To connect to Firebird through JDBC:

1. Start the database connection wizard.
2. Click JDBC Connections.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. In this example, the required .jar file is located at the following path: C:\jdbc\firebird\jaybird-full-2.2.8.jar. Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see also Configuring the CLASSPATH).
4. In the "Driver" box, select org.firebirdsql.jdbc.FBDriver. Note that this entry is available if a valid .jar file path is found either in the "Classpath" text box, or in the operating system's CLASSPATH environment variable (see the previous step).

```
Classpaths: C:\jdbc\firebird\jaybird-full-2.2.8.jar
Driver: org.firebirdsql.jdbc.FBDriver
Username: prod_admin
Password: ********
Database URL: jdbc:firebirdsql://firebirdsev/COMPANY
```

5. Enter the username and password to the database in the corresponding text boxes.
6. Enter the connection string to the database server in the Database URL text box, by replacing the highlighted values with the ones applicable to your database server.

```
jdbc:firebirdsql://<host>[:<port>]/<database path or alias>
```

7. Click Connect.
10.2.12.2 Firebird (ODBC)

This example illustrates how to connect to a Firebird 2.5.4 database running on a Linux server.

**Prerequisites:**

- The Firebird database server is configured to accept TCP/IP connections from clients.
- The Firebird ODBC driver must be installed on your operating system. This example uses the Firebird ODBC driver version 2.0.3.154 downloaded from the Firebird website (https://www.firebirdsql.org/).
- The Firebird client must be installed on your operating system. Note that there is no standalone installer available for the Firebird 2.5.4 client; the client is part of the Firebird server installation package. You can download the Firebird server installation package from the Firebird website (https://www.firebirdsql.org/), look for "Windows executable installer for full Superclassic/Classic or Superserver". To install only the client files, choose "Minimum client install - no server, no tools" when going through the wizard steps.

**Important:**

- The platform of both the Firebird ODBC driver and client (32-bit or 64-bit) must correspond to that of StyleVision.
- The version of the Firebird client must correspond to the version of Firebird server to which you are connecting.

- You have the following database connection details: server host name or IP address, database path (or alias) on the server, user name, and password.

**To connect to Firebird via ODBC:**

1. Start the database connection wizard.
2. Click ODBC Connections.
3. Select User DSN (or System DSN, if you have administrative privileges), and then click Add.
4. Select the Firebird driver, and then click User DSN (or System DSN, depending on what you selected in the previous step). If the Firebird driver is not available in the list, make sure that it is installed on your operating system (see also Viewing the Available ODBC Drivers).
5. Enter the database connection details as follows:

<table>
<thead>
<tr>
<th><strong>Data Source Name (DSN)</strong></th>
<th>Enter a descriptive name for the data source you are creating.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Enter the server host name or IP address, followed by a colon,</td>
</tr>
<tr>
<td><strong>firebirdserv:products</strong></td>
<td>followed by the database alias (or path). In this example, the host</td>
</tr>
<tr>
<td><strong>firebirdserv:products</strong></td>
<td>name is firebirdserv, and the database alias is products, as</td>
</tr>
<tr>
<td></td>
<td>follows:</td>
</tr>
<tr>
<td></td>
<td>firebirdserv:products</td>
</tr>
<tr>
<td></td>
<td>Using a database alias assumes that, on the server side, the</td>
</tr>
<tr>
<td></td>
<td>database administrator has configured the alias products to point</td>
</tr>
<tr>
<td></td>
<td>to the actual Firebird (.fdb) database file on the server (see the</td>
</tr>
<tr>
<td></td>
<td>Firebird documentation for more details).</td>
</tr>
<tr>
<td></td>
<td>You can also use the server IP address instead of the host name,</td>
</tr>
<tr>
<td></td>
<td>and a path instead of an alias; therefore, any of the following sample</td>
</tr>
<tr>
<td></td>
<td>connection strings are valid:</td>
</tr>
<tr>
<td></td>
<td>firebirdservserver:/var/Firebird/databases/butterflies.fdb</td>
</tr>
<tr>
<td></td>
<td>127.0.0.1:D:\Misc\Lenders.fdb</td>
</tr>
</tbody>
</table>
If the database is on the local Windows machine, click **Browse** and select the Firebird (.fdb) database file directly.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Client</strong></td>
<td>Enter the path to the <code>fbclient.dll</code> file. By default, this is the <code>bin</code> subdirectory of the Firebird installation directory.</td>
</tr>
<tr>
<td><strong>Database Account</strong></td>
<td>Enter the database user name supplied by the database administrator (in this example, <strong>PROD_ADMIN</strong>).</td>
</tr>
<tr>
<td><strong>Password</strong></td>
<td>Enter the database password supplied by the database administrator.</td>
</tr>
</tbody>
</table>

6. Click **OK**.

### 10.2.12.3 IBM DB2 (JDBC)

This example illustrates how to connect to an **IBM DB2** database server through JDBC.

**Prerequisites:**

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application **Options**, b) The JVM path found in the Windows registry; c) The `JAVA_HOME` environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK. This example uses Oracle's OpenJDK 11.0 64-bit, and, consequently, the 64-bit version of StyleVision.
- The JDBC driver (one or several .jar files that provide connectivity to the database) must be available on your operating system. This example uses the JDBC driver available after installing the **IBM Data Server Client** version 10.1 (64-bit). For the JDBC drivers to be installed, choose a **Typical** installation, or select this option explicitly on the installation wizard.
If you did not change the default installation path, the required .jar files will be in the `C:\Program Files\IBM\SQLLIB\java` directory after installation.

- You need the following database connection details: host, port, database name, username, and password.

To connect to IBM DB2 through JDBC:

1. Start the database connection wizard.
2. Click JDBC Connections.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. This examples refers to `C:\Program Files\IBM\SQLLIB\java\db2jcc.jar`. You may need to refer to the `db2jcc4.jar` driver, depending on the database server version. For driver compatibility, refer to IBM documentation (http://www-01.ibm.com/support/docview.wss?uid=swg21363866). Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see also Configuring the CLASSPATH).
4. In the "Driver" box, select `com.ibm.db2.jcc.DB2Driver`. This entry becomes available only if a valid .jar file path was found either in the "Classpaths" text box, or in the operating system's CLASSPATH environment variable (see the previous step).
5. Enter the username and password of the database user in the corresponding text boxes.
6. Enter the JDBC connection string in the **Database URL** text box. Make sure to replace the connection details with the ones applicable to your database server.

```
jdbc:db2://hostName:port/databaseName
```

7. Click **Connect**.

### 10.2.12.4 IBM DB2 (ODBC)

This example illustrates how to connect to an IBM DB2 database through ODBC.

**Prerequisites:**

- IBM Data Server Client must be installed and configured on your operating system (this example uses IBM Data Server Client 9.7). For installation instructions, check the documentation supplied with your IBM DB2 software. After installing the IBM Data Server Client, check if the ODBC drivers are available on your machine (see Viewing the Available ODBC Drivers).
- Create a database alias. There are several ways to do this:
  - From IBM DB2 Configuration Assistant
  - From IBM DB2 Command Line Processor
  - From the ODBC data source wizard (for this case, the instructions are shown below)
- You have the following database connection details: host, database, port, username, and password.

**To connect to IBM DB2:**

1. Start the database connection wizard and select IBM DB2 (ODBC/JDBC).
2. Click **Next**.
3. Select ODBC, and click Next. If prompted to edit the list of known drivers for the database, select the database drivers applicable to IBM DB2 (see Prerequisites), and click Next.
4. Select the IBM DB2 driver from the list, and then click **Connect**. (To edit the list of available drivers, click **Edit Drivers**, and then check or uncheck the IBM DB2 drivers you wish to add or remove, respectively.)
5. Enter a data source name (in this example, **DB2DSN**), and then click **Add**.

6. On the **Data Source** tab, enter the user name and password to the database.
7. On the **TCP/IP** tab, enter the database name, a name for the alias, the host name and the port number, and then click OK.
8. Enter again the username and password, and then click **OK**.
10.2.12.5 IBM DB2 for i (JDBC)

This example illustrates how to connect to an IBM DB2 for i database server through JDBC.

Prerequisites:

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application Options; b) The JVM path found in the Windows registry; c) The JAVA_HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK. This example uses Oracle's OpenJDK 11.0 64-bit, and, consequently, the 64-bit version of StyleVision.
- The JDBC driver (one or several .jar files that provide connectivity to the database) must be available on your operating system. This example uses the open source Toolbox for Java/JTOpen version 9.8 (http://jt400.sourceforge.net/). After you download the package and unpack to a local directory, the required .jar files will be available in the lib subdirectory.
- You need the following database connection details: host, username, and password.

To connect to IBM DB2 for i through JDBC:

1. Start the database connection wizard.
2. Click JDBC Connections.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. In this example, the required .jar file is at the following path: C:\jdbc\jtopen_9.8\jt400.jar. Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see also Configuring the CLASSPATH).
4. In the "Driver" box, select com.ibm.as400.access.AS400JDBCDriver. This entry becomes available only if a valid .jar file path was found either in the "Classpaths" text box, or in the operating system's CLASSPATH environment variable (see the previous step).
5. Enter the username and password of the database user in the corresponding text boxes.
6. Enter the JDBC connection string in the Database URL text box. Make sure to replace host with the host name or IP address of your database server.

```
jdbc:as400://host
```
7. Click **Connect**.

10.2.12.6  IBM DB2 for i (ODBC)

This example illustrates how to connect to an *IBM DB2 for i* database through ODBC.

**Prerequisites:**

- *IBM System i Access for Windows* must be installed on your operating system (this example uses *IBM System i Access for Windows V6R1 M0*). For installation instructions, check the documentation supplied with your *IBM DB2 for i* software. After installation, check if the ODBC driver is available on your machine (see [Viewing the Available ODBC Drivers](#)).

- You have the following database connection details: the I. P. address of the database server, database user name, and password.

- Run *System i Navigator* and follow the wizard to create a new connection. When prompted to specify a system, enter the I. P. address of the database server. After creating the connection, it is recommended to verify it (click on the connection, and select **File** > **Diagnostics** > **Verify Connection**). If you get connectivity errors, contact the database server administrator.

To connect to IBM DB2 for i:

1. **Start the database connection wizard**.
2. **Click ODBC connections**.
3. Click **User DSN** (alternatively, click **System DSN**, or **File DSN**, in which case the subsequent instructions will be similar).

4. Click **Add**.

5. Select the **iSeries Access ODBC Driver** from the list, and click **User DSN** (or **System DSN**, if applicable).

6. Enter a data source name and select the connection from the System combo box. In this example, the data source name is **iSeriesDSN** and the System is **192.0.2.0**.

7. Click Connection Options, select **Use the User ID specified below** and enter the name of the database user (in this example, **DBUSER**).
8. Click OK. The new data source becomes available in the list of DSNs.
9. Click Connect.
10. Enter the user name and password to the database when prompted, and then click OK.

10.2.12.7 IBM Informix (JDBC)

This example illustrates how to connect to an IBM Informix database server through JDBC.

Prerequisites:

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application Options; b) The JVM path found in the Windows registry; c) The JAVA_HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC driver (one or several .jar files that provide connectivity to the database) must be available on your operating system. In this example, IBM Informix JDBC driver version 3.70 is used. For the driver's installation instructions, see the documentation accompanying the driver or the "IBM Informix JDBC Driver Programmer's Guide".
- You have the following database connection details: host, name of the Informix server, database, port, username, and password.
To connect to IBM Informix through JDBC:

1. Start the database connection wizard.
2. Click JDBC Connections.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. In this example, the required .jar file is located at the following path: \Informix JDBC Driver\lib\ifxjdbc.jar. Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see also Configuring the CLASSPATH).
4. In the "Driver" box, select com.informix.jdbc.IfxDriver. Note that this entry is available if a valid .jar file path is found either in the "Classpaths" text box, or in the operating system's CLASSPATH environment variable (see the previous step).

5. Enter the username and password to the database in the corresponding text boxes.
6. Enter the connection string to the database server in the Database URL text box, by replacing the highlighted values with the ones applicable to your database server.

7. Click Connect.
10.2.12.8 MariaDB (ODBC)

This example illustrates how to connect to a MariaDB database server through ODBC.

**Prerequisites:**

- The MariaDB Connector/ODBC ([https://downloads.mariadb.org/connector-odbc/](https://downloads.mariadb.org/connector-odbc/)) must be installed.
- You have the following database connection details: host, database, port, username, and password.

**To connect to MariaDB through ODBC:**

1. Start the database connection wizard.
2. Select MariaDB (ODBC), and then click Next.
3. Select Create a new Data Source Name (DSN) with the driver, and choose MariaDB ODBC 3.0 Driver. If no such driver is available in the list, click Edit Drivers, and select any available MariaDB drivers (the list contains all ODBC drivers installed on your operating system).
4. Click Connect.
5. Enter name and, optionally, a description that will help you identify this ODBC data source in future.

6. Fill in the database connection credentials (TCP/IP Server, User, Password), select a database, and then click **Test DSN**. Upon successful connection, a message box appears:
7. Click **Next** and complete the wizard. Other parameters may be required, depending on the case (for example, SSL certificates if you are connecting to MariaDB through a secure connection).

**Note:** If the database server is remote, it must be configured by the server administrator to accept remote connections from your machine's IP address.

### 10.2.12.9 Microsoft Access (ADO)

A simple way to connect to a Microsoft Access database is to follow the wizard and browse for the database file, as shown in Connecting to an Existing Microsoft Access Database. An alternative approach is to set up an ADO connection explicitly, as shown in this topic. This approach is useful if your database is password-protected.

It is also possible to connect to Microsoft Access through an ODBC connection, but it has limitations, so it is best to avoid it.

**To connect to a password-protected Microsoft Access database:**

1. Start the database connection wizard.
2. Click **ADO Connections**.
3. Click **Build**.
4. Select the **Microsoft Office 15.0 Access Database Engine OLE DB Provider**, and then click **Next**.
5. In the Data Source box, enter the path to the Microsoft Access file in UNC format, for example, `\myserver\mynetworkshare\Reports\Revenue.accdb`, where `myserver` is the name of the server and `mynetworkshare` is the name of the network share.

6. On the **All** tab, double click the **Jet OLEDB:Database Password** property and enter the database password as property value.

**Note:** If you are still unable to connect, locate the workgroup information file (`System.MDW`) applicable to your user profile, and set the value of the **Jet OLEDB: System database** property to the path of the `System.MDW` file.

10.2.12.10 Microsoft SQL Server (ADO)

This example illustrates how to connect to a SQL Server database through ADO. These instructions are applicable when you use the recommended Microsoft OLE DB Driver for SQL Server (`MSOLEDBSQL`),

Before following these instructions, make sure that you have downloaded and installed the provider above on your workstation. The ADO provider must match the platform of StyleVision (32-bit or 64-bit).

If you would like to use other ADO providers such as SQL Server Native Client (SQLNCLI) or Microsoft OLE DB Provider for SQL Server (SQLOLEDB), the instructions are similar, but these providers are deprecated and thus not recommended. Also, for the connection to be successful with a deprecated provider, you may need to set additional connection properties as described in Setting up the SQL Server Data Link Properties.

The Microsoft OLE DB Provider for SQL Server (SQLOLEDB) is known to have issues with parameter binding of complex queries like Common Table Expressions (CTE) and nested SELECT statements.

To connect to SQL Server:

1. Start the database connection wizard.
2. Select Microsoft SQL Server (ADO), and then click Next. The list of available ADO providers is displayed. In this example, the Microsoft OLE DB Driver for SQL Server is used. If it's not in the list, make sure that it is installed on your computer, as mentioned above.

3. Click Next. The Data Link Properties dialog box appears.
4. Select or enter the name of the database server, for example, SQLSERV01. If you are connecting to a named SQL Server instance, the server name looks like SQLSERV01\SOMEINSTANCE.
5. If the database server was configured to allow connections from users authenticated on the Windows domain, select Windows Authentication. Otherwise, select SQL Server Authentication, clear the Blank password check box, and enter the database credentials in the relevant boxes.
6. Select the Allow saving password check box and the database to which you are connecting (in this example, "Nanonull").
7. To test the connection at this time, click **Test Connection**. This is an optional, recommended step.
8. Click **OK**.

### 10.2.12.11 Microsoft SQL Server (ODBC)

This example illustrates how to connect to a SQL Server database through ODBC.

**Prerequisites:**

- Download and install the **Microsoft ODBC Driver for SQL Server** from the Microsoft website, see [https://docs.microsoft.com/en-us/SQL/connect/odbc/download-odbc-driver-for-sql-server](https://docs.microsoft.com/en-us/SQL/connect/odbc/download-odbc-driver-for-sql-server). This example uses **Microsoft ODBC Driver 17 for SQL Server** to connect to a **SQL Server 2016** database. You might want to download a different ODBC driver version, depending on the version of SQL Server where you want to connect. For information about ODBC driver versions supported by your SQL Server database, refer to the driver's system requirements.
To connect to SQL Server using ODBC:

1. Start the database connection wizard.
2. Click ODBC Connections.
3. Select User DSN (or System DSN, if you have administrative privileges), and then click Add.
4. Select the driver from the list. Note that the driver appears in the list only after it has been installed.
5. Click User DSN (or System DSN if you are creating a System DSN).

Creating a System DSN requires that StyleVision be run as an administrator. Therefore, in order to create a System DSN, cancel the wizard, make sure that you run StyleVision as an administrator, and perform the steps above again.

6. Enter a name and, optionally, a description to identify this connection, and then select from the list the SQL Server to which you are connecting (SQLSERV01 in this example).
7. If the database server was configured to allow connections from users authenticated on the Windows domain, select **With Integrated Windows authentication**. Otherwise, select one of the other options, as applicable. This example uses **With SQL Server authentication**... , which requires that the user name and password be entered in the relevant boxes.
8. Optionally, select the Change the default database to check box and enter the name of the database to which you are connecting (in this example, Sandbox).
9. Click **Next** and, optionally, configure additional parameters for this connection.
10. Click Finish. A confirmation dialog box listing the connection details opens.
11. Click OK. The data source now appears in the list of User or System data sources, as configured, for example:

10.2.12.12 MySQL (ODBC)

This example illustrates how to connect to a MySQL database server from a Windows machine through the ODBC driver. The MySQL ODBC driver is not available on Windows, so it must be downloaded and installed separately. This example uses MySQL Connector/ODBC 8.0.
Prerequisites:

- MySQL ODBC driver must be installed on your operating system. Check the MySQL documentation for the driver version recommended for your database server version (see https://dev.mysql.com/downloads/connector/odbc/).
- You have the following database connection details: host, database, port, username, and password.

If you installed MySQL Connector/ODBC for 64-bit platform, make sure to install StyleVision for 64-bit platform as well.

To connect to MySQL via ODBC:

1. Start the database connection wizard.
2. Select MySQL (ODBC), and then click Next.

3. Select Create a new Data Source Name (DSN) with the driver, and select a MySQL driver. If no MySQL driver is available in the list, click Edit Drivers, and select any available MySQL drivers (the list contains all ODBC drivers installed on your operating system).

If you installed StyleVision 64-bit, then the 64-bit ODBC drivers are shown in the list. Otherwise, the 32-bit ODBC drivers are shown. See also Viewing the Available ODBC Drivers.

4. Click Connect.
5. In the Data Source Name box, enter a descriptive name that will help you identify this ODBC data source in future.
6. Fill in the database connection credentials (TCP/IP Server, User, Password), select a database, and then click **OK**.

**Note:** If the database server is remote, it must be configured by the server administrator to accept remote connections from your machine's IP address. Also, if you click **Details>>**, there are several additional parameters available for configuration. Check the driver's documentation before changing their default values.

### 10.2.12.13 Oracle (JDBC)

This example shows you how to connect to an Oracle database server from a client machine, using the JDBC interface. The connection is created as a pure Java connection, using the **Oracle Instant Client Package (Basic)** available from the Oracle website. The advantage of this connection type is that it requires only the Java environment and the .jar libraries supplied by the Oracle Instant Client Package, saving you the effort to install and configure a more complex database client.

**Prerequisites:**

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you
may have set in application **Options**; b) The JVM path found in the Windows registry; c) The **JAVA_HOME** environment variable.

- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The **Oracle Instant Client Package (Basic)** must be available on your operating system. The package can be downloaded from the official Oracle website. This example uses Oracle Instant Client Package version 12.1.0.2.0, for Windows 32-bit and, consequently, Oracle JDK 32-bit.
- You have the following database connection details: host, port, service name, username, and password.

To connect to Oracle through the Instant Client Package:

1. Start the database connection wizard.
2. Click **JDBC Connections**.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. In this example, the required .jar file is located at the following path: `C:\jdbc\instantclient_12_1\ojdbc7.jar`. Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see also Configuring the CLASSPATH).
4. In the "Driver" box, select either `oracle.jdbc.OracleDriver` or `oracle.jdbc.driver.OracleDriver`. Note that these entries are available if a valid .jar file path is found either in the "Classpaths" text box, or in the operating system's CLASSPATH environment variable (see the previous step).
5. Enter the username and password to the database in the corresponding text boxes.
6. Enter the connection string to the database server in the Database URL text box, by replacing the highlighted values with the ones applicable to your database server.
Connecting to a Data Source

Databases

10.2.12.14 Oracle (ODBC)

This example illustrates a common scenario where you connect from StyleVision to an Oracle database server on a network machine, through an Oracle database client installed on the local operating system.

The example includes instructions for setting up an ODBC data source (DSN) using the database connection wizard in StyleVision. If you have already created a DSN, or if you prefer to create it directly from the ODBC Data Source administrator in Windows, you can do so, and then select it when prompted by the wizard. For more information about ODBC data sources, see Setting up an ODBC Connection.

Prerequisites:

- The Oracle database client (which includes the ODBC Oracle driver) must be installed and configured on your operating system. For instructions on how to install and configure an Oracle database client, refer to the documentation supplied with your Oracle software.
- The tnsnames.ora file located in Oracle home directory contains an entry that describes the database connection parameters, in a format similar to this:

```plaintext
ORCL =
  (DESCRIPTION =
    (ADDRESS_LIST =
      (ADDRESS = (PROTOCOL = TCP)(HOST = server01)(PORT = 1521))
    )
  (CONNECT_DATA =
    (SID = orcl)
    (SERVER = DEDICATED)
  )
)
```

The path to the tnsnames.ora file depends on the location where Oracle home directory was installed. For Oracle database client 11.2.0, the default Oracle home directory path could be as follows:

```
C:\app\username\product\11.2.0\client_1\network\admin\tnsnames.ora
```

You can add new entries to the tnsnames.ora file either by pasting the connection details and saving the file, or by running the Oracle Net Configuration Assistant wizard (if available). If you want these values to appear in dropdown lists during the configuration process, then you may need to add the path to the admin folder as a TNS_ADMIN environment variable.

To connect to Oracle using ODBC:

1. Start the database connection wizard.
2. Select Oracle (ODBC / JDBC), and then click Next.

7. Click Connect.
3. Select **ODBC**.

4. Click **Edit Drivers**.
5. Select the Oracle drivers you wish to use (in this example, Oracle in OraClient11g_home1). The list displays the Oracle drivers available on your system after installation of Oracle client.

6. Click Back.

7. Select Create a new data source name (DSN) with the driver, and then select the Oracle driver chosen in step 4.
Avoid using the Microsoft-supplied driver called Microsoft ODBC for Oracle driver. Microsoft recommends using the ODBC driver provided by Oracle (see http://msdn.microsoft.com/en-us/library/ms714756%28v=vs.85%29.aspx)

8. Click Connect.
9. In the Data Source Name text box, enter a name to identify the data source (in this example, **Oracle DSN 1**).

10. In the TNS Service Name box, enter the connection name as it is defined in the `tnsnames.ora` file (see prerequisites). In this example, the connection name is **ORCL**. Note: If you wish to have the dropdown list of the combo box populated with the values of the `tnsnames.ora` file, then you may need to add the path to the admin folder as a **TNS_ADMIN** environment variable.

11. Click **OK**.

12. Enter the username and password to the database, and then click **OK**.

---

10.2.12.15 PostgreSQL (ODBC)

This example illustrates how to connect to a PostgreSQL database server from a Windows machine through the ODBC driver. The PostgreSQL ODBC driver is not available on Windows, so it must be downloaded and
installed separately. This example uses the psqlODBC driver (version 11.0) downloaded from the official website (see also Database Drivers Overview).

Note: You can also connect to a PostgreSQL database server directly (without the ODBC driver), see Setting up a PostgreSQL Connection.

Prerequisites:

- psqlODBC driver must be installed on your operating system.
- You have the following database connection details: server, port, database, user name, and password.

To set up a connection to PostgreSQL using ODBC:

1. Start the database connection wizard.
2. Click ODBC Connections.
3. Select the User DSN option.
4. Click Create a new DSN and select the driver from the drop-down list. If no PostgreSQL driver is available in the list, make sure that the PostgreSQL ODBC driver is installed on your operating system, as mentioned in the prerequisites above.
5. Click User DSN.
6. Fill in the database connection credentials (these must be supplied by the database owner), and then click **Save**.

The connection is now available in the list of ODBC connections. To connect to the database, you can either double-click the connection or select it, and then click **Connect**.
10.2.12.16 Progress OpenEdge (JDBC)

This example illustrates how to connect to a Progress OpenEdge 11.6 database server through JDBC.

Prerequisites

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application Options; b) The JVM path found in the Windows registry; c) The JAVA_HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The operating system's PATH environment variable must include the path to the bin directory of the JRE or JDK installation directory, for example C:\Program Files (x86)\Java\jre1.8.0_51\bin.
- The Progress OpenEdge JDBC driver must be available on your operating system. In this example, JDBC connectivity is provided by the openedge.jar and pool.jar driver component files available in C:\Progress\OpenEdge\java as part of the OpenEdge SDK installation.
- You have the following database connection details: host, port, database name, username, and password.

Connecting to OpenEdge through JDBC

1. Start the database connection wizard.
2. Click JDBC Connections.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. In this example, the required .jar file paths are: C:\Progress\OpenEdge\java\openedge.jar;C:\Progress\OpenEdge\java\pool.jar. Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see also Configuring the CLASSPATH).
4. In the "Driver" box, select com.ddtek.jdbc.openedge.OpenEdgeDriver. Note that this entry is available if a valid .jar file path is found either in the "Classpaths" text box, or in the operating system's CLASSPATH environment variable (see the previous step).
5. Enter the username and password to the database in the corresponding text boxes.
6. Enter the connection string to the database server in the Database URL text box, by replacing the highlighted values with the ones applicable to your database server.

```
jdbc:datadirect:openedge://host:port;databaseName=db_name
```

7. Click **Connect**.

### 10.2.12.17 Progress OpenEdge (ODBC)

This example illustrates how to connect to a Progress OpenEdge database server through the Progress OpenEdge 11.6 ODBC driver.

**Prerequisites:**

- The ODBC Connector for Progress OpenEdge driver must be installed on your operating system. The Progress OpenEdge ODBC driver can be downloaded from the vendor's website (see also Database Drivers Overview). Make sure to download the 32-bit driver when running the 32-bit version of StyleVision, and the 64-bit driver when running the 64-bit version. After installation, check if the ODBC driver is available on your machine (see also Viewing the Available ODBC Drivers).
You have the following database connection details: host name, port number, database name, user ID, and password.

Connecting to Progress OpenEdge through ODBC

1. Start the database connection wizard.
2. Click ODBC Connections.
3. Click User DSN (alternatively, click System DSN, or File DSN, in which case the subsequent instructions will be similar).
4. Click Add.
5. Select the Progress OpenEdge Driver from the list, and click User DSN (or System DSN, if applicable).
6. Fill in the database connection credentials (Database, Server, Port, User Name, Password), and then click **OK**. To verify connectivity before saving the entered data, click **Test Connect**.

![ODBC Progress OpenEdge Wire Protocol Driver Setup](image)

7. Click **OK**. The new data source now appears in the list of ODBC data sources.
8. Click **Connect**.

### 10.2.12.18 Sybase (JDBC)

This example illustrates how to connect to a Sybase database server through JDBC.

**Prerequisites:**

- **JRE** (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application **Options**; b) The JVM path found in the Windows registry; c) The **JAVA_HOME** environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- Sybase **jConnect** component must be installed on your operating system (in this example, **jConnect 7.0** is used, installed as part of the **Sybase Adaptive Server Enterprise PC Client** installation). For the installation instructions of the database client, refer to Sybase documentation.
- You have the following database connection details: host, port, database name, username, and password.
To connect to Sybase through JDBC:

1. Start the database connection wizard.
2. Click JDBC Connections.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. In this example, the required .jar file path is: `C:\sybase\jConnect-7_0\classes\jconn4.jar`. Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see also Configuring the CLASSPATH).
4. In the "Driver" box, select `com.sybase.jdbc4.jdbc.SybDriver`. Note that this entry is available if a valid .jar file path is found either in the "Classpaths" text box, or in the operating system's CLASSPATH environment variable (see the previous step).

5. Enter the username and password to the database in the corresponding text boxes.
6. Enter the connection string to the database server in the Database URL text box, by replacing the highlighted values with the ones applicable to your database server.

7. Click Connect.
10.2.12.19 Teradata (JDBC)

This example illustrates how to connect to a Teradata database server through JDBC.

Prerequisites:

- JRE (Java Runtime Environment) or Java Development Kit (JDK) must be installed. This may be either Oracle JDK or an open source build such as Oracle OpenJDK. StyleVision will determine the path to the Java Virtual Machine (JVM) from the following locations, in this order: a) The custom JVM path you may have set in application Options; b) The JVM path found in the Windows registry; c) The JAVA_HOME environment variable.
- Make sure that the platform of StyleVision (32-bit, 64-bit) matches that of the JRE/JDK.
- The JDBC driver (one or more .jar files that provide connectivity to the database) must be available on your operating system. In this example, Teradata JDBC Driver 16.20.00.02 is used. For more information, see https://downloads.teradata.com/download/connectivity/jdbc-driver.
- You have the following database connection details: host, database, port, username, and password.

To connect to Teradata through JDBC:

1. Start the database connection wizard.
2. Click JDBC Connections.
3. Next to "Classpaths", enter the path to the .jar file which provides connectivity to the database. If necessary, you can also enter a semicolon-separated list of .jar file paths. In this example, the .jar files are located at the following path: C:\jdbc\teradata. Note that you can leave the "Classpaths" text box empty if you have added the .jar file path(s) to the CLASSPATH environment variable of the operating system (see Configuring the CLASSPATH).
4. In the "Driver" box, select com.teradata.jdbc.TeraDriver. Note that this entry is available if a valid .jar file path is found either in the "Classpath" text box, or in the operating system's CLASSPATH environment variable (see the previous step).
5. Enter the username and password to the database in the corresponding text boxes.
6. Enter the connection string to the database server in the Database URL text box, by replacing the highlighted value with the one applicable to your database server.

   jdbc:teradata://databaseServerName

7. Click Connect.
10.2.12.20 Teradata (ODBC)

This example illustrates how to connect to a Teradata database server through ODBC.

**Prerequisites:**

- The Teradata ODBC driver must be installed (see [https://downloads.teradata.com/download/connectivity/odbc-driver/windows](https://downloads.teradata.com/download/connectivity/odbc-driver/windows). This example uses Teradata ODBC Driver for Windows version 16.20.00.
- You have the following database connection details: host, username, and password.

**To connect to Teradata through ODBC:**

1. Press the Windows key, start typing "ODBC", and select *Set up ODBC data sources (32-bit)* from the list of suggestions. If you have a 64-bit ODBC driver, select *Set up ODBC data sources (64-bit)* and use 64-bit StyleVision in the subsequent steps.

2. Click the System DSN tab, and then click **Add**.
3. Select **Teradata Database ODBC Driver** and click **Finish**.
4. Enter name and, optionally, a description that will help you identify this ODBC data source in future. Also, enter the database connection credentials (Database server, User, Password), and, optionally, select a database.

5. Click OK. The data source now appears in the list.
6. Run StyleVision and start the database connection wizard.
7. Click **ODBC Connections**.
8. Click **System DSN**, select the data source created previously, and then click **Connect**.

Note: If you get the following error: "The driver returned invalid (or failed to return) SQL_DRIVER_ODBC_VER: 03.80", make sure that the path to the ODBC client (for example, **C:\Program Files\Teradata\Client\16.10\bin**, if you installed it to this location) exists in your system's PATH environment variable. If this path is missing, add it manually.
10.3 DB Data Selection

Selecting the schema and XML data that will be used in the SPS involves selecting one or more tables, or a cell, or a specific schema, depending on whether the database (DB) being used is a non-XML DB (such as MS Access) or an XML DB (IBM DB2 version 9.0, etc). We refer to the selection of the schema and XML data as DB data selection, and it is carried out immediately after connecting to the DB.

How the DB data is selected depends upon the type of DB to which the connection is being made:

- In the case of non-XML databases, you select the table/s for which the SPS is being created. StyleVision automatically generates: (i) a schema based on the structure of the table/s, and (ii) temporary XML files based on this schema and containing the data in the selected table/s. How to select the tables is described in the section DB Data Selection | Non-XML Databases.
- In the case of XML databases, you must do two things. First, select the XML cell of the DB in which the required XML data is stored. This XML data is loaded as the Working XML File of the SPS. Second, select the schema on which the SPS will be based. How to select the XML data and schema is explained in the section DB Data Selection | XML Databases.

10.3.1 Non-XML Databases

After a connection has been made to a non-XML database, the Insert Database Objects dialog appears. This dialog consists of two parts. In the upper Source pane, which contains a graphical representation of the tables in the DB, you select the tables required for the SPS. An XML Schema and XML data files will be generated by StyleVision on the basis of the tables selected. In the lower Preview pane of the Insert Database Objects dialog, you can preview the contents of the selected table.

The Source pane

In the Source pane, the DB tables are displayed graphically (see screenshot below). Select the tables required for the SPS by checking the respective check boxes.
The toolbar of the Source pane (screenshot below) contains three icons, respectively, from left to right: **Filter Folder Contents**, **Checked Objects Only**, and **Object Locator**. The **Checked Objects Only** icon toggles the display between all tables and checked tables.

### Filtering folder contents
To filter objects in the Source pane, do the following:

1. Click the **Filter Folder Contents** icon in the toolbar of the Source pane. The Filter icon appears next to the Tables folder.
2. Click the Filter icon next to the Tables folder, and select the filtering option from the popup menu (screenshot below), for example, **Starts with**.
3. In the entry field that appears, enter the filter string (in the screenshot below, the filter string on the Tables folder is A). The filter is applied as you type.

---

### The object locator
To find a specific database item by its name, you can use the Source pane's Object Locator. This works as follows:
1. In the toolbar of the Source pane, click the Object Locator icon. A combo box appears at the bottom of the Source pane.
2. Enter the search string in the entry field of this list, for example Altova (screenshot below). Clicking the drop-down arrow displays all objects that contain the search string.

3. Click the object in the list to see it in the Source pane.

Adding and editing SELECT statements for local views

You can create SELECT statements in SQL to create local views. When the schema is generated from a DB connection which has local views (or SELECT statements) defined for it, the schema that is generated for the DB will contain a table for each SELECT statement.

To create a SELECT statement, do the following:

1. Click the Add/Edit SELECT Statement tab. This pops up the Enter a SQL Select Statement dialog (screenshot below).
2. Enter the `SELECT` statement. If you connect to an Oracle or IBM DB2 database using JDBC, then the `SELECT` statement must have no final semicolon. If you wish to create a `SELECT` statement for an entire table, right-click the table in the Insert Database Objects dialog and select the context menu command Generate and Add a `SELECT` Statement.

3. Click Add Select Statement. The `SELECT` statement is added to the list of `SELECT` statements in the Insert Database Objects dialog (screenshot below).

![Screenshot of Add Select Statement](image1.png)

**Note:** If you connect to an Oracle or IBM DB2 database using JDBC and use a `SELECT` statement with the Add/Remove Table command to retrieve data, then the `SELECT` statement must have no final semicolon.

When you click Finish in the Insert Database Objects dialog, a table is created for each `SELECT` statement (screenshot below).

![Screenshot of Insert Database Objects](image2.png)
Local relations between tables

You can create local relations between two tables, similar to the primary-key/foreign-key kind of relationship. The relation is local, in StyleVision, which means that the database itself does not have to be modified. The local relationship will be represented in the generated schema.

To create a local relation, do the following:

1. In the Insert Database Objects dialog, click the Add/Edit Relations tab. This pops up the Add/Edit Table Relations dialog (see screenshot below).
2. Click the Add Relation button, and in the Primary/Unique Key column, click the dropdown button of the Select Table combo box (screenshot below). Select a table for the Foreign Key column also. The relationship that will be generated eventually will select rows in which the selected Primary/Unique Key column matches the selected Foreign Key column.

3. Select the Primary/Unique Key table column that must match the Foreign Key table column, and then select the Foreign Key column. Once again, use the combo boxes in the respective columns (see screenshot below). Notice that if there is a type mismatch, an error sign will be displayed.
4. Add more local relations, if required, by repeating steps 2 and 3 above.
5. Click **OK** to complete the relation. When the schema is generated, it will reflect the newly created relations.

Look at the two screenshots above and see how, in the generated schema, **Altova** and **Department** each contain **Address**. Those **Department** rows with **PrimaryKey** values equal to the **ForeignKey** value of the **Address** row will be output. And those **Altova** rows with **PrimaryKey** values equal to the **zip** value of the **Address** row will be output.

**Note:** Local relations between SQL **SELECT** statements are not supported.
Previews and the Preview pane

To preview the structure and contents of a table, select the table in the Source pane and then click the Preview button or Reload button—according to which of the two is displayed—in the Preview pane (screenshot below). The contents of the table are displayed in a table format in the Preview pane (screenshot below).

Generating the XML Schema and Working XML File from the DB

After you have selected the tables for which you wish to use in the SPS, click Finish to generate and load the XML Schema. An XML Schema with a structure corresponding to that of the DB with the selected tables is displayed in the Schema Tree Window. A Working XML File having a structure corresponding to that defined in the generated schema and containing data from the selected tables is also generated and is used for the output previews.
After making the connection to the IBM DB2 database, the Select XML Table dialog (screenshot below) appears.

1. In the Select XML Table dialog, select the table that contains the XML data you wish to create as the Working XML File. In the screenshot below, the table **NHE_TEST** has been selected.
2. Click **Next**. This pops up the Choose XML Field dialog (*screenshot below*). If you wish to filter the selection displayed in the pane, enter an SQL **WHERE** clause and click **Update**. Note that the **WHERE** clause should be just the condition (without the **WHERE** keyword, for example: `NHE_TEST_TEXT= 'Two'`)

3. Select the cell containing the XML data you wish to create as the Working XML File. In the screenshot above, the selected cell is highlighted in blue.

4. Click **Next**. This pops up the Choose XML Schema dialog, in which you select the schema to be used for the SPS. *See next section.*
Note: If you connect to an Oracle or IBM DB2 database using JDBC and use a `SELECT` statement with the Add/Remove Table command to retrieve data, then the `SELECT` statement must have no final semicolon.

Selecting the XML Schema for the SPS

The schema that will be used for the SPS can be either an XML Schema contained in the DB or a schema at a file location that can be accessed by StyleVision. To select the schema, do the following:

1. In the Choose XML Schema dialog (screenshot below), select the appropriate radio button according to whether you wish to select the schema from among those stored in the DB or from a file location. Note that if a non-DB schema is selected—that is, a schema from an external file—then no DB validation will be carried out.

2. Select the schema. Schemas stored in the DB are listed in the dropdown list of the Schemas from Database combo box, and can be selected from there. An external schema can be selected by browsing for it.

3. Click Finish to complete.

The schema tree

After completing the process to select the XML data and the schema, the selected XML data is created as the Working XML File and the schema is loaded into the SPS. Both are displayed in the Schema Tree window (screenshot below).
The SPS can now be built using the usual StyleVision mechanisms. Note that the data in the Working XML File can be edited in Authentic View and saved to the DB.

**Note:** The Working XML File should be valid against the schema selected for the SPS. Also ensure that the schema’s root element corresponds to the root element of the XML document.
10.4  The DB Schema and DB XML files

The DB XML Schema
When you load a non-XML database (non-XML DB) into StyleVision, an XML Schema with a structure based on that of the DB is generated by StyleVision and displayed in the Schema Tree window. (In the case of XML DBs, an existing schema (either stored in the DB or at a file location) is specified as the schema to be used in the SPS.) This section on schemas, therefore, refers only to non-XML DBs.

The XML Schema is created with a document element called DB. The DB element contains child elements which correspond to the top-level tables in the DB. These top-level table elements are also created as entries in the Global Elements list in the Schema Tree Window. The top-level elements in the screenshot below are: Address, Altova, Department, Office, and Person; they correspond to tables in the DB.

Each top-level table element may have an unlimited number of rows (see screenshot below). Each row corresponds to a record in the DB. In the schema tree the rows are represented by a single Row element. Each Row element has attributes which correspond to the fields of the table. One of these attributes is generated by StyleVision for every row of every table: AltovaRowStatus, which holds the current status of the row: added, updated, and/or deleted. The remaining attributes are the fields of the respective DB table.
The structure of the generated XML Schema is as outlined above. Whatever tables are selected during the connection step are included in the structure. The construction of a DB Filter does not affect the structure of the XML Schema.

**New DB Schema Structure**

The structure of the XML Schema generated from DBs starting with the 2005 version of StyleVision is different than the structure generated in previous versions of StyleVision. The new structure enables the editing of databases in the Authentic View of Altova products—a feature which was not available with earlier versions. As a result, any SPS generated with earlier versions of StyleVision will generate an error when opened in versions of StyleVision starting from the 2005 version. To be able to use the DB editing and reporting features of StyleVision, you should recreate the SPS in the current version of StyleVision.
DB XML data files

After a connection to the XML DB has been made, the XML schema and column with XML data selected, the Schema Tree window (screenshot below) will list the selected schema and the column that will be used for the Working XML File.

Two temporary XML files are generated from the DB (see DBs and StyleVision for an illustration):

- A temporary editable XML file, which can be edited in Authentic View
- A temporary non-editable XML File, which is used as the Working XML File (for previews and output generation)

The temporary editable XML file is generated when the DB is loaded into StyleVision. It can be edited in Authentic View after the SPS has been created. The display in Authentic View can be filtered by using the Query mechanism available in Authentic View. Any modification made in Authentic View to the editable data is written to this temporary XML File. Clicking File | Save Authentic XML Data saves the information in the temporary editable XML file to the DB.

The temporary non-editable XML file is generated when the DB is loaded into StyleVision. It is used as the Working XML File and for generating HTML and RTF output. The editable XML file must be saved before changes made in Authentic View can be viewed in a preview.

Note:

- In the Authentic View of other Authentic View products only one temporary (editable) XML file is created when a DB-based SPS is opened. Modifications made in Authentic View are written to this file. When the file is saved, the information in the XML file is written to the DB.
- You can filter the data that goes into the non-editable temporary XML File for report-generation. (See Edit DB Filter for details.)
- You do not have to specifically assign a Working XML File in order to see HTML, Text, and RTF previews. The automatically generated (non-editable) temporary XML file is used for this purpose.
10.5 DB Filters: Filtering DB Data

The data that is imported into the temporary non-editable XML file from the database (DB) can be filtered. (Note that the non-editable XML file is used for report generation, and the effect of a DB filter will therefore be seen only in the HTMLText, and RTF preview; not in Authentic Preview, which displays the temporary editable XML file, and not in Authentic View.) The DB filter (DB Filter) can be created either within the DB itself (if this is supported in your DB application), or it can be created within the SPS (SPS file). In the SPS, one DB Filter can be created for each top-level data table in the XML Schema (i.e. for the data tables that are the children of the DB element). Each time a DB Filter is created or modified, the data from the DB is re-loaded into the temporary non-editable XML file that is generated for the DB. In this way, DB Filters help you to keep the XML file down to an optimal size and to thus make processing for report generation more efficient.

Note: Using a DB Filter modifies the data that is imported into the temporary non-editable XML File. If you save an SPS with a DB Filter and then generate an XML File from the SPS, the generated XML File will be filtered according to the criteria in the DB Filter.

Creating a DB Filter

1. In the Design Document or Schema Tree, select the data table element for which you wish to create a DB Filter (either by clicking the start or end tag of the element, or by selecting the element in the schema tree).

2. Select Database | Edit DB Filters or click the icon in the toolbar. The following dialog is displayed:

   ![Edit Database Filters Dialog]

3. Click the Append AND or Append OR button. This appends an empty criterion for the filter (shown below).
4. Enter the expression for the criterion. An expression consists of: (i) a field name (available from the associated combo-box); (ii) an operator (available from the associated combo-box); and (iii) a value (to be entered directly). For details of how to construct expressions see the Expressions in criteria section below.

5. If you wish to add another criterion, click the Append AND or Append OR button according to which logical operator (AND or OR) you wish to use to join the two criteria. Then add the new criterion. For details about the logical operators, see the section Re-ordering criteria in DB Filters.

Expressions in criteria

Expressions in DB Filter criteria consist of a field name, an operator, and a value. The available field names are the columns of the selected top-level data table; the names of these fields are listed in a combo-box (see screenshot above). The operators you can use are listed below:

- `=` Equal to
- `<>` Not equal to
- `<` Less than
- `<=` Less than or equal to
- `>` Greater than
- `>=` Greater than or equal to
- `LIKE` Phonetically alike
- `NOT LIKE` Phonetically not alike
- `IS NULL` Is empty
- `NOT NULL` Is not empty

If `IS NULL` or `NOT NULL` is selected, the Value field is disabled. Values must be entered without quotes (or any other delimiter). Values must also have the same formatting as that of the corresponding DB field; otherwise the expression will evaluate to FALSE. For example, if a criterion for a field of the date datatype in an MS
Access DB has an expression `StartDate=25/05/2004`, the expression will evaluate to FALSE because the date datatype in an MS Access DB has a format of YYYY-MM-DD.

Using parameters with DB Filters

You can also enter the name of a parameter as the value of an expression. This causes the parameter to be called and its value to be used as the value of that expression. The parameter you enter here can be a parameter that has already been declared for the stylesheet, or it can be a parameter that you declare subsequently. Note, however, that when a parameter that has not been declared is typed into the value field, the OK button is disabled.

Parameters are useful if you wish to use a single value in multiple expressions, or if you wish to pass a value to a parameter from the command line (see StyleVision Server for details).

To enter the name of a parameter as the value of an expression, type $ into the value input field followed (without any intervening space) by the name of the parameter. If the parameter has already been declared (see Parameters), then the entry will be colored green. If the parameter has not been declared, the entry will be red, and you must declare it.

Declaring parameters from the Edit DB Filter dialog

To access the Edit Parameters dialog (in order to declare parameters), do the following:

1. Click the Parameters... button in the Edit DB Filters dialog. This pops up the Edit Parameters dialog shown below.

   ![Edit Parameters Dialog](image)

   In this dialog parameter names are shown without leading '$'.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>10.00</td>
</tr>
<tr>
<td>state</td>
<td>CA</td>
</tr>
<tr>
<td>date</td>
<td>2004-06-24</td>
</tr>
</tbody>
</table>

2. Type in the name and value of the parameter in the appropriate fields.

Alternatively, you can access the Edit Parameters dialog and declare or edit a DB Parameter by selecting Edit | Stylesheet Parameters.

**Note:** The Edit Parameters dialog contains all the parameters that have been defined for the stylesheet. While it is an error to use an undeclared parameter in the SPS, it is not an error to declare a parameter and not use it.
After a DB Filter is created for a data table element, that element in the Schema Tree is displayed with the filter symbol, as shown for the **Addresses** element in the screenshot below.

---

### Re-ordering criteria in DB Filters

The logical structure of the DB Filter and the relationship between any two criteria or sets of criteria is indicated graphically. Each level of the logical structure is indicated by a square bracket. Two adjacent criteria or sets of criteria indicate the AND operator, whereas if two criteria are separated by the word **OR** then the OR operator is indicated. The criteria are also appropriately indented to provide a clear overview of the logical structure of the DB Filter.

The DB Filter shown in the screenshot above may be represented in text as:

\[
\text{State}=\text{CA} \land (\text{City}=\text{Los Angeles} \lor \text{City}=\text{San Diego} \lor (\text{City}=\text{San Francisco} \land \text{CustomerNr}=25))
\]

You can re-order the DB Filter by moving a criterion or set of criteria up or down relative to the other criteria in the DB Filter. To move a criterion or set of criteria, do the following:

1. Select the criterion by clicking on it, or select an entire level by clicking on the bracket that represents that level.
2. Click the Up or Down arrow button in the dialog.

The following points should be noted:

- If the adjacent criterion in the direction of movement is at the same level, the two criteria exchange places.
- A set of criteria (i.e. criteria within a bracket) changes position within the same level; it does not change levels.
- An individual criterion changes position within the same level. If the adjacent criterion is further outward/inward (i.e. not on the same level), then the selected criterion will move outward/inward, one level at a time.

To delete a criterion in a DB Filter, select the criterion and click Delete.

Modifying a DB Filter
To modify a DB Filter, select Database | Edit DB Filters. This pops up the Edit DB Filters dialog box. You can now edit the expressions in any of the listed criteria, add new criteria, re-order criteria, or delete criteria in the DB Filter. After you have completed the modifications, click OK. The data from the DB is automatically re-loaded into StyleVision so as to reflect the modifications to the DB Filter.

Clearing (deleting) a DB Filter
To clear (or delete) a DB Filter, select the element for which the DB Filter has to be cleared either in the Design Window or the Schema Tree. (There is one DB Filter for each (top-level) data table element.) Then click Database | Clear DB Filter. The filter will be cleared, and the filter symbol will no longer appear alongside the name of the element in the Schema Tree.
10.6 SPS Design Features for DB

You can design a DB-based SPS just as you would design any other schema-based SPS, that is by dragging-and-dropping schema nodes from the schema window into the design document; by inserting static content directly in the design document; and by applying suitable formatting to the various design components. The following points, however, are specific to DB-based SPSs.

Creating a dynamic table for a DB table

To create a dynamic table for a DB table, do the following:

1. In the schema tree, select the top-level DB table to be created as a dynamic table, drag it into the design.
2. When you drop it, create is as contents and delete the contents placeholder. If the Auto-Add DB Controls feature is on, your design will look something like this:

3. In the schema tree, select the Row element of the DB table you wish to create as a dynamic table.
4. Drag it to a location inside the Addresses element.
5. When you release the element, select Create Table from the menu that pops up, and select the DB fields you wish to create as columns of the dynamic table. The DB table is created as a dynamic table.

Note: You can also create a DB table in any other format, such as (contents).

Auto-add DB Controls

The Authentic | Auto-add DB Controls menu command or the toolbar icon toggles the auto-insertion of navigation controls for DB tables on and off. When the toggle is switched on, this toolbar icon has a black border; when the toggle is off, the toolbar icon has no border. If the Auto-insert toggle is on, DB Controls (see screenshot below) are automatically inserted when a DB table is dropped into the Design document. It is dropped, by default, immediately after the start tag of the table.

These controls enable the Authentic View user to navigate the records of the DB table in Authentic View. The first (leftmost) button navigates to the first record; the second button navigates to the previous record; the third button is the Goto Record button, which pops up the Goto Record dialog (screenshot below); it pops up a dialog that prompts you for the number of the record to which you wish to go; the fourth button navigates to the next record; and the fifth button navigates to the last record.
To manually insert the navigation controls in the Design document—which is useful if you wish to insert the controls at some other location than the default location—then do the following:

1. Turn the Auto-insert DB Controls toggle off.
2. Place the cursor at the location where you wish the navigation controls to appear (but within the DB table element's start and end tags).
3. Right-click, and from the popup menu, select Insert DB Control | Navigation or Insert DB Control | Navigation+Goto. Alternatively, these commands can be accessed via the Insert menu.

Inserting a DB Query button for

The DB Query button enables the Authentic View user to submit a DB query. This helps the user to build conditions for the records to be displayed in Authentic View. Query buttons can be inserted for individual DB tables anywhere between:

- The start tag of the DB table element and the start tag of the DB table element's (child) Row element.
- The end tag of the DB table element and the end tag of that table element's (child) Row element.

To insert a DB Query button in your Design document, do the following:

1. Place the cursor at the allowed location (see above) where you wish the Query button to appear.
2. Right-click, and from the context menu (or Insert menu), select Insert | DB Control | Query Button. The Query Button is inserted at that point in the Design document.

When it is clicked in Authentic View, the Query button will pop up the Edit Database Query dialog. This dialog is described in the Authentic View documentation.

Records displayed and records fetched

You can control the number of records displayed in Authentic View and the number of records fetched when the file is loaded. To make these settings, do the following:

1. In Design View, select the Row element that corresponds to the records to be displayed/fetched.
2. In the Properties sidebar, select template in the Properties For column, and the Authentic group of properties.
3. For the property **DB Rows Displayed**, select **all** from the dropdown list or enter the number of rows to be displayed.

4. For the property **DB Rows Fetched**, select **all** or **all displayed** from the dropdown list, or enter the number of rows to be fetched. The value **all displayed** is the default. This property determines how many rows are fetched when the DB data is loaded. If the value is less than that of the **DB Rows Displayed** property, then the value of **DB Rows Displayed** is used as the value of **DB Rows Fetched**. The **DB Rows Fetched** property enables you to reduce the number of rows initially loaded, thus speeding up the loading and display time. Additional rows (records) are loaded and displayed when the row navigation buttons in Authentic View are used.

**Note:**
- The number of rows displayed is applied to Authentic View.
- If a large number of tables is open in Authentic View, then the user will get an error message saying that too many tables are open. On the design side, you can reduce the number of tables that are open by reducing the number of rows displayed (because a row can contain tables). On the user side, the user can use queries to reduce the number of tables loaded into Authentic View.

**AltovaRowStatus**

In the XML Schema that is created from a DB, each table has an **AltovaRowStatus** attribute. The value of this attribute is automatically determined by StyleVision and consists of three characters, which are initialized to **---**. If a row is modified, or a new row is added, the value is changed using the following characters.

<table>
<thead>
<tr>
<th>Character(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>The row has been added (but not yet saved to the DB).</td>
</tr>
<tr>
<td>U, u</td>
<td>The row has been updated (but not yet saved to the DB).</td>
</tr>
<tr>
<td>D, d, X</td>
<td>The row has been deleted (but not yet saved to the DB).</td>
</tr>
</tbody>
</table>

These values can be used to provide users with information about rows being edited. The status information exists up to the time when the file is saved. After the file is saved, the status information is initialized (indicated by **---**).
Formatting design document components

When records are added, modified, or deleted, StyleVision formats the added/modified/deleted records in a certain way to enable users to distinguish them from other records. Datatype errors are also flagged by being displayed in red. If you wish to maintain this differentiation, make sure that the formatting you assign to rows in a table do not have the same properties as those assigned by StyleVision. The formatting assigned by StyleVision is as follows:

<table>
<thead>
<tr>
<th>Added</th>
<th>A</th>
<th>Bold, underlined</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modified (Updated)</td>
<td>U, u</td>
<td>Underlined</td>
</tr>
<tr>
<td>Deleted</td>
<td>D, d, X</td>
<td>Strikethrough</td>
</tr>
<tr>
<td>Datatype error</td>
<td></td>
<td>Red text</td>
</tr>
</tbody>
</table>
10.7 Generating Output Files

After you have created a DB-based SPS, you can generate files related to it and save them. The following files can be generated and saved:

- The XML Schema based on the DB structure
- The XML file having the structure of the generated XML Schema and content from the DB
- The XSLT file for HTML output
- The HTML output file
- The XSLT file for RTF output
- The RTF output file

The files can be generated and saved from within the GUI or from the command line.

From within the StyleVision GUI

1. In the File menu, select the Save Generated Files item. This pops up the following submenu.

   ![Save Generated Files Menu]

2. Select the file you wish to generate. This pops up the Save As dialog.
3. Browse for the desired folder, enter the desired filename, and click OK.

From the command line

From the command line, you can call StyleVision so that it generates and saves files associated with a DB-based SPS. You can save not only the XML Schema and XSLT files, but also an XML file with data from the DB, and HTML and RTF output files based on the design in the SPS.
10.8 Query Database

The **Query Database** command in the **Database** menu opens the Database Query window *(screenshot below)*. Once the Query Window is open, its display can be toggled on and off by clicking either the **Database** command or the Query Database toolbar icon.

![Database Query Window](image)

**Overview of the Database Query window**

The Database Query window consists of three parts:

- A **Browser pane** at top left, which displays connection info and database tables.
- A **Query pane** at top right, in which the query is entered.
- A tabbed **Results/Messages pane**. The Results pane displays the query results in what we call the Result Grid. The Messages pane displays messages about the query execution, including warnings and errors.

The Database Query window has a toolbar at the top. At this point, take note of the two toolbar icons below. The other toolbar icons are described in the section, **Query Pane: Description and Features**.

- **Toggles the Browser pane on and off.**
Overview of the Query Database mechanism

The Query Database mechanism is as follows. (It is described in detail in the sub-sections of this section.)

1. A connection to the database is established via the Database Query | Connect to a Data Source window.
2. The connected database or parts of it are displayed in the Browser pane, which can be configured to suit viewing requirements.
3. A query written in a syntax appropriate to the database to be queried is entered in the Query pane, and the query is executed.
4. The results of the query can be viewed through various filters.

10.8.1 Data Sources

In order to query a database, you have to first connect to the required database. This section describes how to:

- Connect to a database, and
- Select the required data source and root object from among multiple existing connections.

Connecting to a database

When you click the Query Database command in the Database menu for the first time in a session (and when no database connection exists), the Connect to a Data Source dialog (screenshot below) pops up to enable you to connect to a database. To make connections subsequently, click the Quick Connect icon in the Database Query window. If connections already exist, you can select the required connection from among these.
How to connect to a database via the Connect to a Data Source dialog is described in the section Connecting to a Data Source.

Supported databases

The following databases are supported. While Altova endeavors to support other databases, successful connection and data processing have only been tested with the databases listed below. If your Altova application is a 64-bit version, ensure that you have access to the 64-bit database drivers needed for the specific database you are connecting to.

<table>
<thead>
<tr>
<th>Database</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firebird 2.5.4, 3.0</td>
<td></td>
</tr>
<tr>
<td>IBM DB2 8.x, 9.1, 9.5, 9.7, 10.1, 10.5, 11.5</td>
<td></td>
</tr>
<tr>
<td>IBM Db2 for i 6.1, 7.1, 7.2, 7.3, 7.4</td>
<td>Logical files are supported and shown as views.</td>
</tr>
<tr>
<td>IBM Informix 11.70, 12.10, 14.10</td>
<td></td>
</tr>
</tbody>
</table>
### Databases

<table>
<thead>
<tr>
<th>Database</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MariaDB 10.2, 10.3, 10.4, 10.5</td>
<td>At the time of writing (early September 2019), there is no Microsoft Access Runtime available for Access 2019. You can connect to an Access 2019 database from Altova products only if Microsoft Access 2016 Runtime is installed and only if the database does not use the &quot;Large Number&quot; data type.</td>
</tr>
<tr>
<td>Microsoft Azure SQL Database</td>
<td>SQL Server 2016 codebase</td>
</tr>
<tr>
<td>Microsoft SQL Server on Linux</td>
<td></td>
</tr>
<tr>
<td>MySQL 5.0, 5.1, 5.5, 5.6, 5.7, 8.0, 8.0.25</td>
<td></td>
</tr>
<tr>
<td>Oracle 9i, 10g, 11g, 12c, 18, 19</td>
<td></td>
</tr>
<tr>
<td>PostgreSQL 8.0, 8.1, 8.2, 8.3, 9.0.10, 9.1.6, 9.2.1, 9.4, 9.5, 9.6, 10, 11, 12.1, 13</td>
<td>PostgreSQL connections are supported both as native connections and driver-based connections through interfaces (drivers) such as ODBC or JDBC. Native connections do not require any drivers.</td>
</tr>
<tr>
<td>Progress OpenEdge 11.6</td>
<td></td>
</tr>
<tr>
<td>SQLite 3.35.5</td>
<td>SQLite connections are supported as native, direct connections to the SQLite database file. No separate drivers are required. In Authentic view, data coming from a SQLite database is not editable. When you attempt to save SQLite data from the Authentic view, a message box will inform you of this known limitation.</td>
</tr>
<tr>
<td>Sybase ASE 15, 16</td>
<td></td>
</tr>
<tr>
<td>Teradata 16</td>
<td></td>
</tr>
</tbody>
</table>

### Selecting the required data source

All the existing connections and the root objects of each are listed, respectively, in two combo boxes in the toolbar of the Database Query window (*screenshot below*). After selecting the required data source in the left-hand combo box, you can select the required root object from the right-hand combo box.
In the screenshot above, the database with the name StyleVision DB has been selected. Of the available root objects for this database, the root object ALTOVA_USER has been selected. The database and the root object are then displayed in the Browser pane.

10.8.2 Browser Pane: Viewing the DB Objects

The Browser pane provides an overview of objects in the selected database. This overview includes database constraint information, such as whether a column is a primary or foreign key. In IBM DB2 version 9 databases, the Browser additionally shows registered XML schemas in a separate folder (see screenshot below).

This section describes the following:

- The layouts available in the Browser pane.
- How to filter database objects.
- How to find database objects.
- How to refresh the root object of the active data source.

Browser pane layouts

The default Folders layout displays database objects hierarchically. Depending on the selected object, different context menu options are available when you right-click an item.
To select a layout for the Browser, click the Layout icon in the toolbar of the Browser pane (screenshot below) and select the layout from the drop-down list. Note that the icon changes with the selected layout.

The available layouts are:

- **Folders**: Organizes database objects into folders based on object type in a hierarchical tree, this is the default setting.
- **No Schemas**: Similar to the Folders layout, except that there are no database schema folders; tables are therefore not categorized by database schema.
- **No Folders**: Displays database objects in a hierarchy without using folders.
- **Flat**: Divides database objects by type in the first hierarchical level. For example, instead of columns being contained in the corresponding table, all columns are displayed in a separate Columns folder.
• **Table Dependencies**: Categorizes tables according to their relationships with other tables. There are categories for tables with foreign keys, tables referenced by foreign keys and tables that have no relationships to other tables.

To sort tables into User and System tables, switch to Folders, No Schemas or Flat layout, then right-click the Tables folder and select **Sort into User and System Tables**. The tables are sorted alphabetically in the User Tables and System Tables folders.

**Filtering database objects**

In the Browser pane (in all layouts except No Folders and Table Dependencies), schemas, tables, and views can be filtered by name or part of a name. Objects are filtered as you type in the characters, and filtering is case-insensitive by default.

To filter objects in the Browser, do the following:

1. Click the Filter Folder Contents icon in the toolbar of the Browser pane. Filter icons appear next to the Tables and Views folders in the currently selected layout (screenshot below).

2. Click the filter icon next to the folder you want to filter, and select the filtering option from the popup menu, for example, **Contains**.

3. In the entry field that appears, enter the filter string (in the screenshot below, the filter string on the **Tables** folder is `NHE`). The filter is applied as you type.
Finding database objects

To find a specific database item by its name, you can use the Browser pane's Object Locator. This works as follows:

1. In the toolbar of the Browser pane, click the Object Locator icon. A drop-down list appears at the bottom of the Browser pane.
2. Enter the search string in the entry field of this list, for example name (screenshot below). Clicking the drop-down arrow displays all objects that contain the search string.

3. Click the object in the list to see it in the Browser pane.
Refreshing the root object
The root object of the active data source can be refreshed by clicking the **Refresh** button of the Browser pane's toolbar.

10.8.3 Query Pane: Description and Features

The Query pane is an intelligent SQL editor for entering queries to the selected database. After entering the query, clicking the **Execute command** of the Database Query window executes the query and displays the result and execution messages in the **Results/Messages pane**. How to work with queries is described in the next section, **Query Pane: Working with Queries**. In this section, we describe the main features of the Query pane:

- **SQL Editor icons** in the Database Query toolbar
- **SQL Editor options**
- **Auto-completion of SQL statements**
- **Definition of regions in an SQL script**
- **Insertion of comments in an SQL script**
- **Use of bookmarks**

SQL Editor icons in the Database Query toolbar
The following icons in the toolbar of the Database Query window are used when working with the SQL Editor:

- **Execute** Executes currently selected SQL statement. If script contains multiple statements and none is selected, then all are executed.
- **Import SQL File** Opens an SQL file in the SQL Editor.
- **Export SQL File** Saves SQL queries to an SQL file.
- **Undo** Undoes an unlimited number of edits in SQL Editor.
- **Redo** Redoes an unlimited number of edits in SQL Editor.
- **Options** Opens the Options dialog of SQL Editor.
- **Open SQL Script in DatabaseSpy** Opens the SQL script in Altova's DatabaseSpy product.

SQL Editor options
Clicking the **Options** icon in the Database Query toolbar pops up the Options dialog. A page of settings can be selected in the left-hand pane, and the options on that page can be selected. Click the **Reset to Page Defaults** button to reset the options on that page to their original settings.
The key settings are as follows:

- **General | Encoding**: Options for setting the encoding of new SQL files, of existing SQL files for which the encoding cannot be detected, and for setting the Byte Order Mark (BOM). (If the encoding of existing SQL files can be detected, the files are opened and saved without changing the encoding.)
- **SQL Editor**: Options for toggling syntax coloring and data source connections on execution on/off. A timeout can be set for query execution, and a dialog to change the timeout can also be shown if the specified time is exceeded. Entry helpers refer to the entry helpers that appear as part of the auto-completion feature. When you type in an SQL statement, the editor displays a list of context-sensitive auto-completion suggestions. These suggestions can be set to appear automatically. If the automatic display is switched off, then you can ask for an auto-completion suggestion in SQL Editor at any point in the SQL query by pressing **Ctrl+Spacebar**. The buffer for the entry helper information can be filled either on connection to the data source or the first time it is needed. The Text View settings button opens a dialog in which you can specify settings such as indentation and tab size of text in the SQL Editor.
- **SQL Editor | SQL Generation**: The application generates SQL statements when you drag objects from the Browser pane into the Query pane. Options for SQL statement generation can be set in the SQL generation tab. Use the **Database** list box to select a database kind and set the statement generation options individually for the different database kinds you are working with. Activating the **Apply to all databases** check box sets the options that are currently selected for all databases. Options include appending semi-colons to statements and surrounding identifiers with escape characters.
- **SQL Editor | Result View**: Options to configure the Result tab.
- **SQL Editor | Fonts**: Options for setting the font style of the text in the Text Editor and in the Result View.
Definition of regions in an SQL script

Regions are sections in SQL scripts that are marked and declared to be a unit. Regions can be collapsed and expanded to hide or display parts of the script. It is also possible to nest regions within other regions. Regions are delimited by `--region` and `--endregion` comments, respectively, before and after the region. Regions can optionally be given a name, which is entered after the `--region` delimiter (see screenshot below).

To insert a region, select the statement/s to be made into a region, right-click, and select Insert Region. The expandable/collapsible region is created. Add a name if you wish. In the screenshot above, also notice the line-numbering. To remove a region, delete the two `--region` and `--endregion` delimiters.

Insertion of comments in an SQL script

Text in an SQL script can be commented out. These portions of the script are skipped when the script is executed.

- To comment out a block, mark the block, right-click, and select Insert/Remove Block Comment. To remove the block comment, mark the comment, right-click and select Insert/Remove Block Comment.
- To comment out a line or part of a line, place the cursor at the point where the line comment should start, right-click, and select Insert/Remove Line Comment. To remove the line comment, mark the comment, right-click and select Insert/Remove Line Comment.

Use of bookmarks

Bookmarks can be inserted at specific lines, and you can then navigate through the bookmarks in the document. To insert a bookmark, place the cursor in the line to be bookmarked, right-click, and select Insert/Remove Bookmark. To go to the next or previous bookmark, right-click, and select Go to Next Bookmark or Go to Previous Bookmark, respectively. To remove a bookmark, place the cursor in the line for which the bookmark is to be removed, right-click, and select Insert/Remove Bookmark. To remove all bookmarks, right-click, and select Remove All Bookmarks.

10.8.4 Query Pane: Working with Queries

After connecting to a database, an SQL script can be entered in the SQL Editor and executed. This section describes:

- How an SQL script is entered in the SQL Editor.
- How the script is executed in the Database Query window.
The following icons are referred to in this section:

- **Execute Query**: Executes currently selected SQL statement. If script contains multiple statements and none is selected, then all are executed.
- **Import SQL File**: Opens an SQL file in the SQL Editor.

### Creating SQL statements and scripts in the SQL Editor

The following GUI methods can be used to create SQL statements or scripts:

- **Drag and drop**: Drag an object from the Browser pane into the SQL Editor. An SQL statement is generated to query the database for that object.
- **Context menu**: Right-click an object in the Browser pane and select **Show in SQL Editor | Select**.
- **Manual entry**: Type SQL statements directly in SQL Editor. The Auto-completion feature can help with editing.
- **Import an SQL script**: Click the **Import SQL File** icon in the toolbar of the Database Query window.

### Executing SQL statements

If the SQL script in the SQL Editor has more than one SQL statement, select the statement to execute and click the **Execute** icon in the toolbar of the Database Query window. If no statement in the SQL script is selected, then all the statements in the script are executed. The database data is retrieved and displayed as a grid in the **Results tab**. Messages about the execution are displayed in the **Messages tab**.

### 10.8.5 Results and Messages

The Results/Messages pane has two tabs:

- The **Results tab** shows the data that is retrieved by the query.
- The **Messages tab** shows messages about the query execution.

#### Results tab

The data retrieved by the query is displayed in the form of a grid in the Results tab (*screenshot below*).
The following operations can be carried out in the Results tab, via the context menu that pops up when you right-click in the appropriate location in the Results tab:

- **Sorting on a column:** Right-click anywhere in the column on which the records are to be sorted, then select **Sorting | Ascending/Descending/Restore Default**.
- **Copying to the clipboard:** This consists of two steps: (i) selecting the data range; and (ii) copying the selection. Data can be selected in several ways: (i) by clicking a column header or row number to select the column or row, respectively; (ii) selecting individual cells (use the **Shift** and/or **Ctrl** keys to select multiple cells); (iii) right-clicking a cell, and selecting **Selection | Row/Column/All**. After making the selection, right-click, and select **Copy Selected Cells**. This copies the selection to the clipboard, from where it can be pasted into another application. To copy the header together with the cells, use the command **Copy Selected Cells with Header**.

The Results tab has the following toolbar icons:

- **Go to Statement**  Highlights the statement in the SQL Editor that produced the current result.
- **Find**  Finds text in the Results pane. XML document content is also searched.

**Messages tab**

The Messages tab provides information on the previously executed SQL statement and reports errors or warning messages.
The toolbar of the Messages tab contains icons that enable you to customize the view, navigate it, and copy messages to the clipboard. The Filter icon enables the display of particular types of messages to be toggled on or off. The Next and Previous icons let you step through the list, downwards and upwards, respectively. Messages can also be copied with or without their child components to the clipboard, enabling them to be pasted in documents. The Find function enables you to specify a search term and then search up or down the listing for this term. Finally, the Clear icon clears the contents of the Report pane.

**Note:** These toolbar icon commands are also available as context menu commands.
11 Authentic View

Authentic View (screenshot below) is a graphical representation of your XML document. It enables XML documents to be displayed without markup and with appropriate formatting and data-entry features such as input fields, combo boxes, and radio buttons. Data that the user enters in Authentic View is entered into the XML file.

Nanonull, Inc.

Location: US

<table>
<thead>
<tr>

</tbody>
</table>

Vereno Office Summary: 4 departments, 15 employees.

The company was established in Vereno in 1995 as a privately held software company. Since 1996, Nanonull has been actively involved in developing nanoelectronic software technologies. It released the first version of its acclaimed NanoSoft Development Suite in February 1999. Also in 1999, Nanonull increased its capital base with investment from a consortium of private investment firms. The company has been expanding rapidly ever since.

Authentic Preview

In StyleVision, while editing an SPS, you are able to preview the Authentic View of the assigned Working XML File. If you click the Authentic View tab when no Working XML File has been assigned to the SPS, you are prompted to assign a Working XML File. In Authentic Preview, you can edit the XML document, similarly to standard Authentic View, and the editing changes can be saved to the Working XML File. This section describes Authentic View and how to edit documents in Authentic View.
11.1 Authentic View Interface

Authentic Preview is enabled by clicking the Authentic tab of the active document. If no Working XML File has been assigned to the SPS, you are prompted to assign one.

This section provides:

- An overview of the interface
- A description of the toolbar icons specific to Authentic View
- A description of viewing modes available in the main Authentic Preview window
- A description of the context menus available at various points in the Authentic View of the XML document

Additional sources of Authentic View information are:

- An Authentic View Tutorial, which shows you how to use the Authentic View interface. This tutorial is available in the documentation of the Altova XMLSpy and Altova Authentic Desktop products (see the Tutorials section), as well as online.
- For a detailed description of Authentic View menu commands, see the User Reference section of your product documentation.

Altova website: XML content editing, XML authoring

11.1.1 Overview of the GUI

The Authentic Preview provides you with menu commands, toolbar icons, and context menus with which to edit the XML document that is displayed in the Main Window.

Menu bar
The menus available in the menu bar are described in detail in the User Reference section of your product documentation.

Toolbar
The symbols and icons displayed in the toolbar are described in the section, Authentic View toolbar icons.

Main window
This is the window in which the Working XML document is displayed and edited. It is described in the section, Authentic View main window.

Status Bar
The Status Bar displays the XPath to the currently selected node. In the Authentic Preview of StyleVision, the XPath to the currently selected node is indicated in the Schema Tree, where the currently selected node is highlighted in gray. The XPath in Authentic Preview is not displayed in a status bar.

Altova website: XML content editing, XML authoring
Context menus
These are the menus that appear when you right-click in the Main Window. The available commands are context-sensitive editing commands, i.e. they allow you to manipulate structure and content relevant to the selected node. Such manipulations include inserting, appending, or deleting a node, adding entities, or cutting and pasting content.

11.1.2 Authentic View Toolbar Icons

Icons in the Authentic View toolbar are command shortcuts. Some icons will already be familiar to you from other Windows applications or Altova products, others might be new to you. This section describes icons unique to Authentic View. In the description below, related icons are grouped together.

Show/hide XML markup
In Authentic View, the tags for all, some, or none of the XML elements or attributes can be displayed, either with their names (large markup) or without names (small markup). The four markup icons appear in the toolbar, and the corresponding commands are available in the Authentic menu.

- Hide markup. All XML tags are hidden except those which have been collapsed. Double-clicking on a collapsed tag (which is the usual way to expand it) in Hide markup mode will cause the node’s content to be displayed and the tags to be hidden.
- Show small markup. XML element/attribute tags are shown without names.
- Show large markup. XML element/attribute tags are shown with names.
- Show mixed markup. In the StyleVision Power Stylesheet, each XML element or attribute can be specified to display (as either large or small markup), or not to display at all. This is called mixed markup mode since some elements can be specified to be displayed with markup and some without markup. In mixed markup mode, therefore, the Authentic View user sees a customized markup. Note, however, that this customization is created by the person who has designed the StyleVision Power Stylesheet. It cannot be defined by the Authentic View user.

Editing dynamic table structures
Rows in a dynamic SPS table are repetitions of a data structure. Each row represents an occurrence of a single element. Each row, therefore, has the same XML substructure as the next.

The dynamic table editing commands manipulate the rows of a dynamic SPS table. That is, you can modify the number and order of the element occurrences. You cannot, however, edit the columns of a dynamic SPS table, since this would entail changing the substructure of individual element occurrences.
The icons for dynamic table editing commands appear in the toolbar, and are also available in the **Authentic** menu.

<table>
<thead>
<tr>
<th>Icon</th>

</tr>
<tr>
<td>![Icon]</td>
<td>Move current row down by one row</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Delete the current row</td>
</tr>
</tbody>
</table>

**Note:** These commands apply only to **dynamic SPS tables**. They should not be used inside static SPS tables.

**DB Row Navigation icons**

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Icon]</td>
<td>This icon opens the Edit Database Query dialog in which you can enter a query. Authentic View displays the queried record/s.</td>
</tr>
</tbody>
</table>

**XML database editing**

The **Select New Row with XML Data for Editing** command enables you to select a new row from the relevant table in an XML DB, such as IBM DB2. This row appears in Authentic View, can be edited there, and then saved back to the DB.

**XML File commands**

The following icons, from left to right, correspond to the commands listed below:

- **Save Authentic XML Data:** Saves the XML data file.
- **Save Authentic XML Data As:** Saves the XML data file as another file.
— **Reload Authentic View:** Reloads the saved XML data file. Any unsaved changes will be lost.
— **Validate:** Validates the XML data file.

### 11.1.3 Authentic View Main Window

There are four viewing modes in Authentic View: Large Markup; Small Markup; Mixed Markup; and Hide All Markup. These modes enable you to view the document with varying levels of markup information. To switch between modes, use the commands in the Authentic menu or the icons in the toolbar (see the previous section, Authentic View toolbar icons).

**Large markup**

This shows the start and end tags of elements and attributes with the element/attribute names in the tags:

```xml
<Department Name='Enter the department'><Name>Person</Name></Department>
```

The element `Name` in the figure above is **expanded**, i.e. the start and end tags, as well as the content of the element, are shown. An element/attribute can be **contracted** by double-clicking either its start or end tag. To expand the contracted element/attribute, double-click the contracted tag.

```xml
<Department><Name>Person</Name></Department>
```

In large markup, attributes are recognized by the equals-to symbol in the start and end tags of the attribute:

```xml
<country=USA>country</country>
```

**Small markup**

This shows the start and end tags of elements/attributes without names:
Nanonull, Inc.

Location: US

Street: 119 Oakstreet, Suite 4876
City: Vereno
State & Zip: DC 29213

Phone: +1 (321) 555 5155 0
Fax: +1 (321) 555 5155 4
E-mail: office@nanonull.com

Vereno Office Summary: 4 departments, 15 employees.

The company was established in Vereno in 1995 as a privately held software company. Since 1996, Nanonull has been actively involved in developing nanoelectronic software technologies. It released the first version of its acclaimed NanoSoft Development Suite in February 1999. Also in 1999, Nanonull increased its capital base with investment from a consortium of private investment firms. The company has been expanding rapidly ever since.

Notice that start tags have a symbol inside them while end tags are empty. Also, element tags have an angular-brackets symbol while attribute tags have an equals sign as their symbol (see screenshot below).

2006-04-01: Boston, USA

To collapse or expand an element/attribute, double-click the appropriate tag. The example below shows a collapsed element (highlighted in blue). Notice the shape of the tag of the collapsed element and that of the start tag of the expanded element to its left.

Office Summary: 4 departments, 15 employees.

Mixed markup

Mixed markup shows a customized level of markup. The person who has designed the StyleVision Power Stylesheet can specify either large markup, small markup, or no markup for individual elements/attributes in the document. The Authentic View user sees this customized markup in mixed markup viewing mode.
Hide all markup
All XML markup is hidden. Since the formatting seen in Authentic View is the formatting of the printed document, this viewing mode is a WYSIWYG view of the document.

Content display
In Authentic View, content is displayed in two ways:

- Plain text. You type in the text, and this text becomes the content of the element or the value of the attribute.

- Data-entry devices. The display contains either an input field (text box), a multiline input field, combo box, check box, or radio button. In the case of input fields and multiline input fields, the text you enter in the field becomes the XML content of the element or the value of the attribute.

Optional nodes
When an element or attribute is optional (according to the referenced schema), a prompt of type add [element/attribute] is displayed:

```
add synopsis
```

Clicking the prompt adds the element, and places the cursor for data entry. If there are multiple optional nodes, the prompt add... is displayed. Clicking the prompt displays a menu of the optional nodes.

11.1.4 Authentic View Entry Helpers

There are three entry helpers in Authentic View: for Elements, Attributes, and Entities. They are displayed as windows down the right side of the Authentic View interface (see screenshot below).
The Elements and Attributes Entry Helpers are context-sensitive, i.e. what appears in the entry helper depends on where the cursor is in the document. The entities displayed in the Entities Entry Helper are not context-sensitive; all entities allowed for the document are displayed no matter where the cursor is.

Each of the entry helpers is described separately below.

Elements Entry Helper

The Elements Entry Helper consists of two parts:

- The upper part, containing an XML tree that can be toggled on and off using the Show XML tree check box. The XML tree shows the ancestors up to the document's root element for the current element. When you click on an element in the XML tree, elements corresponding to that element (as described in the next item in this list) appear in the lower part of the Elements Entry Helper.
The lower part, containing a list of the nodes that can be inserted within, before, and after; removed; applied to or cleared from the selected element or text range in Authentic View. What you can do with an element listed in the Entry Helper is indicated by the icon to the left of the element name in the Entry Helper. The icons that occur in the Elements Entry Helper are listed below, together with an explanation of what they mean.

To use a node from the Entry Helper, click its icon.

- **Insert After Element**
  The element in the Entry Helper is inserted after the selected element. Note that it is appended at the correct hierarchical level. For example, if your cursor is inside a `//sect1/para` element, and you append a `sect1` element, then the new `sect1` element will be appended not as a following sibling of `//sect1/para` but as a following sibling of the `sect1` element that is the parent of that `para` element.

- **Insert Before Element**
  The element in the Entry Helper is inserted before the selected element. Note that, just as with the Insert After Element command, the element is inserted at the correct hierarchical level.

- **Remove Element**
  Removes the element and its content.

- **Insert Element**
  An element from the Entry Helper can also be inserted within an element. When the cursor is placed within an element, then the allowed child elements of that element can be inserted. Note that allowed child elements can be part of an elements-only content model as well as a mixed content model (text plus child elements).

  An allowed child element can be inserted either when a text range is selected or when the cursor is placed as an insertion point within the text.

  - When a text range is selected and an element inserted, the text range becomes the content of the inserted element.
  - When an element is inserted at an insertion point, the element is inserted at that point.

After an element has been inserted, it can be cleared by clicking either of the two Clear Element icons that appear (in the Elements Entry Helper) for these inline elements. Which of the two icons appears depends on whether you select a text range or place the cursor in the text as an insertion point (see below).

- **Apply Element**
  If you select an element in your document (by clicking either its start or end tag in the Show large markup view) and that element can be replaced by another element (for example, in a mixed content element such as `para`, an italic element can be replaced by the bold element), this icon indicates that the element in the Entry Helper can be applied to the selected (original) element. The Apply Element command can also be applied to a text range within an element of mixed content; the text range will be created as content of the applied element.

  - If the applied element has a child element with the same name as a child of the original element and an instance of this child element exists in the original element, then the child element of the original is retained in the new element's content.
  - If the applied element has no child element with the same name as that of an instantiated child of the original element, then the instantiated child of the original element is appended as a sibling of any child element or elements that the new element may have.
• If the applied element has a child element for which no equivalent exists in the original element's content model, then this child element is not created directly but Authentic View offers you the option of inserting it.

If a text range is selected rather than an element, applying an element to the selection will create the applied element at that location with the selected text range as its content. Applying an element when the cursor is an insertion point is not allowed.

Clear Element
This icon appears when text within an element of mixed content is selected. Clicking the icon clears the element from around the selected text range.

Clear Element (when insertion point selected)
This icon appears when the cursor is placed within an element that is a child of a mixed-content element. Clicking the icon clears the inline element.

Attributes Entry Helper
The Attributes Entry Helper consists of a drop-down combo box and a list of attributes. The element that you have selected (you can click the start or end tag, or place the cursor anywhere in the element content to select it) appears in the combo box. The Attributes Entry Helper shown in the figures below has a para element in the combo box. Clicking the arrow in the combo box drops down a list of all the para element's ancestors up to the document's root element, which in this case is OrgChart.

Below the combo box, a list of valid attributes for that element is displayed, in this case for para. If an attribute is mandatory on a given element, then it appears in bold. (In the example below, there are no mandatory attributes except the built-in attribute xsi:type.)

To enter a value for an attribute, click in the value field of the attribute and enter the value. This creates the attribute and its value in the XML document.
Note the following:

- In the case of the `xsi:nil` attribute, which appears in the Attributes Entry Helper when a nillable element has been selected, the value of the `xsi:nil` attribute can only be entered by selecting one of the allowed values (true or false) from the dropdown list for the attribute's value.
- The `xsi:type` attribute can be changed by clicking in the value field of the attribute and then either (i) selecting a value from the dropdown list that appears, or (ii) entering a value. Values displayed in the dropdown list are the available abstract types defined in the XML Schema on which the Authentic View document is based.

Entities Entry Helper

The Entities Entry Helper allows you to insert an entity in your document. Entities can be used to insert special characters or text fragments that occur often in a document (such as the name of a company). To insert an entity, place the cursor at the point in the text where you want to have the entity inserted, then double-click the entity in the Entities Entry Helper.

<table>
<thead>
<tr>
<th>Entities</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Ent</td>
<td></td>
</tr>
<tr>
<td>amp</td>
<td>&amp;</td>
</tr>
<tr>
<td>apos</td>
<td>` '</td>
</tr>
<tr>
<td>gt</td>
<td>&gt;</td>
</tr>
<tr>
<td>lt</td>
<td>&lt;</td>
</tr>
<tr>
<td>quot</td>
<td>&quot;</td>
</tr>
</tbody>
</table>

Note: An internal entity is one that has its value defined within the DTD. An external entity is one that has its value contained in an external source, e.g. another XML file. Both internal and external entities are listed in the Entities Entry Helper. When you insert an entity, whether internal or external, the entity—not its value—is inserted into the XML text. If the entity is an internal entity, Authentic View displays the value of the entity. If the entity is an external entity, Authentic View displays the entity—and not its value. This means, for example, that an XML file that is an external entity will be shown in the Authentic View display as an entity; its content does not replace the entity in the Authentic View display.

You can also define your own entities in Authentic View and these will also be displayed in the entry helper: see Define Entities in the Editing in Authentic View section.

11.1.5 Authentic View Context Menus

Right-clicking on some selected document content or node pops up a context menu with commands relevant to the selection or cursor location.

Inserting elements

The figure below shows the Insert submenu, which is a list of all elements that can be inserted at that current cursor location. The Insert Before submenu lists all elements that can be inserted before the current element. The Insert After submenu lists all elements that can be inserted after the current element. In the figure below, the current element is the `para` element. The bold and italic elements can be inserted within the current para element.
As can be seen below, the para and Office elements can be inserted before the current para element.

The node insertion, replacement (Apply), and markup removal (Clear) commands that are available in the context menu are also available in the Authentic View entry helpers and are fully described in that section.

**Insert entity**

Positioning the cursor over the Insert Entity command rolls out a submenu containing a list of all declared entities. Clicking an entity inserts it at the selection. See Define Entities for a description of how to define entities for the document.

**Insert CDATA Section**

This command is enabled when the cursor is placed within text. Clicking it inserts a CDATA section at the cursor insertion point. The CDATA section is delimited by start and end tags; to see these tags you should switch on large or small markup. Within CDATA sections, XML markup and parsing is ignored. XML markup characters (the ampersand, apostrophe, greater than, less than, and quote characters) are not treated as markup, but as literals. So CDATA sections are useful for text such as program code listings, which have XML markup characters.

**Remove node**

Positioning the mouse cursor over the Remove command pops up a menu list consisting of the selected node and all its removable ancestors (those that would not invalidate the document) up to the document element. Click the element to be removed. This is a quick way to delete an element or any removable ancestor. Note that clicking an ancestor element will remove all its descendants, including the selected element.

**Clear**

The Clear command clears the element markup from around the selection. If the entire node is selected, then the element markup is cleared for the entire node. If a text segment is selected, then the element markup is cleared from around that text segment only.

**Apply**

The Apply command applies a selected element to your selection in the main Window. For more details, see Authentic View entry helpers.
Copy, Cut, Paste

These are the standard Windows commands. Note, however, that the Paste command pastes copied text either as XML or as Text, depending on what the designer of the stylesheet has specified for the SPS as a whole. For information about how the Copy as XML and Copy as Text commands work, see the description of the Paste As command immediately below.

Paste As

The Paste As command offers the option of pasting as XML or as text an Authentic View XML fragment (which was copied to the clipboard). If the copied fragment is pasted as XML it is pasted together with its XML markup. If it is pasted as text, then only the text content of the copied fragment is pasted (not the XML markup, if any). The following situations are possible:

- **An entire node together with its markup tags** is highlighted in Authentic View and copied to the clipboard. (i) The node can be pasted as XML to any location where this node may validly be placed. It will not be pasted to an invalid location. (ii) If the node is pasted as text, then only the node's text content will be pasted (not the markup); the text content can be pasted to any location in the XML document where text may be pasted.

- **A text fragment** is highlighted in Authentic View and copied to the clipboard. (i) If this fragment is pasted as XML, then the XML markup tags of the text—even though these were not explicitly copied with the text fragment—will be pasted along with the text, but only if the XML node is valid at the location where the fragment is pasted. (ii) If the fragment is pasted as text, then it can be pasted to any location in the XML document where text may be pasted.

**Note:** Text will be copied to nodes where text is allowed, so it is up to you to ensure that the copied text does not invalidate the document. The copied text should therefore be: (i) lexically valid in the new location (for example, non-numeric characters in a numeric node would be invalid), and (ii) not otherwise invalidate the node (for example, four digits in a node that accepts only three-digit numbers would invalidate the node).

**Note:** If the pasted text does in any way invalidate the document, this will be indicated by the text being displayed in red.

Delete

The Delete command removes the selected node and its contents. A node is considered to be selected for this purpose by placing the cursor within the node or by clicking either the start or end tag of the node.
11.2 Editing in Authentic View

This section describes important features of Authentic View in detail. Features have been included in this section either because they are frequently used or because the mechanisms or concepts involved require explanation.

The section explains the following:

- The Date Picker is a graphical calendar that enters dates in the correct XML format when you click a date. See Date Picker.
- An entity is shorthand for a special character or text string. You can define your own entities, which allows you to insert these special characters or text strings by inserting the corresponding entities. See Defining Entities for details.
- What image formats can be displayed in Authentic View.

To learn how to use all the features of Authentic View, please do the Authentic View Tutorial using either XMLSpy or Authentic Desktop. The Authentic View Tutorial is available with these products.

Altova website: XML content editing, XML authoring

11.2.1 Basic Editing

When you edit in Authentic View, you are editing an XML document. Authentic View, however, can hide the structural XML markup of the document, thus displaying only the content of the document (first screenshot below). You are therefore not exposed to the technicalities of XML, and can edit the document as you would a normal text document. If you wish, you could switch on the markup at any time while editing (second screenshot below).

Vereno Office Summary: 4 departments, 16 employees.

The company was established in Vereno in 1995 as a privately held software company. Since 1996, Nanonull has been actively involved in developing nanoelectronic software technologies. It released the first version of its acclaimed NanoSoft Development Suite in February 1999. Also in 1999, Nanonull increased its capital base with investment from a consortium of private investment firms. The company has been expanding rapidly ever since.

An editable Authentic View document with no XML markup.
An editable Authentic View document with XML markup tags.

**Inserting nodes**

Very often you will need to add a new node to the Authentic XML document. For example, a new **Person** element might need to be added to an address book type of document. In such cases the XML Schema would allow the addition of the new element. All you need to do is right-click the node in the Authentic View document before which or after which you wish to add the new node. In the context menu that appears, select **Insert Before** or **Insert After** as required. The nodes available for insertion at that point in the document are listed in a submenu. Click the required node to insert it. The node will be inserted. All mandatory descendant nodes are also inserted. If a descendant node is optional, a clickable link, **Add NodeName**, appears to enable you to add the optional node if you wish to.

If the node being added is an element with an abstract type, then a dialog (something like in the screenshot below) appears containing a list of derived types that are available in the XML Schema.

---

The company was established **in Vereno in 1995** as a privately held software company. Since 1996, Nanonull has been actively involved in developing nanoelectronic software technologies. It released the first version of its acclaimed **NanoSoft Development Suite** in February 1999. Also in 1999, Nanonull increased its capital base with investment from a consortium of private investment firms. The company has been expanding rapidly ever since.

---

An editable Authentic View document with XML markup tags.
The screenshot above pops up when a Publication element is added. The Publication element is of type PublicationType, which is an abstract complex type. The two complex types BookType and MagazineType are derived from the abstract PublicationType. Therefore, when a Publication element is added to the XML document, one of these two concrete types derived from Publication's abstract type must be specified. The new Publication element will be added with an xsi:type attribute:

```xml
<Publication xsi:type="BookType"> ... </Publication>
<Publication xsi:type="MagazineType"> ... </Publication>
...
<Publication xsi:type="MagazineType"> ... </Publication>
```

Selecting one of the available derived types and clicking OK does the following:

- Sets the selected derived type as the value of the xsi:type attribute of the element
- Inserts the element together with the descendant nodes defined in the content model of the selected derived type.

The selected derived type can be changed subsequently by changing the value of the element's xsi:type attribute in the Attributes Entry Helper. When the element's type is changed in this way, all nodes of the previous type's content model are removed and nodes of the new type's content model are inserted.

**Text editing**

An Authentic View document will essentially consist of text and images. To edit the text in the document, place the cursor at the location where you wish to insert text, and type. You can copy, move, and delete text using familiar keystrokes (such as the Delete key) and drag-and-drop mechanisms. One exception is the Enter key. Since the Authentic View document is pre-formatted, you do not—and cannot—add extra lines or space between items. The Enter key in Authentic View therefore serves to append another instance of the element currently being edited, and should be used exclusively for this purpose.
Copy as XML or as text
Text can be copied and pasted as XML or as text.

- If text is pasted as XML, then the XML markup is pasted together with the text content of nodes. The XML markup is pasted even if only part of a node's contents has been copied. For the markup to be pasted it must be allowed, according to the schema, at the location where it is pasted.
- If text is pasted as text, XML markup is not pasted.

To paste as XML or text, first copy the text (Ctrl+C), right-click at the location where the text is to be pasted, and select the context menu command Paste As | XML or Paste As | Text. If the shortcut Ctrl+V is used, the text will be pasted in the default Paste Mode of the SPS. The default Paste Mode will have been specified by the designer of the SPS. For more details, see the section Context Menus.

Alternatively, highlighted text can be dragged to the location where it is to be pasted. When the text is dropped, a pop-up appears asking whether the text is to be pasted as text or XML. Select the desired option.

Text formatting
A fundamental principle of XML document systems is that content be kept separate from presentation. The XML document contains the content, while the stylesheet contains the presentation (formatting). In Authentic View, the XML document is presented via the stylesheet. This means that all the formatting you see in Authentic View is produced by the stylesheet. If you see bold text, that bold formatting has been provided by the stylesheet. If you see a list or a table, that list format or table format has been provided by the stylesheet. The XML document, which you edit in Authentic View contains only the content; it contains no formatting whatsoever. The formatting is contained in the stylesheet. What this means for you, the Authentic View user, is that you do not have to—not can you—format any of the text you edit. You are editing content. The formatting that is automatically applied to the content you edit is linked to the semantic and/or structural value of the data you are editing. For example, an email address (which could be considered a semantic unit) will be formatted automatically in a certain way because it is an email. In the same way, a headline must occur at a particular location in the document (both a structural and semantic unit) and will be formatted automatically in the way the stylesheet designer has specified that headlines be formatted. You cannot change the formatting of either email address or headline. All that you do is edit the content of the email address or headline.

In some cases, content might need to be specially presented; for example, a text string that must be presented in boldface. In all such cases, the presentation must be tied in with a structural element of the document. For example, a text string that must be presented in boldface, will be structurally separated from surrounding content by markup that the stylesheet designer will format in boldface. If you, as the Authentic View user, need to use such a text string, you would need to enclose the text string within the appropriate element markup. For information about how to do this, see the Insert Element command in the Elements Entry Helper section of the documentation.

Using RichEdit in Authentic View
In Authentic View, when the cursor is placed inside an element that has been created as a RichEdit component, the buttons and controls in the RichEdit toolbar (screenshot below) become enabled. Otherwise they are grayed out.
Select the text you wish to style and specify the styling you wish to apply via the buttons and controls of the RichEdit toolbar. RichEdit enables the Authentic View user to specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of text. The text that has been styled will be enclosed in the tags of the styling element.

**Inserting entities**

In XML documents, some characters are reserved for markup and cannot be used in normal text. These are the ampersand (&), apostrophe (‘), less than (<), greater than (>), and quote (“) characters. If you wish to use these characters in your data, you must insert them as entity references, via the Entities Entry Helper (screenshot below).

XML also offers the opportunity to create custom entities. These could be: (i) special characters that are not available on your keyboard, (ii) text strings that you wish to re-use in your document content, (iii) XML data fragments, or (iv) other resources, such as images. You can define your own entities within the Authentic View application. Once defined, these entities appear in the Entities Entry Helper and can then be inserted as in the document.

**Inserting CDATA sections**

CDATA sections are sections of text in an XML document that the XML parser does not process as XML data. They can be used to escape large sections of text if replacing special characters by entity references is undesirable; this could be the case, for example, with program code or an XML fragment that is to be reproduced with its markup tags. CDATA sections can occur within element content and are delimited by `<![CDATA[` and `]]>` at the start and end, respectively. Consequently the text string `]>` should not occur within a CDATA section as it would prematurely signify the end of the section. In this case, the greater than character should be escaped by its entity reference (`&gt;`). To insert a CDATA section within an element, place the cursor at the desired location, right-click, and select Insert CDATA Section from the context menu. To see the CDATA section tags in Authentic View, switch on the markup display. Alternatively, you could highlight the text that is to be enclosed in a CDATA section, and then select the Insert CDATA section command.

**Note:** CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). CDATA sections can only be entered within elements that are displayed in Authentic View as text content components.
Editing and following links

A hyperlink consists of two parts: the link text and the target of the link. You can edit the link text by clicking in the text and editing. But you cannot edit the target of the link. (The target of the link is set by the designer of the stylesheet (either by typing in a static target address or by deriving the target address from data contained in the XML document).) From Authentic View, you can go to the target of the link by pressing Ctrl and clicking the link text. (Remember: merely clicking the link will set you up for editing the link text.)

11.2.2 Tables in Authentic View

The three table types fall into two categories: SPS tables (static and dynamic) and CALS/HTML Tables.

SPS tables are of two types: static and dynamic. SPS tables are designed by the designer of the StyleVision Power Stylesheet to which your XML document is linked. You yourself cannot insert an SPS table into the XML document, but you can enter data into SPS table fields and add and delete the rows of dynamic SPS tables. The section on SPS tables below explains the features of these tables.

CALS/HTML tables are inserted by you, the user of Authentic View. Their purpose is to enable you to insert tables at any allowed location in the document hierarchy should you wish to do so. The editing features of CALS/HTML Tables and the CALS/HTML Table editing icons are described below.

11.2.2.1 SPS Tables

Two types of SPS tables are used in Authentic View: static tables and dynamic tables.

Static tables

Static tables are fixed in their structure and in the content-type of cells. You, as the user of Authentic View, can enter data into the table cells but you cannot change the structure of these tables (i.e., add rows or columns, etc.) or change the content-type of a cell. You enter data either by typing in text, or by selecting from options presented in the form of check-box or radio button alternatives or as a list in a combo-box. After you enter data, you can edit it.

<table>
<thead>
<tr>
<th>Nanonull, Inc.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Street:</strong> 119 Oakstreet, Suite 4876</td>
</tr>
<tr>
<td><strong>City:</strong> Vereno</td>
</tr>
<tr>
<td><strong>State &amp; Zip:</strong> DC 29213</td>
</tr>
</tbody>
</table>

**Note:** The icons or commands for editing dynamic tables must not be used to edit static tables.
Dynamic tables

Dynamic tables have rows that represent a repeating data structure, i.e. each row has an identical data structure (not the case with static tables). Therefore, you can perform row operations: append row, insert row, move row up, move row down, and delete row. These commands are available under the Authentic menu and as icons in the toolbar (shown below).

To use these commands, place the cursor anywhere in the appropriate row, and then select the required command.

```
To move among cells in the table, use the Up, Down, Left, and Right arrow keys. To move forward from one cell to the next, use the Tab key. Pressing the Tab key in the last cell of the last row creates a new row.
```

```
11.2.2.2 CALS/HTML Tables

CALS/HTML tables can be inserted by you, the user of Authentic View, for certain XML data structures that have been specified to show a table format. There are three steps involved when working with CALS/HTML tables: inserting the table; formatting it; and entering data. The commands for working with CALS/HTML tables are available as icons in the toolbar (see CALS/HTML table editing icons).

Inserting tables

To insert a CALS/HTML table do the following:

1. Place your cursor where you wish to insert the table, and click the icon. (Note that where you can insert tables is determined by the schema.) The Insert Table dialog (screenshot below) appears. This
```
dialog lists all the XML element data-structures for which a table structure has been defined. For example, in the screenshot below, the *informaltable* element and *table* element have each been defined as both a CALS table as well as an HTML table.

2. Select the entry containing the element and table model you wish to insert, and click **OK**.
3. In the next dialog (*screenshot below*), select the number of columns and rows, and specify whether a header and/or footer is to be added to the table and whether the table is to extend over the entire available width. Click **OK** when done.

For the specifications given in the dialog box shown above, the following table is created.

By using the Table menu commands, you can add and delete columns, and create row and column joins and splits. But to start with, you must create the broad structure.
Formatting tables and entering data

The table formatting will already have been assigned in the document design. However, you might, under certain circumstances, be able to modify the table formatting. These circumstances are as follows:

- The elements corresponding to the various table structure elements must have the relevant CALS or HTML table properties defined as attributes (in the underlying XML Schema). Only those attributes that are defined will be available for formatting. If, in the design, values have been set for these attributes, then you can override these values in Authentic View.
- In the design, no style attribute containing CSS styles must have been set. If a style attribute containing CSS styles has been specified for an element, the style attribute has precedence over any other formatting attribute set on that element. As a result, any formatting specified in Authentic View will be overridden.

To format a table, row, column, or cell, do the following:

1. Place the cursor anywhere in the table and click the (Table Properties) icon. This opens the Table Properties dialog (see screenshot), where you specify formatting for the table, or for a row, column, or cell.

2. Set the cellspacing and cellpadding properties to "0". Your table will now look like this:

```plaintext
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

3. Place the cursor in the first row to format it, and click the (Table Properties) icon. Click the Row tab.
Since the first row will be the header row, set a background color to differentiate this row from the other rows. Note the Row properties that have been set in the figure above. Then enter the column header text. Your table will now look like this:

<table>
<thead>
<tr>
<th>Name</th>
<th>Telephone</th>
<th>Email</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notice that the alignment is centered as specified.

4. Now, say you want to divide the "Telephone" column into the sub-columns "Office" and "Home", in which case you would need to split the horizontal width of the Telephone column into two columns. First, however, we will split the vertical extent of the header cell to make a sub-header row. Place the cursor in the "Telephone" cell, and click the (Split vertically) icon. Your table will look like this:

<table>
<thead>
<tr>
<th>Name</th>
<th>Telephone</th>
<th>Email</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. Now place the cursor in the cell below the cell containing "Telephone", and click the (Split horizontally) icon. Then type in the column headers "Office" and "Home". Your table will now look like this:

<table>
<thead>
<tr>
<th>Name</th>
<th>Telephone</th>
<th>Email</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Now you will have to split the horizontal width of each cell in the "Telephone" column.

You can also add and delete columns and rows, and vertically align cell content, using the table-editing icons. The CALS/HTML table editing icons are described in the section titled, CALS/HTML Table Editing Icons.

**Moving among cells in the table**

To move among cells in the CALS/HTML table, use the Up, Down, Right, and Left arrow keys.

**Entering data in a cell**

To enter data in a cell, place the cursor in the cell, and type in the data.

**Formatting text**

Text in a CALS/HTML table, as with other text in the XML document, must be formatted using XML elements or attributes. To add an element, highlight the text and double-click the required element in the Elements Entry Helper. To specify an attribute value, place the cursor within the text fragment and enter the required attribute value in the Attributes Entry Helper. After formatting the header text bold, your table will look like this.

<table>
<thead>
<tr>
<th>Name</th>
<th>Telephone</th>
<th>Email</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Office</td>
<td>Home</td>
</tr>
</tbody>
</table>

The text above was formatted by highlighting the text, and double-clicking the element `strong`, for which a global template exists that specifies bold as the font-weight. The text formatting becomes immediately visible.

**Note:** For text formatting to be displayed in Authentic View, a global template with the required text formatting must have been created in StyleVision for the element in question.

### 11.2.2.3 CALS/HTML Table Editing Icons

The commands required to edit CALS/HTML tables are available as icons in the toolbar, and are listed below. Note that no corresponding menu commands exist for these icons. For a full description of when and how CALS/HTML Tables are to be used, see CALS/HTML Tables.

**Insert table**

The "Insert Table" command inserts a **CALS/HTML table** at the current cursor position.
The "Delete table" command deletes the currently active table.

The "Append row" command appends a row to the end of the currently active table.

The "Append column" command appends a column to the end of the currently active table.

The "Insert row" command inserts a row above the current cursor position in the currently active table.

The "Insert column" command inserts a column to the left of the current cursor position in the currently active table.

The "Join cell left" command joins the current cell (current cursor position) with the cell to the left. The tags of both cells remain in the new cell, the column headers remain unchanged and are concatenated.

The "Join cell right" command joins the current cell (current cursor position) with the cell to the right. The contents of both cells are concatenated in the new cell.

The "Join cell below" command joins the current cell (current cursor position) with the cell below. The contents of both cells are concatenated in the new cell.

The "Join cell above" command joins the current cell (current cursor position) with the cell above. The contents of both cells are concatenated in the new cell.

The "Split cell horizontally" command creates a new cell to the right of the currently active cell. The size of both cells, is now the same as the original cell.

The "Split cell vertically" command creates a new cell below the currently active cell.

This command aligns the cell contents to the top of the cell.

This command centers the cell contents.
Align bottom

This command aligns the cell contents to the bottom of the cell.

Table properties

The "Table properties" command opens the Table Properties dialog box. This icon is only made active for HTML tables, it cannot be clicked for CALS tables.

11.2.3 Editing a DB

In Authentic View, you can edit database (DB) tables and save data back to a DB. This section contains a full description of interface features available to you when editing a DB table. The following general points need to be noted:

- The number of records in a DB table that are displayed in Authentic View may have been deliberately restricted by the designer of the StyleVision Power Stylesheet in order to make the design more compact. In such cases, only that limited number of records is initially loaded into Authentic View. Using the DB table row navigation icons (see Navigating a DB Table), you can load and display the other records in the DB table.
- You can query the DB to display certain records.
- You can add, modify, and delete DB records, and save your changes back to the DB. See Modifying a DB Table.

Note: In Authentic View, data coming from a SQLite database is not editable. When you attempt to save SQLite data in Authentic View, a message box will inform you of this known limitation.
11.2.3.1 Navigating a DB Table

The commands to navigate DB table rows are available as buttons in the Authentic View document. Typically, one navigation panel with either four or five buttons accompanies each DB table.

The arrow icons are, from left to right, Go to First Record in the DB Table; Go to Previous Record; Open the Go to Record dialog (see screenshot); Go to Next Record; and Go to Last Record.

To navigate a DB table, click the required button.

XML Databases

In the case of XML DBs, such as IBM DB2, one cell (or row) contains a single XML document, and therefore a single row is loaded into Authentic View at a time. To load an XML document that is in another row, use the Authentic | Select New Row with XML Data for menu command.

11.2.3.2 DB Queries

A DB query enables you to query the records of a table displayed in Authentic View. A query is made for an individual table, and only one query can be made for each table. You can make a query at any time while editing. If you have unsaved changes in your Authentic View document at the time you submit the query, you will be prompted about whether you wish to save all changes made in the document or discard all changes. Note that even changes made in other tables will be saved/discarded. After you submit the query, the table is reloaded using the query conditions.

Note: If you get a message saying that too many tables are open, then you can reduce the number of tables that are open by using a query to filter out some tables.

To create and submit a query:

1. Click the Query button for the required table in order to open the Edit Database Query dialog (see screenshot). This button typically appears at the top of each DB table or below it. If a Query button is not present for any table, the designer of the StyleVision Power Stylesheet has not enabled the DB Query feature for that table.
2. Click the Append AND or Append OR button. This appends an empty criterion for the query (shown below).

3. Enter the expression for the criterion. An expression consists of: (i) a field name (available from the associated combo-box); (ii) an operator (available from the associated combo-box); and (iii) a value (to be entered directly). For details of how to construct expressions see the Expressions in criteria section.

4. If you wish to add another criterion, click the Append AND or Append OR button according to which logical operator (AND or OR) you wish to use to join the two criteria. Then add the new criterion. For details about the logical operators, see the section Re-ordering criteria in DB Queries.
Expressions in criteria

Expressions in DB Query criteria consist of a field name, an operator, and a value. The available field names are the child elements of the selected top-level data table; the names of these fields are listed in a combo-box (see screenshot above). The operators you can use are listed below:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equal to</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Not equal to</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td>LIKE</td>
<td>Phonetically alike</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Phonetically not alike</td>
</tr>
<tr>
<td>IS NULL</td>
<td>Is empty</td>
</tr>
<tr>
<td>NOT NULL</td>
<td>Is not empty</td>
</tr>
</tbody>
</table>

If IS NULL or NOT NULL is selected, the Value field is disabled. Values must be entered without quotes (or any other delimiter). Values must also have the same formatting as that of the corresponding DB field; otherwise the expression will evaluate to FALSE. For example, if a criterion for a field of the date datatype in an MS Access DB has an expression StartDate=25/05/2004, the expression will evaluate to FALSE because the date datatype in an MS Access DB has a format of YYYY-MM-DD.

Using parameters with DB Queries

You can enter the name of a parameter as the value of an expression when creating queries. Parameters are variables that can be used instead of literal values in queries. When you enter it in an expression, its value is used in the expression. Parameters that are available have been defined by the SPS designer in the SPS and can be viewed in the View Parameters dialog (see screenshot below). Parameters have been assigned a default value in the SPS, which can be overridden by passing a value to the parameter via the command line (if and when the output document is compiled via the command line).

To view the parameters defined for the SPS, click the Parameters button in the Edit Database Query dialog. This opens the View Parameters dialog (see screenshot).
The View Parameters dialog contains all the parameters that have been defined for the stylesheet in the SPS and parameters must be edited in the stylesheet design.

Re-ordering criteria in DB Queries

The logical structure of the DB Query and the relationship between any two criteria or sets of criteria is indicated graphically. Each level of the logical structure is indicated by a square bracket. Two adjacent criteria or sets of criteria indicate the AND operator, whereas if two criteria are separated by the word **OR** then the OR operator is indicated. The criteria are also appropriately indented to provide a clear overview of the logical structure of the DB Query.

The DB Query shown in the screenshot above may be represented in text as:
State=CA AND (City=Los Angeles OR City=San Diego OR (City=San Francisco AND CustomerNr=25))

You can re-order the DB Query by moving a criterion or set of criteria up or down relative to the other criteria in the DB Query. To move a criterion or set of criteria, do the following:

1. Select the criterion by clicking on it, or select an entire level by clicking on the bracket that represents that level.
2. Click the Up or Down arrow button in the dialog.

The following points should be noted:

- If the adjacent criterion in the direction of movement is at the same level, the two criteria exchange places.
- A set of criteria (i.e. criterion within a bracket) changes position within the same level; it does not change levels.
- An individual criterion changes position within the same level. If the adjacent criterion is further outward/inward (i.e. not on the same level), then the selected criterion will move outward/inward, one level at a time.

To delete a criterion in a DB Query, select the criterion and click **Delete**.

### Modifying a DB Query

To modify a DB Query:

1. Click the Query button. The Edit Database Query dialog box opens. You can now edit the expressions in any of the listed criteria, add new criteria, re-order criteria, or delete criteria in the DB Query.
2. Click **OK**. The data from the DB is automatically re-loaded into Authentic View so as to reflect the modifications to the DB Query.

### 11.2.3.3 Modifying a DB Table

#### Adding a record

To add a record to a DB table:

1. Place the cursor in the DB table row and click the [append] icon (to append a row) or the [insert] icon (to insert a row). This creates a new record in the temporary XML file.
2. Click the **File | Save Authentic XML Data...** command to add the new record in the DB. In Authentic View a row for the new record is appended to the DB table display. The AltovaRowStatus for this record is set to **A** (for Added).

When you enter data for the new record it is entered in bold and is underlined. This enables you to differentiate added records from existing records—if existing records have not been formatted with these text formatting properties. Datatype errors are flagged by being displayed in red.
The new record is added to the DB when you click **File | Save Authentic XML Data**. After a new record is saved to the DB, its **AltovaRowStatus** field is initialized (indicated with ---) and the record is displayed in Authentic View as a regular record.

**Modifying a record**

To modify a record, place the cursor at the required point in the DB table and edit the record as required. If the number of displayed records is limited, you may need to navigate to the required record (see [Navigating a DB Table](#)).

When you modify a record, entries in all fields of the record are underlined and the **AltovaRowStatus** of all primary instances of this record is set to **U** (for Updated). All secondary instances of this record have their **AltovaRowStatus** set to **u** (lowercase). Primary and secondary instances of a record are defined by the structure of the DB—and correspondingly of the XML Schema generated from it. For example, if an Address table is included in a Customer table, then the Address table can occur in the Design Document in two types of instantiations: as the Address table itself and within instantiations of the Customer table. Whichever of these two types is modified is the type that has been primarily modified. Other types—there may be more than one other type—are secondary types. Datatype errors are flagged by being displayed in red.

The modifications are saved to the DB by clicking **File | Save Authentic XML Data**. After a modified record is saved to the DB, its **AltovaRowStatus** field is initialized (indicated with ---) and the record is displayed in Authentic View as a regular record.

**Note the following points:**

- If even a single field of a record is modified in Authentic View, the entire record is updated when the data is saved to the DB.
- The date value 0001-01-01 is defined as a NULL value for some DBs, and could result in an error message.

**Deleting a record**

To delete a record:

1. Place the cursor in the row representing the record to be deleted and click the icon. The record to be deleted is marked with a strikethrough. The **AltovaRowStatus** is set as follows: primary instances of the record are set to **D**; secondary instances to **d**; and records indirectly deleted to **X**. Indirectly deleted records are fields in the deleted record that are held in a separate table. For example, an Address table might be included in a Customer table. If a Customer record were to be deleted, then its corresponding Address record would be indirectly deleted. If an Address record in the Customer table were deleted, then the Address record in the Customer table would be primarily deleted, but the same record would be secondarily deleted in an independent Address table if this were instantiated.
2. Click **File | Save Authentic XML Data** to save the modifications to the DB.

**Note:** Saving data to the DB resets the Undo command, so you cannot undo actions that were carried out prior to the save.

### 11.2.4 Working with Dates

There are two ways in which dates can be edited in Authentic View:
Dates are entered or modified using the Date Picker.
Dates are entered or modified by typing in the value.

The method the Authentic View user will use is defined in the SPS. Both methods are described in the two sub-sections of this section.

Note on date formats
In the XML document, dates can be stored in one of several date datatypes. Each of these datatypes requires that the date be stored in a particular lexical format in order for the XML document to be valid. For example, the xs:date datatype requires a lexical format of YYYY-MM-DD. If the date in an xs:date node is entered in anything other than this format, then the XML document will be invalid.

In order to ensure that the date is entered in the correct format, the SPS designer can include the graphical Date Picker in the design. This would ensure that the date selected in the Date Picker is entered in the correct lexical format. If there is no Date Picker, the Authentic View should take care to enter the date in the correct lexical format. Validating the XML document could provide useful tips about the required lexical format.

11.2.4.1 Date Picker
The Date Picker is a graphical calendar used to enter dates in a standard format into the XML document. Having a standard format is important for the processing of data in the document. The Date Picker icon appears near the date field it modifies (see screenshot).

To display the Date Picker (see screenshot), click the Date Picker icon.
To select a date, click on the desired date, month, or year. The date is entered in the XML document, and the date in the display is modified accordingly. You can also enter a time zone if this is required.

### 11.2.4.2 Text Entry

For date fields that do not have a Date Picker (see screenshot), you can edit the date directly by typing in the new value.

<table>
<thead>
<tr>
<th>Invoice Number: 001</th>
</tr>
</thead>
<tbody>
<tr>
<td>2006-03-10</td>
</tr>
<tr>
<td>Customer: The ABC Company</td>
</tr>
<tr>
<td>Invoice Amount: 40.00</td>
</tr>
</tbody>
</table>

#### Errors

The following types of error will be flagged:

- If you edit a date and change it such that it is out of the valid range for dates, the date turns red to alert you to the error. If you place the mouse cursor over the invalid date, an error message appears (see screenshot).

<table>
<thead>
<tr>
<th>Invoice Number: 001</th>
</tr>
</thead>
<tbody>
<tr>
<td>2006-03-32</td>
</tr>
<tr>
<td>Customer: The ABC Company</td>
</tr>
<tr>
<td>Invoice Amount: 40.00</td>
</tr>
</tbody>
</table>

- If you try to change the format of the date, the date turns red to alert you to the error. (In the screenshot below, slashes are used instead of hyphens).

<table>
<thead>
<tr>
<th>Invoice Number: 001</th>
</tr>
</thead>
<tbody>
<tr>
<td>2006/03/10</td>
</tr>
<tr>
<td>Customer: The ABC Company</td>
</tr>
<tr>
<td>Invoice Amount: 40.00</td>
</tr>
</tbody>
</table>

### 11.2.5 Defining Entities

#### About entities

You can define entities for use in Authentic View, whether your document is based on a DTD or an XML Schema. Once defined, these entities are displayed in the Entities Entry Helper and in the Insert Entity submenu of the context menu. When you double-click on an entity in the Entities Entry Helper, that entity is inserted at the cursor insertion point.
An entity is useful if you will be using a text string, XML fragment, or some other external resource in multiple locations in your document. You define the entity, which is basically a short name that stands in for the required data, in the Define Entities dialog. After defining an entity you can use it at multiple locations in your document. This helps you save time and greatly enhances maintenance.

**Types of entity**

There are two broad types of entity you can use in your document: a parsed entity, which is XML data (either a text string or a fragment of an XML document), or an unparsed entity, which is non-XML data such as a binary file (usually a graphic, sound, or multimedia object). Each entity has a name and a value. In the case of parsed entities the entity is a placeholder for the XML data. The value of the entity is either the XML data itself or a URI that points to a .xml file that contains the XML data. In the case of unparsed entities, the value of the entity is a URI that points to the non-XML data file.

**Defining entities**

To define an entity:

1. Click **Authentic | Define XML Entities**. This opens the Define Entities dialog (screenshot below).

2. Enter the name of your entity in the Name field. This is the name that will appear in the Entities Entry Helper.

3. Enter the type of entity from the drop-down list in the Type field. The following types are possible: An Internal entity is one for which the text to be used is stored in the XML document itself. Selecting PUBLIC or SYSTEM specifies that the resource is located outside the XML file, and will be located with the use of a public identifier or a system identifier, respectively. A system identifier is a URI that gives the location of the resource. A public identifier is a location-independent identifier, which enables some processors to identify the resource. If you specify both a public and system identifier, the public identifier resolves to the system identifier, and the system identifier is used.

4. If you have selected PUBLIC as the Type, enter the public identifier of your resource in the PUBLIC field. If you have selected Internal or SYSTEM as your Type, the PUBLIC field is disabled.

5. In the Value/Path field, you can enter any one of the following:
   - If the entity type is Internal, enter the text string you want as the value of your entity. Do not enter quotes to delimit the entry. Any quotes that you enter will be treated as part of the text string.
   - If the entity type is SYSTEM, enter the URI of the resource or select a resource on your local network by using the Browse button. If the resource contains parsed data, it must be an XML file (i.e., it must have a .xml extension). Alternatively, the resource can be a binary file, such as a GIF file.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>PUBLIC</th>
<th>Value/Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>nano_dc</td>
<td>Internal</td>
<td>Nancnull, Inc</td>
<td>...</td>
</tr>
<tr>
<td>nano_eu</td>
<td>Internal</td>
<td>Nancnull Europe, AG</td>
<td>...</td>
</tr>
<tr>
<td>nano_na</td>
<td>Internal</td>
<td>Nancnull Partners, Inc</td>
<td>...</td>
</tr>
<tr>
<td>website</td>
<td>Internal</td>
<td><a href="http://www.nancnull.com">http://www.nancnull.com</a></td>
<td>...</td>
</tr>
<tr>
<td>branches</td>
<td>SYSTEM</td>
<td>branches.xml</td>
<td>...</td>
</tr>
<tr>
<td>logo</td>
<td>SYSTEM</td>
<td>nancnull.gif</td>
<td>...</td>
</tr>
</tbody>
</table>
• If the entity type is PUBLIC, you must additionally enter a system identifier in this field.

6. The NDATA entry tells the processor that this entity is not to be parsed but to be sent to the appropriate processor. The NDATA field must therefore contain some value to indicate that the entity is an unparsed entity.

Dialog features
You can do the following in the Define Entities dialog:

• Append entities
• Insert entities
• Delete entities
• Sort entities by the alphabetical value of any column by clicking the column header; clicking once sorts in ascending order, twice in descending order.
• Resize the dialog box and the width of columns.
• Locking. Once an entity is used in the XML document, it is locked and cannot be edited in the Define Entities dialog. Locked entities are indicated by a lock symbol in the first column. Locking an entity ensures that the XML document is valid with respect to entities. (The document would be invalid if an entity is referenced but not defined.)
• Duplicate entities are flagged.

Limitations of entities

• An entity contained within another entity is not resolved, either in the dialog, Authentic View, or XSLT output, and the ampersand character of such an entity is displayed in its escaped form, i.e. \&amp;.
• External unparsed entities that are not image files are not resolved in Authentic View. If an image in the design is defined to read an external unparsed entity and has its URI set to be an entity name (for example: 'logo'), then this entity name can be defined in the Define Entities dialog (see screenshot above) as an external unparsed entity with a value that resolves to the URI of the image file (as has been done for the logo entity in the screenshot above).

11.2.6 Images in Authentic View

Authentic View allows you to specify images that will be used in the final output document (HTML, RTF, PDF and Word 2007+). You should note that some image formats might not be supported in some formats or by some applications. For example, the SVG format is supported in PDF, but not in RTF and would require a browser add-on for it to be viewed in HTML. So, when selecting an image format, be sure to select a format that is supported in the output formats of your document. Most image formats are supported across all the output formats (see list below).

Authentic View is based on Internet Explorer, and is able to display most of the image formats that your version of Internet Explorer can display. The following commonly used image formats are supported:

• GIF
• JPG
• PNG
• BMP
• WMF (Microsoft Windows Metafile)
· EMF (Enhanced Metafile)
· SVG (for PDF output only)

Relative paths
Relative paths are resolved relative to the SPS file.

11.2.7 Keystrokes in Authentic View

The Enter key
In Authentic View the Enter key is used to append additional elements when it is in certain cursor locations. For example, if the chapter of a book may (according to the schema) contain several paragraphs, then pressing Enter inside the text of the paragraph causes a new paragraph to be appended immediately after the current paragraph. If a chapter can contain one title and several paragraphs, pressing Enter inside the chapter but outside any paragraph element (including within the title element) causes a new chapter to be appended after the current chapter (assuming that multiple chapters are allowed by the schema).

Note: The Enter key does not insert a new line. This is the case even when the cursor is inside a text node, such as paragraph.

Using the keyboard
The keyboard can be used in the standard way, for typing and navigating. Note the following special points:

· The Tab key moves the cursor forward, stopping before and after nodes, and highlighting node contents; it steps over static content.
· The add... and add Node hyperlinks are considered node contents and are highlighted when tabbed. They can be activated by pressing either the spacebar or the Enter key.
12 Authentic Scripting

The Authentic Scripting feature provides more flexibility and interactivity to SPS designs. These designs can be created or edited in StyleVision Enterprise and Professional editions, and can be viewed in the Authentic View of the Enterprise and Professional editions of Altova products. A complete listing of support for this feature in Altova products is given in the table below. Note, however, that in the trusted version of Authentic Browser plug-in, internal scripting is turned off because of security concerns.

<table>
<thead>
<tr>
<th>Altova Product</th>
<th>Authentic Scripts Creation</th>
<th>Authentic Scripts Enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>StyleVision Enterprise</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>StyleVision Professional</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>StyleVision Basic *</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>XMLSpy Enterprise</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>XMLSpy Professional</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Authentic Desktop Enterprise</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Authentic Browser Ent Trusted **</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Authentic Browser Ent Untrusted</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

* No AuthenticView

** Scripted designs displayed. No internal macro execution or event handling. External events fired.

Authentic Scripts behave in the same way in all Altova products, so no product-specific code or settings are required.

Authentic Script Warning Dialog

If a PXF file, or an XML file linked to an SPS, contains a script and the file is opened or switched to Authentic View (in Altova products other than StyleVision), then a warning dialog (screenshot below) pops up.

![Authentic Script Warning Dialog](screenshot below)

You can choose one of the following options:

- Click Yes to add the folder containing the file to the Trusted Locations list for Authentic scripts. Subsequently, all files in the trusted folder will be opened in Authentic View without this warning dialog being displayed first. The Trusted Locations list can be accessed via the menu command Authentic | Trusted Locations, and modified.
Click No to not add the folder containing the file to the Trusted Locations list. The file will be displayed in Authentic View with scripts disabled. The Authentic Script Warning dialog will appear each time this file is opened in Authentic View. To add the file's folder to the Trusted Locations list subsequently, open the Trusted locations dialog via the menu command Authentic | Trusted Locations, and add the folder or modify as required.

Note: When StyleVision is accessed via its COM interface (see Programmers’ Reference to see how this can be done), the security check is not done and the Authentic Script Warning dialog is not displayed. The warning dialog described above appears in the Authentic View of Altova products other than StyleVision. You, as an SPS designer, should be aware of this.

How Authentic Scripting works
The designer of the SPS design can use Authentic Scripting in two ways to make Authentic documents interactive:

- By assigning scripts for user-defined actions (macros) to design elements, toolbar buttons, and context menu items.
- By adding to the design event handlers that react to Authentic View events.

All the scripting that is required for making Authentic documents interactive is done within the StyleVision GUI (Enterprise and Professional editions). Forms, macros and event handlers are created within the Scripting Editor interface of StyleVision and these scripts are saved with the SPS. Then, in the Design View of StyleVision, the saved scripts are assigned to design elements, toolbar buttons, and context menus. When an XML document based on the SPS is opened in an Altova product that supports Authentic Scripting (see table above), the document will have the additional flexibility and interactivity that has been created for it.

In this section
In this section we explain how Authentic Scripting works. The section is organized into the following sub-sections:

- Scripting Editor, which describes the interface in which a scripting project containing the scripts for the SPS are saved
- Macros, which shows how macros can be associated with design elements, Authentic toolbar buttons, and Authentic context menus
- Event Handlers, which shows how event handler scripts are created and used
- Scripting Options, which documents the options

Example files
Example SPS files with Authentic Scripting are in the Authentic\Scripting folder of the Examples project in the Project window of StyleVision.
12.1 Scripting Editor

StyleVision's Scripting Editor (screenshot below) enables you to add scripts for forms, macros, and event handlers to the SPS.

The Scripting Editor can be started either with the menu command Authentic | Edit Authentic Scripts or by clicking the Authentic Script item in the view switcher menu of the Design View tab.

The scripting language can be changed by doing the following:

1. Right-click the Project item, which is at the top of the Project Tree (see screenshot above).
2. In the context menu that pops up, select Project Settings.
3. In the Project Settings dialog that appears, select either JScript or VBScript as the scripting language and specify the target .NET framework. The user can then access and use classes and extensions of the selected Microsoft .NET framework: for example, for creating forms.

The Scripting Editor and its features are described in detail in the Programmers' Reference.

Every SPS has a single scripting project, which is saved in the SPS. Clicking the Save button in Scripting Editor does not save the script to the SPS; it merely saves changes to the scripting project in memory. Changes in the scripting project are saved to the SPS only when the SPS is saved.
12.2 Macros

Macros are single programs that are executed when a user action occurs. Macros do not take a parameter, do not return a value, and do not call other macros directly. However, code that needs to be reused by multiple macros or event handlers can be put in a function in the Global Declarations area.

A macro that is not assigned to a specific user action will not be executed. Valid user actions may be an interaction with a specific design element, a toolbar button click, or the selection of a user-defined context menu item.

The EventContext property

An SPS design element can appear in multiple places. To determine in which context a macro is executed, the AuthenticView interface has a property called EventContext to hold the context. Via the EventContext property, a macro can query the XPath location where the macro was started, evaluate XPath expressions in the current node, and access variables defined in the scope of the location. For more details, see the section AuthenticView API.

Checking macro references

The designer might accidentally rename a macro or delete it from the script project, though it is still referenced in the design. To help prevent or correct such errors, the command Authentic | Check Macro References checks for invalid references. A dialog will pop up to help the user replace or delete the reference.

In this section

In this section we look at how macros can be associated with valid user actions:

- Macros on Design Elements
- Macros on Toolbar Buttons
- Macros on Context Menu Items

12.2.1 Macros on Design Elements

Macros can be assigned to design elements via the Authentic Properties window. In the screenshot below the macro named OnResetAll has been selected from a list of available macros and assigned to a button’s OnClick event.
Different design elements support different user actions for which macros can be assigned. The table below gives a complete list.

<table>
<thead>
<tr>
<th>User action</th>
<th>Supported design element</th>
<th>Can cancel event</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnClick</td>
<td>Button, Image</td>
<td>No</td>
</tr>
<tr>
<td>OnBeforeLinkClick</td>
<td>Link</td>
<td>Yes</td>
</tr>
<tr>
<td>OnBeforeChange</td>
<td>Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox</td>
<td>Yes</td>
</tr>
<tr>
<td>OnAfterChange</td>
<td>Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox</td>
<td>No</td>
</tr>
<tr>
<td>OnSetFocus</td>
<td>Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox</td>
<td>No</td>
</tr>
<tr>
<td>OnKillFocus</td>
<td>Content, Rest-of-Content, Input Field, Multiline Input Field, Checkbox, Radiobutton, Combobox</td>
<td>No</td>
</tr>
</tbody>
</table>

Macros assigned to these user actions will be called only on primary user input. They are not called on an undo action, or when the action was from outside Authentic View (for example, from a COM API call). If a macro is to be used to cancel further event processing, the user needs to place a COM API call `AuthenticView.DoNotPerformStandardAction()` in the macro where it is required. For example, it can be put in the macro `BeforeChangeToEU (listing below)` which has been assigned to a `OnBeforeChange` event for a radio button:

```javascript
if ( !confirm( "Are you sure to change address data to EU?\nAll existing address data will be deleted!" ) )
    AuthenticView.DoNotPerformStandardAction();
```

This will prevent the changing of the radio button value if the user canceled the confirm dialog. This example is in the file `OnChange.sps` is in the `Authentic\Scripting` folder of the `Examples` project in the Project window. You can open this file and see how the macro works.
Useful features

After a macro has been assigned in the Properties window (screenshot below), it can be quickly accessed for editing in the Scripting Editor by clicking the Edit Macro button to the right of its name (see screenshot below).

![Properties Window Screenshot]

12.2.2 Macros on Context Menu Items

Macros can also be used to customize Authentic context menus. This enables the SPS designer to add custom menu items that each execute a macro.

There is no GUI to aid in this process. The SPS designer must add an event handler for the On_AuthenticContextMenuActivated event, and then manipulate the menu via the AuthenticView API. This can be seen in the example file OnContextMenu.sps which is in the Authentic\Scripting folder of the Examples project in the Project window. The screenshot below shows the On_AuthenticContextMenuActivated event handler script in the Scripting Editor.
The event handler for the `On_AuthenticContextMenuActivated` event creates two menu items and assigns macros to them. This example file also contains an event handler for the `On-AuthenticLoad` event, which disables entry helpers and markup buttons when AuthenticView is loaded.

```plaintext
function On_AuthenticLoad( )
{
    // We are disabling all entry helpers in order to prevent user from manipulating XML tree
    AuthenticView.DisableElementEntryHelper();
    AuthenticView.DisableAttributeEntryHelper();

    // We are also disabling the markup buttons for the same purpose
    AuthenticView.SetToolbarButtonState( 'AuthenticMarkupSmall', authenticToolbarButtonDisabled );
    AuthenticView.SetToolbarButtonState( 'AuthenticMarkupLarge', authenticToolbarButtonDisabled );
    AuthenticView.SetToolbarButtonState( 'AuthenticMarkupMixed', authenticToolbarButtonDisabled );
}
```

### 12.2.3 Custom Buttons

In the SPS design you can create a custom button to add to the Authentic toolbar and specify what macro it will trigger. To add a custom button to the Authentic toolbar, first select the command **Authentic | Custom Toolbar Buttons**, then click the **Add** button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select the type of custom button you want.

There are two types of custom buttons:

- **Text State Icons** are buttons that change the style of text (say, to bold or italic) and are associated with a particular element. Such elements would typically occur within elements of mixed-content type (that is, in elements that can contain both text and child elements). For example, a `para` element would be of mixed context because it can contain text, and, say, bold child elements, and italic child elements. In such a case, you can associate a Text State Icon (which is a bitmap image) to a child element of the mixed-content element. So, the **bold** element, for example, could be assigned a specific button image (its Text State Icon). A global template for the **bold** element is then defined to
provide the bold formatting of the bold element. In Authentic View, the Text State Icon for the bold element will appear as a toolbar button. When the Authentic View user selects text within a para element of the example cited above and clicks the bold element's toolbar button, the selected text will be enclosed with the bold element tags and the bold formatting of the bold element's global template will be applied to the text.

- **Custom toolbar buttons** are associated with a particular macro.

Custom buttons take the following parameters:

- The location of an image for the button (in the Bitmap field) or text for the button (in the Text field).
- In the Element Name field (available for Text State Icons), enter the name of the element with which you wish to associate the Text State Icon.
- In the Macro Name combo box (available for Custom Toolbar Buttons), select the macro from the dropdown list that you wish to associate with the Custom Toolbar Button. The macros listed here are those that have been saved with the SPS. When you click the Create button, the Scripting Editor of StyleVision opens in its own window, enabling you to quickly and easily create a macro. Clicking the Edit button opens the selected macro for editing in the Scripting Editor.
- You can optionally enter a tooltip (in the Tooltip field) as a guide for the Authentic View user when he or she mouses over the custom button.
- In the Identifier field enter a text string that will be used as the identifier of the custom button. This identifier can then be used in scripting code if the designer wishes to control the button state via the AuthenticView API.
The screenshot above shows the the custom button **US** has the `ChangeAddressToUS` macro assigned to it. This custom button uses an image named `US.bmp`. Text for the button can be entered as a fallback. A tooltip has been entered and the custom button has the identifier `Address_US`. This example is from the file `ToolbarButtons.sps` is in the `Authentic\Scripting` folder of the `Examples` project in the Project window.
12.3 Event Handlers

Authentic Scripting offers the possibility to define event handlers to react to general—not design-element-specific—user actions. They represent the same mechanism as adding COM listeners for AuthenticView events in external applications, but they can be more conveniently edited and stored within the design.

To add an event handler script, start the Scripting Editor (Authentic | Edit Authentic Scripts). The available event handlers are displayed in the Project pane under the AuthenticView Events node.

Double-click an event to access its script template in the scripting window. In the scripting window, edit the event handler script template as required. See the section Macros on Context Menu Items for an example of how event handlers can be used.
12.4 Scripting Options

To show interactive documents with Authentic Scripting, Authentic Scripting must be turned on in the SPS file properties. Do this by selecting the command **File | Properties.** In the Properties dialog that pops up (screenshot below) select the Authentic tab and check **Enable Authentic Scripts.**

Additionally, you can specify whether macros can be run in debug mode from outside StyleVision (that is, in the Authentic View of other Altova products) or not. This feature is useful if you wish to test and debug a macro outside the StyleVision environment.
13 Automated Processing

The functionality of StyleVision together with the various XSLT and output files generated by StyleVision provide powerful automation possibilities. This section describes these capabilities.

StyleVision's file-generation functionality

After you have created an SPS design with StyleVision, you can generate several kinds of XSLT and output files from within the GUI, depending on which edition of StyleVision you are using (Enterprise, Professional, or Basic). The following files can be generated with the File | Save Generated Files command:

- XSLT files for HTML, Text, and RTF output.
- HTML, Text, and RTF output.

As you will notice from the list above, the files that can be saved with StyleVision are of two types:

1. The XSLT files generated by the SPS design, and
2. The final output files (such as HTML).

Note: Additionally, if database sources are used, XML Schema and XML data files can be generated based on the database structure and content.

The processes to generate the final HTML, Text, and RTF output files are all one-step processes in which the XML document is transformed by an XSLT stylesheet to the output format.

StyleVision Server and RaptorXML: generating files from outside the GUI

Additionally to generating XSLT stylesheets and the required output formats via the StyleVision GUI (File | Save Generated Files command), you can generate output files using two other methods:

1. With StyleVision Server, which calls StyleVision's file generation functionality without opening the GUI, you can produce various kinds of output.
2. With RaptorXML, a standalone Altova application that contains Altova's XML(+XBRL) Validator, and XSLT and XQuery Engines. The XSLT Engines in RaptorXML can be used for transformations of XML to an output format by processing XML documents with XSLT stylesheets. The XSLT file will have to be created in advance so that it can be used by RaptorXML. (RaptorXML does not take an SPS as an input parameter.) The advantages of using RaptorXML are: (i) speed, as a result enabling fast transformations of large files; and (ii) in addition to a command line interface, RaptorXML provides interfaces for COM, Java, and .NET, and can therefore be easily called from within these environments. How to use RaptorXML for transformations is explained in the sub-section RaptorXML.
3. Multiple transformations can be carried out according to pre-set triggers (such as a daily time) using Altova StyleVision Server within an Altova FlowForce Server workflow. This is described in the section Automation with FlowForce Server.
13.1 Command Line Interface

StyleVision functionality can be called from the command line in two ways:

- By calling the **StyleVision executable**. This provides access to StyleVision's XSLT-file-generation functionality. The XSLT files are generated from the SPS file.
- By using **StyleVision Server** to generate output files (HTML, etc). The output files are generated from a PXF file, which is a package of an SPS file with its related files (XML, XSD, image files, etc). The PXF file is generated from StyleVision.

How to use the command line

There are two ways you can use the command line:

- Commands can be entered singly on the command line and be executed immediately. For example, in a command prompt window, you can enter a command for StyleVision or **StyleVision Server**, and press **Enter** to execute the command.
- A series of commands can be entered in a **batch file** for batch processing. For example:

  ```bash
  @ECHO OFF
  CLS
  StyleVision TestEN.sps -outxslt=HTML-EN.xslt
  StyleVision TestDE.sps -outxslt=HTML-DE.xslt
  StyleVision TestES.sps -outxslt=HTML-ES.xslt
  ```

  When the batch file is processed, the commands are executed and the files are generated.

StyleVision functionality in scheduled tasks

Using the Scheduled Tasks tool of Windows, StyleVision commands can be set to execute according to a predefined schedule. Either a single command or a batch file can be specified as the task to be executed. How to create such commands is described in **How to Automate Processing**.

13.1.1 StyleVision

The syntax for command line use is:

```
StyleVision [<SPS File>] [<options>]
```

where

- **StyleVision** calls StyleVision, which is located in the StyleVision application folder
- **<SPS File>** specifies the SPS file
- **<options>** One or more of the options listed below.

When a command is executed StyleVision runs silently (i.e. without the GUI being opened), generates the required output files, and closes. If an error or warning is encountered, the GUI is opened and the corresponding message is displayed in a message box.
Note: For the SPS to load correctly in StyleVision, the XSD and Working XML files that the SPS uses must be at the locations specified for them in the SPS.

Options
Options may be entered in any order. Note that FO, PDF, and Word 2007+ output-related options are available in the Enterprise edition only; these options are indicated with the words Enterprise edition in the list below.

- **XSLT file output**
  - -OutXSLT=<file>
  - -OutXSLRTF=<file>
  - -OutXSLText=<file>
  - -OutXSLFO= <file>
    
    Writes XSLT-for-HTML to the specified file
  - -OutXSLWord2007=<file>
    
    (Enterprise edition only)
    
    Writes XSLT-for-Word 2007+ to the specified file (Enterprise edition only)

- **DB data output**
  - -OutDBXML=<file>
    
    Writes XML generated from DB to the specified file.
  - -OutDBSchema=<file>
    
    Writes XML Schema generated from DB to the specified file.

Examples

StyleVision "QuickStart.sps" -outxslt="QuickStartHTML.xslt"
StyleVision "C:\Test\QuickStart.sps" -outxslt="C:\Test\QuickStartHTML.xslt"

Points to note
Note the following points:

- Paths may be absolute or relative and should use backslashes.
- If the filename or the path to it contains a space, then the entire path should be enclosed in quotes. For example: "c:\My Files\MyXML.xml" or "c:\MyFiles\My XML.xml".
- Commands, paths, and folder and file names are case-insensitive.

13.1.2 StyleVision Server

StyleVision Server can be used via its command line interface (CLI) on Windows, Linux, and Mac OS systems to transform XML files into output HTML, PDF, RTF, and DOCX documents. The StyleVision Server CLI's generate command takes an XML file and a PXF file as its two arguments, and the desired output formats
as its parameters. The XSLT stylesheets for the transformation are obtained from the PXF file submitted as input.

An advantage of using StyleVision Server's CLI over RaptorXML Server's CLI is that StyleVision Server can take PXF files as its input (RaptorXML takes an XSLT file as its input). StyleVision Server is however best used when used as part of an Altova FlowForce workflow. A FlowForce workflow can start transformation jobs according to preset triggers: Multiple files can be transformed automatically within a network when the FlowForce job is triggered. See the section Automation with FlowForce Server for more information.

For more information about the StyleVision Server CLI, see the StyleVision Server documentation.

Output files
StyleVision Server can generate one or more of the following files from the specified PXF file:

- HTML (.html) file/s using the XML and XSLT-for-HTML files specified in the PXF, or using alternative XML files
- Text file using the text document and XSLT-for-Text files specified in the PXF
- RTF file using the XML and XSLT-for-RTF files specified in the PXF, or using alternative XML files
13.2 Using RaptorXML

Altova RaptorXML is Altova’s third-generation, hyper-fast XML and XBRL processor. It has been built to be optimized for the latest standards and parallel computing environments. Designed to be highly cross-platform capable, the engine takes advantage of today’s ubiquitous multi-core computers to deliver lightning fast processing of XML and XBRL data.

RaptorXML is available in two editions:

- RaptorXML Server edition, which can be accessed over a network and can transform multiple files at a time.
- RaptorXML+XBRL Server edition, which can be accessed over a network, can transform multiple files at a time, and additionally supports XBRL validation.

For more information about RaptorXML, see the Altova website.

Typical use-cases

The functionality of RaptorXML that would be most relevant to StyleVision users is the XSLT transformation functionality. Typically, this functionality would be used as follows:

1. An XSLT stylesheet is generated from an SPS with the File | Save Generated Files command. Note that RaptorXML cannot be used to generate XSLT stylesheets from an SPS file.
2. The generated XSLT stylesheet is used to transform XML documents with RaptorXML. With RaptorXML you can generate HTML, Text, and RTF output.

Advantages of RaptorXML

The advantages of using RaptorXML are as follows:

- RaptorXML provides very fast validation and XSLT transformation, and is therefore useful for dealing with large files.
- Easy use with command line, COM, Java, and .NET interfaces.
- Automation and scheduling with the use of batch files and the scheduling processes such as the Scheduled Tasks process of Windows.

For a description of how RaptorXML can be used to automate the production of output documents (such as HTML) from XML source documents, see the section How to Automate Processing.

For additional and more detailed information about using RaptorXML, including how to use RaptorXML’s COM, Java, and .NET interfaces, see the RaptorXML user documentation.

13.2.1 PDF Output

To generate PDF output from an XML document requires two steps:

1. The XML document is transformed by an XSLT stylesheet. An XSLT transformation engine (such as that of RaptorXML) is used for this transformation. The result is an FO document.
2. The FO document is processed by an FO processor (such as Apache's FOP) to generate the PDF output. StyleVision can be set up to pass the FO result of an XSLT transformation to an FO processor. In StyleVision, the result of PDF generation is displayed in the PDF Preview window or can be saved as a file (via the File | Save Generated Files command).

RaptorXML and PDF
Since RaptorXML does not provide parameters to direct the FO output of an XSLT transformation to an FO processor, you will be left with an FO document as the result of the XSLT transformation step (the first step of the two-step PDF-generation process).

The FO document must now be passed to an FO processor for second-step processing from FO to PDF. The instructions for carrying out this step vary according to the processor being used. For example, in the case of the Apache FOP processor, the following simple command can be used to identify the input FO document and specify the name and location of the output PDF document:

```
fop -fo input.fo -pdf output.pdf
```

FOP offers other parameters, and these are listed in the FOP user reference.

FOP and XSLT
One FOP option enables you to specify an input XML file, an input XSLT file, and an output PDF file:

```
fop -xml input.xml -xslt input.xslt -pdf output.pdf
```

In this situation, FOP uses its built-in XSLT engine to carry out the first-step XML-to-FO transformation. It then passes the result FO document to FOP for the second-step FO-to-PDF processing.

You should be aware, however, that FOP's built-in engine might not support all the XSLT features that StyleVision and RaptorXML support. Consequently, there could be errors if an XSLT stylesheet generated by StyleVision is specified as an input for an XML transformation using FOP's built-in XSLT engine. In such cases, use the XSLT engine of RaptorXML+XBRL Server to transform to FO, and then supply the FO file to FOP for processing to PDF.

Batch processing to PDF
A quick and simple way to generate PDF by using RaptorXML for the first-step XSLT transformation and FOP for the second-step FO processing would be to write a batch file that combines the two commands. For example:

```
raptorxmlserver xslt --input=Test.xml --output=Test.fo Test.xslt
fop -fo Test.fo -pdf Test.pdf
```

The first command calls RaptorXML and produces test.fo as output. The second command passes test.fo to the FOP processor, which generates the PDF file test.pdf. For more information about batch processing and how batch files can be used to automate processes, see the following section: How to Automate Processing.
13.3 Automation with FlowForce Server

Transformations can be automated over a network by using Altova's FlowForce Server, which is available on Windows, Linux, and Mac OS systems. The process works as follows:

1. From StyleVision, a PXF file is deployed to FlowForce Server (with the File | Deploy to FlowForce command) as a .transformation file. The .transformation file contains all the files and information required to carry out transformations as designed in the SPS. (In the diagram below, the deployment is represented by the connector line running along the top.)

2. After the .transformation file has been deployed to FlowForce Server, jobs can be created in FlowForce that use the .transformation file to generate transformations according to triggers specified in the job definition. (A trigger could be, for example, a specific time every day.) Flow Force jobs are created in the FlowForce Web Server interface (shown in the center of the diagram below), which can be accessed from StyleVision or via an HTTP address. For information about creating FlowForce jobs, see the FlowForce documentation.

3. At execution time, FlowForce Server passes the transformation instructions and relevant files to StyleVision Server, which then carries out the transformation (see diagram below).

The role of StyleVision Server in the FlowForce workflow is shown in the diagram below. (The role of MapForce Server in the workflow is also displayed since FlowForce jobs can be created that send Altova MapForce mappings to the Altova MapForce Server for execution.)
Note that additionally to being invoked by a FlowForce job, StyleVision Server can also be invoked via its command line. Usage is described in the StyleVision Server documentation.
13.4 How to Automate Processing

A batch file (a text file saved with the file extension .bat) contains a sequence of commands that will be executed from the command line. When the batch file is executed, each command in the batch file will be executed in turn, starting with the first and progressing through the sequence. A batch file is therefore useful in the following situations:

- Executing a series of commands automatically (see below).
- Creating a chain of processing commands, where a command requires input produced by a preceding command. (For example, an XML file produced as output of one transformation is used as the input of a subsequent transformation.)
- Scheduling a sequence of tasks to be executed at a particular time.

Batch file with sequence of commands

A sequence of commands to be executed is entered as follows:

```bash
@ECHO OFF
CLS
StyleVision TestEN.sps -outxslt=HTML-EN.xslt
StyleVision TestDE.sps -outxslt=HTML-DE.xslt
StyleVision TestES.sps -outxslt=HTML-ES.xslt
```

When the batch file is processed, the commands are executed and the files generated. The batch file above uses StyleVision to generate three XSLT files from an SPS file.
14 StyleVision in Visual Studio

StyleVision can be integrated into the Microsoft Visual Studio 2010/2012/2013/2015/2017/2019. This unifies the best of both worlds, integrating advanced SPS file creation capabilities with the advanced development environment of Visual Studio.

In this section, we describe:

- The [broad installation process](#) and the integration of the StyleVision plugin in Visual Studio.
- Differences between the Visual Studio version and the standalone version.
14.1 Installing the StyleVision Plugin

To install the StyleVision Plugin for Visual Studio, you need to do the following:

2. Install StyleVision (Enterprise or Professional Edition).
3. Download and run the StyleVision integration package for Microsoft Visual Studio. This package is available on the StyleVision (Enterprise and Professional Editions) download page at www.altova.com. (Please note: You must use the integration package corresponding to your StyleVision version (current version is 2022).)

Once the integration package has been installed, you will be able to use StyleVision in the Visual Studio environment.
14.2 Differences with StyleVision Standalone

This section lists the ways in which the Visual Studio versions differ from the standalone versions of StyleVision.

Entry helpers (Tool windows in Visual Studio)
The entry helpers of StyleVision are available as Tool windows in Visual Studio. The following points about them should be noted. (For a description of entry helpers and the StyleVision GUI, see the section, User Interface.)

- You can drag entry helper windows to any position in the development environment.
- Right-clicking an entry helper tab allows you to further customize your interface. Entry helper configuration options are: dockable, hide, floating, and auto-hide.

StyleVision commands as Visual Studio commands
Some StyleVision commands are present as Visual Studio commands in the Visual Studio GUI. These are:

- **Undo, Redo**: These Visual Studio commands affect all actions in the Visual Studio development environment.
- **Projects**: StyleVision projects are handled as Visual Studio projects.
- **Customize Toolbars, Customize Commands**: The Toolbars and Commands tabs in the Customize dialog (Tools | Customize) contain both visual Studio commands as well as StyleVision commands.
- **Views**: In the View menu, the command **StyleVision** contains options to toggle on entry helper windows and other sidebars, and to switch between the editing views, and toggle certain editing guides on and off.
- **StyleVision Help**: This StyleVision menu appears as a submenu in Visual Studio's Help menu.

**Note**: In Visual Studio 2019 and later, StyleVision functionality can be accessed in the Extensions menu of Visual Studio. In earlier versions of Visual Studio, StyleVision features are available in top-level menus of Visual Studio.
15 StyleVision in Eclipse

Eclipse is an open source framework that integrates different types of applications delivered in the form of plugins.

The StyleVision Plugin for Eclipse enables you to access the functionality of StyleVision from within the Eclipse 2021-09, 2021-06, 2021-03, 2020-12 Platform. It is available on Windows platforms. In this section, we describe how to install the StyleVision Plugin for Eclipse and how to set up the StyleVision perspective. After you have done this, components of the StyleVision GUI and StyleVision menu commands will be available within the Eclipse GUI.
15.1 Installing the StyleVision Plugin for Eclipse

Prerequisites

- A Java Runtime Environment (JRE) or Java Development Kit (JDK) for the 64-bit platform.
- StyleVision Enterprise or Professional Edition 64-bit.
- StyleVision Integration Package 64-bit, available for download at https://www.altova.com/components/download. You can perform the Eclipse integration as part of this installation, as further described below.

Note: All the prerequisites listed above must have the 64-bit platform. Integration with older Eclipse 32-bit platforms is no longer supported, although it may still work.

Installing the StyleVision plug-in for Eclipse

You can perform the integration of the StyleVision plug-in into Eclipse in one of the following ways:

1. Automatically, during the installation of the StyleVision Integration Package (this is the recommended option).
2. Install the StyleVision Integration Package first, and then integrate the plug-in manually from Eclipse.

To integrate StyleVision Plug-in for Eclipse:

1. Run the StyleVision Integration Package to start the installation wizard.
2. When prompted, select the Install the Eclipse plug-in option, and then click Next.
3. When prompted to choose how the StyleVision plug-in should be integrated into Eclipse, do one of the following:
   - To complete the plug-in installation automatically, select Let this wizard integrate Altova StyleVision plug-in into Eclipse, and browse for the directory where the Eclipse executable (eclipse.exe) is located.
   - To complete the plug-in installation later in Eclipse, clear the Let this wizard... check box.
4. Click Next, and complete the installation. If you chose the automatic integration, the StyleVision perspective and menus become available in Eclipse next time when you start Eclipse.

Note: Eclipse must be closed while you install or uninstall the StyleVision Integration Package.

Integrating the StyleVision plug-in for Eclipse manually

1. In Eclipse, select the menu command Help | Install New Software.
2. In the Install dialog box, click Add.
3. In the "Add Repository" dialog box, click Local. Browse for the folder C:\Program Files\Altova\Common2022\eclipse\UpdateSite, and select it. Provide a name for the site (such as "Altova").

4. Repeat the steps 2-3 above, this time selecting the folder C:\Program Files\Altova\StyleVision2022\eclipse\UpdateSite, and providing a name such as "Altova StyleVision".

5. On the Install dialog box, select Only Local Sites. Next, select the "Altova category" folder, and click Next.

6. Review the items to be installed, and click Next to proceed.

7. To accept the license agreement, select the respective check box.

8. Click Finish to complete the installation.

Note: If there are problems with the plug-in (missing icons, for example), start Eclipse from the command line with the -clean flag.
15.2 StyleVision Entry Points in Eclipse

The following entry points in Eclipse can be used to access StyleVision functionality:

- **StyleVision Perspective**, which provides StyleVision's GUI features within the Eclipse GUI.
- **StyleVision menu and toolbar**

StyleVision Perspective

In Eclipse, a perspective is a configured GUI view with functionality from various applications. When the StyleVision Plugin for Eclipse is integrated in Eclipse, a default StyleVision perspective is automatically created. This perspective is a GUI that includes StyleVision's GUI elements: its editing views, menus, entry helpers, and other sidebars.

When a file having a filetype associated with StyleVision is opened (`.sps`, for example), this file can be edited in the StyleVision perspective. Similarly, a file of another filetype can be opened in another perspective in Eclipse. Additionally, for any active file, you can switch the perspective, thus allowing you to edit or process that file in another environment. There are therefore two main advantage of perspectives:

1. Being able to quickly change the working environment of the active file, and
2. Being able to switch between files without having to open a new development environment (the associated environment is available in a perspective)

Working with the StyleVision perspective involves the following:

- Switching to the StyleVision perspective.
- Setting preferences for the StyleVision perspective.
- Customizing the StyleVision perspective.

Switching to the StyleVision perspective

In Eclipse, select the command **Window | Perspective | Open Perspective | Other**. In the dialog that pops up (**screenshot below**), select **StyleVision**, and click **Open**.
The empty window or the active document will now have the StyleVision perspective. This is how the user switches the perspective via the menu. To access a perspective faster from another perspective, the required perspective can be listed in the Open Perspective submenu, above the Other item; this setting is in the customization dialog (see further below).

Perspectives can also be switched when a file is opened or made active. The perspective of the application associated with a file's filetype will be automatically opened when that file is opened for the first time. Before the perspective is switched, a dialog appears asking whether you wish to have the default perspective automatically associated with this filetype (screenshot below).

Check the Do Not Ask Again option if you wish to associate the perspective with the filetype without having to be prompted each time a file of this filetype is opened and then click OK.
Setting preferences for the StyleVision perspective

The preferences of a perspective include: (i) a setting to automatically change the perspective when a file of an associated filetype is opened (see above), and (ii) options for including or excluding individual StyleVision toolbars. To access the Preferences dialog (screenshot below), select the command Window | Preferences.

In the list of perspectives in the left pane, select StyleVision, then select the required preferences. Finish by clicking OK.

Customizing the StyleVision perspective

The customization options enable you to determine what shortcuts and commands are included in the perspective. To access the Customize Perspective dialog of a perspective (screenshot below shows dialog for the StyleVision perspective), make the perspective active (in this case the StyleVision perspective), and select the command Window | Perspective | Customize Perspective.

In the Tool Bar Visibility and Menu Visibility tabs, you can specify which toolbars and menus are to be displayed. In the Action Set Availability tab, you can add action sets to their parent menus and to the toolbar. If you wish to enable an action group, check its check box. In the Shortcuts tab of the Customize Perspective dialog, you can set shortcuts for submenus. Select the required submenu in the Submenus combo box. Then
select a shortcut category, and check the shortcuts you wish to include for the perspective. Click Apply & Close to complete the customization and for the changes to take effect.

**StyleVision menu and toolbar**

The **StyleVision** menu contains commands that are relevant even if a document type recognized by StyleVision is not currently open in Eclipse. In the standalone version of StyleVision, some of these commands are in the **File** menu.

The StyleVision toolbar contains the following buttons (*screenshot below*).

These are for, from left: (i) opening the StyleVision Help, and (ii) accessing StyleVision commands (as an alternative to accessing them from the **StyleVision** menu).
16 Menu Commands and Reference

This section contains a complete description of StyleVision toolbars, Design View symbols, and menu commands. It is divided into the following broad parts:

- An explanation of symbols used in Design View.
- A description of the Edit XPath Expression dialog.
- A description of all the toolbars with their icons, as well as a description of how to customize the views of the toolbars.
- All menu commands.

While the User Reference section contains a description of individual commands, the mechanisms behind various StyleVision features are explained in detail in the relevant sections. The mechanisms have been organized into the following groups:

- SPS File Content
- SPS File Structure
- SPS File Advanced Features
- SPS File Presentation
- SPS File Additional Functionality
- SPS File and Databases

For command line usage, see Command Line Interface: StyleVisionBatch.

- Quick Start Tutorial
16.1 Design View Symbols

An SPS design will typically contain several types of component. Each component is represented in the design by a specific symbol. These symbols are listed below and are organized into the following groups:

- Nodes in the XML document
- XML document content
- Data-entry devices
- Predefined formats
- XPath objects
- URI objects

Each of these component types can:

- be moved using drag and drop;
- be cut, copied, pasted, and deleted using (i) the commands in the Edit menu, or (ii) the standard Windows shortcuts for these commands;
- have formatting applied to it;
- have a context menu pop up when right-clicked.

Nodes in the XML document

Element and attribute nodes in the XML document are represented in the SPS design document by tags. Each node has a start tag and end tag. Double-clicking either the start or end tag collapses that node. When a node is collapsed all its contents are hidden. Double-clicking a collapsed node expands it and displays its content.

The following types of node are represented:

- **Document node**

![Document node](image)

The document node (indicated with $XML$) represents the XML document as a whole. It is indicated with a green $XML$ tag when the schema source is associated with an XML document, and with $DB$ when the schema source is associated with a DB. The document node in the screenshot at left is expanded and contains the OrgChart element, which is collapsed. The document node in the screenshot at right is collapsed; its contents are hidden.

- **Element node**

![Element node](image)

An element node is inserted together with all its ancestor elements if the ancestors are not present at the insertion point. In the screenshot above, the Name element node is shown expanded (left) and collapsed (right).

- **Attribute node**
An attribute node is inserted together with all its ancestor elements if the ancestors are not present at the insertion point. Attribute names contain the prefix `=`. In the screenshot above, the href attribute node is shown expanded (left) and collapsed (right).

Nodes are included in the design as node templates. For information on the various kind of templates that can be included in the design, see the section, Templates and Design Fragments.

**XML document content**

XML document content is represented by two placeholders:

- `(contents)`
- `(rest-of-contents)`

The contents placeholder represents the contents of a single node. All the text content of the node is output. If the node is an attribute node or a text-only element node, the value of the node is output. If the node is an element node that contains mixed content or element-only content, the text content of all descendants is output. In XSLT terms, the contents placeholder is equivalent to the `xsl:apply-templates` element with its `select` attribute set for that node.

**Note:** When applied to an element node, the contents placeholder does not output the values of attributes of that element. To output attribute nodes, you must explicitly include the attribute in the template (main or global).

The rest-of-contents placeholder applies templates to the rest of the child elements of the current node. The template that is applied for each child element in this case will be either a global template (if one is defined for that element) or the default template for elements (which simply outputs text of text-only elements, and applies templates to child elements). For example, consider an element `book`, which contains the child elements: `title`, `author`, `isbn`, and `pubdate`. If the definition of `book` specifies that only the `title` child element be output, then none of the other child elements (`author`, `isbn`, and `pubdate`) will be output when this definition is processed. If, however, the definition of `book` includes the rest-of-contents placeholder after the definition for the `title` element, then for each of the other child elements (`author`, `isbn`, and `pubdate`), a global template (if one exists for that element), or the default template for elements, will be applied.

**Data-entry devices**

In order to aid the Authentic View user edit the XML document correctly and enter valid data, data-entry devices can be used in the design. You can assign any of the following data-entry devices to a node:

- **Input fields (single line or multi-line)**
- **Combo boxes**
Check boxes

Radio buttons

These tags can be collapsed and expanded by double-clicking an expanded and the collapsed tag, respectively. For a detailed description of how each of these data-entry devices is used, see Data-Entry Devices.

Predefined formats

Predefined formats are shown in mauve tags, which can be expanded/collapsed by double-clicking.

XPath objects

StyleVision features two mechanisms that use XPath expressions:

Conditional templates

Condition tags are blue. The start tag contains cells. The leftmost cell contains a question mark. Other cells each contain either (i) a number, starting with one, for each when condition; and/or (ii) an asterisk for the optional otherwise Condition. A condition branch can be selected by clicking it. The number of the selected condition branch is highlighted in the start tag, and the template for that branch is displayed (within the start and end tags of the condition). The XPath expression for the selected condition branch is also highlighted in the Design Tree. Note that tags for conditions cannot be expanded/collapsed.

Auto-Calculations
Auto-Calculations are represented in Design View by the \(=\{\text{AutoCalc}\}\) object (see screenshot above). The XPath expression for the selected Auto-Calculation is highlighted in the Design Tree. The dialog to edit the Auto-Calculation is accessed via the Properties sidebar.

URI objects
There are three URI-based objects that can be inserted in a design:

- **Images**
  If an image is inserted in the SPS design and can be accessed by StyleVision, it becomes visible in Design View. If it cannot be accessed, its place in the SPS is marked by an image placeholder.

- **Bookmarks (Anchors)**
  Bookmark tags are yellow and indicated with the character \(\text{A}\) (screenshots above). A bookmark is created with the command **Insert | Insert Bookmark**, and can be empty or contain content. Content must always be inserted after the anchor is created. Anchor tags can be expanded (screenshot above left) or collapsed (screenshot above right).

- **Links**
  Link tags are yellow and indicated with the character \(\text{A}\) (screenshots above). A link is created with the command **Insert | Hyperlink**. The object around which the link is created can be inserted in the design before or after the link is created. If an item is to be created as a link, it should be selected and the link created around it. Link tags can be expanded (screenshot above left) or collapsed (screenshot above right).

16.2 Edit XPath Expression Dialog

The Edit XPath Expression dialog (screenshot below) is used to build, test, and edit XPath expressions. It is accessible at all places in Design View where an XPath expression may be entered, such as when entering expressions for conditional processing or the values of Styles and Properties.

The dialog automatically supports the XPath version that corresponds to the XSLT version of the SPS (XPath 1.0 for XSLT 1.0; XPath 2.0 for XSLT 2.0; and XPath 3.1 for XSLT 3.0). To switch the XPath version, switch the XSLT version of the SPS.

Dialog layout
The Edit XPath Expression dialog contains the following panes (see screenshot below): (i) an Expression pane (top left); (ii) a Sources pane (top right); (iii) a Results pane (bottom). In Builder Mode, the Results pane is augmented by additional entry helper panes.

Evaluation Mode and Debug Mode
The Edit XPath Expression dialog has two modes:
• **Evaluation Mode**, in which an XPath expression is evaluated with respect to the assigned Working XML File/s. The expression is entered in the **Expression pane**, and the result is displayed in the **Results pane**. You can click nodes in the result to go to that node in the Sources pane of the dialog.

• **Debug Mode**, in which you can debug an XPath expression as it applies to the assigned Working XML File/s. You can set breakpoints and tracepoints, and go step-by-step through the evaluation. At each step you can see the content of variables, as well as set custom Watch expressions to check additional aspects of the evaluation.

To switch between the two modes, select the appropriate command in the **Start Evaluation/Debugging** dropdown menu that is located in the left-hand corner of the window's toolbar (see screenshot below).

![Start Evaluation/Debugging](image)

How to use the two modes is described in the sub-sections of this section.

**XPath/XQuery Expression Builder**

In both modes, the **Expression Builder** can be used to help you construct syntactically correct expressions.

Switch **Expression Builder** on/off with the **Builder Mode** button of the main toolbar.

### 16.2.1 Evaluator

Select Evaluation Mode by selecting **Start Evaluation** in the **Start Evaluation/Debugging** dropdown menu (see screenshot below).

![Start Evaluation/Debugging](image)

In Evaluation Mode, click the **Evaluator** button (see screenshot below). The evaluator has the following panes (see screenshot below): (i) an Expression pane (**top left**); (ii) a Sources pane (**top right**); (iii) a Results pane (**bottom**).
The XPath expression and its evaluation

The XPath expression is entered in the Expression pane. The results of the evaluation are displayed in the Results pane (see screenshot above).

Note the following points:

- In order for an expression to be evaluated against an XML file, that file must be assigned as the Working XML file of one of the sources of the SPS.
- Results can be displayed even as you type the expression (select the Evaluate on Typing icon in the toolbar), or they can be displayed when you click the toolbar button Start Evaluation/Debugging (F5) (located at top left of the toolbar).
- To enter the XPath locator expression of a node in a source tree, double-click that node in the Sources pane.
- In the Sources pane, you can switch on/off the display of: (i) processing instructions, (ii) comments, (iii) attributes, and (iv) elements. Do this via the buttons below the Sources pane.
- The context node is that of the design component within which the expression is being created. To set another node as the context node of the expression: (i) select the node in the Sources pane, and (ii) click Set Evaluation Context (located below the Sources pane). To save this context node for the expression, click the toggle command button Remember Evaluation Context (located below the
Sources pane). Note, however, that the actual context node for the expression will be the context node of the current design component, and this is the context node that will be used at runtime.

- You can use the functions of the Java and .NET programming languages in the XPath expression. The buttons Using Java and Using .NET at the bottom of the dialog display info boxes with explanations about how to use Java and .NET extension functions in XPath expressions. For more information about this, see the Extension Functions section of this documentation.
- To create the expression over multiple lines (for easier readability), use the Return key.
- To increase/decrease the size of text in the expression field, click in the expression field, then press Ctrl and turn the scroll wheel. Note that this also applies in the Results pane.
- Instead of manually entering the locator path expression of a node, you can do the following: (i) Place the cursor at the point in the XPath expression where you want to enter the locator path; (ii) In the Sources tree, double-click the node you want to target. This enters the locator path of the selected node in the expression. The locator path will be an absolute path starting at the root node of the document.

Results pane
The Results pane is shown in the screenshot below, at bottom. Note that it has its own toolbar.

The Results pane has the following functionality:

- The result list consists of two columns: (i) a node name or a datatype; (ii) the content of the node.
• If the XPath expression returns nodes (such as elements or attributes), you can select whether the entire contents of the nodes should be shown as the value of the node. To do this, switch on the toggle Show Complete Result.

• When the result contains a node (including a text node)—as opposed to expression-generated literals—clicking that node in the Results pane highlights the corresponding node in the XML document in the Sources tree.

• You can copy both columns of a result sub-line, or only the value column. To copy all columns, right-click a sub-line and toggle on Copying Includes All Columns. (Alternatively you can toggle the command on/off via its icon in the toolbar of the Results pane.) Then right-click the sub-line you want to copy and select either Copy Subline (for that subline) or Copy All (for all sublines).

**Toolbar of the Results pane**

The toolbar of the Results pane contains icons that provide navigation, search, and copy functionality. These icons, starting from the left, are described in the table below. The corresponding commands are also available in the context menu of result list items.

<table>
<thead>
<tr>
<th>Icon</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Next, Previous</td>
<td>Selects, respectively, the next and previous item in the result list</td>
</tr>
<tr>
<td>Copy the selected text line to the clipboard</td>
<td>Copies the value column of the selected result item to the clipboard. To copy all columns, toggle on the Copying includes all columns command (see below)</td>
</tr>
<tr>
<td>Copy all messages to the clipboard</td>
<td>Copies the value column of all result items to the clipboard, including empty values. Each item is copied as a separate line</td>
</tr>
<tr>
<td>Copying includes all columns</td>
<td>Switches between copying (i) all columns, or (ii) only the value column. The column separator is a single space</td>
</tr>
<tr>
<td>Find</td>
<td>Opens a Find dialog to search for any string, including special characters, in the result list</td>
</tr>
<tr>
<td>Find previous</td>
<td>Finds the previous occurrence of the term that was last entered in the Find dialog</td>
</tr>
<tr>
<td>Find next</td>
<td>Finds the next occurrence of the term that was last entered in the Find dialog</td>
</tr>
<tr>
<td>Clear</td>
<td>Clears the result list</td>
</tr>
<tr>
<td>Collapse multi-line results to a single line</td>
<td>If the value column of a result item contains multi-line text (text that includes newline character/s), you can toggle between a multi-line and single-line display</td>
</tr>
<tr>
<td>Show complete result</td>
<td>Shows the entire content of nodes as the value of the node</td>
</tr>
</tbody>
</table>

**16.2.2 Debugger**

The Debugger enables you to debug an XPath expression in the context of a Working XML File. To access the Debugger, selecting Start Debugging in the Start Evaluation/Debugging dropdown menu (screenshot below). This sets the mode to Debug Mode. You can then switch between the Builder (for help with building the expression) and Evaluator (for debugging the expression). To start debugging, click Start Evaluation/Debugging (F5)
After you have entered an expression, you can start debugging by clicking **Start Evaluation/Debugging (F5)** (after making sure that you are in Debug Mode).

- **Buttons for setting up Debug Mode**

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Start Debugging" /></td>
<td><strong>Start Evaluation/Debugging (F5)</strong> Starts the debugger</td>
</tr>
<tr>
<td><img src="image" alt="Switch to Builder" /></td>
<td><strong>Switch to Builder</strong> Switches to Expression Builder mode, which provides context-sensitive entry helpers to help construct expressions</td>
</tr>
<tr>
<td><img src="image" alt="Evaluation on typing" /></td>
<td><strong>Evaluation on typing</strong> Switches on the evaluation of expressions while the expression is being typed</td>
</tr>
</tbody>
</table>

**Layout of Debug Mode**

In Debug Mode, two additional panes are added to the Results pane *(see screenshot below)*:

- the Call Stack and Debug Points pane, each of which has a separate tab in the pane
- the Variables and Watch Expressions pane; both watch expressions and variables are shown in the same pane.
Debugger Mode offers the following features:

- Enables you to step into the XPath evaluation process, one step at a time to see how the XPath expression is being evaluated. Use the Step Into (F11) toolbar button for this. At each evaluation step, the part of the expression being currently evaluated is highlighted in yellow (see screenshot above), while the result of evaluating that step is shown in the Results pane. For example, in the screenshot above, all the section descendant elements of the book element have been selected.
- Set breakpoints where you want to pause the evaluation and check results at these points. You can step through the evaluation by pausing only at breakpoints. Use the Start Debugging (F5) toolbar button for this. This is quicker than pausing at every step with Step Into (F11).
- Set tracepoints to see a report of results at the steps marked as tracepoints. The evaluation will not pause (except at breakpoints), but the tracepoint results will be displayed in a list in the Results pane.
- Watch expressions can be used to check information (such as document data or aspects of the evaluation). This is especially useful at breakpoints.
- Variables that are in scope, including their values, are displayed in the Variables and Watch Expressions pane.
- Processor calls of an evaluation step are shown in the Call Stack tab of the Call Stack and Debug Points pane.
- If breakpoints and tracepoints have been set, then these are displayed in the Debug Points tab of the Call Stack and Debug Points pane.

For more information about these features, see their descriptions below.

**Running the Debugger**

The broad steps for debugging an XPath expression are as follows:
1. Enter the XPath expression in the expression pane.
2. Set any breakpoints or tracepoints you want. A breakpoint is a point at which the evaluation is paused. A tracepoint is a point in the evaluation that is recorded; tracepoints thus provide a traceable path of evaluation results.
3. If you click **Start Debugger**, evaluation is carried out in one step to the end unless a breakpoint has been marked in the expression. Click **Start Debugger** repeatedly to progress through each breakpoint to the end of the evaluation.
4. Use the Step Into/Out/Over functionality to go step-by-step through the evaluation.

### Buttons for debugging

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="F5" alt="Start Debugger" /></td>
<td>Starts the debugger. Evaluation goes directly to the end, stopping only for breakpoints</td>
</tr>
<tr>
<td><img src="Shift+F5" alt="Stop Debugger" /></td>
<td>Exits the evaluation and stops the debugger</td>
</tr>
<tr>
<td><img src="F11" alt="Step Into" /></td>
<td>Proceeds through the evaluation, one step at a time.</td>
</tr>
<tr>
<td><img src="Shift+F11" alt="Step Out" /></td>
<td>Steps out of the current evaluation step, and goes to the parent step</td>
</tr>
<tr>
<td><img src="Ctrl+F11" alt="Step Over" /></td>
<td>Steps over descendant steps</td>
</tr>
<tr>
<td><img src="F9" alt="Insert/Remove Breakpoint" /></td>
<td>Inserts/removes a breakpoint at the expression step where you place the cursor</td>
</tr>
<tr>
<td><img src="Shift+F9" alt="Insert/Remove Tracepoint" /></td>
<td>Inserts/removes a tracepoint at the expression step where you place the cursor</td>
</tr>
</tbody>
</table>

**Stepping in, out, and over evaluation steps**

The **Step Into** functionality enables you to go step-by-step through the evaluation. Each click of this command takes you through the next step of the evaluation; the current step is shown by the highlighting in the expression (see screenshot below). The **Step Out** functionality takes you to a step on a higher level as the current step, whereas the **Step Over** functionality steps over lower-level steps and takes you to the next step on the same level. You can try out the **Stepping** functionality by using the expression shown in the screenshot below and clicking the three **Step** buttons to see how they work.

The screenshot below shows the evaluation when processing has been paused on reaching the locator step `newsitem`. At this step, the result shows the four `newsitem` node.
Breakpoints

Breakpoints are points where you want the Debugger to stop after it has been started with Start Debugger. They are useful if you wish to analyze a specific part of the expression. When the Debugger stops at the breakpoint, you can check the result and could then use the Step Into functionality to display the results of the next steps of the evaluation. To set a breakpoint, place the cursor in the expression at the point where you want the breakpoint, and click the Insert/Remove Breakpoint (F9) toolbar button. The breakpoint will be marked with a dashed red overline. To remove a breakpoint, select it and click Insert/Remove Breakpoint (F9).

Also see Debug Points below.

Tracepoints

Tracepoints are points at which the results are recorded. These results are displayed in the Traces tree of the Result tab (see screenshot below). This enables you to see all the evaluation results of particular parts of the expression. For example, in the screenshot below, tracepoints have been set on the team node and member node. The results at these tracepoints are shown in the Traces tree.

To set a tracepoint, place the cursor at the point where you want the tracepoint, and click the toolbar button Insert/Remove Tracepoint (Shift+F9). The tracepoint will be marked with a dashed blue overline (see screenshot below). To remove a tracepoint, select it and click Insert/Remove Tracepoint (F9).
Note: If both a breakpoint and a tracepoint are set on a part of the expression, then the overline is composed of alternating red and blue dashes.

Also see Debug Points below.

Variables, Watch Expressions, and Call Stack

Variables and watch expressions are displayed in the Variables and Watch Expressions pane (bottom center pane in the screenshot below).
Variables
Variables that have been declared in the expression and that are in scope in the current evaluation step will be displayed together with their respective current values. For example, in the screenshot above, processing has been paused at the breakpoint on headline. The $i variable is in scope at this evaluation step. So $i is displayed with its current value, which in the screenshot above is the first newsitem node.

Watch expressions
Watch expressions are expressions that you can enter, either before evaluation starts or during a pause in evaluation. They can be used for the following purposes:

- To test specific conditions. For example in the screenshot above, the watch expression $i/metainfo/enteredBy/@id="NED" is used to test whether this news item has been entered by the team member with the id of NED. The result true in the case of the first news item tells us that this condition has been met.
- To find data within a certain context. For example, within the context of a company element, we could enter a watch expression @id to look up that company's customer code in the target XML document.
- To generate additional data. For example, a suitable string can be generated to indicate the total number of news items.

To enter a watch expression, click Add Watch Entry in the pane's toolbar (encircled in red in the screenshot above), then enter the expression and click Enter when done. To remove a watch expression, select it and click Remove Selected Watch Entry in the toolbar. If, during debugging, the expression cannot be correctly evaluated for some reason (for example, if one of its variables is out of scope), then the watch expression turns red.
**Call stack**

The **Call Stack** tab of the Call Stack and Debug Points pane (bottom right pane in the screenshot above) displays the processor calls up to that point in the debugging. The current processor call is highlighted in yellow. Note that only the calls that directly led to the current evaluation step are displayed.

**Debug Points**

The Debug Points tab of the Call Stack and Debug Points pane (bottom right pane in the screenshot below) shows the breakpoints (with solid red circles) and tracepoints (solid blue circles) that you have set on the expression. Each debug point is listed with its line and character number. For example, `AxisStep@2:12` means that there is a debug point on line 2, character 12 of the expression in the Expression pane.

Note the following features:

- For breakpoints, you can enter a **break condition** by (i) double-clicking `Enter break condition` in the Debug Points pane, (ii) entering the expression for the condition, and (iii) pressing `Enter`. That breakpoint will be enabled only when the condition evaluates to true. For example, in the screenshot above, the break condition `$i/metainfo/enteredBy/@id="ABE"` will enable the breakpoint on the headline of each news item that was entered by the team member with the id ABE. The screenshot shows the evaluation paused at this breakpoint. (Notice also that the Watch expression at this breakpoint returns `false`.)
- You can enable/disable all debug points by clicking their respective toolbar buttons: **Enable All Debug Points** and **Disable All Debug Points** (buttons encircled in green in the screenshot above). When a debug point is disabled, it is deactivated for all evaluations till it is enabled again.
- You can enable/disable individual breakpoints in their respective context menus.
_toolbar commands in panes

The panes of the Edit XPath Expression dialog in Debug Mode (see screenshot above) contain buttons that provide navigation, search, and copy functionality. These buttons, starting from the left, are described in the table below. The corresponding commands are also available in the context menu of listed items.

<table>
<thead>
<tr>
<th>Icon</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td>Next, Previous</td>
<td>Selects, respectively, the next and previous item in the result list</td>
</tr>
<tr>
<td>Copy the selected text line to the clipboard</td>
<td>Copies the value column of the selected result item to the clipboard. To copy all columns, toggle on the Copying includes all columns command (see below)</td>
</tr>
<tr>
<td>Copy all messages to the clipboard</td>
<td>Copies the value column of all result items to the clipboard, including empty values. Each item is copied as a separate line</td>
</tr>
<tr>
<td>Copying includes all columns</td>
<td>Switches between copying (i) all columns, or (ii) only the value column. The column separator is a single space</td>
</tr>
<tr>
<td>Find</td>
<td>Opens a Find dialog to search for any string, including special characters, in the result list</td>
</tr>
<tr>
<td>Find previous</td>
<td>Finds the previous occurrence of the term that was last entered in the Find dialog</td>
</tr>
<tr>
<td>Find next</td>
<td>Finds the next occurrence of the term that was last entered in the Find dialog</td>
</tr>
<tr>
<td>Clear</td>
<td>Clears the result list</td>
</tr>
<tr>
<td>Collapse multi-line results to a single line</td>
<td>If the value column of a result item contains multi-line text (text that includes newline character/s), you can toggle between a multi-line and single-line display</td>
</tr>
<tr>
<td>Show complete result</td>
<td>Shows the entire content of nodes as the value of the node</td>
</tr>
</tbody>
</table>

16.2.3 Expression Builder

When the Builder button in the Edit XPath Expression dialog is clicked (see screenshot below), entry helper panes to help you build an XPath expression become visible. Double-click an entry in any of these entry helpers to enter it at the current cursor point in the XPath expression.
There are three entry helper panes:

- A schema tree for entering element and attribute nodes in the XPath expression. If the Relative XPath check box is checked, then the location path to the selected node is entered relative to the context node (the node in the design within which the XPath expression is being built). The context node is shown below the schema tree pane. An absolute XPath expression starts at the document root, and is used for the selected node if the Relative XPath check box is unchecked.

- An entry helper pane for operators and expressions. These include: (i) axes (`ancestor::*`, `parent::*`, etc), (ii) operators (for example `eq` and `div`), and (iii) expressions (`for # in # return #`, etc). The items of the pane can be either listed alphabetically or grouped by functional category. Select the option you want by choosing Hierarchical or Flat from the dropdown menu in the title bar of the pane.

- An entry helper with the functions of the active XPath version either listed alphabetically or grouped by functional category. Select the option you want by choosing Hierarchical or Flat from the dropdown menu in the title bar of the pane. The Names/Types option enables you to choose whether the arguments of functions are displayed as names or datatypes.

Features of the Builder

- To view a text description of an item in either pane, hover over the item.
Each function is listed with its signature (that is, with its arguments, the datatypes of the arguments, and the datatype of the function's output).

Signatures are listed using either the names or datatypes of the function's arguments and output. Select Names or Types from the dropdown menu in the title bar of the pane.

Double-clicking an item in any of the panes (operator, expression, or function), inserts that item at the cursor location in the expression. Functions are inserted with their arguments indicated by placeholders (the # symbol).

If (i) text is selected in the XPath expression's edit field, and (ii) an expression or function that contains a placeholder is double-clicked to insert it, then the text that was selected is inserted instead of the placeholder.

After you have entered a function in the expression, hovering over the function name displays the function's signature and a text description of the function. If different signatures exist for a function having the same name, these are indicated with an overload factor at the bottom of the display. If you place the cursor within the parentheses of the function and press Ctrl+Shift+Spacebar, you can view the signatures of the various overloads of that function name.

**Building XPath expressions**

The Edit XPath Expression dialog helps you to build XPath expressions in the following ways.

- **Context node and schema tree**
  The Selection text box in the Sources pane immediately shows you the context node. The expression will be inserted at a location within this context node, and it will be evaluated with this node as its context.

- **Inserting a node from the schema tree**
  In the Sources pane, the entire schema is displayed. Double-click a node in the schema tree to insert it in the XPath expression. If the Relative XPath check box is checked, the selected node will be inserted with a location path expression that is relative to the context node.

- **Namespace information**
  The schema tree in the Sources pane contains a Namespace item. Expanding this item displays all the namespaces declared in the stylesheet. This information can be useful for checking the prefixes of a namespace you might want to use in an XPath expression.

- **Inserting XPath axes, operators and expressions**
  The Select Operator/Expression pane lists the XPath axes (ancestor::, parent::, etc), operators (for example, eq and div), and expressions (for # in # return #, etc) for the XPath version selected as the XSLT version for the SPS. The display can be toggled between an alphabetical listing and a hierarchical listing (which groups the items according to functionality). To insert an axis, operator, or axis in the XPath expression, double-click the required item.

- **Inserting XPath functions**
  The Select Function pane lists XPath functions alphabetically or grouped according to functionality (click the respective icon at the top of the pane to switch between the two arrangements). Each function is listed with its signature. If a function has more than one signature, that function is listed as many times as the number of signatures. Arguments in a signature are separated by commas, and each argument can have an occurrence indicator (? indicates a sequence of zero or one items of the specified type; * indicates a sequence of zero or more items of the specified type). The arguments can be displayed as names or as datatypes; select Names or Types in the title bar of the pane. Each function also specifies the return type of that function. For example: => date ? indicates that the
expected return datatype is a sequence of none or one date item. Placing the mouse over a function displays a brief description of the function. To insert a function in the XPath expression, double-click the required function.

- Java and .NET extension functions can be used in XPath expressions, enabling you to access the functions of these programming languages. The Java and .NET buttons at the bottom of the dialog, pop up info boxes with explanations about how to use Java and .NET extension functions in XPath expressions. For more information about this, see the Extension Functions section of this documentation.

Intelligent editing during direct text entry

If you type an expression directly in the Expression text box, options that are available at that point are displayed in a popup (see screenshot below).

These include elements, XPath functions, and XPath axes. Go up and down the list of options using the Up and Down keys, and press Enter if you wish to select an option and enter it in the expression.

The Otherwise check box

The Otherwise toggle (see the red arrow in the screenshot below) adds an Otherwise branch to a conditional template as its last branch. Only one Otherwise branch may be present in a conditional template. When a conditional template is evaluated, the first branch to evaluate to true is executed. If no branch evaluates to true, then, the Otherwise branch is executed if present, otherwise the conditional template is exited without any of its branches being executed. Since the Otherwise branch is triggered only in the event that no preceding branch evaluates to true, it does not need to have a condition defined for it. As a result, when the Otherwise check box is selected, the entry field of the XPath expression is disabled.
For details of how to use the Otherwise condition, see Conditional Templates.
16.3 Toolbars

A number of StyleVision commands are available as toolbar shortcuts, organized in the following toolbars:

- Formatting
- Table
- Authentic
- RichEdit
- Insert Design Elements
- Design Filter
- Global Resources
- Standard

The icons in each toolbar are listed in the sub-sections of this section, each with a brief description of the corresponding command.

Positioning the toolbars

A toolbar can float freely on the screen or can be placed in a toolbar area along any edge of the GUI. Toolbars are most commonly placed along the top edge of the GUI, just below the Menu bar. However, they can also be placed along the side or bottom edges of the GUI.

To position a toolbar in a toolbar area, do the following:

1. Grab the toolbar by its handle (if the toolbar is already in a toolbar area) or by its title bar (if the toolbar is floating).
2. Drag the toolbar to the desired toolbar area, if it exists, and drop it at the desired location in that toolbar area. If no toolbar area exists at the edge along which you wish to place the toolbar, dragging the toolbar to that edge will automatically create a toolbar area there when the toolbar is dropped.

To make a toolbar float freely grab it by its handle, drag it away from the toolbar area, and drop it anywhere on the screen except at an edge or in an existing toolbar area.

Switching the display of toolbars on and off

The display of individual toolbars can be switched on and off using any of the following three methods:

- In the View | Toolbars menu (screenshot below), select or deselect a toolbar to, respectively, show or hide that toolbar.
Right-click any toolbar area to display a context menu (screenshot below) that allows you to toggle the display of individual toolbars on and off.

In the Toolbars tab of the Customize dialog (Tools | Customize), toggle the display of individual toolbars on or off by clicking a toolbar's check-box. When done, click the Close button to close the dialog.

Adding and removing toolbar buttons

Individual toolbar buttons can be added to or removed from a toolbar, that is, they can be made visible or be hidden. To add or remove a button from a toolbar, do the following:

1. In the toolbar where the button to be added or removed is, click the More Buttons button (if the toolbar is in a toolbar area) or the Toolbar Options button (if the toolbar is a floating toolbar). The More Buttons button is an arrowhead located at the right-hand side of the toolbar (in horizontal toolbar areas) or at the bottom of the toolbar (in vertical toolbar areas). The Toolbar Options button is an arrowhead located at the right-hand side of the floating toolbar.
2. In the Add or Remove Buttons menu that pops up, place the cursor over the Add or Remove Buttons menu item (screenshot below). This rolls out a menu which contains the names of the toolbars in that toolbar area plus the Customize menu item (screenshot below).
3. Place the cursor over the toolbar that contains the toolbar button to be added or removed (screenshot above).
4. In the menu that rolls out (screenshot above), click on the name of the toolbar button to add or remove that button from the toolbar.
5. Clicking the Customize item pops up the Customize dialog.

The Reset Toolbar item below the list of buttons in each toolbar menu resets the toolbar to the state it was in when you downloaded StyleVision. In this state, all buttons for that toolbar are displayed.

**Note:** The buttons that a toolbar contains are preset and cannot be disassociated from that toolbar. The process described above displays or hides the button in the toolbar that is displayed in the GUI.

### 16.3.1 Format

The **Format toolbar** (screenshot below) is enabled in Design View and contains commands that assign commonly used inline and block formatting properties to the item/s selected in the SPS design.

![Format Toolbar](image)

**Predefined HTML formats**
The HTML format selected from the dropdown list is applied to the selection in Design View. For example, a selection of `div` applies HTML’s Block (`div`) element around the current selection in Design View. The HTML format is converted to the corresponding RTF properties for the RTF output.

**Text properties**
The bold, italic, underline, and strikethrough inline text properties can be directly applied to the current selection in Design View by clicking on the appropriate button. Font style, font size, foreground and background color can also be applied via toolbar buttons.

**Alignment**
Alignment properties (left-aligned, centered, right-aligned, and justified) can be directly applied to the selection in Design View.

**Lists**
Lists can be inserted at the cursor insertion point, or the selection in the SPS can be converted to a list.

**Hyperlinks**
Inserts a hyperlink at the cursor insertion point. See Hyperlink for a description of how to use this command.
16.3.2 Table

The Table toolbar contains commands to structure and format static and dynamic tables in Design View. These commands are shown in the screenshot below (which is that of the Table toolbar customization menu, available when you click the **Customize** button at the right of the toolbar).

---

**Row and Column operations**

Rows and columns in any SPS table (static or dynamic) can be inserted, appended, or deleted with reference to the cursor location. Rows and columns are inserted before the current cursor location or appended after all rows/columns. The row/column in which the cursor is can also be deleted. These operations are achieved with the **Insert Row/Column**, **Append Row/Column**, or **Delete Row/Column** buttons. You can also add table headers and footers as either columns or rows **Add Table Header/Footer Column/Row**.
Cell operations
An SPS table cell in which the cursor is located can be joined to any one of the four cells around it. The joining
operation is similar to that of spanning table cells in HTML. The buttons to be used for these operations are
Join Cell Right/Left/Above/Below. Also, an SPS table cell in which the cursor is located can be split, either
horizontally or vertically, using the Split Cell Horizontally and Split Cell Vertically buttons, respectively.
SPS table cell content can be aligned vertically at the top, in the middle, and at the bottom. The display of cell
borders can be switched on and off with the View Cell Bounds toggle.

Table operations, properties, display
Placing the cursor in a static or dynamic table and clicking Delete Table deletes that table. Table markup
can be toggled on and off with the View Table Markup command. The Table Properties command pops up the
Table Properties dialog, in which properties of the table can be defined.

16.3.3 Authentic

The Authentic toolbar contains commands for customizing Authentic View and editing XML documents in
Authentic View. These commands are shown in the screenshot below (the customization menu for adding and
removing Authentic toolbar buttons, available when you click the Customize button at the right of the
toolbar).

All these features are available to the Authentic View user. They enable you, as the SPS designer, to test the
SPS using features at the Authentic View users's disposal.
Validating, saving, and reloading XML documents

While editing an XML document in Authentic View, you can check the validity of the Working XML File by using the Validate XML button. Editing changes can be saved to the Working XML File with the Save Authentic XML Data button. The XML document can also be reloaded at any time from the last saved version.

Select new row with XML data for editing

This command is enabled only in SPSs that are based on an XML DB. The command enables a new row from the XML column to be loaded into Authentic View for editing. See the description of the command for details.

Markup tags in Authentic View

In Authentic View, the display of markup tags can be customized. Markup tags can be hidden (Hide Markup), can be shown with node names (Show Large Markup), without node names (Show Small Markup), or with any of these three options for individual nodes (Show Mixed Markup).

Editing of dynamic tables in Authentic View

In Authentic View, row operations can be performed on dynamic tables. Rows can be inserted, appended, and duplicated, as well as be moved up and down, using the appropriate toolbar buttons (Insert Row, Append Row, Duplicate Row, Move Row Up, Move Row Down, and Delete Row).

Defining XML Entities

Entities can be defined at any time while editing the Working XML File in Authentic View. Clicking the Define XML Entities button pops up the Define XML Entities dialog. (See Authentic | Define Entities for details of usage.)
16.3.4 RichEdit

The RichEdit toolbar contains commands for marking up text in Authentic View with text-styling properties.

In Authentic View, when the cursor is placed inside an element that has been created as a RichEdit component, the buttons and controls in the RichEdit toolbar (screenshot below) become enabled. Otherwise they are grayed out.

![RichEdit toolbar screenshot](image)

RichEdit enables the Authentic View user to specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of text. Select the text you wish to style in Authentic View and specify the styling you wish to apply via the buttons and controls of the RichEdit toolbar. The text that has been styled will be enclosed in the tags of the styling element.

16.3.5 Insert Design Elements

The Insert Design Elements toolbar contains icons for commands to insert design elements in the SPS design, and for related commands. The various design elements that can be inserted via these toolbar icons are shown in the screenshot below. There are three types of items in the toolbar:

1. Design elements, which are context-node-sensitive (the majority of elements in the toolbar),
2. Layout elements, which are independent of node context, and
3. Grid-related toggles to aid design.
Design elements

The design elements are the context-node-sensitive elements that are available in the **Insert** menu. To insert a design element using its toolbar icon, do the following:

1. Select the toolbar icon for the element you wish to insert.
2. Click the location in the design where the element is to be inserted. A *Insert Design Element for the selected design element (screenshot below)* pops up. This displays the schema tree with the context node highlighted. The context node is the node within which the cursor has been placed for the insertion of the design element.
3. If you wish to insert the design element within the currently selected context node, click OK. If you wish to select another context node, do so in the schema tree and then click OK.

4. In the case of some design elements, such as Auto-Calculations, a further step is required, such as the definition of an Auto-Calculation. In other cases, such as the insertion of a user-defined template, the Insert Design Element dialog is skipped. In such cases, another dialog, such as the Edit XPath Expression dialog will pop up. Carry out the required step and press the dialog's OK button.

The design element will be inserted at the end of Step 3 or Step 4, depending on the kind of design element being inserted.

**Layout elements**

There are three layout element commands in the Insert Design Elements toolbar: to insert (i) a layout container; (ii) a layout box; and (iii) a line. Note that layout boxes and lines can only be inserted within a layout container.

To insert a layout container, select the Insert Layout Container icon and then click at the location in the design where you wish to insert the layout container. You will be prompted about the size of the layout container, on selecting which the layout container will be inserted. To insert a layout box, click the Insert Layout Box icon, then move the cursor to the location within the layout container at which you wish to insert the layout box and click. The layout box is inserted. Click inside the layout box to start typing. To insert a line, click the Insert Line icon, then move the cursor to the location within the layout container at which you wish to start drawing the line. Click to define the start point of the line and then drag the cursor to the desired endpoint.
Release the cursor at the end point. The line is inserted and extends from the indicated start point to the indicated end point.

To re-size layout containers and layout boxes, place the cursor over the right or bottom border of the layout container or layout box and drag the border so as to obtain the desired size. To move a layout box, place the cursor over the top or left border of the layout box and, when the cursor turns to a cross, drag the layout box to the new location.

**Grid-related toggles**

The **Show Grid** command toggles the display of the drawing grid on and off. When the **Snap to Grid** command is toggled on, elements created within the layout container, such as layout boxes and lines, snap to grid lines and grid line intersections. The properties of the grid can be set in the Design tab of the Options dialog (Tools | Options).

### 16.3.6 Design Filter

The **Design Filter toolbar** (screenshot below) contains commands that enable you to filter which templates are displayed in the design. Each icon in the toolbar is explained below.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Icon]</td>
<td><strong>Show only one template</strong></td>
<td>Shows the selected template only. Place the cursor in a template and click to show that template only.</td>
</tr>
<tr>
<td>![Icon]</td>
<td><strong>Show all template types</strong></td>
<td>Shows all templates in the SPS (main, global, named, and layout).</td>
</tr>
<tr>
<td>![Icon]</td>
<td><strong>Show imported templates</strong></td>
<td>Toggles the display of imported templates on and off.</td>
</tr>
<tr>
<td>![Icon]</td>
<td><strong>Show/Hide main template</strong></td>
<td>Toggles the display of the main template on and off.</td>
</tr>
<tr>
<td>![Icon]</td>
<td><strong>Show/Hide global templates</strong></td>
<td>Toggles the display of global templates on and off.</td>
</tr>
<tr>
<td>![Icon]</td>
<td><strong>Show/Hide Design Fragments</strong></td>
<td>Toggles the display of Design Fragments on and off.</td>
</tr>
</tbody>
</table>

The Design Filter combo box (screenshot below) displays a list of all the templates in the SPS.
Selecting a template in the combo box causes the template to be selected in the design. The combo box, therefore, enables you to quickly navigate to the desired template in the design, which is useful if the design has several templates, some of which might be currently hidden.

### 16.3.7 Global Resources

The **Global Resources toolbar** *(screenshot below)* enables you: (i) to select the active configuration for the application, and (ii) to access the Altova Global Resources dialog.

Select the active configuration from among the options in the dropdown list of the combo box. Click the Manage Global Resources icon to access the Altova Global Resources dialog.

### 16.3.8 Standard

The **Standard toolbar** contains buttons for commands that provide important file-related and editing functionality. These icons are listed below with a brief description. For a fuller description of a command, click the command to go to its description in the Reference section.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Command</th>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Icon" /></td>
<td><strong>New from XML Schema / DTD</strong></td>
<td>Ctrl+N</td>
<td>Creates a new SPS document based on a schema. Clicking the dropdown arrow enables you to create the SPS from a DB or an HTML document, or an empty SPS.</td>
</tr>
<tr>
<td><img src="image2.png" alt="Icon" /></td>
<td><strong>Open</strong></td>
<td>Ctrl+O</td>
<td>Opens an existing SPS document.</td>
</tr>
<tr>
<td><img src="image3.png" alt="Icon" /></td>
<td><strong>Reload</strong></td>
<td></td>
<td>Reloads the SPS from the last saved version.</td>
</tr>
<tr>
<td><img src="image4.png" alt="Icon" /></td>
<td><strong>Save Design</strong></td>
<td>Ctrl+S</td>
<td>Saves the active SPS document.</td>
</tr>
<tr>
<td><img src="image5.png" alt="Icon" /></td>
<td><strong>Save All</strong></td>
<td>Ctrl+Shift+S</td>
<td>Saves all open SPS documents.</td>
</tr>
<tr>
<td><img src="image6.png" alt="Icon" /></td>
<td><strong>Print</strong></td>
<td>Ctrl+P</td>
<td>Prints the Authentic View of the Working XML file.</td>
</tr>
<tr>
<td><img src="image7.png" alt="Icon" /></td>
<td><strong>Print Preview</strong></td>
<td></td>
<td>Displays a print preview of the Authentic View of the Working XML File.</td>
</tr>
<tr>
<td>Icon</td>
<td>Command</td>
<td>Shortcut</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td><img src="image" alt="Cut" /></td>
<td>Cut</td>
<td>Shift+Del</td>
<td>Cuts the selection and places it in the clipboard.</td>
</tr>
<tr>
<td><img src="image" alt="Copy" /></td>
<td>Copy</td>
<td>Ctrl+C</td>
<td>Copies the selection to the clipboard.</td>
</tr>
<tr>
<td><img src="image" alt="Paste" /></td>
<td>Paste</td>
<td>Ctrl+P</td>
<td>Pastes the clipboard item to the cursor location.</td>
</tr>
<tr>
<td><img src="image" alt="Delete" /></td>
<td>Delete</td>
<td>Del</td>
<td>Deletes the selection.</td>
</tr>
<tr>
<td><img src="image" alt="Undo" /></td>
<td>Undo</td>
<td>Alt+Backspace</td>
<td>Undoes an editing change. An unlimited number of Undo actions can be performed at a time.</td>
</tr>
<tr>
<td><img src="image" alt="Redo" /></td>
<td>Redo</td>
<td>Ctrl+Y</td>
<td>Redoes an undo.</td>
</tr>
<tr>
<td><img src="image" alt="Find" /></td>
<td>Find</td>
<td>Ctrl+F</td>
<td>Finds text in Authentic View and Output Views.</td>
</tr>
<tr>
<td><img src="image" alt="Find Next" /></td>
<td>Find Next</td>
<td>F3</td>
<td>Finds the next occurrence of the searched text.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom" /></td>
<td>Zoom</td>
<td></td>
<td>Sets the Zoom Factor of Design View.</td>
</tr>
<tr>
<td><img src="image" alt="Show Small Design Markup" /></td>
<td>Show Small Design Markup</td>
<td></td>
<td>Switches markup tags to small markup format.</td>
</tr>
<tr>
<td><img src="image" alt="Show Large Design Markup" /></td>
<td>Show Large Design Markup</td>
<td></td>
<td>Switches markup tags to large markup format.</td>
</tr>
<tr>
<td><img src="image" alt="XSLT 1.0" /></td>
<td>XSLT 1.0</td>
<td></td>
<td>Sets XSLT 1.0 as the stylesheet language.</td>
</tr>
<tr>
<td><img src="image" alt="XSLT 2.0" /></td>
<td>XSLT 2.0</td>
<td></td>
<td>Sets XSLT 2.0 as the stylesheet language.</td>
</tr>
<tr>
<td><img src="image" alt="XSLT 3.0" /></td>
<td>XSLT 3.0</td>
<td></td>
<td>Sets XSLT 3.0 as the stylesheet language.</td>
</tr>
<tr>
<td><img src="image" alt="Spelling" /></td>
<td>Spelling</td>
<td></td>
<td>Runs a spelling check on the SPS document.</td>
</tr>
<tr>
<td><img src="image" alt="Toggle DB Query" /></td>
<td>Toggle DB Query</td>
<td></td>
<td>Shows/hides the Database Query dialog.</td>
</tr>
</tbody>
</table>
16.4 File Menu

The File menu contains commands for working with SPSs and related files. The following commands are available:

- **New**, to create a new SPS from a variety of sources.
- **Open, Reload, Close, Close All**, to open and close the active file, and to reload the active file.
- **Save Design, Design As, All**, which are commands to save the active SPS and all open SPS files.
- **Export as MobileTogether Design File**, to generate a MobileTogether design from the active SPS file.
- **Save Authentic XML Data, Save As**, enabled in Authentic View, it saves changes to the Working XML File.
- **Save Generated Files**, to save output files that can be generated using the SPS.
- **Web Design**, generates all the files required to run an ASPX application, in the folder location you specify.
- **Properties**, to set the encoding of the output documents, the CSS compatibility mode of the browser, how relative image paths in Authentic View should be resolved, and whether images should be embedded or linked in the RTF (Enterprise and Professional editions) and Word 2007+ (Enterprise edition only) outputs.
- **Print Preview, Print**, enabled in Authentic View and output views, these commands print what is displayed in the previews.
- **Most Recently Used Files, Exit**, respectively, to select a recently used file to open, and to exit the program.

16.4.1 New

Placing the cursor over the New command pops out a submenu (screenshot below) that enables you to create a new SPS document of one of different types:

- A new SPS file based on an XML Schema or DTD or XML Schema generated from an XML file (New from XML Schema / DTD / XML). The selected schema is added to the Design Overview sidebar and a graphical tree representation is added to the schema tree (in the Schema Tree sidebar). In Design View, the SPS is created with an empty main template. A new SPS can also be created from a file (schema or XML) via a URL or global resource (see below).
- A new SPS file based on an XML Schema generated from a DB you select (New from DB or New from XML Column in IBM DB2). The connection process is described in the section Connecting to a DB and Setting up the SPS. The SPS is created in Design View with an empty main template.
A new SPS based on a user-defined schema you create node-by-node from an HTML file (New from HTML File). The user-defined schema is added to the Design Overview sidebar and Schema Tree sidebar. In the schema tree, it will have a single document element (root element), and the HTML file is loaded in Design View.

An SPS can be created from an XSLT-for-HTML or an XSLT-for-FO or an FO file. Template structure and styling in the XSLT will be created in the SPS. You can then modify the SPS components and add content and formatting to the SPS. See New from XSLT for details.

A new SPS that contains the content of a MS Word document as the design's static text.

A new SPS that contains the content of a MS Excel document as the design's static text.

A new empty SPS (New (empty)). No schema is added to either the Design Overview sidebar or the schema tree. An empty main template will be created in Design View.

Note: A global resource can be used to locate a file or DB resource.

Selecting the type of design

After you have selected (XSD and XML) sources files, if required, the Create New Design dialog appears.

The Create New Design dialog (screenshot below) prompts you to select either: (i) a free-flowing document design, or (ii) a form-based document design (in which components are positioned absolutely, as in a layout program).

Create New Design

StyleVision supports two types of document design: free-flow and form-based. Please read the explanations below and choose one. Note that you can mix both design types on different pages of a single document, or even on the same page. Almost all design items such as text, tables, images, edit fields, etc., can be used in both designs.

Create a free-flow document

A free-flow design is what you need when designing books, newspapers, documentation, reports. Text, images, tables, etc. can all be mixed on a page and are automatically positioned according to their size. Pages are automatically generated, text can be wrapped to fit to the page, and the table auto-width setting can be used to fit the table to the page size.

Create a form-based document (absolute positioning)

A form-based design is perfect for creating input forms containing edit controls, labels, images or tables arbitrarily placed on a page using absolute coordinates. Every page is usually designed independently.

If you already have an existing form on paper, you can scan it and supply it as a blueprint image file for your design. This will allow you to position design items on the blueprint, thus enabling you to match the original form locations.

In a free-flowing document design, document content is laid out to fit the output media object or viewer (paper or screen). Items in the document content can only be placed relative to each other, and not absolutely. This kind of design is suited for documents such as reports, articles, and books.

In a form-based document, a single Layout Container is created, in which design components can be
positioned absolutely. The dimensions of the Layout Container are user-defined, and Layout Boxes can be positioned absolutely within the Layout Container and document content can be placed within individual Layout Boxes. If you wish the design of your SPS to replicate a specific form-based design, you can use an image of the original form as a blueprint image \[\text{image}\]. The blueprint image can then be included as the background image of the Layout Container. The blueprint image is used to help you design your form; it will not be included in the output.

Selecting files via URLs and Global Resources
In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Select the \textbf{Switch to URL} or \textbf{Switch to Global Resource} to go to one of these selection processes.

Selecting files via URLs
To select a file via a URL, do the following:

1. Click the \textbf{Switch to URL} command. This switches to the URL mode of the Open dialog (screenshot below).
2. Enter the URL you want to access, in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.

3. If the server is password protected, enter your User-ID and password in the User and Password fields.

4. Click Browse to view and navigate the directory structure of the server.

5. In the folder tree, browse for the file you want to load and click it.
6. Click the **Open** button to load the file. The file you open appears in the main window.

**Note:** The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.

**Note:** To give you more control over the loading process, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

**Microsoft® SharePoint® Server Notes**

Note the following points about files on Microsoft® SharePoint® Servers:

- In the directory structure that appears in the Available Files pane (**screenshot below**), file icons have symbols that indicate the check-in/check-out status of files.
Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

- The various file icons are shown below:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Checked out by another user. Not available for check-out." /></td>
<td>Checked out by another user. Not available for check-out.</td>
</tr>
<tr>
<td><img src="image" alt="Checked out locally. Can be edited and checked-in." /></td>
<td>Checked out locally. Can be edited and checked-in.</td>
</tr>
</tbody>
</table>

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot above), or via the context menu that pops up when you click the file tab in the Main Window of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out command in the context menu. This has the effect of returning the file unchanged to the server.
- If you check out a file in one Altova application, you cannot check it out in another Altova application.
The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: **Check In** and **Undo Check Out**.

**Opening and saving files via Global Resources**

To open or save a file via a global resources, click **Switch to Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, Using Global Resources. For a general description of Global Resources, see the Global Resources section in this documentation.

### 16.4.2 Open, Reload, Close, Close All

The **Open** (Ctrl+O) command allows you to open an existing SPS or PXF file. The familiar Open dialog of Windows systems is opened and allows you to select a file with an extension of .sps.

The **Reload** command reloads the SPS file from the file saved to disk. Any changes made since the file was last saved will be lost. The Working XML file will also be reloaded, enabling you to update the Working XML File if it has been changed externally.

The **Close** command closes the currently active SPS document. Note that while several files can be open, only one is active. The active document can also be closed by clicking the Close button at the top right of the Main Window. If you have unsaved changes in the document, you will be prompted to save these changes.

The **Close All** command closes all the open SPS documents. If you have unsaved changes in an open document, you will be prompted to save these changes.

**Selecting and saving files via URLs and Global Resources**

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource *(see screenshot below)*. Click **Switch to URL** or **Global Resource** to go to one of these selection processes.
Selecting files via URLs
To select a file via a URL (either for opening or saving), do the following:

1. Click the **Switch to URL** command. This switches to the URL mode of the Open or Save dialog *(the screenshot below shows the Open dialog)*.
2. Enter the URL you want to access in the Server URL field (screenshot above). If the server is a Microsoft® SharePoint® Server, check the Microsoft® SharePoint® Server check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.

3. If the server is password protected, enter your User-ID and password in the User and Password fields.

4. Click Browse to view and navigate the directory structure of the server.

5. In the folder tree, browse for the file you want to load and click it.
The file URL appears in the File URL field (see screenshot above). The **Open** or **Save** button only becomes active at this point.

6. Click **Open** to load the file or **Save** to save it.

**Note the following:**

- The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.
- To give you more control over the loading process when opening a file, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

**Microsoft® SharePoint® Server Notes**

Note the following points about files on Microsoft® SharePoint® Servers:

- In the directory structure that appears in the Available Files pane (screenshot below), file icons have symbols that indicate the check-in/check-out status of files.
Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

- The various file icons are shown below:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Checked in" /></td>
<td>Checked in. Available for check-out.</td>
</tr>
<tr>
<td><img src="image" alt="Checked out by another user" /></td>
<td>Checked out by another user. Not available for check-out.</td>
</tr>
<tr>
<td><img src="image" alt="Checked out locally" /></td>
<td>Checked out locally. Can be edited and checked-in.</td>
</tr>
</tbody>
</table>

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot above), or via the context menu that pops up when you right-click the file tab in the Main Window of your application (screenshot below).

- When a file is checked out by another user, it is not available for check-out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out
command in the context menu. This has the effect of returning the file unchanged to the server.

- If you check out a file in one Altova application, you cannot check it out in another Altova application. The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: **Check In** and **Undo Check Out**.

\section*{Opening and saving files via Global Resources}

To open or save a file via a global resource, click **Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, **Using Global Resources**. For a general description of Global Resources, see the **Global Resources** section in this documentation.

\subsection*{16.4.3 Save Design, Save All}

The **Save Design (Ctrl+S)** command saves the currently open document as an SPS file (with the file extension .sps).

The **Save All (Ctrl+Shift+S)** command saves all the open SPS documents.

\section*{Selecting and saving files via URLs and Global Resources}

In several File Open and File Save dialogs, you can choose to select the required file or save a file via a URL or a global resource (see screenshot below). Click **Switch to URL** or **Global Resource** to go to one of these selection processes.
Selecting files via URLs

To select a file via a URL (either for opening or saving), do the following:

1. Click the **Switch to URL** command. This switches to the URL mode of the Open or Save dialog *(the screenshot below shows the Open dialog)*.
2. Enter the URL you want to access in the **Server URL** field (*screenshot above*). If the server is a Microsoft® SharePoint® Server, check the **Microsoft® SharePoint® Server** check box. See the Microsoft® SharePoint® Server Notes below for further information about working with files on this type of server.

3. If the server is password protected, enter your **User-ID** and password in the **User** and **Password** fields.

4. Click **Browse** to view and navigate the directory structure of the server.

5. In the folder tree, browse for the file you want to load and click it.
The file URL appears in the File URL field (see screenshot above). The **Open** or **Save** button only becomes active at this point.

6. Click **Open** to load the file or **Save** to save it.

**Note the following:**

- The Browse function is only available on servers which support WebDAV and on Microsoft SharePoint Servers. The supported protocols are FTP, HTTP, and HTTPS.
- To give you more control over the loading process when opening a file, you can choose to load the file through the local cache or a proxy server (which considerably speeds up the process if the file has been loaded before). Alternatively, you may want to reload the file if you are working, say, with an electronic publishing or database system; select the **Reload** option in this case.

**Microsoft® SharePoint® Server Notes**

Note the following points about files on Microsoft® SharePoint® Servers:

- In the directory structure that appears in the Available Files pane (screenshot below), file icons have symbols that indicate the check-in/check-out status of files.
Right-clicking a file pops up a context menu containing commands available for that file (screenshot above).

- The various file icons are shown below:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Icon](Checked in)</td>
<td>Checked in. Available for check-out.</td>
</tr>
<tr>
<td>![Icon](Checked out by another user)</td>
<td>Checked out by another user. Not available for check-out.</td>
</tr>
<tr>
<td>![Icon](Checked out locally)</td>
<td>Checked out locally. Can be edited and checked-in.</td>
</tr>
</tbody>
</table>

- After you check out a file, you can edit it in your Altova application and save it using File | Save (Ctrl+S).
- You can check-in the edited file via the context menu in the Open URL dialog (see screenshot above), or via the context menu that pops up when you right-click the file tab in the Main Window of your application (screenshot below).

- When a file is checked out by another user, it is not available for check out.
- When a file is checked out locally by you, you can undo the check-out with the Undo Check-Out
command in the context menu. This has the effect of returning the file unchanged to the server.

- If you check out a file in one Altova application, you cannot check it out in another Altova application. The file is considered to be already checked out to you. The available commands at this point in any Altova application supporting Microsoft® SharePoint® Server will be: Check In and Undo Check Out.

## Opening and saving files via Global Resources

To open or save a file via a global resource, click **Global Resource**. This pops up a dialog in which you can select the global resource. These dialogs are described in the section, [Using Global Resources](#). For a general description of Global Resources, see the [Global Resources](#) section in this documentation.

### 16.4.4 Save As

The **Save As** command enables the design to be saved: (i) as an SPS file or (ii) as a PXF file (Portable XML Form file). Clicking the command pops up the Save Design dialog *(screenshot below)*. Select the required format and click **OK**.

![Save Design dialog](image)

The **SPS format** is the standard Altova format for StyleVision designs. The **PXF format** is an Altova format that allows all files related to the design (schema files, XML files, images files, generated XSLT stylesheets, etc) to be embedded with the design. This format is very useful for transporting all the files required to open the design in Authentic View and/or to generate HTML, Text, and/or RTF output based on the design.

#### Save as SPS

Selecting the SPS option causes the familiar Save As dialog of Windows systems to pop up. Saving works exactly as described for the **Save Design** command. The advantage of using the **Save As** command is that files that have already been saved with a filename can be saved with another filename.
Save as PXF

Selecting the PXF option causes the familiar Save As dialog of Windows systems to pop up. Saving works exactly as described for the Save Design command—with the additional step of selecting the files you wish to include in the PXF file. After you specify the PXF filename, the Configure PXF dialog (screenshot below) will appear, in which you can select/deselect the files you wish to embed.

In the Global Configuration pane of the Design-time Files tab, you can select/deselect the design-related source files to be embedded/omitted. You can additionally choose to embed XSLT files generated from the design. In the XSLT files pane, select the output formats for which you wish to generate and embed XSLT files. If an XSLT file is included in the PXF file and the PXF file is opened in the Authentic View of an Altova product, then the toolbar button to generate and view that output format is enabled in Authentic View (screenshot below).
Note: If XSLT files for outputs supported only in a higher edition of StyleVision (high to low: Enterprise, Professional, Basic) were created in a PXF file and if that PXF file is then opened in a lower edition, then on saving the PXF file the XSLT files for outputs not supported in the lower edition will not be saved. A prompt appears, asking whether you wish to continue saving the PXF file. You can then save without the unsupported formats, or abort the save and retain the unsupported formats.

In the Additional Files tab (screenshot below), you can specify any additional files you wish to include that are not design-time files. These could be, for example, image files referenced in the design by a URL generated with an XPath expression. In the screenshot below, the image file NewsItems.bmp located in the Images folder is selected for inclusion in the PXF file.

To include an additional file in the PXF file, click the Add Document button and then browse for the file you want. The Open dialog (in which you browse for the required file) opens the folder in which the SPS is located.
Files from this folder or any descendant folder may be selected. After an additional file has been added to the PXF file, it and the folder structure leading to it are displayed. The screenshot above indicates that the additional file NewsItems.bmp is in a folder named Images, which is itself contained in the folder in which the SPS file is located.

If a file is selected from a folder located in any level above the folder containing the SPS file, an error is reported.

In the SPS design, any reference to an additional file must be made with a relative path and must use the folder structure shown in the Additional Files pane. For example, NewsItems.bmp in the screenshot above must be referenced with the relative path: Images/NewsItems.bmp.

**Note:** In order to save PXF files, the option *Embed Images for RTF and Word 2007+* (File | Properties | Images) must be selected.

### 16.4.5 Export as MobileTogether Design File

This command generates an Altova MobileTogether design file from the active SPS design. A MobileTogether design file is used to execute solutions in the MobileTogether app for mobile devices. For example, a MobileTogether solution can be opened in a mobile device, such as a smartphone, to view and edit the contents of a database. A MobileTogether solution is designed in Altova MobileTogether Designer. This command enables you to convert an SPS design into a MobileTogether design that can be edited in MobileTogether Designer. For more information, see the [MobileTogether web page](#) and MobileTogether Designer documentation. Conversions options are available in the MobileTogether Design tab of the Options dialog  ([Tools | Options](#)).

**Note:** Not all SPS design features have correspondences in MobileTogether designs. After running this command, you should therefore open the generated file in MobileTogether Designer to review it and, if necessary, correct it. The following design features are known not to be exported to MobileTogether designs: (i) Sources beyond the first one listed in the StyleVision design(an Enterprise feature); (ii) global templates; (ii) modules.

### 16.4.6 Save Authentic XML Data, Save As

In Authentic View, you can edit the Working XML File or DB related to the SPS. The **Save Authentic XML Data** command saves these modifications to the Working XML File or DB. Alternatively to editing the XML file in StyleVision, you can edit an XML document or DB in the Authentic View of Altova XMLSpy or Altova Authentic Desktop.

The **Save Authentic XML Data As** command enables you to save the Authentic XML document as another file.
16.4.7 Save Generated Files

The **Save Generated Files** command pops up a submenu which contains options for saving the following files (*screenshot below*). For perspective on how the generated files fit into the general usage procedure, see Usage Procedure | Generated Files.

Save Generated XSLT-HTML File
The Save Generated XSLT-HTML File command generates an XSLT file for HTML output from your SPS. You can use this XSLT file subsequently to transform an XML document to HTML.

Save Generated HTML File(s)
The Save Generated HTML File(s) command generates an HTML file or files. Multiple HTML files will be generated if multiple document output has been specified in the design. This operation requires two input files:

- The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, the **Save Generated HTML File** command is disabled. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see The DB Schema and DB XML files); you do not assign a Working XML File.
- An XSLT file, which is automatically generated from the currently active SPS file.

Save Generated XSLT-RTF File
The Save Generated XSLT-RTF File command generates an XSLT file for RTF output from your SPS. You can use this XSLT file subsequently to transform an XML document to RTF.

Save Generated RTF File(s)
The Save Generated RTF File(s) command generates an RTF file. Multiple RTF files will be generated if multiple document output has been specified in the design. This operation requires two input files:
• The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, the command is disabled. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see The DB Schema and DB XML files); you do not assign a Working XML File.

• An XSLT-for-RTF file, which is automatically generated from the currently active SPS file.

Save Generated XSLT-Text File

The Save Generated XSLT-Text File command generates an XSLT file for Text output from your SPS. You can use this XSLT file subsequently to transform an XML document to a text document.

Save Generated Text File(s)

The Save Generated Text File(s) command generates a text file. Multiple text files will be generated if multiple document output has been specified in the design. This operation requires two input files:

• The Working XML File assigned to the currently active SPS file. If no Working XML File has been assigned, the command is disabled. For DB-based SPSs, the automatically generated non-editable XML file is the Working XML File (see The DB Schema and DB XML files); you do not assign a Working XML File.

• An XSLT-for-Text file, which is automatically generated from the currently active SPS file when this command is executed.

Save Generated DB Schema

When you connect to a DB in order to create a DB-based SPS, StyleVision generates and loads a temporary XML Schema based on the DB structure. The Save Generated DB Schema command enables you to save this generated XML Schema. Note that for XML DBs, StyleVision does not generate a schema file; it uses a schema file from the DB or some other external file location. Consequently, this command is not enabled for XML DBs.

Save Generated DB XML Data

The Save Generated DB XML Data command generates and saves an XML file that contains data from the DB in an XML structure conformant with the structure of the XML Schema generated from the DB. If DB Filters have been defined in the StyleVision Power Stylesheet, these are applied to the data import. Note that for XML DBs, StyleVision does not generate an XML file, but uses XML data in the XML columns of the XML DB. Consequently, this command is not enabled for XML DBs.

Save Generated User-Defined Schema

This command is activated when the SPS involves a user-defined schema. The schema you create in the Schema Tree sidebar is saved as an XML Schema with the .xsd extension.

Save Generated User-Defined XML Data

The data in the imported HTML file that corresponds to the user-defined schema is saved as an XML file. The corresponding data are the nodes in the HTML document (in Design View) that have been created as XML Schema nodes.
16.4.8 Deploy to FlowForce

The **Deploy to FlowForce** command enables you to deploy a `.transformation` file to your Altova FlowForce Server. The `.transformation` file contains all the files and information required to carry out transformations as designed in the SPS. After the `.transformation` file has been deployed to the FlowForce Server, you can create jobs in Altova FlowForce that use the `.transformation` file to generate transformations according to triggers specified in the job definition. For information about creating FlowForce jobs, see the FlowForce documentation.

A `.transformation` file is generated from a Portable XML Format (PXF) file. So, the **Deploy to FlowForce** command can be used when a PXF file is active. (If an SPS file is active, the **Deploy to FlowForce** command will be active, but clicking it will prompt you to save the SPS file as a PXF file. To create a PXF file from an SPS file, use the **File | Save As** command and select PXF as the format to save as.)

Note the following points:

- When a PXF file is saved, an option is provided for including external files (such as image files) in it. If an external file is not included in the PXF file but is required for the transformation, then the external file must be saved on the FlowForce Server. Since the external files will be accessed from the working directory (specified in the FlowForce job definition), they should be placed relative to the working directory, in such a way that links originating in the working directory will correctly access them.
- When a FlowForce job requiring a StyleVision transformation is executed, the job is passed to StyleVision Server, and StyleVision Server will extract the contents of the PXF file to the working directory that was specified in the job's parameters. To ensure that there is no filename collision when this extraction occurs, there should be no file in the working directory that has the same name as a file contained in the PXF file.

Before running the **Deploy to FlowForce** command, make sure that Altova FlowForce Server and Altova StyleVision Server are correctly licensed and running. See the Altova FlowForce documentation for more information about setting up FlowForce Server. (StyleVision Server is packaged with FlowForce Server.)

**The Deploy command**

The **Deploy to FlowForce** command pops up the Deploy Transformation dialog (*screenshot below*).
In this dialog, you specify the following:

- The address and port number of the FlowForce Web Server (not the FlowForce Server), together with access details (user and password) for the FlowForce Server.
- The filename of the transformation file and the location on the FlowForce Server where it is to be saved. The filepath must start with a slash, which represents the root directory of the FlowForce Server.
- If changes have been made to the design since the file was last saved, the Save design changes before deploying check box will be enabled. Check the box if you wish to save these changes; otherwise uncheck the box.
- To deploy the mapping through a SSL-encrypted connection, select the Use SSL check box. This assumes that FlowForce Server is already configured to accept SSL connections. For more information, refer to FlowForce Server documentation.

On clicking OK, the .transformation file is deployed to the FlowForce Server at the location specified. If you have checked the Open web browser to create new job check box (see screenshot above), the FlowForce Web Server interface is opened in a web browser, and the job created during the deployment step can be edited directly in the browser.

Multiple versions of StyleVision Server
If the server where you deploy the .transformation file has multiple versions of StyleVision Server running under FlowForce Server management (applicable to Windows servers only), then a Select StyleVision Server dialog appears, in which you are prompted to specify the version of StyleVision Server with which you want this mapping to be executed. You can select the version you want to use manually, or let the server select the most suitable version automatically.

This dialog appears when the FlowForce Server installation directory contains a .tool file for each StyleVision Server version which runs under FlowForce Server management. By default, a StyleVision Server .tool file is
added automatically to this directory when you install StyleVision Server as part of a FlowForce Server installation. The path where the .tool files are stored in FlowForce is: c:\Program Files\Altova\FlowForceServer2022\tools. If you have additional versions of StyleVision Server which you want to run under FlowForce Server management, their .tool files may need to be copied manually to the directory above. The .tool file of StyleVision Server can be found at: c:\Program Files\Altova\StyleVisionServer2022\etc.

**Note:** For information about how to work with FlowForce Server, see the [FlowForce documentation](#).

### 16.4.9 Web Design

The **Web Design** command rolls out a submenu containing the **Generate ASPX Web Application** command. This latter command generates all the files required to run an ASPX application, in the folder location you specify. A web browser will read the ASPX file that is the output document. C# code in this file will start a process whereby data in the source database or XML file will be transformed dynamically using an XSLT file in the ASPX package. The ASPX file (the output document of the transform process) will be updated with the latest data in the source database or XML file.

For more information, see [ASPX Interface for Web Applications](#).

### 16.4.10 Properties

The **Properties** command pops up the Properties dialog (*screenshot below shows the dialog in the Enterprise Edition*), in which you can set various properties for the active SPS.
Output
The following properties can be set in the Output tab:

- **Output Encoding**: In the Output Encoding pane you can select the encoding of your output documents. Changing the encoding in this dialog changes the encoding for the currently active SPS. You can also specify the application-wide default encoding for all SPS documents in the Encoding tab of the Options dialog.

- **HTML output mode**: You can select whether an entire HTML document or only the child elements of the HTML body element are output. The child elements are output parallel to each other—that is, on the same level—and will contain all descendants recursively. As a result, the output documents can be fragments of HTML code..

- **HTML output mode (DOCTYPE)**: You can select whether an HTML5, HTML 4.01 Transitional document, or XHTML 1.0 Transitional document is generated for the HTML output. This setting can be changed at any time while creating or editing the SPS document.
• **Internet Explorer Compatibility and CSS support:** CSS support in versions of Internet Explorer (IE) prior to IE 6 was incomplete and in some respects incorrectly interpreted. CSS support was enhanced and corrected in IE 6, and further improved and extended in IE 7, IE 9, and higher.

In an SPS, you can select the desired compatibility mode in the Properties dialog (screenshot above). You can select either IE 5, IE 7, or IE 9. (Note that for IE 9 compatibility to apply, IE 9 or higher must be installed.) The specified level of IE support is immediately available in Authentic View and HTML Preview. Note that new SPS documents are created with IE7 compatibility selected. SPS documents created in earlier versions of Altova StyleVision can be re-saved in the required Compatibility Mode (selected in the Properties dialog).

**XSD/XSLT**

In this tab (screenshot below shows the dialog in the Enterprise Edition), you can specify which XSD validator to use for XML validation and which XSLT version to use in the SPS.

StyleVision has both an XSD 1.0 validator and an XSD 1.1 validator. You can choose from among the following options:
• Use the XSD 1.1 validator if the XSD document's /xs:schema/@vc:minVersion attribute is set to 1.1; otherwise use the XSD 1.0 validator.
• Always use the XSD 1.1 validator.
• Always use the XSD 1.0 validator.

Select the XSLT version for the active document in this tab. Checking the option about the xsi:import-schema statement causes the xsi:import-schema element of the XSLT 2.0 and 3.0 specifications to be included in the XSLT document generated by StyleVision. It is recommended that you select this option in order for datatypes to be read from the schema in the event that there is no xsi:schemaLocation attribute in the XML document.

For Text output, you can specify the following:

• The end-of-line characters to use. The default is \r\n (which indicates the carriage-return and linefeed characters on Windows systems).
• The character to indicate the end of a table cell. The default is the semicolon character.

Images
This tab provides settings for selecting whether images are linked to or embedded in the RTF output. Embedding is possible when XSLT 2.0 is used. This setting is made for each SPS individually. To embed images, do the following:

1. With the required SPS active, open the Properties dialog (File | Properties).
2. Check the Embed Images for RTF and Word 2007+ check box (default setting is checked). Note that images will only be embedded if XSLT 2.0 is set as the XSLT version of the active SPS.
3. Click OK and save the SPS. The setting is saved for the active SPS.

If the Embed Images check box is not checked, images will be linked according to the image file path specified in the image's properties (select the image and select URL in the Properties entry helper). For information about how paths are resolved, see the section Image URLs.

This setting must be selected in order to save PXF files.

Note: The RTF format supports embedded images only for EMF, JPG, and PNG files.

Paths
Default paths for various files created by the SPS file and for paths saved in the SPS file are specified in the settings of this tab (screenshot below shows the dialog in the Enterprise Edition).
The following defaults are set in the Paths tab:

- Whether preview files are created in the directory of the SPS file or the Working XML File of the main schema source.
- Where additionally generated files (image files, barcode image files, chart image files, etc.) are created.
- Whether file paths in the SPS are relative only when the target directory is in the directory tree of the SPS file, or relative even when the target directory is outside the directory tree of the SPS file.

Resolution

The resolution factor resolves how lengths that are specified as pixels in the design are to be converted to non-screen (print) units of length. You can select 72dpi, 96dpi, or 120dpi from the dropdown list of the combo box. The higher the dpi, the smaller will each pixel and the corresponding absolute length be. The conversion factors (for obtaining the number of points from the number of pixels) for each dpi are, respectively, 1.0, 0.75, and 0.6. For a complete explanation, see *Pixel Resolution*.

Authentic

The following Authentic properties can be set:
● **Default paste mode for Authentic:** Specifies whether an Authentic View selection that has been saved to the clipboard will be pasted, by default, as XML or text in Authentic View. If it is pasted as XML, it will be pasted with markup (XML tags), if the copied selection contains markup. Otherwise the default paste mode copies the text content of nodes without markup. The default paste mode can be overridden in Authentic View by right-clicking at the insertion point and, in the context menu that appears, selecting the command **Paste As | XML** or **Paste As | Text**, as required. The default paste mode can be changed at any time while editing the SPS document.

You can also specify whether, when text is dragged and dropped in Authentic View, the user is given the option of selecting how to paste the text or whether the default paste mode is used. To give the user the choice of deciding the past mode, select the radio button **Ask on every drag-and-drop**; to use the default paste mode without consulting the user, select the radio button **Use default mode for paste**.

● **Authentic scripting:** These are options for scripts that are saved with an SPS: (i) Scripts can be enabled or not; (ii) Events in the scripts can be processed or can be disabled; (iii) Macros in the scripts can be run in debug mode from outside StyleVision (that is in the Authentic View of other Altova products) or can be disallowed. This feature is useful if you wish to test and debug a macro outside the StyleVision environment.

● **Maximum template call depth:** Specifies the maximum number of template calls that can be made recursively in the Authentic View output. If the number of template calls exceeds the number specified here, an error is returned. This setting can be used to prevent Authentic View from entering an unending loop.

### 16.4.11 Print Preview, Print

The **Print Preview** command is enabled in Design View and Authentic View (*Authentic View is supported in the Enterprise and Professional editions only*). The **Print Preview** command opens a window containing a preview of the SPS design (when Design View is active) or of the Authentic View of the Working XML File when Authentic View is active). The preview will show the design with or without tags according to what is on screen.

You can do the following in the Print Preview window, via the toolbar commands at the top of the page (*screenshot above*) and the page navigation icons at the bottom of the page. The commands in the Print Preview toolbar are as follows, starting from the left.

- Print the page using the Print button.
- Set paper orientation to portrait or landscape.
- Set page properties by clicking the **Page Setup** button to get the Page Setup dialog.
- Toggle on/off the display and printout of headers and footers.
- Set the view so that either the page width or page height occupies, respectively, the full screen width or full screen height.
- Set how many pages are to fit within the screen.
- Change the zoom factor of the preview pages using the Zoom In and Zoom Out buttons or the combo box to select a zoom factor.
The **Print** command is enabled in the Authentic View and output preview tabs. It prints out the selected view of the Working XML File according to the page setup for that view. Note that the page setup for Authentic View can be edited in the Page Setup dialog, which you access via the Print Preview window.

**Note:** To enable background colors and images in Print Preview, do the following: (i) In the **Tools** menu of Internet Explorer, click **Internet Options**, and then click the Advanced tab; (ii) In the Settings box, under Printing, select the **Print background colors and images** check box, and (iii) Then click **OK**.

### 16.4.12 Most Recently Used Files, Exit

The list of most recently used files, shows the file name and path information for the nine most recently used files. Clicking one of these entries, causes that file to be opened in a new tab in the Main Window.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>1 OrgChart.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>1.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>CBTMenu_Schema_5.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>CBTMenu_Schema_4.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>HTML-Orgchart.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>OrgChart.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>ExpReport.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>CBTMenu_Schema_4_sol1.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>C:\work\area\jayant\test.sps</td>
</tr>
<tr>
<td><img src="image" alt="Print..." /></td>
<td>Exit</td>
</tr>
</tbody>
</table>

To access these files using the **keyboard**, press **ALT+F** to open the File menu, and then the number of the file you wish to open; for example, pressing **1** will open the first file in the list, **2** the second file, and so on.

The **Exit** command is used to quit StyleVision. If you have an open file with unsaved changes, you will be prompted to save these changes.
16.5 Edit Menu

The Edit menu contains commands that aid the editing of SPS and Authentic View documents. Besides the standard editing commands, such as Cut (Shift+Del or Ctrl+X), Copy (Ctrl+C), Paste (Ctrl+V), and Delete (Del), which are not described in this section, the following commands are available:

- **Undo, Redo, Select All**, to undo or restore your previous actions, and to select all content of the SPS.
- **Find, Find Next, Replace**, to find text in the SPS, Authentic View, and XSLT stylesheet previews, and to replace text in Authentic View.
- **Stylesheet Parameters**, to edit parameters declared globally for the SPS.
- **Collapse/Expand Markup**, to collapse and expand SPS design component tags.

Commands are also available via the context menu which appears when you right-click a component or right-click at a cursor insertion point. Additionally, some commands are available as keyboard shortcuts and/or toolbar icons. Note, however, that commands which are not applicable in a particular document view or at a given location are grayed out in the menu.

16.5.1 Undo, Redo, Select All

The **Undo (Ctrl+Z)** command enables you to undo an editing change. An unlimited number of Undo actions is supported. Every action can be undone and it is possible to undo one command after another till the first action that was made since the document was opened.

The **Redo (Ctrl+Y)** command allows you to redo any number of previously undone commands. By using the Undo and Redo commands, you can step backward and forward through the history of commands.

The **Select All** command selects the entire contents of the Design Document window.

16.5.2 Find, Find Next, Replace

The **Find (Ctrl+F)** command allows you to find words or fragments of words in the Design View, JavaScript Editor, Authentic View, and XSLT stylesheets.

**Design View, HTML Preview, and Authentic View**

Clicking the **Find** command in Design View, HTML Preview, or Authentic View activates the **Find and Replace** sidebar.

Note the following:

- In Design View, the static data is searched, but not node names.
- In Authentic View, the dynamic data (XML data) is searched, not text from the static (XSLT) input.
- To match the entry with whole words, check "Match whole word only". For example, an entry of soft will find only the whole word soft; it will not find, for example, the soft in software.
To match the entry with fragments of words, leave the "Match whole word only" check box unchecked. Doing this would enable you, for example, to enter soft and software.

To make the search case-insensitive, leave the "Match case" checkbox unchecked. This would enable you to find, say, Soft with an entry of soft.

**XSLT and JavaScript Editor**

Clicking the **Find** command in the XSLT-for-HTML, XSLT-for-RTF or JavaScript Editor tab displays the following dialog:

You can select from the following options:

- **Match case**: Case-sensitive search when toggled on (Address is not the same as address).
- **Match whole word**: Only the exact words in the text will be matched. For example, for the input string fit, with Match whole word toggled on, only the word fit will match the search string; the fit in fitness, for example, will not be matched.
- **Regular expression**: If toggled on, the search term will be read as a regular expression. See [Regular expressions](#) below for a description of how regular expressions are used.
- **Find anchor**: When a search term is entered, the matches in the document are highlighted and one of these matches will be marked as the current selection. The Find anchor toggle determines whether that first current selection is made relative to the cursor position or not. If Find anchor is toggled on, then the first currently selected match will be the next match from the current cursor location. If Find anchor is toggled off, then the first currently selected match will be the first match in the document, starting from the top.
- **Find in selection**: When toggled on, locks the current text selection and restricts the search to the selection. Otherwise, the entire document is searched. Before selecting a new range of text, unlock the currently selection by toggling off the Find in Selection option.

**Find Next command**

The **Find Next (F3)** command repeats the last Find command to search for the next occurrence of the requested text. See [Find](#) for a description of how to use the search function.

**Replace (Ctrl+H)**

The Replace command is enabled in Design View, JavaScript Editor, and Authentic View (not supported in Basic edition) and enables you to search for a text string and replace it with another text string.

**Using regular expressions**

You can use regular expressions (regex) to find a text string. To do this, first, switch the Regular expression option on (see above). This specifies that the text in the search term field is to be evaluated as a regular expression. Next, enter the regular expression in the search term field. For help with building a regular expression, click the Regular Expression Builder button, which is located to the right of the search term field. Click an item in the Builder to enter the corresponding regex metacharacter/s in the search term field. See below for a brief description of metacharacters.
### Regular expression metacharacters

Given below is a list of regular expression metacharacters.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>Matches any character. This is a placeholder for a single character.</td>
</tr>
<tr>
<td>(</td>
<td>Marks the start of a tagged expression.</td>
</tr>
<tr>
<td>)</td>
<td>Marks the end of a tagged expression.</td>
</tr>
<tr>
<td>{abc}</td>
<td>The { and } metacharacters mark the start and end of a tagged expression. Tagged expressions may be useful when you need to tag (&quot;remember&quot;) a matched region for the purpose of referring to it later (back-reference). Up to nine expressions can be tagged (and then back-referenced later, either in the Find or Replace field). For example, (the) \1 matches the string the the. This expression can be literally explained as follows: match the string &quot;the&quot; (and remember it as a tagged region), followed by a space character, followed by a back-reference to the tagged region matched previously.</td>
</tr>
<tr>
<td>\n</td>
<td>Where n is a variable that can take integer values from 1 through 9. The expression refers to the first through ninth tagged region when replacing. For example, if the find string is Fred([1-9])XXX and the replace string is Sam\1YYY, this means that in the find string there is one tagged expression that is (implicitly) indexed with the number 1; in the replace string, the tagged expression is referenced with \1. If the find-replace command is applied to Fred2XXX, it would generate Sam2YYY.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Matches the start of a word.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Matches the end of a word.</td>
</tr>
<tr>
<td>\x</td>
<td>Allows you to use a character x, which would otherwise have a special meaning. For example, [ would be interpreted as [ and not as the start of a character set.</td>
</tr>
<tr>
<td>[...]</td>
<td>Indicates a set of characters. For example, [abc] means any of the characters a, b or c. You can also use ranges: for example [a-z] for any lower case character.</td>
</tr>
<tr>
<td>[^...]</td>
<td>The complement of the characters in the set. For example, [^A-Za-z] means any character except an alphabetic character.</td>
</tr>
<tr>
<td>^</td>
<td>Matches the start of a line (unless used inside a set, see above).</td>
</tr>
<tr>
<td>$</td>
<td>Matches the end of a line. Example: A+$ to find one or more a’s at end of line.</td>
</tr>
<tr>
<td>*</td>
<td>Matches 0 or more times. For example, Sa*m matches Sm, Sam, Saam, Saaam and so on.</td>
</tr>
<tr>
<td>+</td>
<td>Matches 1 or more times. For example, Sa+m matches Sam, Saam, Saaam and so on.</td>
</tr>
</tbody>
</table>

### Representation of special characters

Note the following expressions.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\r</td>
<td>Carriage Return (CR). You can use either CR (\r) or LF (\n) to find or create a new line</td>
</tr>
<tr>
<td>\n</td>
<td>Line Feed (LF). You can use either CR (\r) or LF (\n) to find or create a new line</td>
</tr>
<tr>
<td>\t</td>
<td>Tab character</td>
</tr>
<tr>
<td>\</td>
<td>Use this to escape characters that appear in regex expression, for example: \n</td>
</tr>
</tbody>
</table>
Regular expression examples

This example illustrates how to find and replace text using regular expressions. In many cases, finding and replacing text is straightforward and does not require regular expressions at all. However, there may be instances where you need to manipulate text in a way that cannot be done with a standard find and replace operation. Consider, for example, that you have an XML file of several thousand lines where you need to rename certain elements in one operation, without affecting the content enclosed within them. Another example: you need to change the order of multiple attributes of an element. This is where regular expressions can help you, by eliminating a lot of work which would otherwise need to be done manually.

Example 1: Renaming elements

The sample XML code listing below contains a list of books. Let’s suppose your goal is to replace the <Category> element of each book to <Genre>. One of the ways to achieve this goal is by using regular expressions.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<books xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="books.xsd">
  <book id="1">
    <author>Mark Twain</author>
    <title>The Adventures of Tom Sawyer</title>
    <category>Fiction</category>
    <year>1876</year>
  </book>
  <book id="2">
    <author>Franz Kafka</author>
    <title>The Metamorphosis</title>
    <category>Fiction</category>
    <year>1912</year>
  </book>
  <book id="3">
    <author>Herman Melville</author>
    <title>Moby Dick</title>
    <category>Fiction</category>
    <year>1851</year>
  </book>
</books>
```

To solve the requirement, follow the steps below:

1. Press Ctrl+H to open the Find and Replace dialog box.
2. Click Use regular expressions.
3. In the Find field, enter the following text: `<category>(.+)</category>` . This regular expression matches all category elements, and they become highlighted.
To match the inner text of each element (which is not known in advance), we used the tagged expression (\.+). The tagged expression (\.+) means "match one or more occurrences of any character, that is \.+, and remember this match". As shown in the next step, we will need the reference to the tagged expression later.

4. In the Replace field, enter the following text: <genre>\1</genre>. This regular expression defines the replacement text. Notice it uses a back-reference \1 to the previously tagged expression from the Find field. In other words, \1 in this context means "the inner text of the currently matched <category> element".

5. Click Replace All and observe the results. All category elements have now been renamed to genre, which was the intended goal.

Example 2: Changing the order of attributes

The sample XML code listing below contains a list of products. Each product element has two attributes: id and size. Let's suppose your goal is to change the order of id and size attributes in each product element (in other words, the size attribute should come before id). One of the ways to solve this requirement is by using regular expressions.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<products xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="products.xsd">
  <product id="1" size="10"/>
  <product id="2" size="20"/>
  <product id="3" size="30"/>
  <product id="4" size="40"/>
  <product id="5" size="50"/>
  <product id="6" size="60"/>
</products>
```

To solve the requirement, follow the steps below:

1. Press Ctrl+H to open the Find and Replace dialog box.
2. Click **Use regular expressions**.

3. In the Find field, enter the following: `<product id="(.+)" size="(.+)"/>`. This regular expression matches a product element in the XML document. Notice that, in order to match the value of each attribute (which is not known in advance), a tagged expression `(.+)` is used twice. The tagged expression `(.+)` matches the value of each attribute (assumed to be one or more occurrences of any character, that is `.+`).

4. In the Replace field, enter the following: `<product size="$2" id="$1"/>`. This regular expression contains the replacement text for each matched product element. Notice that it uses two references \1 and \2. These correspond to the tagged expressions from the Find field. In other words, \1 means "the value of attribute id" and \2 means "the value of attribute size".

6. Click **Replace All** and observe the results. All product elements have now been updated so that attribute size comes before attribute id.

### 16.5.3 Stylesheet Parameters

The **Stylesheet Parameters** command enables you to declare and edit parameters and their default values. The command is available in both the Design Document view and the Authentic Editor View. When you click this command, the Edit Parameters dialog (shown below) pops up.

The following points should be noted:
• You can insert, append, edit and delete parameters for the entire stylesheet and for the DB Filters.
• Parameter names must begin with a letter, and can contain the characters A to Z, a to z, 0 to 9, and the underscore.
• The Edit Parameters dialog contains all the user-defined parameters in an SPS.
• Parameters can also be declared in the Design Overview sidebar.

16.5.4 Collapse/Expand Markup

The Collapse/Expand Markup command is a toggle command, which collapses and expands the selected tag. It can be applied to any kind of tag: node, predefined format, SPS mechanism, etc. To collapse/expand a tag, double-click the tag; the end tag of an expanded tag may also be double-clicked to collapse that tag.

The screenshots below show how a series of tags are collapsed. Double-clicking a collapsed tag expands it.

Collapsing a tag can be useful for optimizing the display according to your editing needs.
16.6 Project Menu

The Project menu (screenshot below) enables you to create, structure, and modify projects. You can quickly set up a project, specify files in the project, and organize files by file type into separate folders. A project is displayed graphically in the Project sidebar, from where files can be accessed for use in the SPS design.

The Project menu contains the following commands, which are explained in detail in the sub-sections of this section:

- **New Project**, for creating a new project
- **Open Project**, for opening an existing project
- **Reload Project**, for refreshing a project in the Projects sidebar
- **Close Project**, for closing a project in the Project sidebar
- **Save Project**, for saving and naming a project
- **Add Files to Project**, for adding files to a project in the Project sidebar
- **Add Global Resource to Project**, for adding Altova Global Resources to a project in the Project sidebar
- **Add URL to Project**, for adding a file via a URL to a project in the Project sidebar
- **Add Active File to Project**, for adding the currently active SPS file to a project
- **Add Active and Related Files to Project**, for adding the currently active SPS file and its related files
- **Add Project Folder to Project**, for adding folders to a project in the Project sidebar
- **Add External Folder to Project**, for adding local folders to a project in the Project sidebar
- **Add External Web Folder to Project**, for adding folders via URL to a project in the Project sidebar
Recent projects
At the bottom of the Project menu, the file names of the nine most recently used projects are listed, thus allowing quick access to these files.

Drag-and-drop
In the Project window, a folder can be dragged to another folder or to another location within the same folder. A file can be dragged to another folder, but cannot be moved within the same folder (within which files are arranged alphabetically). Additionally, files and folders can be dragged from Windows File Explorer to the Project sidebar.

16.6.1 New Project, Open Project, Reload Project

The New Project command creates a new project. The new project replaces the previous project (if any) in the Projects sidebar. If the project you have been working on has unsaved changes, a prompt appears asking whether you wish to save changes to the project. Note that the New Project command only creates a new project without saving it; you have to explicitly save the project using the Save Project command.

The Open Project command opens an existing project and displays it in the Projects sidebar. If a project was previously open in the Projects sidebar, it is replaced by the opened project. If the previous project has unsaved changes, a prompt appears asking whether you wish to save changes to that project before it is replaced in the Projects sidebar.

The Reload Project command reloads the current project. This command is especially useful if you are working in a multi-user environment, where other users might make changes to the project.

16.6.2 Close Project, Save Project

The Close Project command closes the active project. If the project contains unsaved changes, a prompt appears asking whether you wish to save the project before closing it. A project with unsaved changes is indicated with an asterisk after the project name in the Project sidebar (screenshot below).
The **Save Project** command saves the current project. Note that it is when a project is saved for the first time that it is named. A project can only be renamed outside StyleVision; for example, by using Windows File Explorer to locate and rename the file.

### 16.6.3 Add Files / Global Resource / URL to Project

**Add Files to Project**

The **Add Files to Project** command adds files to the current project. The command pops up an Open dialog box, in which you select a single file or a group of files to add to the project. The file/s will be added to sub-folders within the project folder according to the file type extensions defined for each sub-folder. If the same file type extension has been defined for more than one folder, then a file with that file type extension will be added to the first folder (in the Projects sidebar) having that file type extension.

To add a file to a folder or sub-folder within the main project folder, right-click that folder, select the command **Add Files**, and then browse for the required file/s.

**Add Global Resource to Project**

The **Add Global Resource to Project** command pops up a dialog that lists global resources in the currently active Global Resources XML File and enables you to select one of these resources to add to the active project. Select the required global resource and click **OK**.

**Add URL to Project**

The **Add URL to Project** command adds a URL to the current project. URLs in a project cause the target object of the URL to be included in the project. The command pops up the Add URL to Project dialog *(screenshot below).*
You can enter either a file URL (with or without the file: protocol) or a server URL. For the server URL, enter your user name and password, then enter the server URL. Click **Browse** to connect to the server, then, from the list that appears in the Available Files display, click the file you wish to add to the project folder.

Note that URLs can also be added to folders and sub-folders of the main project folder. To do this, right-click the project folder and select the command **Add URL**. This pops up the Add URL dialog. Proceed as described above.

**Drag-and-drop**

A file can be dragged to another folder, but cannot be moved within the same folder (within which files are arranged alphabetically). Additionally, files can be dragged from Windows File Explorer to the Project window.

**Deleting Files, Resources, and URL**

To delete a file, Altova Resource, or URL, select that object in the Project sidebar, right-click, and, from the context menu, select **Delete**.

### 16.6.4 Add Active (and Related) Files to Project

**Add Active File to Project**

The **Add Active File to Project** command adds the active SPS file to the current project. This file is added to the first folder defined for the .sps file type extension. If you wish to add not just the SPS but the related schema, Working XML, Template XML, CSS and image files, use the **Add Active and Related Files to Project** command (see below). To add the active file to a folder or sub-folder within the main project folder, right-click that folder, select the command **Add Active File**.

**Add Active and Related Files to Project**

The **Add Active and Related Files to Project** command adds the currently active SPS file as well as the related schema files, and, if any, the Working XML, Template XML, CSS and image files. Each file is added to the first folder defined for that particular file type extension. To add the active file and related files to a folder or sub-folder within the main project folder, right-click that folder, select the command **Add Active and Related Files**.

**Deleting Files**

To delete a file, select the file in the Project sidebar, right-click, and, from the context menu, select **Delete**.

### 16.6.5 Add Project and External Folders to Project

**Add Project Folder to Project**

The **Add Project Folder to Project** command adds a new folder to the current project. When you click the command, the Properties dialog (**screenshot below**) pops up, in which you enter the name and file type extensions for the folder (file type extensions are separated by a semi-colon). When a file having the file type
extension defined for the folder is added to the project, the file will automatically be added to this folder. The newly added project folder is appended to the list of project folders in the Project sidebar.

To create a sub-folder of any given project folder, right-click the folder for which the sub-folder is required. In the context-menu that pops up, select **Add Project Folder**. In the Properties dialog, enter the folder name and the file type extensions for the folder.

### Add External Folder to Project

The **Add External Folder to Project** command adds a new external folder to the current project. The command adds a local or network folder, with all its contents, to the current project. The added external folder can be expanded and collapsed. To add an external folder to a project folder as a sub-folder, right-click the project folder and, from the context menu, select the command **Add External Folder**.

### Add External Web Folder to Project

The **Add External Web Folder to Project** command adds a new external folder via a URL to the current project. The added external folder can be expanded and collapsed. To add an external web folder to a project folder as a sub-folder, right-click the project folder and, from the context menu, select the command **Add External Web Folder**.

On clicking the command, the Add Web Folder dialog pops up (screenshot below). Do the following:

1. Click in the Server URL field to enter the server URL, and enter the login ID in the User and Password fields.
2. Click **Browse** to connect to the server and view the folders available there.

3. Click the folder you want to add to the project view. The **OK** button only becomes active once you do this. The folder name and server URL now appear in the File URL field.

4. Click **OK** to add the folder to the project.

5. Click the plus icon to view the folder contents.

6. To define the file types to display for the web folder, right-click, select **Properties** from the context menu, and enter the required file type extensions.
Drag-and-drop
In the Project window, a folder can be dragged to another folder or to another location within the same folder. Additionally, folders can be dragged from Windows File Explorer to the Project window.

Deleting Folders
To delete a folder or multiple folders, select the file in the Project sidebar, right-click, and, from the context menu, select Delete.
16.7 View Menu

The View menu (screenshot below) enables you to change the look of the GUI and to toggle on and off the display of GUI components. You can switch the display of individual toolbars, individual design sidebars, design filters, and the status bar on and off.

16.7.1 Toolbars and Status Bar

Placing the cursor over the Toolbars item pops out a submenu (screenshot below), which enables you to turn on and off the display of the different toolbars.

When a toolbar is checked, it is displayed. In the screenshot above all the toolbars are displayed. To toggle on or off the display of a toolbar, click the appropriate toolbar. For a complete description of toolbars, see the section Reference | Toolbars.
Status Bar
The display of the Status Bar, which is located at the bottom of the application window, can be switched on or off by clicking the **Status Bar** toggle command.

### 16.7.2 Design Sidebars

The **View** menu contains toggle commands to switch the display of each sidebar on and off (screenshot below).

When a sidebar is toggled on (the command's icon is framed) it is displayed in the GUI. Click a sidebar to set its display on or off, as required. This command is also used to make a hidden sidebar visible again. The display setting specified for a sidebar is View-specific: a setting made in a particular View (Design View, Authentic View, Output View, no document open) is retained for that particular View till changed.

### 16.7.3 Design Filter, Zoom

**Design Filter**
The **Design Filter** menu item rolls out a sub-menu containing commands that enable you to filter the templates that are displayed in Design View. This is useful if your design is very long or contains several templates. Using the Design Filter mechanism, you can specify what kinds of template to display. The following filter options are available:
<table>
<thead>
<tr>
<th>Icon</th>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1" alt="Icon" /></td>
<td>Show only one template</td>
<td>Shows the selected template only. Place the cursor in a template and click to show that template only.</td>
</tr>
<tr>
<td><img src="image2" alt="Icon" /></td>
<td>Show all template types</td>
<td>Shows all templates in the SPS (main, global, named, and layout).</td>
</tr>
<tr>
<td><img src="image3" alt="Icon" /></td>
<td>Show imported templates</td>
<td>Toggles the display of imported templates on and off.</td>
</tr>
<tr>
<td><img src="image4" alt="Icon" /></td>
<td>Show/Hide main template</td>
<td>Toggles the display of the main template on and off.</td>
</tr>
<tr>
<td><img src="image5" alt="Icon" /></td>
<td>Show/Hide global templates</td>
<td>Toggles the display of global templates on and off.</td>
</tr>
<tr>
<td><img src="image6" alt="Icon" /></td>
<td>Show/Hide Design Fragments</td>
<td>Toggles the display of Design Fragments on and off.</td>
</tr>
</tbody>
</table>

Note that these commands are also available as toolbar icons in the Design Filters toolbar.

**Zoom**

The **Zoom** command enables you to select a Zoom factor from the submenu that rolls out. You can also zoom in or out by changing the Zoom factor in the Zoom combo box (in the Standard toolbar), or by pressing the **Ctrl** key and scrolling with the mouse.
16.8 Insert Menu

The Insert menu provides commands enabling you to insert a variety of design components into the SPS. Some of these commands are available as toolbar icons. Additionally, Insert menu commands are also available via context menus which appear when, in the SPS design, you right-click a cursor insertion point. In the context menus, commands that are not available at that location in the SPS are disabled.

Note: Since the Insert commands are used for constructing the SPS, they are available in Design View only.

16.8.1 Contents

The Contents command inserts a (content) placeholder at the cursor location point. There (content) placeholder can be inserted within two types of node, element and attribute, and it indicates that all children of the current node will be processed.

- If the current node is an element node, the node's children element nodes and text nodes will be processed. For the processing of children element nodes, global templates will be used if these exist. Otherwise the built-in template rule for elements will be used. For the processing of text nodes, the built-in template rule for text nodes will be used, the effect of which is to output the text. Effectively, the built-in template rule for elements, outputs the text of all descendant text nodes. It is important to note that the values of attributes will not be output when the (content) placeholder is used—unless a global template is defined for the attribute's parent element or one of its ancestors and the attribute is explicitly output, using either the (content) placeholder or any other content-rendering component.
- If the current node is an attribute node, the built-in template rule for the attribute's child text node will be used. This template copies the text of the text node to the output, effectively outputting the attribute's value.

The (content) placeholder can also be inserted for a node by placing the cursor inside the node tags, right-clicking, and selecting Insert | Contents or by clicking the Insert Contents icon in the Insert Design Elements toolbar, and then clicking the location in the design where the element is to be inserted.

Styling the contents

The (content) placeholder can be formatted by selecting it and using a predefined format and/or properties in Styles sidebar. This formatting is visible in the design, and, in the output, it will be applied to the contents of the node.

Replacing contents

If another node from the schema tree is dropped into a node containing a (content) placeholder, then the existing (content) placeholder is replaced by the new node.

Deleting contents

The (content) placeholder can be deleted by selecting it and pressing the Delete key on the keyboard.
**Note:** You can create an empty template rule by deleting the (content) placeholder of a node. An empty template rule is useful if you wish to define that some node have no template applied to it, i.e. produce no output.

### 16.8.2 Rest of Contents

The **Rest of Contents** command inserts the (rest-of-contents) placeholder for that node. This placeholder represents the content of unused child nodes of the current node; it corresponds to the xsl:apply-templates rule of XSLT applied to the unused elements and text nodes of the current element. Note that templates are not applied for child attributes. The (rest-of-contents) placeholder can also be inserted for an element by placing the cursor inside the element tags, right-clicking, and selecting **Insert Rest of Contents**.

Use the (rest-of-contents) placeholder in situations where you wish to process one child element in a specific way and apply templates to its siblings. It is important to apply templates to siblings in order to avoid the possibility that the siblings are not processed. This enables you to reach elements lower down in the document hierarchy.

The (rest-of-contents) placeholder can be deleted by selecting it and pressing the **Delete** key on the keyboard.

### 16.8.3 RichEdit

The **RichEdit** command inserts a RichEdit component at the cursor location. For the first RichEdit component, the RichEdit Configuration dialog (screenshot below) pops up. This RichEdit configuration is valid for all RichEdit components in the document. As a result, for RichEdit components inserted subsequently, the RichEdit Configuration dialog does not appear.
In the RichEdit Configuration dialog, enter the name of the styling element and its attribute that is to contain the RichEdit styling properties. You can also select the required element and attribute from the schema tree. Click the respective Select buttons to open the schema tree. When done, click OK. The RichEdit component is created (see screenshot below), and an uneditable RichEdit global template having the name of the styling element (Style in the screenshot below) is created in the design.
For more information about the RichEdit feature in context, see Text-Styling Flexibility in Authentic.

16.8.4 Form Controls

Mousing over the Form Controls command rolls out a submenu (screenshot below) containing commands to insert various form controls (data-entry devices).

How to create each of these form controls is described in the section Using Data-Entry Devices. After a form control has been created, its properties can be edited by selecting it and then editing the required property in the Properties sidebar.

Form controls can also be inserted in the design by right-clicking at the insertion point and selecting Insert | Form Controls, or by clicking the respective Form Control icon in the Insert Design Elements toolbar, and then clicking the location in the design where the element is to be inserted.

Note: CDATA sections cannot be inserted into input fields (that is, in text boxes and multiline text boxes). CDATA sections can only be entered within elements that are displayed in Authentic View as text content components.

16.8.5 DB Control

Mousing over the DB Controls command rolls out a submenu containing commands to insert controls in Authentic View that enable the Authentic View user to navigate the display of records in Authentic View and to
query the DB. These control can be inserted in the design and will appear in the Authentic View document at the corresponding locations.

The list of commands is as follows.

- Navigation
- Navigation + Goto
- Query Button

For details about how these controls are created and what they do, see the section SPS Design Features for DB.

16.8.6 Auto-Calculation

An Auto-Calculation uses an XPath expression to calculate a value. This value is displayed at the point where the Auto-Calculation is inserted. An Auto-Calculation can be inserted in the SPS as a text value, input field, or multiline input field. Place the cursor at the location where the Auto-Calculation is to be inserted, then either right-click or use the command in the Insert menu. When the cursor is placed over Insert | Auto-Calculation, a menu pops out (screenshot below), enabling you to choose how the Auto-Calculation should be inserted. Alternatively, you can use the Auto-Calculation icon in the Insert Design Elements toolbar.

The value of the Auto-Calculation will be displayed accordingly in Authentic View and the output document.

The XPath expression for the Auto-Calculation

On selecting how the Auto-Calculation should be represented, the Edit XPath Expression dialog (screenshot below) pops up.
The context node for the expression being built is highlighted in the schema tree in the pane at extreme left. You can enter the XPath expression directly in the text box, or you can double click an item (in any of the three panes) to insert that item. Nodes inserted from the schema tree in the left-hand pane are inserted relative to the context node (if the Absolute XPath check box is unchecked) or as an absolute expression starting from the document node (if the Absolute XPath check box is checked).

After completing the XPath expression, click OK to finish inserting the Auto-Calculation.

**Updating an XML node with an Auto-Calculation**

A node in an XML document can be updated with the result of an Auto-Calculation. How to do this is described in the section, [Updating Nodes with Auto-Calculations](#).

### 16.8.7 Date Picker

The **Date Picker** command inserts a Date Picker at the current cursor position. It will be enabled only when the cursor is within an `xs:date` or `xs:dateTime` node and if the element has been created as (contents) or an input field.
16.8.8  Paragraph, Special Paragraph

The **Paragraph** command inserts an HTML paragraph `<p>` element around the selected component. A component is considered selected for this purpose when the entire node is selected (by clicking either of its tags) or when static text is selected. If the cursor is placed within static text, the paragraph element is inserted (start and end tags) at this point. A paragraph can also be inserted by using the **Insert Paragraph** icon in the **Insert Design Elements toolbar**.

The **Special Paragraph** command allows you to assign a predefined format to the selected node. The available predefined formats can also be selected from the combo box in the toolbar.

Each paragraph type has particular formatting features that can be used to advantage. Note that the **pre** format type enables carriage returns to be output as such instead of them being normalized to whitespace.

16.8.9  Barcode

The **Insert Barcode** command pops up the Insert Barcode dialog (*screenshot below*).
Two properties, Type and Text, are mandatory; the others are optional and/or have appropriate default values. After entering values for the mandatory properties and any other properties you wish to set, click OK. The barcode you have specified (such as that for the ISBN shown below) will be inserted in the design. For detailed information about the various barcode properties, see the section, Barcodes.

Important: For barcodes to work, a Java Runtime Environment must be installed. This must be version 1.4 or later in a bit version that corresponds to the bit version of the StyleVision package installed on your system: 32-bit or 64-bit.

Important: For barcodes to be generated in the output, you must use Altova's XSLT processor to generate the output. This is because the barcodes in an SPS are generated by calling special Java extension functions that are not part of the XSLT standard. Altova's XSLT processors support these specific extension functions, whereas other XSLT processors very probably do not. As a result, barcodes will not be generated if processed with a non-Altova XSLT processor. The Altova XSLT processor is packaged with StyleVision, and is automatically called when you generate output via the Generate commands in the File menu. Alternatively, you can use RaptorXML Server, which is a Altova's standalone XSLT processor.

16.8.10 Image

The Image command pops up the Insert Image dialog (see screenshots below), in which you can specify the image to insert. The Insert Image icon in the Insert Design Elements toolbar also pops up the Insert Image dialog.

The Insert Image dialog has four tabs, each of which provides a different way to specify the image location. These are:

- **Static**: for entering the image URI directly
- **Dynamic**: for obtaining the image URI from the XML document or generating it with an XPath expression
- **Static and dynamic**: for combining the static and dynamic methods
- **Inline data**: for selecting an image that is stored in an XML file as Base-16 or Base-64 encoded text

The tabs are described in detail below.

**Static**

The image URI is entered directly in the Address field (see screenshot below). In the screenshot below the image URI is: http://www.altova.com/pix/Marketing/logo.png.
You can specify whether the URI is absolute (Absolute check box checked) or relative (Absolute check box unchecked). If a relative URI is entered, it will be resolved relative to the SPS file location. To enter the (absolute or relative) URI automatically, click Browse and browse for the image file.

Dynamic

An XPath expression returns the image URI. In the screenshot below, the XPath expression is @deptlogo. This assumes that the image URI is stored in the deptlogo attribute of the context node. The context node is the node within which the image is being created.

Click the Edit XPath button to pop up the XPath Expression Builder. In the schema tree of the XPath Expression Builder, the context node will be highlighted.

If the SPS is DTD-based and uses unparsed entities, then, an unparsed entity that references the image URI can be used. First, check the Treat as unparsed entity checkbox. Then enter an XPath expression that selects the node containing the unparsed entity. For details of how to use unparsed entities, see Unparsed Entity URIs.

Static and Dynamic

Use both the static and dynamic mechanisms together to generate the URI.
If the deptname attribute of the context node has a value of Marketing, then the image URI composed in the screenshot above will be: http://www.altova.com/pix/Marketing/logo.png. Note that you can use the XPath Expression Builder for the dynamic part.

**Inline data**

An image can be stored in an XML file as Base-16 or Base-64 encoded text. The XPath expression in the Insert Image dialog (see screenshot below) selects the node containing the encoded text. The Encoding combo box specifies the encoding used in the source XML so that StyleVision can correctly read the encoded text. And the Image Format combo box indicates in what format the image file must be generated. (An image file is generated from the encoded text data, and this file is then used in the output document.)

The Image File Settings dialog (accessed by clicking the Image File Settings button) enables you to give a name for the image file that will be created. You can choose not to provide a name, in which case StyleVision will generate a name.

### 16.8.11 Horizontal Line

The Horizontal Line command inserts a horizontal line at the cursor insertion point. This command is not available when an SPS component is selected. To set properties for the horizontal line, select the line in the design, and in the Properties sidebar, select line, and specify values for properties in the HTML group (see screenshot below).
You can specify the following properties for the line: its color, size (thickness), width (in the design), alignment, and the noshade property.

16.8.12 Table

The Insert Table command pops up the Create Table dialog (screenshot below).

According to whether you wish to create a static table or a dynamic table, select the appropriate button. How to proceed with each type of table is described in the section: Static SPS Tables and Dynamic SPS Tables.

Note that tables can also be created by using the Table | Insert Table menu command and the Insert Table icon in the Insert Design Elements toolbar.

16.8.13 Bullets and Numbering

The Bullets and Numbering command allows you to create a list, either static or dynamic. The list items of a static list are entered in the SPS, while those of dynamic lists are the values of sibling nodes in the XML document.

To create a list do the following:
1. Place the cursor at the location where you wish to insert the list and click the **Bullets and Numbering** command. This pops up a dialog asking whether you wish to create a static list or dynamic list (screenshot below).

   ![Static List Dialog](image1)

   If you click **Static List**, the Bullets and Numbering dialog described in Step 3 pops up. If you click **Dynamic List**, the XPath Selector dialog pops up (screenshot below).

2. In the XPath Selector dialog, notice that the XPath Context is the context of the insertion location, and that it cannot be changed in the dialog. Select the node that is to be created as the dynamic list. In the screenshot below, the context node is `n1:Department`, and the `n1:Person` node has been selected as the node to be created as a list. This means that the content of each `n1:Person` node will be created as an item in the list.

   ![XPath Selector Dialog](image2)
If you select the User-defined XPath option, then you can enter an XPath expression to select the node to be created as the dynamic table. Clicking OK pops up the Bullets and Numbering dialog described in the next step.

3. In the Bullets and Numbering dialog, select the kind of list you wish to create. You can choose from a bulleted list (with a bullet, circle, or square as the list item marker), or a numbered list. Clicking OK creates the list with the type of list item marker you selected.

Note: A static list can also be created by placing the cursor at the location where the list is to be created and then clicking the Bulleted List icon or Numbered List icon in the Insert Design Elements toolbar as required. A dynamic list can also be created by dragging a node from the Schema Tree into the design.

16.8.14 Bookmark

The Bookmark command allows you to insert a bookmark (or anchor) anywhere in the SPS. A bookmark can be referenced by a Hyperlink.

To insert a bookmark, do the following:

1. Place the cursor at the location where you wish to create the bookmark.
2. Select Insert | Bookmark, or right-click and select Insert | Bookmark. The Insert Bookmark dialog appears.
3. In the **Insert Bookmark dialog**, select a tab according to whether the name of the bookmark should be static (Static tab), dynamically obtained from the XML document (Dynamic), or composed of both static and dynamic parts (Static and Dynamic). In the screenshot above a dynamic bookmark is created, which has a name that is a unique ID for each Name child of the context node.

4. Click **OK**. The bookmark is defined.

**Note**: Bookmarks are created at the location specified in the design. If that location is within an element that repeats, a bookmark is created within each instance of that repeating element. If a static name is given, then each bookmark will have the same name. Therefore, it is better in such cases (of repeating elements) to give a dynamic name, which can be, for example, the name of a child element of the context node (the element within which the bookmark is created). If the node selected for the dynamic name might have the same content across multiple instances, then the uniqueness of the bookmark name can be ensured by using the `generate-id()` function to generate the name (see screenshot above). To reference such a bookmark, the same ID can be generated as the `href` value of a hyperlink. In this case make sure you use the fragment-identifier `#` in front of the `generate-id()` function. The XPath expression would be: `concat('#', generate-id(nodeXXX))`.

You can edit the name of a bookmark after it has been created. Do this by right-clicking the bookmark and selecting the **Edit Bookmark Name** command from the context menu that appears. Alternatively, in the Properties sidebar, in the **Bookmark** group of properties for the bookmark, you can click the **Edit** button of the bookmark name attribute and make the required changes.

### Deleting a bookmark

To delete a bookmark, select it in the design and press the **Delete** key.

### 16.8.15 Hyperlink

The **Hyperlink** command enables you to insert a link from any part of the output document (HTML or RTF) to an anchor within the output document or to an external document or document fragment. Note that links are created only in the output document; linking is not available in Authentic View.

To insert a hyperlink, do the following:
1. A hyperlink can be created around an existing design component or inserted at any point in the document (with the link text inserted subsequently). Select the SPS component or text fragment to be made into a hyperlink or place the cursor at the point where the link is to be inserted.

2. Click the Hyperlink icon in the toolbar, or select Insert | Hyperlink, or right-click and select Insert | Hyperlink (when no design component is selected) or Enclose With | Hyperlink (when a design component is selected). A hyperlink can also be inserted by using the Insert Hyperlink icon in the Insert Design Elements toolbar.

3. In the Insert Hyperlink dialog that appears, specify the document or document fragment you wish to link to. If you are linking to a document fragment (that is, to a bookmark within a document), remember to include the # symbol. The URI for the hyperlink is specified in one of the following forms:

   - As a static address (entered directly; you can select an HTML file via the Browse button, and a fragment in the current document via the Bookmark button). Examples would be: http://www.altova.com (static Web page URI); U:\documentation\index.html (via Browse button); or #top_of_page (via Bookmark button).
   - As a dynamic address (which comes from a node in the XML document; you specify the node). An example would be a node such as //otherdocs/doc1. If the name of a bookmark has been generated using the generate-id() function, then the href of the hyperlink should be generated using the same generate-id() function. For information, see Defining Hyperlinks.
   - As a combination of static and dynamic text for an address (you specify the static text and the XML document node). An example would be www.altova.com -- department/name -- #intropara.

4. Click OK. The hyperlink is created.

Note: When specifying the node for a dynamic hyperlink entry, you can enter the XPath expression as an absolute XPath expression by checking the Absolute Path check box. If this check box is not checked, the XPath expression will be relative to the context node, which is the node within which the hyperlink is being inserted.

Using unparsed entities

If you are using a DTD as your schema, then in the dynamic part of a hyperlink address, you can use the URI declared for an unparsed entity in the DTD. For details of how to use unparsed entities, see Using unparsed entity URLs.

Editing a hyperlink

You can edit the href of a hyperlink after it has been created. Do this by right-clicking the hyperlink and selecting the Edit URL command. Alternatively, in the Properties sidebar, in the Link group of properties for the link, you can click the Edit button of the URL attribute and make the required changes.

Deleting a hyperlink

To delete a hyperlink, select it in the design and press the Delete key.

16.8.16 Footnote

You can insert footnotes in a document by adding the Footnote component (Insert | Insert Footnote) at the location where you want the footnote number to be. Footnotes are available in paged media output (PDF, RTF, and Word 2007+ in the Enterprise Edition; and RTF in the Professional Edition).
Note the following points:

- The text of the footnote must be placed within the tags of the footnote component, and the footnote text can be formatted.
- In the output, the footnote number appears at the location where the footnote was added. The footnote text appears at the bottom of the page, together with the corresponding footnote number.
- In the output, footnote text will be formatted according to the formatting of the text within the footnote component in the design.
- In the output, footnotes are numbered automatically through to the end of the document.
- In the case of multiple output documents, numbering is re-started for each output document.

In the screenshot below, two footnote components (Insert | Insert Footnote) have been inserted. The footnote text has been placed within the tags of the component, and the text has been formatted.

The screenshots below show the output. The screenshot at left shows the complete page, while the screenshots at right show closeups of the footnote numbers (top) and footnote texts (bottom).
16.8.17  **Condition, Output-Based Condition**

The **Condition** command enables you to insert a condition at the cursor point or around the selection. A condition consists of one or more branches, with each branch containing a specific set of processing rules. In this way, different sets of processing rules can be specified for different branches. For example, if the content of a node is the string *Stop*, the branch can test this, and specify that the contents of the node be colored red; a second branch can test whether the contents of the node is the string *Go*, and, if yes, color the contents of the node green; a third branch can specify that if the contents of the node is neither the string *Stop* nor the string *Go*, the contents of the node should be colored black.

To insert a condition, do the following:

1. Place the cursor at the desired location in the design or select the component around which the condition is to be inserted.
2. Select the menu command **Insert | Condition** or right-click and select the context menu command **Insert | Condition**.
3. In the **Edit XPath Expression dialog** that pops up (*screenshot below*), enter the XPath expression.
The context node for the expression being built is highlighted in the schema tree in the pane at extreme left. You can enter the XPath expression directly in the text box, or you can double click an item (in any of the three panes) to insert that item. Nodes inserted from the schema tree in the left-hand pane are inserted relative to the context node (if the Absolute XPath check box is unchecked) or as an absolute expression starting from the document node (if the Absolute XPath check box is checked).

4. Click **OK** to finish inserting the condition. The condition is created with one branch, the test for which is the XPath expression you entered.

### Insert Output-Based Condition

This command inserts an output based-condition at the cursor location or around the selected component. Each branch of the condition represents a single output (Authentic View, RTF, Text or HTML). To determine which branch represents which output, mouse over the branch tag or check the XPath expression of the selected branch (in the Properties sidebar, in the Condition Branch entry, **click the Edit button**). If the output-based condition was created at a cursor insertion point, all branches will be empty and content will have to be inserted for each branch. If the output-based condition was created around a component, each branch will contain that component. For more details about output-based conditions, see [Output-Based Conditions](#).

You can edit, move, and delete output-based conditions in the same way you would with a standard condition.

### Editing the XPath expressions of branches

To edit the XPath expression of a branch, select the branch in Design View. Then, in the Properties sidebar,
select condition branch | when. Click the Edit button for the XPath item. This pops up the Edit XPath Expression dialog (screenshot above), in which you can edit the expression. Click OK when done.

Adding branches, changing the order of branches, and deleting branches
To add new branches, change the order of branches, and delete branches, right-click the required branch and select the relevant item from the context menu.

16.8.18 Template

The Template command inserts, at the cursor insertion point, an empty template for the schema tree node you select. Insert a template as follows.

1. Place the cursor in the design at the location where the template is to be inserted.
2. Click the Insert | Template command. This pops up the Insert Template dialog (screenshot below).

3. The XPath Context field contains the context node of the cursor insertion point and will be the context node for the template when it is created. Select the node for which you wish to create the template. In the screenshot above the strings node is selected as the node for which the template is being created.
4. Click OK to finish.

An empty template for the selected node will be created (in the screenshot below, an empty template for the strings node has been created).
16.8.19  User-Defined Template

The User-Defined Template command inserts, at the cursor insertion point, an empty template that selects a node the user specifies in an XPath expression. Insert a user-defined template as follows.

1. Place the cursor in the design at the location where the template is to be inserted.
2. Click the Insert | User-Defined Template command. This pops up the Edit XPath Expression dialog.
3. Enter the XPath expression to select the node you want. There are a few points to note in this connection: (i) The XPath expression will be evaluated in the context of the node within which the user-defined template is being created; (ii) The XPath expression can select any node anywhere in the document as well as in another XML document.
4. After you have entered the XPath expression, click OK to finish.

An empty user-defined template for the targeted node will be created.

For more detailed information, see the section, SPS File: Contents | User-Defined Templates.

16.8.20  Variable Template

A Variable Template is a template that targets a variable and, by default outputs its content. It is inserted with the Insert | Variable Template or Enclose with | Variable command, which inserts, at the cursor insertion point, a template for a variable defined in the SPS. The variable template (screenshot below) contains a content placeholder by default, and this serves to output the contents of the variable. You can insert additional content (static as well as dynamic) in the variable template as required, or modify it as you would any other template. A variable template is indicated with a dollar symbol in its start and end tags.

To insert a variable template, do the following:

1. Place the cursor in the design at the location where the template is to be inserted.
2. Click the Insert | Variable Template command. This pops up the Insert Variable Template dialog (screenshot below).
3. The dialog contains a list of all the user-declared parameters and variables defined in the SPS. Select the variable for which you wish to add a variable template.
4. Click OK to finish.

16.8.21 Design Fragment

Mousing over the Design Fragment command rolls out a submenu containing all the Design Fragments currently in the design. Clicking a Design Fragment in the submenu inserts it at the cursor insertion point.

16.8.22 Layout Container, Layout Box, Line

The Insert | Layout Container command enables a Layout Container to be inserted anywhere in the design. A Layout Box and a Line can be inserted in a Layout Container, and both these commands are enabled only when a Layout Container is selected.

Layout Containers, Layout Boxes, and Lines can also be inserted via the respective icons in the Insert Design Elements toolbar. To insert via the toolbar icons, you must first select the appropriate toolbar icon and then click in the design at the location where you wish to insert the layout item.

For a detailed description of Layout modules and how to insert and use them in the design, see the section Layout Modules.

16.8.23 Table of Contents

Mousing over the Table of Contents command rolls out a submenu containing commands to insert various commands relating to the creation of a Table of Contents (TOC) template, TOC bookmarks, and a design document structure for the TOC.

The list of commands is as follows. For the details of how to use them click on the respective links, which will take you to the section on how to use that particular TOC component.

- Insert Table of Contents
- TOC Bookmark
Note: These commands are also available as commands in a context menu, depending on where you right-click in the design.

### 16.8.24 New Document

The **Insert New Document** command inserts a New Document template *(screenshot below)* at the cursor insertion point.

The New Document template contains an empty Initial Document Section. Content can now be entered in the Initial Document Section. If desired, additional Document Sections can be appended to the Initial Document Section via the **Insert | Insert Page / Column / Document Section** command.

A New Document template creates a new document in the output. As a result, the output will consist of multiple output-documents.

For a detailed description of how to work with multiple output-documents, see the section, [Multiple Document Output](#).

### 16.8.25 Page / Column / Document Section

With the **Page / Column / Document Section** command you can insert, for paged media output, a page break (HTML printouts and RTF outputs) and page number (RTF output). Such insertions are possible only at cursor insertion points.

**New Page**

Click **New Page** to insert a page break at the cursor insertion point. The page break is displayed as a dashed line across the whole of the Design window. In HTML output, while the page break has no effect in the browser view, a page break will be inserted when the browser view of the HTML file is printed out. In RTF output, a page break is inserted at the specified locations.
Page Number
Click **Page | Number** to insert the current page number in the RTF outputs. The page number appears as a block (i.e. as a separate line) or as an inline (embedded in document text), depending on where in the document the page number has been inserted. For example, if the page number is inserted within a paragraph element, then the page number appears inline within the paragraph. If, on the other hand, the page number is inserted, say, between two elements, then it appears on a separate line by itself.

Page Total
Click **Page | Total** to insert the total number of pages in the PDF output. The page total can be inserted anywhere in the document design, including in headers and footers. It is particularly useful when numbering pages. For example, the page total can be inserted in a header design as follows: Page: (page number) / (page total). This would produce output in the form: Page: 1/25.

New Column
The number of columns that a page in a given section must have is specified in the page properties of that section. In the output, text will fill the columns on a multi-column page one by one. Text can however be forced into a new column by inserting a column break (new column) in the design. To insert a new column in a document, place the cursor at the location in the design where the new section is to be added and click the **New Column** command, which is also available via the context menu.

New Document Section
A document is made up of one initial section and, optionally, additional sections. Each section has its own page properties. To insert a new section in a document, place the cursor at the location in the design where the new section is to be added and click the **New Document Section** command, which is also available via the context menu.

Deleting Page Breaks, Page Numbers, and Page Total
To delete page breaks, page numbers, and page total, select the placeholder and click **Delete**.

16.8.26 User-Defined Item
Mousing over the **Insert | User-Defined Item** command causes a sub-menu to roll out that contains commands to insert a **User-Defined Element** or a **User-Defined XML Text Block**. How to use these two components is described in the section **SPS File: Content | User-Defined Elements, XML Text Blocks**.
16.9 Enclose With Menu

The **Enclose with** menu provides commands enabling you to enclose a selection in the design with a variety of design components. Some of these commands are available as [toolbar icons](#) that enable you to insert the component in the design (equivalent commands are available in the [Insert menu](#)). Additionally, **Enclose with** menu commands are also available via context menus which appear when, in the SPS design, you right-click a selection. In the menus and context menus, commands that are not available at that location in the SPS are disabled.

**Note:** Since the **Enclose with** commands are used for constructing the SPS, they are available in Design View only.

16.9.1 Template

The **Enclose with | Template** command encloses the selected design component or text with a template for the schema tree node you select. Do this as follows.

1. Select the design component or text you wish to enclose with a template.
2. Click the **Enclose with | Template** command. This pops up the Schema Selector dialog (*screenshot below*).

3. The XPath Context field contains the context node of the selection and will be the context node of the template when it is created. Select the node for which you wish to create the template. In the screenshot above the **n1:Name** node is selected as the node for which the template is being created.
4. Click OK to finish.

A template for the selected node will be created around the selection.

### 16.9.2 User-Defined Template

The Enclose with | User-Defined Template command encloses the selection with a template for a node the user specifies in an XPath expression. Insert a user-defined template as follows.

1. Select the component in the design that you wish to enclose with a user-defined template.
2. Click the Enclose with | User-Defined Template command. This pops up the Edit XPath Expression dialog.
3. Enter the XPath expression to select the node you want. There are a few points to note in this connection: (i) The XPath expression will be evaluated in the context of the node within which the user-defined template is being created; (ii) The XPath expression can select any node anywhere in the document as well as in another XML document.
4. After you have entered the XPath expression, click OK to finish.

A user-defined template for the targeted node will be created around the selection.

For more information, see the section, SPS File: Structure | Templates and Design Fragments | User-Defined Templates.

### 16.9.3 Variable Template

The Enclose with | Variable Template command encloses the selection with a template for a variable defined in the SPS design.

1. Select the component in the design that you wish to enclose with a variable template.
2. Click the Enclose with | Variable Template command. This pops up the Enclose with Variable Template dialog.
3. From the list in the dialog, select the variable for which you wish to create the template.
4. Click OK to finish.

A variable template will be created around the selection.

For more information, see the section, SPS File: Structure | Templates and Design Fragments | Variable Templates.

### 16.9.4 Paragraph, Special Paragraph

The Paragraph command inserts an HTML paragraph `<p>` element around the selected component. A component is considered selected for this purpose when the entire node is selected (by clicking either of its tags) or when static text is selected. If the cursor is placed within static text, the paragraph element is inserted.
(start and end tags) at this point. A paragraph can also be inserted by using the **Insert Paragraph** icon in the **Insert Design Elements toolbar**.

The **Special Paragraph** command allows you to assign a predefined format to the selected node. The available predefined formats can also be selected from the combo box in the toolbar.

Each paragraph type has particular formatting features that can be used to advantage. Note that the `pre` format type enables carriage returns to be output as such instead of them being normalized to whitespace.

### 16.9.5 Bullets and Numbering

The **Enclose with Bullets and Numbering** command creates a static list and list items around the selection. If the selection contains a CR-LF, carriage-return and/or linefeed (inserted by pressing the **Enter** key), then separate list items are created for each text fragment separated by a CR-LF.

When this command is selected, the Bullets and Numbering dialog (**screenshot below**) pops up.

![Bullets and Numbering dialog](image)

Select the list item marker you want and click **OK**. A list is created. The number of list items in the list corresponds to the number of CR-LFs (carriage-returns and/or linefeeds) in the selection. You can add more list items to the list by pressing **Enter**.

**Note:** You can obtain the same results by selecting static content and then clicking the Bulleted List or Numbered List icons in the **Insert Design Elements toolbar**.
16.9.6 Bookmarks and Hyperlinks

The Enclose with | Bookmark and Enclose With | Hyperlink commands are enabled when some text or component in the SPS design is selected. These commands enable a bookmark and hyperlink, respectively, to be created around the selection. For more information about how bookmarks and hyperlinks work and how to create them, see the section Advanced Features | Table of Contents, Referencing, Bookmarks.

16.9.7 Condition, Output-Based Condition

The Condition command enables you to insert a condition at the cursor point or around the selection. A condition consists of one or more branches, with each branch containing a specific set of processing rules. In this way, different sets of processing rules can be specified for different branches. For example, if the content of a node is the string Stop, the branch can test this, and specify that the contents of the node be colored red; a second branch can test whether the contents of the node is the string Go, and, if yes, color the contents of the node green; a third branch can specify that if the contents of the node is neither the string Stop nor the string Go, the contents of the node should be colored black.

To insert a condition, do the following:

1. Place the cursor at the desired location in the design or select the component around which the condition is to be inserted.
2. Select the menu command Insert | Condition or right-click and select the context menu command Insert | Condition.
3. In the Edit XPath Expression dialog that pops up (screenshot below), enter the XPath expression.
The context node for the expression being built is highlighted in the schema tree in the pane at extreme left. You can enter the XPath expression directly in the text box, or you can double click an item (in any of the three panes) to insert that item. Nodes inserted from the schema tree in the left-hand pane are inserted relative to the context node (if the Absolute XPath check box is unchecked) or as an absolute expression starting from the document node (if the Absolute XPath check box is checked).

4. Click **OK** to finish inserting the condition. The condition is created with one branch, the test for which is the XPath expression you entered.

### Insert Output-Based Condition

This command inserts an output based-condition at the cursor location or around the selected component. Each branch of the condition represents a single output (Authentic View, RTF, Text or HTML). To determine which branch represents which output, mouseover the branch tag or check the XPath expression of the selected branch (in the Properties sidebar, in the Condition Branch entry, **click the Edit button**). If the output-based condition was created at a cursor insertion point, all branches will be empty and content will have to be inserted for each branch. If the output-based condition was created around a component, each branch will contain that component. For more details about output-based conditions, see [Output-Based Conditions](#).

You can edit, move, and delete output-based conditions in the same way you would with a standard condition.

### Editing the XPath expressions of branches

To edit the XPath expression of a branch, select the branch in Design View. Then, in the Properties sidebar,
select condition branch | when. Click the Edit button for the XPath item. This pops up the Edit XPath Expression dialog (screenshot above), in which you can edit the expression. Click OK when done.

Adding branches, changing the order of branches, and deleting branches
To add new branches, change the order of branches, and delete branches, right-click the required branch and select the relevant item from the context menu.

16.9.8 TOC Bookmarks and TOC Levels

When a component in the design is selected, it can be enclosed with one or more relevant Table of Contents (TOC) components. The list of TOC commands is as follows. For the details of how to use them click on the respective links, which will take you to the section on how to use that particular TOC component.

- TOC Bookmark
- TOC Bookmark (Wizard)
- Level
- Level Reference

Note: These commands are also available as commands in a context menu, depending on where you right-click in the design.

16.9.9 New Document

The Enclose With New Document command encloses the current selection with a New Document template (screenshot below).
The New Document template contains an Initial Document Section that contains the design selection that was highlighted when the Enclose With New Document command was selected. In the screenshot above, the TOC design component was selected and enclosed with a New Document template. Content can now be entered in the Initial Document Section. If desired, additional Document Sections can be appended to the Initial Document Section via the Insert | Insert Page / Column / Document Section command.

A New Document template creates a new document in the output. As a result, the output will consist of multiple output-documents.

For a detailed description of how to work with multiple output-documents, see the section, Multiple Document Output.

16.9.10 User-Defined Element

The Enclose with | User-Defined Element command creates a User-Defined Element around the selection in the design. How to use user-defined elements is described in the section SPS File: Content | User-Defined Elements.
16.10 Table Menu

The Table menu provides commands enabling you to insert a static or dynamic table and to change the structure and properties of static and dynamic tables. You can edit table structure by appending, inserting, deleting, joining, and splitting rows and columns. Properties of the table as well as of individual columns, rows, and cells are defined using CSS styles and HTML properties for tables and its sub-components.

The Table commands are available in the Table menu (see list below) and as icons in the Table toolbar. The availability of various table commands depends on the current cursor position. A table can be inserted at any location in the SPS by clicking the Insert Table command. To edit the table structure, place the cursor in the appropriate cell, column, or row, and select the required editing command. To edit a formatting property, place the cursor in the appropriate cell, column, row, or table, and, in the Styles sidebar and/or Properties sidebar, define the required property for that table component.

The following commands are available in the Table menu:

- Insert Table, Delete Table
- Add Table Headers, Footers
- Append/Insert Row/Column
- Delete Row, Column
- Join Cell Left, Right, Below, Above
- Split Cell Horizontally, Vertically
- View Cell Bounds, Table Markup
- Table Properties
- Vertical Alignment of Cell Content

Headers and footers

When you create a dynamic table, you can specify whether you wish to include headers and/or footers. (Footers are allowed only when the table grows top–down.) You can create a header and footer in a static table by manually inserting a top and bottom row, respectively. The structures of headers and footers in both static and dynamic tables can be modified by splitting and joining cells.

Navigating in tables
Use the Tab and arrow keys to navigate the table cells.

Adding cell content
Any type of SPS component can be inserted as the content of a cell. The component should be formatted using the standard formatting tools.

16.10.1 Insert Table, Delete Table

The Insert Table command inserts an empty table in the design tab. Selecting this command opens a dialog box in which you select whether you wish to create a static or dynamic table.

- If you choose to create a static table, a dialog prompts you for the size of the table (in terms of its rows and columns).
If you choose to create a dynamic, the XPath Selector dialog pops up, in which you can select the node that is to be created as a dynamic table. On clicking OK, the Create Dynamic Table dialog pops up, in which you can select the child nodes you wish to display as the fields of each table item. For details, see Creating dynamic tables.

You can change the structure of a table subsequently by appending, inserting, and deleting rows and/or columns.

The Delete Table command deletes the static or dynamic table in which the cursor is.

16.10.2 Add Table Headers, Footers

Table headers can appear as a header row (above the table body) or as a header column (to the left of the table body, though markup-wise a header column might be placed inside the table body). Similarly, table footers can appear as a footer row (below the table body) or as a footer column (to the right of the table body, though markup-wise a footer might be placed inside the table body).

Note: In the HTML output since table headers are enclosed in \texttt{th} elements, they appear bold (because the bold formatting is inherent in the \texttt{th} element).

The Add Table Header and Add Table Footer commands add table headers and footers as columns and rows, as follows:

- \textbf{Add Table Header Column}: Adds a header column to the left of the table body.
- \textbf{Add Table Footer Column}: Adds a footer column to the right of the table body.
- \textbf{Add Table Header Row}: Adds a header row above the table body.
- \textbf{Add Table Footer Row}: Adds a footer row below the table body.

16.10.3 Append/Insert Row/Column

The Append Row command appends a row to the static or dynamic table in which the cursor is.

The Insert Row command inserts a row above the row in which the cursor is. This command applies to both static and dynamic tables.

The Append Column command appends a column to the static or dynamic table in which the cursor is.

The Insert Column command inserts a column to the left of the column in which the cursor is. This command applies to both static and dynamic tables.
16.10.4  Delete Row, Column

The **Delete Row** command deletes the row in which the cursor is. This command applies to both static and dynamic tables.

The **Delete Column** command deletes the column in which the cursor is. This command applies to both static and dynamic tables.

16.10.5  Join Cell Left, Right, Below, Above

The **Join Cell Left** command joins the cell in which the cursor is to the adjacent cell on the left. The contents of both cells are concatenated in the new cell. All property values of the cell to the left are passed to the new cell. This command applies to both static and dynamic tables.

The **Join Cell Right** command joins the cell in which the cursor is to the cell on the right. The contents of both cells are concatenated in the new cell. All property values of the cell to the left are passed to the new cell. This command applies to both static and dynamic tables.

The **Join Cell Below** command joins the cell in which the cursor is to the cell below. The contents of both cells are concatenated in the new cell. All property values of the cell on the top are passed to the new cell. This command applies to both static and dynamic tables.

The **Join Cell Above** command joins the cell in which the cursor is to the cell above. The contents of both cells are concatenated in the new cell. All property values of the cell on top are passed to the new cell. This command applies to both static and dynamic tables.

16.10.6  Split Cell Horizontally, Vertically

The **Split Cell Horizontally** command creates a new cell to the right of the cell in which the cursor is. The contents of the original cell stay in the original cell. All properties of the original cell are passed to the new cell. This command applies to both static and dynamic tables.

The **Split Cell Vertically** command creates a new cell below the cell in which the cursor is. The contents of the original cell remain in the upper cell. All properties of the original cell are passed to the new cell. This command applies to both static and dynamic tables.
16.10.7 View Cell Bounds, Table Markup

The View Cell Bounds and View Table Markup commands display the boundaries of cells and table column and row markup, respectively. With these two options switched on, you can better understand the structure of the table. Switched off, however, you can visualize the table more accurately.

- The View Cell Bounds command toggles the display of table boundaries (borders) on and off for tables that have a table border value of 0.
- The View Table Markup command toggles the display of the blue column and row markers on and off.

16.10.8 Table Properties

The Table Properties command is enabled when the cursor is placed inside a static or dynamic table. Clicking the command, pops up the Properties sidebar, with the Table component selected (screenshot below).

You can now edit the properties of the table. Click OK when done.
16.10.9 Edit CALS/HTML Tables

The Edit CALS/HTML Tables command enables data structures in the XML document that follow the CALS table model or HTML table model to be generated in the output as tables. The table markup in the output formats is derived directly from the XML document. However, additional table formatting styles can be added via the SPS.

Selecting this command pops up the Edit CALS/HTML Tables dialog (screenshot below).

For details about CALS/HTML tables, see the section Tables.

16.10.10 Vertical Alignment of Cell Content

Commands to set the vertical alignment of cell content are available as icons in the Table toolbar. Place the cursor anywhere in the cell, and click the required icon.

- **Vertically Align Top** vertically aligns cell content with the top of the cell.
- **Vertically Align Middle** vertically aligns cell content with the middle of the cell.
- **Vertically Align Bottom** vertically aligns cell content with the bottom of the cell.
16.11 Authentic Menu

The Authentic menu contains commands that enable you to:

- Customize aspects of the Authentic View of an XML document that will be displayed using the SPS.
- Edit documents in the Authentic View preview of StyleVision.

The commands in the Authentic menu are listed below:

- Edit Authentic Scripts
- Custom Toolbar Buttons
- Check Macro References
- Auto-Add Date Picker
- Auto-Add DB Controls
- Reload, Validate XML
- Select New Row with XML Data for Editing
- Define XML Entities
- Markup Commands
- (Dynamic Table) Row Commands

Each of these commands is described in detail in the sub-sections of this section.

16.11.1 Edit Authentic Scripts

The Edit Authentic Scripts command pops up StyleVision's Scripting Editor (screenshot below), in which you can create Forms, Event, and Macros for use in Authentic View.
For an overview of how scripts can be used in Authentic View, see the section, Scripting for Authentic. For a description of how the Scripting Editor works, see the section, Scripting in the Programmers' Reference.

### 16.11.2 Custom Toolbar Buttons

Clicking the **Custom Toolbar Buttons** command pops up the Authentic Custom Buttons dialog (screenshot below), in which you can design a customized Authentic toolbar. After the Authentic toolbar has been saved with an SPS, the toolbar will appear in the Authentic View of Enterprise and Professional editions of Altova products whenever an XML file associated with this SPS is edited in Authentic View.

**Note:** Altova products that have an Authentic View window are: the Enterprise and Professional editions of XMLSpy, and StyleVision and the Enterprise edition of Authentic Desktop and Authentic Browser.
Adding a button

To add a button or separator to the Authentic toolbar, click the Add button at the top right of the dialog. This pops up a menu in which you can select what you wish to add: (i) a text state icon, (ii) a custom button to execute a macro, or (iii) a separator line in the toolbar to separate groups of buttons. Text state icons and custom buttons are described in detail below.

Moving a button and deleting a button

To move a button or separator to another location in the toolbar, select it and drag it to the new position. To delete a button or separator, select it and click the Delete button at the top right of the dialog.

Text state icons

A text state icon defines an icon for a global element. When the Authentic View user selects text in the Authentic View document and clicks a text state icon, then the element that the icon defines is inserted around the selected text. Text state icons are intended for elements that provide inline formatting, such as bold and italic formatting.

To add a text state icon to the Authentic toolbar, click the Add button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select Add Text State Icon. Enter the name of the XML element for which the text state icon is being created, then browse for a bitmap image file for the button or enter a text for the button. You can optionally enter a tooltip as a guide for the Authentic View user when he or she mouses over the text state icon. Click OK to add the button to the Authentic toolbar.
### Custom buttons

When an Authentic View user clicks a custom button in the Authentic toolbar, a macro is executed. In the SPS design you can create a custom button and specify what macro it will trigger.

To add a custom button to the Authentic toolbar, click the **Add** button at the top right of the Authentic Custom Buttons dialog (see screenshot below) and select **Add Custom Toolbar Button**.

---

**Authentic Custom Buttons**

<table>
<thead>
<tr>
<th>Authentic Custom Toolbar</th>
<th>Add text state icon</th>
<th>Add custom toolbar button</th>
<th>Add separator</th>
</tr>
</thead>
<tbody>
<tr>
<td>US EU Clear All B I</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Text State Icon**

Text State Icons are toolbar buttons for specific schema elements which modify text styles, such as bold and italic. Authentic will activate and process them automatically in a mix-content only when allowed by schema. See documentation for more details. Please enter the Element Name and either the Bitmap file path with button picture or button Text. Tooltip is optional.

<table>
<thead>
<tr>
<th>Element Name:</th>
<th>bold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bitmap:</td>
<td>bold.bmp</td>
</tr>
<tr>
<td>Text:</td>
<td>Bold</td>
</tr>
<tr>
<td>Tooltip:</td>
<td></td>
</tr>
<tr>
<td>Identifier:</td>
<td></td>
</tr>
</tbody>
</table>

The screenshot above shows the text state icon for the *bold* element selected. This text state icon uses an image named *bold.bmp*. Text for the button can be entered as a fallback. For the text state icon defined in the screenshot above, if the image cannot be found, then the text *Bold* will be used as the button text.
Custom buttons take the following parameters:

- The location of an image for the button (in the Bitmap field) or text for the button (in the Text field).
- In the Macro Name combo box select a macro from the dropdown list. The macros listed here are those that have been saved with the SPS. When you click the **New** button, the Scripting Editor of StyleVision opens in its own window, enabling you to quickly and easily create a macro and save it with the SPS. Clicking the **Edit** button opens the selected macro for editing in the Scripting Editor.
- You can optionally enter a tooltip as a guide for the Authentic View user when he or she mouses over the custom button.
- In the Identifier field enter a text string that will be used as the identifier of the custom button. This identifier can then be used in scripting code.

The screenshot above shows custom button for the `ChangeAddressToUS` macro. This custom button uses an image named `US.bmp`. Text for the button can be entered as a fallback. A tooltip has been entered and the custom button has the identifier `Address_US`. These examples are from the file `ToolbarButtons.sps` is in the Authentic\Scripting folder of the Examples project in the Project window.

### 16.11.3 Check Macro References

The **Check Macro References** command checks that references from toolbar buttons and scripts to macros are correct. If any incorrect reference is found an error message is displayed.
16.11.4 Auto-Add Date Picker

This is a toggle command that switches the Auto-Add Date Picker feature on and off. When the Auto-Add Date Picker feature is ON, any \texttt{xs:date} or \texttt{xs:dateTime} datatype element that is created as contents or as an input field will have the Date Picker automatically inserted within the element tags and after the \texttt{contents} placeholder or input field.

16.11.5 Auto-Add DB Controls

This is a toggle command that switches the Auto-Add DB Controls feature on and off.

When the Auto-Add DB Controls is on, then, whenever a DB table element is dropped into the design, the DB Controls panel (shown below) is inserted immediately before the \texttt{Row} child element of that DB table element.

The DB Controls panel enables the Authentic View user to navigate the rows of the DB table in Authentic View. The first (leftmost) button navigates to the first record; the second button navigates to the previous record; the third button is the Goto button; it pops up a dialog (screenshot below) that prompts you for the number of the record to which you wish to go; the fourth button navigates to the next record; and the fifth button navigates to the last record.

When the Auto-Add DB Controls toggle is turned off, the DB Controls panel is not inserted when a DB table is dropped into the Design document.

\textbf{Note}: You can manually insert navigation buttons by placing the cursor anywhere between the start and end tags of the DB table and selecting the required option from the \texttt{Insert | DB Controls} submenu. Note that in this submenu the DB Controls panel can be inserted as the four navigation buttons or as the four navigation buttons plus the button that calls the Goto Record dialog.

16.11.6 Reload Authentic View, Validate XML

The \texttt{Reload} command reloads the Authentic XML data file. This can be useful if the file has been modified outside StyleVision, especially by another user working from another machine.
The Validate XML (F8) command checks the validity of the XML file against the associated schema. Whether StyleVision's XSD 1.0 or XSD 1.1 validator is used can be specified in the Properties dialog. Any additional validation requirement that you have entered for individual nodes (Properties sidebar: Additional validation in the Authentic group of properties) is also checked. The result of the validation check is displayed in a pop-up message box.

### 16.11.7 Select New Row with XML Data for Editing

The Select New Row with XML Data for Editing command enables you to select a new row from the relevant table in an XML DB, such as IBM DB2. This row appears in Authentic View, can be edited there, and then saved back to the DB.

When an XML DB is used as the XML data source, the XML data that is displayed in Authentic View is the XML document contained in one of the cells of the XML data column. The Select New Row with XML Data for Editing command enables you to select an XML document from another cell (or row) of that XML column. Selecting the Select New Row... command pops up the Choose XML Field dialog (screenshot below), which displays the table containing the XML column.

![Choose XML field](image)

You can enter a filter for this table. The filter should be an SQL WHERE clause (just the condition, without the WHERE keyword, for example: CID>1002). Click Update to refresh the dialog. In the screenshot above, you can see the result of a filtered view. Next, select the cell containing the required XML document and click OK. The XML document in the selected cell (row) is loaded into Authentic View.
16.11.8 Define XML Entities

The Define XML Entities command is available only in Authentic View. With the Define Entities command in Authentic View, you can define entities that you want to add to your XML document. After an entity has been defined, it can be inserted in the XML document by right-clicking at the location where you wish to insert the entity, and, from the context menu that pops up, selecting Insert Entity, and then the name of the entity to be inserted.

An entity that you define with this command can be any of three types:

- Internal parsed entity. The value of the entity is a text string that usually occurs frequently in the document. Using an entity ensures that all occurrences are expanded to the value defined here.
- External parsed entity. This is an external XML file that will replace each occurrence of the entity. The value of the entity is the URI of the external XML file.
- External unparsed entity. This is an external resource that will be called when the entity is processed. The value of the entity is the URI of the external resource.

Clicking the command, pops up the Define Entities dialog (screenshot below).

![Define Entities dialog]

For a description of how to use this dialog, see Define Entities in the Authentic View documentation.

16.11.9 View Markup

The View Markup command has a submenu with options to control markup in the Authentic XML document. With the four markup commands (screenshot below), you can select between the Hide Markup and the various Show Markup modes.
The markup refers to how the various node tags are displayed in Authentic View. These are mutually exclusive options, and one option must be selected at any given time. With Hide Markup selected node tags are not displayed. Small Markup shows opening and closing tags without node names. Large Markup shows opening and closing node tags with their respective node names. Mixed Markup refers to the markup specified in the Authentic Node Properties of individual nodes. Since the default markup property for individual nodes is Hide Markup, no markup (either small or large) will be displayed—unless you have specified (as a node property) small or large markup for some node/s.

16.11.10 RichEdit

Mousing over the RichEdit command pops out a submenu containing the RichEdit markup commands (screenshot below). The menu commands in this submenu are enabled only in Authentic View and when the cursor is placed inside an element that has been created as a RichEdit component.

The text-styling properties of the RichEdit menu will be applied to the selected text when a RichEdit command is clicked. The Authentic View user can specify the font, font-weight, font-style, font-decoration, font-size, color, background color and alignment of the selected text.

For more information about the RichEdit feature in context, see Text-Styling Flexibility in Authentic.

16.11.11 (Dynamic Table) Row Commands

The (Dynamic Table) Row commands are enabled in Authentic View when the cursor is placed inside the row of a dynamic table. They enable you to manipulate the rows of a dynamic table. You can append, insert, duplicate, and delete rows, and you can move the selected row up and down relative to the other rows of the table. Since a row in a dynamic table represents a fixed data structure, the Authentic View user will be manipulating units of a data structure in the context of the data structure represented by the dynamic table.
A row is selected by placing the cursor inside it. An empty row can then be inserted (before) or appended (after) the selected row. A row can be duplicated, in the sense that a copy of the row plus its content is created after the selected. A row can also be moved up or down relative to adjacent rows.
16.12 Database Menu

The Database menu contains commands to query the connected database and to edit and clear the filters applied to the connected database.

- **Query Database** starts up the Connect to Database process and opens the Database Query window.
- **Edit DB Filter, Clear DB Filter**, to access the Edit DB Filters dialog and clear DB Filters, respectively.

16.12.1 Query Database

The Query Database command pops up the Database Query window (screenshot below), via which you can connect to a database and query it. How to use the Database Query window is explained in the section Query Database.

The Database Query window is toggled on and off by clicking the Query Database command.
16.12.2  Edit DB Filter, Clear DB Filter

The **Edit DB Filter** command allows you to create and edit a filter for a database table (a DB Filter). A DB Filter determines what data from the selected database table is imported and displayed. A DB Filter consists of one or more criteria. When you specify criteria, you use an expression, which is a combination of operators (= or >) and values (text or numbers). Additionally, criteria can be joined by the logical operators **AND** or **OR**.

To create or edit a DB Filter, do the following:

1. Select the top-level data table element for which you wish to create or edit a DB Filter. Do this by clicking either the element tag in Design View or the element name in the schema tree.
2. Select **Database | Edit DB Filter** or click the toolbar icon for the command. This pops up the Edit Database Filters dialog.

3. To add criteria use the **Append AND** and **Append OR** buttons. To move a criterion up or down, use the arrow buttons. To delete a criterion, use the Delete button.
4. Specify the criteria for the DB Filter. Each criterion consists of three parts: **Field Name + Operator + Value**. The options for Field Names and Operators are available in combo boxes. The value of the expression must be keyed in, and may be a parameter (indicated by a preceding $ character).

**Clear DB Filter command**

The **Clear DB Filter** command deletes the filter after asking for and receiving a confirmation from you.
16.13 Properties Menu

The Properties menu contains commands that enable you to insert lists and define datatype formats for the input formatting feature. The description of the commands is organized into the following sub-sections:

- **Bullets and Numbering** command, to insert lists.
- **Predefined Format Strings** command, to define numeric datatype formats for a given SPS.

16.13.1 Edit Bullets and Numbering

The Edit Bullets and Numbering command enables you to insert a list at the cursor location. Clicking the command pops up the Bullets and Numbering dialog (screenshot below), in which you can select the list style; in the case of a numbered list, the initial number can also be specified.

![Bullets and Numbering dialog]

16.13.2 Predefined Value Formatting Strings

Any (content) placeholder, input field, or Auto-Calculation which is of a numeric, date, time, dateTime or duration datatype can be assigned a custom format with the Value Formatting dialog. In the Value Formatting dialog, you can either create a format directly or select from a drop-down list of predefined formats.
The predefined formats that are available in the dropdown list are of two types:

- Predefined formats that have been delivered with StyleVision, and
- Predefined formats that the user creates with the **Predefined Value Formatting Strings** command (this command). When a user creates predefined value formats, these are created for the currently open SPS file—not for the entire application. After the user creates predefined value formats, the SPS file must be saved in order for the formats to be available when the file is next opened.

## Creating a predefined value formatting string

A predefined value format string is specific to a datatype. To create a predefined value formatting string, do the following:

1. Click **Properties | Predefined Value Formatting Strings**. The following dialog appears:

   ![Predefined Value Formatting Strings dialog](image)

   2. Select a datatype from the drop-down list in the combo box, and then click the **Append** or **Insert** icon as required. This pops up the Edit Format String dialog:

   ![Edit Format String dialog](image)

   If you click the down arrow of the combo box, a drop-down list with the StyleVision-supplied predefined formats for that datatype is displayed (shown in the screenshot below).
You can either select a format from the list and modify it, or you can enter a format directly into the input field. The syntax for defining a format is explained in the section, Value Formatting. If you need help with the syntax, use the Insert Field and Field Options buttons.

3. After you have defined a format, click OK and save the SPS file. The formatting string is added to the list of predefined formats for that datatype, and it will appear as an option in the Value Formatting dialog (of the current SPS file) when the selected element is of the corresponding datatype.

Note the following points:

- You can add as many custom format strings for different datatypes as you want.
- The sequential order of format strings in the Predefined Format Strings dialog determines the order in which these format strings appear in the Value Formatting dialog. The customized format strings appear above the supplied predefined formats.
- To edit a custom format string, double-click the entry in the Predefined Format Strings dialog.
- To delete a custom format string, select it, and click the Delete icon in the Predefined Value Formatting Strings dialog.
16.14 Tools Menu

The Tools menu contains the spell-check command and commands that enable you to customize StyleVision.

The description of the Tools menu commands is organized into the following sub-sections:

- Spelling
- Spelling Options
- Global Resources
- Active Configuration
- Customize
- Options

16.14.1 Spelling

The Spelling command runs a spelling check on the SPS (in Design View) or the document in Authentic View, depending on which is active. You can use what language to use from the spellchecker's built-in language dictionaries (see note below).

Note: The selection of built-in dictionaries that ship with Altova software does not constitute any language preferences by Altova, but is largely based on the availability of dictionaries that permit redistribution with commercial software, such as the MPL, LGPL, or BSD licenses. Many other open-source dictionaries exist, but are distributed under more restrictive licenses, such as the GPL license. Many of these dictionaries are available as part of a separate installer located at http://www.altova.com/dictionaries. It is your choice as to whether you can agree to the terms of the license applicable to the dictionary and whether the dictionary is appropriate for your use with the software on your computer.

On clicking this command, the dialog shown below appears. Words that are not present in the selected dictionary are displayed, in document order and one at a time, in the Not in Dictionary field of the dialog and highlighted in the Design Document.
You can then select an entry from the list in the Suggestions pane and click Change or Change All to change the highlighted instance of this spelling or all its instances, respectively. (Double-clicking a word in the Suggestions list causes it to replace the unknown word.) Alternatively, you can ignore this instance of the unknown word (Ignore Once); or ignore all instances of this unknown word (Ignore All); or add this unknown word to the user dictionary (Add to Dictionary). Adding the unknown word to the dictionary causes the spell-checker to treat the word as correct and to pass on to the next word not found in the dictionary. You can recheck the document from the beginning (Recheck Document) or close the dialog (Close) at any time.

The Options button opens the Spelling Options dialog, in which you can specify options for the spelling check.

### 16.14.2 Spelling Options

The Spelling options command opens a dialog box (shown below) in which you specify options for the spelling check.
Always suggest corrections:
Activating this option causes suggestions (from both the language dictionary and the user dictionary) to be displayed in the Suggestions list box. Disabling this option causes no suggestions to be shown.

Make corrections only from main dictionary:
Activating this option causes only the language dictionary (main dictionary) to be used. The user dictionary is not scanned for suggestions. It also disables the User Dictionary button, preventing any editing of the user dictionary.

Ignore words in UPPER case:
Activating this option causes all upper case words to be ignored.

Ignore words with numbers:
Activating this option causes all words containing numbers to be ignored.

Split CamelCase words
CamelCase words are words that have capitalization within the word. For example the word "CamelCase" has the "C" of "Case" capitalized, and is therefore said to be CamelCased. Since CamelCased words are rarely found in dictionaries, the spellchecker would flag them as errors. To avoid this, the Split CamelCase words option splits CamelCased words into their capitalized components and checks each component individually. This option is checked by default.

Dictionary Language
Use this combo box to select the dictionary language for the spellchecker. The default selection is US English. Other language dictionaries are available for download free of charge from the Altova website.

Adding dictionaries for the spellchecker
For each dictionary language there are two Hunspell dictionary files that work together: a .aff file and .dic
All language dictionaries are installed in a Lexicons folder at the following location: 
C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons.

Within the Lexicons folder, different language dictionaries are each stored in a different folder: <language name><dictionary files>. For example, files for the two English-language dictionaries (English (British) and English (US)) will be stored as below:

C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (British)\en_GB.aff
C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (British)\en_GB.dic
C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (US)\en_US.aff
C:\ProgramData\Altova\SharedBetweenVersions\SpellChecker\Lexicons\English (US)\en_US.dic

In the Spelling Options dialog, the dropdown list of the Dictionary Language combo box displays the language dictionaries. These dictionaries are those available in the Lexicons folder and have the same names as the language subfolders in the Lexicons folder. For example, in the case of the English-language dictionaries shown above, the dictionaries would appear in the Dictionary Language combo box as: English (British) and English (US).

All installed dictionaries are shared by the different users of the machine and the different major versions of Altova products (whether 32-bit or 64-bit).

You can add dictionaries for the spellchecker in two ways, neither of which require that the files be registered with the system:

- By adding Hunspell dictionaries into a new subfolder of the Lexicons folder. Hunspell dictionaries can be downloaded, for example, from https://wiki.openoffice.org/wiki/Dictionaries or http://extensions.services.openoffice.org/en/dictionaries. (Note that OpenOffice uses the zipped OXT format. So change the extension to .zip and unzip the .aff and .dic file to the language folders in the Lexicons folder. Also note that Hunspell dictionaries are based on Myspell dictionaries. So Myspell dictionaries can also be used.)
- By using the Altova dictionary installer, which installs a package of multiple language dictionaries by default to the correct location on your machine. The installer can be downloaded via the link in the Dictionary language pane of the Spelling Options dialog (see screenshot below). Installation of the dictionaries must be done with administrator rights, otherwise installation will fail with an error.

Note: It is your choice as to whether you agree to the terms of the license applicable to the dictionary and whether the dictionary is appropriate for your use with the software on your computer.

Working with the user dictionary

Each user has one user dictionary, in which user-allowed words can be stored. During a spellcheck, spellings are checked against a word list comprising the words in the language dictionary and the user dictionary. You can add words to and delete words from the user dictionary via the User Dictionary dialog (screenshot below). This dialog is accessed by clicking the User Dictionary button in the Spelling Options dialog (see second
To add a word to the user dictionary, enter the word in the Word text box and click **Add**. The word will be added to the alphabetical list in the Dictionary pane. To delete a word from the dictionary, select the word in the Dictionary pane and click **Delete**. The word will be deleted from the Dictionary pane. When you have finished editing the User Dictionary dialog, click **OK** for the changes to be saved to the user dictionary.

Words may also be added to the User Dictionary during a spelling check. If an unknown word is encountered during a spelling check, then the Spelling dialog pops up prompting you for the action you wish to take. If you click the **Add to Dictionary** button, then the unknown word is added to the user dictionary.

The **user dictionary** is located at: \C:\Users\<user>\Documents\Altova\SpellChecker\Lexicons\user.dic

### 16.14.3 Global Resources

The **Global Resources** command pops up the Altova Global Resources dialog (screenshot below), in which you can:

- Specify the Altova Global Resources XML File to use for global resources.
- Add file, folder, and database global resources (or aliases)
- Specify various configurations for each global resource (alias). Each configuration maps to a specific resource.
How to define global resources is described in detail in the section, Defining Global Resources.

Note: The Altova Global Resources dialog can also be accessed via the Global Resources toolbar (View | Toolbars | Global Resources).

16.14.4 Active Configuration

Mousing over the Active Configuration menu item rolls out a submenu containing all the configurations defined in the currently active Global Resources XML File (screenshot below).

The currently active configuration is indicated with a bullet. In the screenshot above the currently active configuration is Default. To change the active configuration, select the configuration you wish to make active.

Note: The active configuration can also be selected via the Global Resources toolbar (View | Toolbars | Global Resources).
16.14.5 Customize

The customize command lets you customize StyleVision to suit your personal needs.

Commands tab

The Commands tab of the Customize dialog allows you to place individual commands in the menu bar and the toolbar.

To add a command to the menu bar or toolbar, select the command in the Commands pane of the Commands tab, and drag it to the menu bar or toolbar. When the cursor is placed over a valid position an I-beam appears, and the command can be dropped at this location. If the location is invalid, a check mark appears. When you drop the command it is created as an icon if the command already has an associated icon; otherwise the command is created as text. After adding a command to the menu bar or toolbar, you can edit its appearance by right-clicking it and then selecting the required action.

To delete a menu bar or toolbar item, with the Customize dialog open, right-click the item to be deleted, and select Delete.

Note:

- The customization described above applies to the application, and applies whether a document is open in StyleVision or not.
- To reset menus and toolbars to the state they were in when StyleVision was installed, go to the Toolbars tab and click the appropriate Reset button.
Toolbars tab
The **Toolbars** tab allows you to activate or deactivate specific toolbars, to show text labels for toolbar items, and to reset the menu bar and toolbars to their installation state.

Each toolbar can be divided into groups of commands. Commands can be added to a toolbar via the Commands tab. A toolbar can be dragged from its docked position to any location on the screen. Double-clicking a toolbar’s (maximized or minimized) title bar docks and undocks the toolbar.

In the Toolbars tab of the Customize dialog, you can toggle a toolbar on and off by clicking in its checkbox. When a toolbar is selected (in the Toolbars tab), you can cause the text labels of that toolbar’s items to be displayed by clicking the **Show text labels** check box. You can also reset a selected toolbar to the state it was in when StyleVision was installed by clicking the **Reset** button. You can reset all toolbars and the menu bar by clicking the **Reset All** button.

**Note about Menu Bar**
Commands can be added to, and items deleted from, the menu bar: see Commands above. To reset the menu bar to the state it was in when StyleVision was installed, select Menu Bar in the Toolbars tab of the Customize dialog, and click the **Reset** button. (Clicking the **Reset All** button will reset the toolbars as well.)

Keyboard tab
The **Keyboard** tab allows you to define (or change) keyboard shortcuts for any StyleVision command.
To assign a shortcut to a command

1. Select the category in which the command is by using the Category combo box.
2. Select the command you want to assign a shortcut to in the Commands list box.
3. Click in the Press New Shortcut Key input field, and press the shortcut keys that are to activate the command. The shortcut immediately appears in the Press New Shortcut Key input field. If this shortcut has already been assigned to a command, then that command is displayed below the input field. (For example, in the screenshot above, Ctrl+C has already been assigned to the Copy command and cannot be assigned to the Open File command.) To clear the New Shortcut Key input field, press any of the control keys, Ctrl, Alt, or Shift.
4. Click the Assign button to permanently assign the shortcut. The shortcut now appears in the Current Keys list box.

To de-assign (or delete) a shortcut

1. Select the command for which the shortcut is to be deleted.
2. Click the shortcut you want to delete in the Current Keys list box.
3. Click the Remove button (which has now become active).

To reset all keyboard assignments

1. Click the Reset All button to go back to the original, installation-time shortcuts. A dialog box appears prompting you to confirm whether you want to reset all keyboard assignments.
2. Click Yes if you want to reset all keyboard assignments.

Set accelerator for
Currently no function is available.
Menu tab

The Menu tab allows you to customize the main menu bar as well as the context menus (right-click menus). There are two types of main menu bar: Default (which appears when no document is open), and SPS (which appears when an SPS document is open).

To customize a menu
1. Select the menu bar you want to customize (SPS menu in the screenshot above).
2. Click the Commands tab, and drag the commands to the menu bar of your choice.

To delete commands from a menu
1. In the Application Frame Menus pane, select either Default (which shows available menus when no document is open) or SPS (which shows available menus when one or more documents are open).
2. With the Customize dialog open, select (i) the menu you want to delete from the application's menu bar, or (ii) the command you want to delete from one of these menus.
3. Either (i) drag the menu from the menu bar or the menu command from the menu, or (ii) right-click the menu or menu command and select Delete.

To reset either of the menu bars
1. Select the menu entry you want to reset in the combo box of the Application Frame Menus pane.
2. Click the Reset button just below the menu name. A prompt appears asking if you are sure you want to reset the menu bar.

To customize a context menu (a right-click menu)
1. Select the context menu from the combo box.
2. Click the Commands tab and drag the commands to the context menu that is now open.
To delete commands from a context menu
1. Click right on the command or icon representing the command.
2. Select the **Delete** option from the popup menu or drag the command away from the context menu and drop it as soon as the check mark icon appears below the mouse pointer.

To reset a context menu
1. Select the context menu from the combo box, and
2. Click the **Reset** button just below the context menu name. A prompt appears asking if you are sure you want to reset the context menu.

To close a context menu window
- Click on the **Close** icon at the top right of the title bar, or
- Click the **Close** button of the Customize dialog box.

**Menu animations**
The menu animation option specifies the way a menu is displayed when a menu is clicked. Select an option from the drop-down list of menu animations.

**Menu shadows**
If you wish to have menus displayed with a shadow around it, select this option. All menus will then have a shadow.

**Options tab**
The **Options** tab allows you to customize additional features of the toolbar.

Screen Tips for toolbar items will be displayed if the Show Screen Tips option is checked. The Screen Tips option has a sub-option for whether shortcuts (where available) are displayed in the Screen Tips or not.

### 16.14.6 Restore Toolbars and Windows

This command restores toolbars, windows, entry helpers and other GUI components to their default state. You will need to restart StyleVision for the changes to take effect.

### 16.14.7 Options

The **Options** command opens a dialog (*screenshot below*) in which you can specify the encoding of the HTML output file.

**Design options**
In the Design tab (*screenshot below*), you can set the application-wide general options for designs.
The following options can be set:

- Maximum width (in pixels) of markup tags. Enter the positive integer that is the required number of pixels.
- Grid size of layout containers in absolute length units. The specified lengths are the distances between two points on the respective grid axis.
- Default additional width and height of Layout Boxes. These additional lengths are added to all layout boxes in order to provide the extra length that is often required to accommodate the bigger text renditions of print formats. These values can be specified as percentage values or as absolute length units.
- The default behavior when a node-template is created at a location where the context node is not known. This option typically applies to User-Defined Templates in which the template has been created for items that cannot be placed in context in the schema source of the design. If a node is created within such a user-defined template, then the node can be created with (i) only its name, or (ii) with the full path to it from the schema root. You can set one of these options as the default behavior, or, alternatively, ask to be prompted each time this situation arises. The default selection for this option is *Always Ask*. 
Schema options
In the Schema Tree, elements and attributes can be listed alphabetically in ascending order. To do this, check the respective check boxes in the Schema Options tab. By default, attributes are listed alphabetically and elements are listed in an order corresponding to the schema structure, as far as this is possible.

Project options
In the Project sidebar, when an XML file or XSD file is double-clicked, one of three actions is executed depending on the options set in the Project tab of the Options dialog: (i) Edit the file in XMLSpy; (ii) Create a new design based on the selected file; (iii) Ask the user which action to execute.

Default encoding
In the Default Encoding tab (screenshot below), you can set default encodings for the various outputs separately. The encoding specifies the codepoints sets for various character sets. The dropdown list of each combo box displays a list of encoding options. Select the encoding you require for each output type, and click OK. Every new SPS you create from this point on will set the respective output encodings as defined in this tab.

In the XSLT-for-HTML, the output encoding information is registered at the following locations:

- In the encoding attribute of the stylesheet's xsl:output element:
  `<xsl:output version="1.0" encoding="UTF-8" indent="no" omit-xml-declaration="no"
  media-type="text/html"` /`

- In the charset attribute of the content-type meta element in the HTML header:
  `<meta http-equiv="Content-Type" content="text/html; charset=UTF-8"` /

In the XSLT-for-RTF, the output encoding information is registered in the encoding attribute of the stylesheet's xsl:output element:

 `<xsl:output version="1.0" encoding="ISO-8859-1" indent="no" method="text" omit-xml-declaration="yes"
  media-type="text/rtf"` /

Note: These settings are the default encodings, and will be used for new SPSs. You cannot change the encoding of the currently open SPS using this dialog. To change the encoding of the currently open SPS, use the File | Properties command.

XSL options
In the meta information of HTML output files, the line, 'Generated by StyleVision', will be generated by default. Purchased versions of the product provide an option to disable the generation of this line.

Network Proxy options
The Network Proxy section enables you to configure custom proxy settings. These settings affect how the application connects to the Internet (for XML validation purposes, for example). By default, the application uses the system's proxy settings, so you should not need to change the proxy settings in most cases. If necessary, however, you can set an alternative network proxy using the options below.

Note: The network proxy settings are shared among all Altova MissionKit applications. So, if you change the settings in one application, all MissionKit applications will be affected.
Use system proxy settings
Uses the Internet Explorer (IE) settings configurable via the system proxy settings. It also queries the settings configured with `netsh.exe winhttp`.

Automatic proxy configuration
The following options are provided:

- **Auto-detect settings**: Looks up a WPAD script (`http://wpad.LOCALDOMAIN/wpad.dat`) via DHCP or DNS, and uses this script for proxy setup.
- **Script URL**: Specify an HTTP URL to a proxy-auto-configuration (.pac) script that is to be used for proxy setup.
- **Reload**: Resets and reloads the current auto-proxy-configuration. This action requires Windows 8 or newer, and may need up to 30s to take effect.

Manual proxy configuration
Manually specify the fully qualified host name and port for the proxies of the respective protocols. A supported scheme may be included in the host name (for example: `http://hostname`). It is not required that the scheme is the same as the respective protocol if the proxy supports the scheme.

The following options are provided:

- **Use this proxy for all protocols**: Uses the host name and port of the HTTP Proxy for all protocols.
- **No Proxy for**: A semi-colon (:) separated list of fully qualified host names, domain names, or IP addresses for hosts that should be used without a proxy. IP addresses may not be truncated and IPv6
addresses have to be enclosed by square brackets (for example: 

- **Do not use the proxy server for local addresses**: If checked, adds <local> to the No Proxy for list. If this option is selected, then the following will not use the proxy: (i) 127.0.0.1, (ii) [:1], (iii) all host names not containing a dot character (\(\dot{\ })

**Current proxy settings**

Provides a verbose log of the proxy detection. It can be refreshed with the **Refresh** button to the right of the **Test URL** field (for example, when changing the test URL, or when the proxy settings have been changed).

- **Test URL**: A test URL can be used to see which proxy is used for that specific URL. No I/O is done with this URL. This field must not be empty if proxy-auto-configuration is used (either through **Use system proxy settings** or **Authomatic proxy configuration**).

**MobileTogether Design**

The options listed below are available for the conversion of SPS files to MobileTogether Design (MTD) files. (These conversions are done via the **Export as MobileTogether Design File** command.)

- Static text and paragraph-level text that contain inline formatting (for example a paragraph element that contains a bold or italic element) is by default converted into a single MTD label, where the text will have the formatting of the block-level text. You can however set an option to split this kind of text (block-level text with inline formatting) into multiple MTD labels, where each label has the formatting that corresponds to the original text fragment.
- If the SPS has a condition with branches, then the conversion to MTD will, by default, convert all branches of the condition and will position them in sequence one below the other in the MTD document. You can optionally choose to suppress the conversion of the condition (and all its branches).

**Java options**

On the **Java** tab, you can optionally enter the path to a Java VM (Virtual Machine) on your file system. Note that adding a custom Java VM path is not always necessary. By default, StyleVision attempts to detect the Java VM path automatically by reading (in this order) the Windows registry and the JAVA_HOME environment variable. The custom path added on this dialog box will take priority over any other Java VM path detected automatically.

You may need to add a custom Java VM path, for example, if you are using a Java virtual machine which does not have an installer and does not create registry entries (for example, Oracle's OpenJDK). You might also want to set this path if you need to override, for whatever reason, any Java VM path detected automatically by StyleVision.
Note the following:

- The Java VM path is shared between Altova desktop (not server) applications. Consequently, if you change it in one application, it will automatically apply to all other Altova applications.
- The path must point to the `jvm.dll` file from the `\bin\server` or `\bin\client` directory, relative to the directory where the JDK was installed.
- The StyleVision platform (32-bit, 64-bit) must be the same as that of the JDK.
- After changing the Java VM path, you may need to restart StyleVision for the new settings to take effect.

Changing the Java VM path affects the following areas:

- JDBC connectivity
- Java extension functions for XSLT/XPath
- Barcode support
16.15 Window Menu

The **Window menu** has commands to specify how StyleVision windows should be displayed in the GUI (cascaded, tiled, or maximized). To maximize a window, click the maximize button of that window.

Additionally, all currently open document windows are listed in this menu by document name, with the active window being checked. To make another window active, click the name of the window you wish to make active.

**Windows dialog**

At the bottom of the list of open windows is an entry for the Windows dialog. Clicking this entry opens the Windows dialog, which displays a list of all open windows and provides commands that can be applied to the selected window/s. (A window is selected by clicking on its name.)

**Warning:** To exit the Windows dialog, click **OK**; do not click the Close Window(s) button. The Close Window(s) button closes the window/s currently selected in the Windows dialog.
16.16  Help Menu

The Help menu contains commands to access the onscreen help manual for StyleVision, commands to provide information about StyleVision, and links to support pages on the Altova web site. The Help menu also contains the Registration dialog, which lets you enter your license key-code once you have purchased the product.

The description of the Help menu commands is organized into the following sub-sections:

- **Table of Contents, Index, Search**
- **Activation, Order Form, Registration, Updates**
- **Other Commands**

16.16.1  Table of Contents, Index, Search

**Table of Contents**

**Description**

Opens the onscreen help manual of StyleVision with the Table of Contents displayed in the left-hand-side pane of the Help window. The Table of Contents provides an overview of the entire Help document. Clicking an entry in the Table of Contents takes you to that topic.

**Index**

**Description**

Opens the onscreen help manual of StyleVision with the Keyword Index displayed in the left-hand-side pane of the Help window. The index lists keywords and lets you navigate to a topic by double-clicking the keyword. If a keyword is linked to more than one topic, a list of these topics is displayed.

**Search**

**Description**

Opens the onscreen help manual of StyleVision with the Search dialog displayed in the left-hand-side pane of the Help window. To search for a term, enter the term in the input field, and (i) press Enter or (ii) click List Topics. The Help system performs a full-text search on the entire Help documentation and returns a list of hits. Double-click any item to display that item.

16.16.2  Activation, Order Form, Registration, Updates

**Software Activation**

**Description**

After you download your Altova product software, you can license—or activate—it using either a free
evaluation key or a purchased permanent license key.

- **Free evaluation license.** When you first start the software after downloading and installing it, the Software Activation dialog will pop up. In it is a button to request a free evaluation license. Enter your name, company, and e-mail address in the dialog that appears, and click **Request.** A license file is sent to the e-mail address you entered and should reach you in a few minutes. Save the license file to a suitable location. When you clicked **Request,** an entry field appeared at the bottom of the Request dialog. This field takes the path to the license file. Browse for or enter the path to the license file, and click **OK.** (In the Software Activation dialog, you can also click **Upload a New License** to access a dialog in which the path to the license file is entered.) The software will be unlocked for a period of 30 days.

- **Permanent license key.** The Software Activation dialog contains a button to purchase a permanent license key. Clicking this button takes you to Altova's online shop, where you can purchase a permanent license key for your product. Your license will be sent to you by e-mail in the form of a license file, which contains your license-data. There are three types of permanent license: installed, concurrent user, and named user. An **installed license** unlocks the software on a single computer. If you buy an **installed license** for \( N \) computers, then the license allows use of the software on up to \( N \) computers. A **concurrent-user license** for \( N \) concurrent users allows \( N \) users to run the software concurrently. (The software may be installed on \( 10N \) computers.) A **named-user license** authorizes a **specific user** to use the software on up to 5 different computers. To activate your software, click **Upload a New License,** and, in the dialog that appears, browse for or enter the path to the license file, and click **OK.**

**Note:** For multi-user licenses, each user will be prompted to enter his or her own name.

---

**Your license email and the different ways to license (activate) your Altova product**

The license email that you receive from Altova will contain your license file as an attachment. The license file has a `.altova_licenses` file extension.

To activate your Altova product, you can do one of the following:

- Save the license file (`.altova_licenses`) to a suitable location, double-click the license file, enter any requested details in the dialog that appears, and finish by clicking **Apply Keys.**
- Save the license file (`.altova_licenses`) to a suitable location. In your Altova product, select the menu command **Help | Software Activation,** and then **Upload a New License.** Browse for or enter the path to the license file, and click **OK.**
- Save the license file (`.altova_licenses`) to any suitable location, and upload it from this location to the license pool of your Altova LicenseServer. You can then either: (i) acquire the license from your Altova product via the product’s Software Activation dialog (*see below*), or (ii) assign the license to the product from Altova LicenseServer. For more information about licensing via LicenseServer, read the rest of this topic.

---

The Software Activation dialog (*screenshot below*) can be accessed at any time by clicking the **Help | Software Activation** command.
You can activate the software by either:

- **Registering the license in the Software Activation dialog.** In the dialog, click **Upload a New License**, and browse for and select the license file. Click **OK** to confirm the path to the license file and to confirm any data you entered (your name in the case of multi-user licenses). Finish by clicking **Save**.

- **Licensing via an Altova LicenseServer on your network:** To acquire a license via an Altova LicenseServer on your network, click **Use Altova LicenseServer**, located at the bottom of the Software Activation dialog. Select the machine on which the LicenseServer you want to use has been installed. Note that the auto-discovery of License Servers works by means of a broadcast sent out on the LAN. As these broadcasts are limited to a subnet, License Server must be on the same subnet as the client machine for auto-discovery to work. If auto-discovery does not work, then type in the name of the server. The Altova LicenseServer must have a license for your Altova product in its license pool. If a license is available in the LicenseServer pool, this is indicated in the Software Activation dialog (see screenshot below showing the dialog in Altova XMLSpy). Click **Save** to acquire the license.

![Screenshot of Software Activation dialog](image)

After a machine-specific (aka installed) license has been acquired from a LicenseServer, it cannot be returned to the LicenseServer for a period of seven days. After that time, you can return the machine license to LicenseServer (click **Return License**) so that this license can be acquired from LicenseServer by another client. (A LicenseServer administrator, however, can unassign an acquired license at any time via the administrator's Web UI of LicenseServer.) Note that the returning of licenses applies only to machine-specific licenses, not to concurrent licenses.

**Check out license**

You can check out a license from the license pool for a period of up to 30 days so that the license is stored on the product machine. This enables you to work offline, which is useful,
for example, if you wish to work in an environment where there is no access to your Altova LicenseServer (such as when your Altova product is installed on a laptop and you are traveling). While the license is checked out, LicenseServer displays the license as being in use, and the license cannot be used by any other machine. The license automatically reverts to the checked-in state when the check-out period ends. Alternatively, a checked-out license can be checked in at any time via the Check In button of the Software Activation dialog.

To check out a license, do the following: (i) In the Software Activation dialog, click Check out License (see screenshot above); (ii) In the License Check-out dialog that appears, select the check-out period you want and click Check out. The license will be checked out. After checking out a license, two things happen: (i) The Software Activation dialog will display the check-out information, including the time when the check-out period ends; (ii) The Check out License button in the dialog changes to a Check In button. You can check the license in again at any time by clicking Check In. Because the license automatically reverts to the checked-in status after the check-out period elapses, make sure that the check-out period you select adequately covers the period during which you will be working offline.

**Note:** For license check-outs to be possible, the check-out functionality must be enabled on LicenseServer. If this functionality has not been enabled, you will get an error message to this effect when you try to check out. In this event, contact your LicenseServer administrator.

*Copy Support Code*

Click Copy Support Code to copy license details to the clipboard. This is the data that you will need to provide when requesting support via the online support form.

Altova LicenseServer provides IT administrators with a real-time overview of all Altova licenses on a network, together with the details of each license, as well as client assignments and client usage of licenses. The advantage of using LicenseServer therefore lies in administrative features it offers for large-volume Altova license management. Altova LicenseServer is available free of cost from the Altova website. For more information about Altova LicenseServer and licensing via Altova LicenseServer, see the Altova LicenseServer documentation.
Checks with the Altova server whether a newer version than yours is currently available and displays a message accordingly.

16.16.3 Other Commands

- **Support Center**
  
  *Description*
  
  A link to the Altova Support Center on the Internet. The Support Center provides FAQs, discussion forums where problems are discussed, and access to Altova's technical support staff.

- **FAQ on the Web**
  
  *Description*
  
  A link to Altova's FAQ database on the Internet. The FAQ database is constantly updated as Altova support staff encounter new issues raised by customers.

- **Download Components and Free Tools**
  
  *Description*
  
  A link to Altova's Component Download Center on the Internet. From here you can download a variety of companion software to use with Altova products. Such software ranges from XSLT and XSL-FO processors to Application Server Platforms. The software available at the Component Download Center is typically free of charge.

- **StyleVision on the Internet**
  
  *Description*
  
  A link to the Altova website on the Internet. You can learn more about StyleVision and related technologies and products at the Altova website.

- **About StyleVision**
  
  *Description*
  
  Displays the splash window and version number of your product. If you are using the 64-bit version of StyleVision, this is indicated with the suffix (x64) after the application name. There is no suffix for the 32-bit version.
17 Programmers' Reference

StyleVision as an Automation Server

StyleVision is an Automation Server. That is, it is an application that exposes programmable objects to other applications (called Automation Clients). As a result, an Automation Client can directly access the objects and functionality that the Automation Server makes available. This is beneficial to an Automation Client because it can make use of the functionality of StyleVision. For example, an Automation Client can generate an XSLT file from an SPS via StyleVision. Developers can therefore improve their applications by using the ready-made functionality of StyleVision.

The programmable objects of StyleVision are made available to Automation Clients via the StyleVision API, which is a COM API. A complete description of all available objects are provided in this documentation (see the section Application API).
17.1 Scripting Editor

Scripting Editor is a development environment built into StyleVision from where you can customize the functionality of the Authentic View with the help of JScript or VBScript scripts. For example, you can add a new toolbar button that performs a custom task such as text formatting, or you can have StyleVision display a notification message box each time when an action is taken in the Authentic View. To make this possible, you create scripting projects—files with .asprj extension (Altova Scripting Project).

Scripting Editor

Scripting projects are portable; you can create them as part of the .sps (StyleVision Power Stylesheet) file. An Altova application that consumes the .sps file will be able to execute the macros inside the project—this can be not only StyleVision, but also XMLSpy or Authentic Desktop.

17.1.1 Creating a Scripting Project

All scripts and scripting information created in the Scripting Editor are stored in Altova Scripting Projects (.asprj files). A scripting project may contain macros, application event handlers, and forms (which can have their own event handlers). In addition, you can add global variables and functions to a "Global Declarations" script—this makes such variables and functions accessible across the entire project. To start a new project:

1. Create or open the .sps file that the scripting project should be part of.
2. Do one of the following:
   - On the Authentic menu, click Authentic Scripts.
   - Click the Design tab at the base of the main window, and then select Authentic Script.

Each .sps file can have a single scripting project assigned to it. To open an existing scripting project associated with an .sps file, follow the same instructions as above. This opens the Scripting Editor window. As you edit the scripting project, you can temporarily save changes in memory, by clicking the Save button at the base of Scripting Editor. To save the scripting project to disk, first click Save & Close in Scripting Editor, and then save the .sps file.

The languages supported for use in a scripting project are JScript and VBScript (not to be confused with Visual Basic, which is not supported). These scripting engines are available by default on Windows and have no special requirements to run. You can select a scripting language as follows:

1. Right-click the Project item in the upper-left pane, and select Project settings from the context menu.
2. Select a language (JScript or VBScript), and click OK.

From the Project settings dialog box above, you can also change the target .NET Framework version. This is typically necessary if your scripting project requires features available in a newer .NET Framework version. Note that any clients using your scripting project will need to have the same .NET Framework version installed (or a later compatible version).

By default, a scripting project references several .NET assemblies, like System, System.Data, System.Windows.Forms, and others. If necessary, you can import additional .NET assemblies, including assemblies from .NET Global Assembly Cache (GAC) or custom .dll files. You can import assemblies as follows:

1. Statically, by adding them manually to the project. Right-click Project in the top-left pane, and select Add .NET Assembly from the context menu.
2. Dynamically, at runtime, by calling the CLR.LoadAssembly command from the code.
The next sections focus on the parts that your scripting project may need: global declarations, macros, forms, and events. For further information about scripting and examples of scripting projects, see Authentic Scripting.

17.1.1.1 Overview of the Environment

The Scripting Editor consists of the following parts:

- Toolbar
- Project pane
- Properties pane
- Main window
- Toolbox

The scripting project is saved when you save the .sps file of which the scripting project is part of. The Save button illustrated above creates only a temporary in-memory copy.

**Toolbar**

The toolbar includes the Undo (Ctrl+Z) and Redo (Ctrl+Y) commands and editor commands (Copy, Cut, Delete, Paste). When editing source code, the Find and Replace commands are additionally available, as well as the Print command.
Project pane
The project pane helps you view and manage the structure of the project. A scripting project consists of several components that can work together and may be created in any order:

- A "Global Declarations" script. As the name suggests, this script stores information available globally across the project. You can declare in this script any variables or functions that you need to be available in all forms, event handler scripts, and macros.
- Forms. Forms are typically necessary to collect user input, or provide some informative dialog boxes. A form is invoked by a call to it either within a function (in the Global Declarations script) or directly in a macro.
- Events. The "Events" folder displays StyleVision application events provided by the COM API. To write a script that will be executed when an event occurs, double-click any event, and then type the handling code in the editor. The application events should not be confused with form events; the latter are handled at form level, as further detailed below.
- Macros. A macro is a script that can be invoked either on demand from a context menu or be executed automatically when StyleVision starts. Macros do not have parameters or return values. A macro can access all variables and functions declared in the Global Declarations script and it can also display forms.

Right-click any of the components to see the available context menu commands and their shortcuts. Double-click any file (such as a form or a script) to open it in the main window.

The toolbar buttons provide the following quick commands:

- New macro  Adds a new macro to the project, in the Macros directory.
- New form  Adds a new form to the project, in the Forms directory.

Properties pane
The Properties pane is very similar to the one in Visual Studio. It displays the following:

- Form properties, when a form is selected
- Object properties, when an object in a form is selected
- Form events, when a form is selected
- Object events, when an object in a form is selected

To switch between the properties and events of the selected component, click the Properties or Events buttons, respectively.

The Categorized and Alphabetical icons display the properties or events either organized by category or organized in ascending alphabetical order.

When a property or event is selected, a short description of it is displayed at the bottom of the Properties pane.
Main window
The main window is the working area where you can enter source code or modify the design of the form. When editing forms, you can work in two tabs: the Design tab and the Source tab. The Design tab shows the layout of the form, while the Source tab contains the source code such as handler methods for the form events.

The source code editor provides code editing aids such as syntax coloring, source code folding, highlighting of starting and ending braces, zooming, autocompletion suggestions, bookmarks.

Autocompletion suggestions
JScript and VBScript are untyped languages, so autocompletion is limited to COM API names and StyleVision built-in commands. The full method or property signature is shown next to the autocompletion entry helper.

Placing the mouse over a known method or property displays its signature (and documentation if available), for example:
The auto-completion entry helper is normally shown automatically during editing, but it can also be obtained on demand by pressing Ctrl+Space.

Bookmarks
- To set or remove a bookmark, click inside a line, and then press Ctrl+F2
- To navigate to the next bookmark, press F2
- To navigate to the previous bookmark, press Shift+F2
- To delete all bookmarks, press Ctrl+Shift+F2

Zooming in/out
- To zoom in or out, hold the Ctrl key pressed and then press the "+" or "-" keys or rotate the mouse wheel.

Text view settings
To trigger text settings, right-click inside the editor, and select Text View Settings from the context menu.

Font settings
To change the font, right-click inside the editor, and select Text View Font from the context menu.
Toolbox
The Toolbox contains all the objects that are available for designing forms, such as buttons, text boxes, combo boxes, and so on.

To add a Toolbox item to a form:

1. Create or open a form and make sure that the Design tab is selected.
2. Click the Toolbox object (for example, Button), and then click at the location in the form where you wish to insert it. Alternatively, drag the object directly onto the form.

Some objects such as Timer are not added to the Form but are created in a tray at the bottom of the main window. You can select the object in the tray and set properties and event handlers for the object from the Properties pane. For an example of handling tray components from the code, see Handling form events.

You can also add registered ActiveX controls to the form. To do this, right-click the Toolbox area and select Add ActiveX Control from the context menu.

17.1.1.2 Global Declarations
The "Global Declarations" script is present by default in any scripting project; you do not need to create it explicitly. Any variables or functions that you add to this script are considered global across the entire project. Consequently, you can refer to such variables and functions from any of the project's macros and events. The following is an example of a global declarations script that imports the System.Windows.Forms namespace into the project. To achieve that, the code below invokes the CLR.Import command built into Scripting Editor.

```javascript
// import System.Windows.Forms namespace for all macros, forms and events:
CLR.Import( "System.Windows.Forms" );
```

Note: Every time a macro is executed or an event handler is called, the global declarations are re-initialized.

17.1.1.3 Macros
Macros are scripts that contain JScript (or VBScript, depending on your project's language) statements, such as variable declarations and functions.

If your projects should use macros, you can add them as follows: right-click inside the Project pane, select Add Macro from the context menu, and then enter the macro's code in the main form. The code of a macro could be as simple as an alert, for example:

```javascript
alert("Hello, I'm a macro!");
```

More advanced macros can contain variables and local functions. Macros can also contain code that invokes forms from the project. The listing below illustrates an example of a macro that shows a form. It is assumed that this form has already been created in the "Forms" folder and has the name "SampleForm", see also Forms.
// display a form
ShowForm( "SampleForm" );

In the code listing above, `ShowForm` is a command built into Scripting Editor. For reference to other similar commands that you can use to work with forms and .NET objects, see the [Built-in Commands](#).

Only one macro can be run at a time. After a macro (or event) is executed, the script is closed and global variables lose their values.

To run a macro directly in Script Editor, click **Run Macro**. To debug a macro using the Visual Studio debugger, click **Debug Macro**.

**Running macros**

To run a macro, you need to first bind the macro to an Authentic event. The macro will run when that Authentic event is triggered. For example, say you wish to run a macro before editing text in Authentic. You must go about this as follows:

1. In Design View, select the editable content for which the macro is to be set.
2. In the Properties sidebar (screenshot below), select the **Authentic** group of properties of the relevant design component.

![Properties Sidebar Screenshot](screenshot)

3. Select the Authentic event that will trigger the macro and open the dropdown list of this event’s **Value** combo box. All the macros defined in the Scripting Project of the SPS will be listed. Select the macro you wish to associate with this function.
4. In Authentic View, when any Authentic event that has a macro assigned to it is triggered, then the macro will be executed.

See the section, [Authentic Scripting >> Macros](#), for a detailed description of how to use macros in a StyleVision design document.
17.1.1.4 Forms

Forms are particularly useful if you need to collect input data from users or display data to users. A form can contain miscellaneous controls to facilitate this, such as buttons, check boxes, combo boxes, and so on.

To add a form, right-click inside the Project pane, and then select Add Form from the context menu. To add a control to a form, drag it from the Toolbox available to the right side of Scripting Editor and drop it onto the form.

You can change the position and size of the controls directly on the form, by using the handles that appear when you click any control, for example:

All form controls have properties that you can easily adjust in the Properties pane. To do this, first select the control on the form, and then edit the required properties in the Properties pane.

Handling form events

Each form control also exposes various events to which your scripting project can bind. For example, you might want to invoke some StyleVision COM API method whenever a button is clicked. To create a function that binds to a form event, do the following:

1. In the Properties pane, click Events 🍀.
2. In the Action column, double-click the event where you need the method (for example, in the image below, the handled event is "Click").
You can also add handler methods by double-clicking a control on the form. For example, double-clicking a button in the form design generates a handler method for the "Click" event of that button.

Once the body of the handler method is generated, you can type code that handles this event, for example:

```javascript
// Occurs when the component is clicked.
function MyForm_ButtonClick( objSender, e_EventArgs )
{
    alert("A button was clicked");
}
```

To display a work-in-progress form detached from the Scripting Editor, right-click the form in the Project window, and select Test Form from the context menu. Note that the Test Form command just displays the form; the form's events (such as button clicks) are still disabled. To have the form react to events, call it from a macro, for example:

```javascript
// Instantiate and display a form
ShowForm( "SampleForm" );
```

**Accessing form controls**

You can access any components on a form from your code by using field access syntax. For example, suppose there is a form designed as follows:

```javascript
// MyForm
//   ButtonPanel
//     OkButton
//     CancelButton
//   TextEditor
//     AxMediaPlayer1
//   TrayComponents
//   MyTimer
```

The code below shows how to instantiate the form, access some of its controls using field access syntax, and then display the form:

```javascript
// Instantiate the form
var objForm = CreateForm("MyForm");
```
// Disable the OK button

// Change the text of TextEditor
objForm.TextEditor.Text = "Hello";

// Show the form
objForm.ShowDialog();

When you add certain controls such as timers to the form, they are not displayed on the form; instead, they are shown as tray components at the base of the form design, for example:

To access controls from the tray, use the `GetTrayComponent` method on the form object, and supply the name of the control as argument. In this example, to get a reference to `MyTimer` and enable it, use the following code:

```javascript
var objTimer = objForm.GetTrayComponent("MyTimer");
objTimer.Enabled = true;
```

For ActiveX Controls, you can access the underlying COM object via the OCX property:

```javascript
var ocx = lastform.AxMediaPlayer1.OCX; // get underlying COM object
ocx.enableContextMenu = true;
ocx.URL = "mms://apasf.apa.at/fm4_live_worldwide";
```

17.1.1.5 Events

Your scripting project may optionally include scripts that handle events in the Authentic View, such as cutting, copying, or pasting text, or opening a context menu. These events are provided by the StyleVision COM API,
and you can find them in the "Events" folder of your scripting project. Note that these events are StyleVision-specific, as opposed to form events.

To create an event handler script, right-click an event, and select Open from the context menu (or double-click the event). The event handler script is displayed in the main window, where you can start editing it. For example, the event handler illustrated below calls a function when a toolbar button is executed. The function definition is in the Global Declarations script, so it is available to the event handler script.

The name of the event handler function must not be changed; otherwise, the event handler script will not be called.

You can optionally define local variables and helper functions within event handler scripts, for example:

```javascript
var local;

function On_AuthenticLoad() {
    local = "OnAuthenticLoad";
    Helper();
}

function Helper() {
    alert("I'm a helper function for " + local);
}
```

17.1.1.6 JScript Programming Tips

Below are a few JScript programming tips that you may find useful while developing a scripting project in StyleVision Scripting Editor.

Out parameters
Out parameters from methods of the .NET Framework require special variables in JScript. For example:
```javascript
var dictionary = 
dictionary.Add("1", "A");
dictionary.Add("2", "B");

// use JScript method to access out-parameters
var strOut = new Array(1);
if ( dictionary.TryGetValu("1", strOut) ) // TryGetValue will set the out parameter
    alert( strOut[0] ); // use out parameter
```

### Integer arguments

.NET Methods that require integer arguments should not be called directly with JScript number objects which are floating point values. For example, instead of:

```javascript
var objCustomColor = CLR.Static("System.Drawing.Color").FromArgb(128,128,128);
```

use:

```javascript
var objCustomColor = 
CLR.Static("System.Drawing.Color").FromArgb(Math.floor(128),Math.floor(128),Math.floor(128));
```

### Iterating .NET collections

To iterate .NET collections, the JScript Enumerator as well as the .NET iterator technologies can be used, for example:

```javascript
// iterate using the JScript iterator
var itr = new Enumerator( coll );
for ( ; !itr.atEnd(); itr.moveNext() )
    alert( itr.item() );

// iterate using the .NET iterator
var itrNET = coll.GetEnumerator();
while ( itrNET.MoveNext() )
    alert( itrNET.Current );
```

### .NET templates

.NET templates can be instantiated as shown below:

```javascript
```

or

```javascript
CLR.Import("System");
CLR.Import("System.Collections.Generic");
```
var dictionary = CLR.Create("Dictionary<String,Dictionary<String,String>>");

.NET enumeration values
.NET enumeration values are accessed as shown below:

Enumeration literals
The enumeration literals from the StyleVision API can be accessed as shown below (there is no need to know their numerical value).

objExportXMIFileDlg.XMIType = eXML21ForUML23;

17.1.2 Built-in Commands

This section provides reference to all the commands you can use in the StyleVision Scripting Editor.

- alert
- confirm
- CLR.Create
- CLR.Import
- CLR.LoadAssembly
- CLR.ShowImports
- CLR.ShowLoadedAssemblies
- CLR.Static
- CreateForm
- doevents
- lastform
- prompt
- ShowForm
- watchdog

17.1.2.1 alert

Displays a message box that shows a given message and the "OK" button. To proceed, the user will have to click "OK".
Signature
For JScript, the signature is:

```
alert(strMessage : String) -> void
```

For VBScript, the signature is:

```
MsgBox(strMessage : String) -> void
```

Example
The following JScript code displays a message box with the text "Hello World".

```
alert("Hello World");
```

17.1.2.2 confirm
Opens a dialog box that shows a given message, a confirmation button, and a cancel button. The user will have to click either "OK" or "Cancel" to proceed. Returns a Boolean that represents the user's answer. If the user clicked "OK", the function returns true; if the user clicked "Cancel", the function returns false.
Signature

```
confirm(strMessage : String) -> result : Boolean
```

Example (JScript)

```
if ( confirm( "Continue processing?" ) == false )
  alert("You have cancelled this action");
```

Example (VBScript)

```
If ( confirm( "Continue processing?" ) = false ) Then
  MsgBox("You have cancelled this action")
End If
```

17.1.2.3 CLR.Create

Creates a new .NET object instance of the type name supplied as argument. If more than one argument is passed, the successive arguments are interpreted as the arguments for the constructor of the .NET object. The return value is a reference to the created .NET object

Signature

```
CLR.Create(strTypeNameCLR : String, constructor arguments ... ) -> object
```

Example

The following JScript code illustrates how to create instances of various .NET classes.

```
// Create an ArrayList
var objArray = CLR.Create("System.Collections.ArrayList");

// Create a ListViewItem
var newItem = CLR.Create( "System.Windows.Forms.ListViewItem", "NewItemText" );

// Create a List<string>
var coll = CLR.Create( "System.Collections.Generic.List<System.String>" );

// Import required namespaces and create a Dictionary object
CLR.Import( "System" );
CLR.Import( "System.Collections.Generic" );
var dictionary = CLR.Create( "Dictionary< String, Dictionary< String, String > >" );
```

17.1.2.4 CLR.Import

Imports a namespace. This is the scripting equivalent of C# using and VB.Net imports keyword. Calling CLR.Import makes it possible to leave out the namespace part in subsequent calls like CLR.Create() and CLR.Static().
**Note:** Importing a namespace does not add or load the corresponding assembly to the scripting project. You can add assemblies to the scripting project dynamically (at runtime) in the source code by calling `CLR.LoadAssembly`.

**Signature**

```csharp
CLR.Import(strNamespaceCLR : String) -> void
```

**Example**

Instead of having to use fully qualified namespaces like:

```csharp
if ( ShowForm( "FormName" ) == CLR.Static( "System.Windows.Forms.DialogResult" ).OK )
{
  var sName = lastform.textboxFirstName.Text + " " + lastform.textboxLastName.Text;
  CLR.Static( "System.Windows.Forms.MessageBox" ).Show( "Hello " + sName );
}
```

One can import namespaces first and subsequently use the short form:

```csharp
CLR.Import( "System.Windows.Forms" );

if ( ShowForm( "FormName" ) == CLR.Static( "DialogResult" ).OK )
{
  var sName = lastform.textboxFirstName.Text + " " + lastform.textboxLastName.Text;
  CLR.Static( "MessageBox" ).Show( "Hello " + sName );
}
```

### 17.1.2.5 CLR.LoadAssembly

Loads the .NET assembly with the given long assembly name or file path. Returns Boolean `true` if the assembly could be loaded; `false` otherwise.

**Signature**

```csharp
CLR.LoadAssembly(strAssemblyNameCLR : String, showLoadErrors : Boolean) -> result : Boolean
```

**Example**

The following JScript code attempts to set the clipboard text by loading the required assembly dynamically.

```csharp
// set clipboard text (if possible)
// System.Windows.Clipboard is part of the PresentationCore assembly, so load this assembly first:
if ( CLR.LoadAssembly( "PresentationCore, Version=3.0.0.0, Culture=neutral, PublicKeyToken=31bf3856ad364e35", true ) )
```
```javascript
{  
    var clipboard = CLR.Static("System.Windows.Clipboard");  
    if (clipboard != null)  
        clipboard.SetText("HelloClipboard");  
}
```

### 17.1.2.6 CLR.ShowImports

Opens a message box that shows the currently imported namespaces. The user will have to click "OK" to proceed.

#### Signature

```
CLR.ShowImports() -> void
```

#### Example

The following JScript code first imports a namespace, and then displays the list of imported namespaces:

```
CLR.Import("System.Windows.Forms");
CLR.ShowImports();
```

![ShowImports Info](image)

### 17.1.2.7 CLR.ShowLoadedAssemblies

Opens a message box that shows the currently loaded assemblies. The user will have to click "OK" to proceed.

#### Signature

```
CLR.ShowLoadedAssemblies() -> void
```

#### Example

```
CLR.ShowLoadedAssemblies();
```
17.1.2.8 CLR.Static

Returns a reference to a static .NET object. You can use this function to get access to .NET types that have no instances and contain only static members.

Signature

CLR.Static(strTypeNameCLR : String) -> object

Example (JScript)

```javascript
// Get the value of a .NET Enum into a variable

// Set the value of the Windows clipboard
var clipboard = CLR.Static( "System.Windows.Clipboard" );
clipboard.SetText( "HelloClipboard" );

// Check the buttons pressed by the user on a dialog box
if ( ShowForm( "FormName" ) == CLR.Static( "System.Windows.Forms.DialogResult" ).OK )
    alert( "ok" );
else
    alert( "cancel" );
```
17.1.2.9 CreateForm

Instantiates the Form object identified by the name supplied as argument. The form must exist in the "Forms" folder of the scripting project. Returns the form object (System.Windows.Forms.Form) corresponding to the given name, or null if no form with such name exists.

Signature

CreateForm (strFormName : String) -> System.Windows.Forms.Form | null

Example

Let's assume that a form called "FormName" exists in the scripting project.

The following JScript code instantiates the form with some default values and displays it to the user.

```javascript
var myForm = CreateForm( "FormName" );
if ( myForm != null ) {
  myForm.textboxFirstName.Text = "Daniela";
  myForm.textboxLastName.Text = "Heidegger";
  var dialogResult = myForm.ShowDialog();
}
```

The dialogResult can subsequently be evaluated as follows:

```javascript
  alert( "ok" );
else
  alert( "cancel" );
```

Note: The code above will work only if the DialogResult property of the "OK" and "Cancel" buttons is set correctly from the Properties pane (for example, it must be OK for the "OK" button).
17.1.2.10 doevents

Processes all Windows messages currently in the message queue.

Signature

doevents() -> void

Example (JScript)

```javascript
for ( i=0; i < nLongLastingProcess; ++i )
{
    // do long lasting process
    doevents(); // process Windows messages; give UI a chance to update
}
```

17.1.2.11 lastform

This is a global field that returns a reference to the last form object that was created via CreateForm() or ShowForm().

Signature

lastform -> formObj : System.Windows.Forms.Form

Example

The following JScript code shows the form "FormName" as a dialog box.

```javascript
CreateForm( "FormName" );
if ( lastform != null )
{
    lastform.textboxFirstName.Text = "Daniela";
    lastform.textboxLastName.Text = "Heidegger";
    var dialogResult = lastform.ShowDialog();
}
```

The values of both textbox controls are initialized with the help of lastform.
17.1.2.12 prompt

Opens a dialog box that shows a message and a textbox control with a default answer. This can be used to let the user input a simple string value. The return value is a string that contains the textbox value or null if the user selected "Cancel".

Signature

`prompt(strMessage : String, strDefault : String) -> val : String`

Example

```
var name = prompt( "Please enter your name", "Daniel Smith" );
if ( name != null )
    alert( "Hello " + name + "!" );
```

17.1.2.13 ShowForm

Instantiates a new form object from the given form name and immediately shows it as dialog box. The return value is an integer that represents the generated `DialogResult` (System.Windows.Forms.DialogResult). For the list of possible values, refer to the documentation of the `DialogResult` Enum (https://docs.microsoft.com/en-us/dotnet/api/system.windows.forms.dialogresult?view=netframework-4.8).
Signature

ShowForm(strFormName : String) -> result : Integer

Example

The following JScript code

var dialogResult = ShowForm( "FormName" );

Shows the form "FormName" as a dialog box:

The DialogResult can subsequently be evaluated, for example:

```
    alert( "ok" );
else
    alert( "cancel" );
```

Note: The code above will work only if the DialogResult property of the "OK" and "Cancel" buttons is set correctly from the Properties pane (for example, it must be OK for the "OK" button).

17.1.2.14 watchdog

Long running CPU-intensive scripts may ask the user if the script should be terminated. The watchdog() method is used to disable or enable this behavior. By default, the watchdog is enabled.

Calling watchdog(true) can also be used to reset the watchdog. This can be useful before executing long running CPU-intensive tasks to ensure they have the maximum allowed script processing quota.

Signature

watchdog(bEnable : boolean) -> void
Example

```plaintext
watchdog( false );  // disable watchdog - we know the next statement is CPU intensive but it will terminate for sure
doCPUIntensiveScript();
watchdog( true );  // re-enable watchdog
```
17.2 Application API

The COM-based API of StyleVision (also called the Application API from now on) enables other applications to use the functionality of StyleVision.

StyleVision and its Application API follow the common specifications for automation servers set out by Microsoft. It is possible to access the methods and properties of the Application API from common development environments, such as those using C#, C++, VisualBasic, and Delphi, and with scripting languages like JScript and VBScript.

Execution environments for the Application API

The Application API can be accessed from the following execution environments:

- External programs (described below and in the Overview part of this section)
- From within the built-in Scripting Editor of StyleVision. For a description of the scripting environment, see the section, Scripting Editor.
- Via an ActiveX Control, which is available if the integration package is installed. For more information, see the section ActiveX Integration.

External programs

In the Overview part of this section, we describe how the functionality of StyleVision can be accessed and automated from external programs.

Using the Application API from outside StyleVision requires an instance of StyleVision to be started first. How this is done depends on the programming language used. See the section, Programming Languages, for information about individual languages.

Essentially, StyleVision will be started via its COM registration. Then the Application object associated with the StyleVision instance is returned. Depending on the COM settings, an object associated with an already running StyleVision can be returned. Any programming language that supports creation and invocation of COM objects can be used. The most common of these are listed below.

- JScript script files have a simple syntax and are designed to access COM objects. They can be run directly from a DOS command line or with a double click on Windows Explorer. They are best used for simple automation tasks.
- C# is a full-fledged programming language that has a wide range of existing functionality. Access to COM objects can be automatically wrapped using C#.
- C++ provides direct control over COM access but requires relatively larger amounts of code than the other languages.
- Java: Altova products come with native Java classes that wrap the Application API and provide a full Java look-and-feel.
- Other programming languages that make useful alternatives are: Visual Basic for Applications, Perl, and Python.

Programming points

The following limitations must be considered in your client code:

- Be aware that if your client code crashes, instances of StyleVision may still remain in the system.
- Don’t hold references to objects in memory longer than you need them, especially those from the XMLData interface. If the user interacts between two calls of your client, then there is no guarantee that these references are still valid.
- Don’t forget to disable dialogs if the user interface is not visible.

### 17.2.1 Overview

This overview of the Application API is organized as follows:

- **The Object Model** describes the relationships between the objects of the Application API.
- **Programming Languages** explains how the most commonly used programming languages (JScript, VBScript, C#, and Java) can be used to access the functionality of the Application API. Code listings from the example files supplied with your application package are used to describe basic mechanisms.

#### 17.2.1.1 Object Model

The starting point for every application which uses the Application API is the **Application** object. This object contains general methods like import/export support and references to the open documents and any open project.

The Application object is created differently in various programming languages. In scripting languages such as JScript or VBScript, this involves calling a function which initializes the application’s COM object. For examples, see the **Programming Languages** section.

The chart below shows the links between the main objects of the Application API:

```
Application
|-- Documents
  |-- Document
    |-- Methods for assigning working XML file, saving files
    |-- Methods for saving generated files
    |-- Methods for activating, saving, closing SPS file
```

In addition there are objects for schema sources and properties, as well as methods for AuthenticView events.

Once you have created an Application object you can start using the functionality of StyleVision.

#### 17.2.1.2 Programming Languages

Programming languages differ in the way they support COM access. A few examples for the most frequently used languages ([links below](#)) will help you get started. The code listings in this section show how basic functionality can be accessed. The files in the **API** subfolder of the **Examples** folder can be used to test this functionality:
JScript
The JScript listings demonstrate the following basic functionality:

- Start application or attach to a running instance
- Simple document access
- Iteration

VBScript
VBScript is different than JScript only syntactically; otherwise it works in the same way. For more information, refer to the JScript examples.

C#
C# can be used to access the Application API functionality. The code listings show how to access the API for certain basic functionality.

- Start StyleVision: Starts StyleVision, which is registered as an automation server, or activates StyleVision if it is already running.
- Open OrgChart.pxf: Locates one of the example documents installed with StyleVision and opens it. If this document is already open it becomes the active document.
- OnDocumentOpened Event On/Off: Shows how to listen to StyleVision events. When turned on, a message box will pop up after a document has been opened.
- Open ExpReport.xml: Opens another example document.
- Shutdown StyleVision: Stops StyleVision.

Java
The StyleVision API can be accessed from Java code. The Java sub-section of this section explains how some basic StyleVision functionality can be accessed from Java code. It is organized into the following subsections:

- Mapping Rules for the Java Wrapper
- Example Java Project
- Application Startup and Shutdown
- Simple Document Access
- Iterations
- Event Handlers

17.2.1.2.1 JScript
This section contains listings of JScript code that demonstrate the following basic functionality:

- Start application or attach to a running instance
Example files
The code listings in this section are available in example files that you can test as is or modify to suit your needs. The JScript example files are located in the JScript subfolder of the API Examples folder:

| Windows 7, Windows 8, Windows 10 | C:\Users\<username>\Documents\Altova\StyleVision\2022\%APPNAME%>Examples |

The example files can be run in one of two ways:

- **From the command line:** Open a command prompt window, change the directory to the path above, and type the name of one of the example scripts (for example, Start.js).
- **From Windows Explorer:** In Windows Explorer, browse for the JScript file and double-click it.

The script is executed by Windows Script Host that is packaged with Windows operating system. For more information about Windows Script Host, refer to MSDN documentation (https://msdn.microsoft.com).

17.2.1.2.1.1 Start Application

The JScript below starts the application and shuts it down. If the COM object of the 32-bit StyleVision cannot be found, the code attempts to get the COM object of the 64-bit application; otherwise, an error is thrown. If an instance of the application is already running, the running instance will be returned.

**Note:** For 32-bit StyleVision, the registered name, or programmatic identifier (ProgId) of the COM object is StyleVision.Application. For 64-bit StyleVision, the name is StyleVision_x64.Application. Be aware, though, that the calling program will access the CLASSES registry entries in its own registry hive, or group (32-bit or 64-bit). Therefore, if you run scripts using the standard command prompt and Windows Explorer on 64-bit Windows, the 64-bit registry entries will be accessed, which point to the 64-bit StyleVision. For this reason, if both StyleVision 32-bit and 64-bit are installed, special handling is required in order to call the 32-bit StyleVision. For example, assuming that Windows Scripting Host is the calling program, do the following:

1. Change the current directory to C:\Windows\SysWOW64.
2. At the command line, type `wscript.exe` followed by the path to the script that you would like to run, for example:

   ```shell
   wscript.exe "C:\Users\...\Documents\Altova\StyleVision2022\StyleVisionExamples\API\JScript\start.js"
   ```

   ```javascript
   // Initialize application's COM object. This will start a new instance of the application and
   // return its main COM object. Depending on COM settings, the main COM object of an
   ```
already
// running application might be returned.
try {
    objStyleVision = WScript.GetObject("", "StyleVision.Application");
} catch (err) {}

if (typeof objStyleVision == "undefined") {
    try {
        objStyleVision = WScript.GetObject("", "StyleVision_x64.Application")
    } catch (err) {
        WScript.Echo("Can't access or create StyleVision.Application");
        WScript.Quit();
    }
}

// if newly started, the application will start without its UI visible. Set it to visible.
objStyleVision.Visible = true;
WScript.Echo(objStyleVision.Edition + " has successfully started.");

objStyleVision.Visible = false; // will shutdown application if it has no more COM connections
//objStyleVision.Visible = true; // will keep application running with UI visible

The JScript code listed above is available in the sample file Start.js (see Example Files).

17.2.1.2.1.2 Simple Document Access

After you have started the application as shown in Start Application, you will most likely want to programmatically open a document in order to work with it. The JScript code listing below illustrates how to open two documents from the StyleVision Examples folder.

// Locate examples via USERPROFILE shell variable. The path needs to be adapted to major release versions.
objWshShell = WScript.CreateObject("WScript.Shell");
majorVersionYear = objStyleVision.MajorVersion + 1998
strExampleFolder = objWshShell.ExpandEnvironmentStrings("%USERPROFILE%") + "\My Documents\Altova\StyleVision" + majorVersionYear + "\StyleVisionExamples\"

// Tell StyleVision to open two documents. No dialogs
objDoc1 = objStyleVision.Documents.OpenDocument(strExampleFolder + "OrgChart.pxf");
objStyleVision.Documents.OpenDocument(strExampleFolder + "BiggestCitiesPerContinent.sps");

The JScript code listed above is available in the sample file DocumentAccess.js (see Example Files).
17.2.1.2.1.3 Iteration

The JScript listing below shows how to iterate through the open documents. It is assumed that you have already started the application and opened some documents as shown in the previous sections.

```javascript
// go through all open documents using a JScript Enumerator
for (var iterDocs = new Enumerator(objStyleVision.Documents); !iterDocs.atEnd(); iterDocs.moveNext())
{
    objName = iterDocs.item().Name;
    WScript.Echo("Document name: " + objName);
}

// go through all open documents using index-based access to the document collection
for (i = objStyleVision.Documents.Count; i > 0; i--)
    objStyleVision.Documents.Item(i).Close();
```

The JScript code listed above is available in the sample file DocumentAccess.js (see Example Files).

17.2.1.2.2 C#

The C# programming language can be used to access the Application API functionality. You could use Visual Studio 2010/2012/2013/2015/2017/2019 to create the C# code, saving it in a Visual Studio project. Create the project as follows:

1. In Microsoft Visual Studio, add a new project using File | New | Project.
2. Add a reference to the StyleVision Type Library by clicking Project | Add Reference. The Add Reference dialog appears. Browse for the StyleVision Type Library component, which is located in the StyleVision application folder, and add it.
3. Enter the code you want.
4. Compile the code and run it.

Example C# project

Your StyleVision package contains an example C# project, which is located in the API\C# subfolder of the Examples folder:

```
Windows 7, Windows 8, Windows 10
C:\Users\<username>\Documents\Altova\StyleVision\2022\%APPNAME%>Examples
```

You can compile and run the project from within Visual Studio 2010/2012/2013/2015/2017/2019. The code listing below shows how basic application functionality can be used. This code is similar to the example C# project in the API Examples folder of your application package, but might differ slightly.
Platform configuration

If you have a 64-bit operating system and are using a 32-bit installation of StyleVision, you must add the x86 platform in the solution's Configuration Manager and build the sample using this configuration. A new x86 platform (for the active solution in Visual Studio) can be created in the New Solution Platform dialog (Build | Configuration Manager | Active solution platform | <New…>).

What the code listing below does

The example code listing below creates a simple user interface (screenshot below) with buttons that invoke basic StyleVision operations:

• **Start StyleVision**: Starts StyleVision, which is registered as an automation server, or activates the application if it is already running.
• **Open OrgChart.pxf**: Locates one of the example documents installed with StyleVision and opens it. If this document is already open it becomes the active document.
• **Open MultiFileOutput.sps**: Opens another example document.
• **Shut down StyleVision**: Stops StyleVision.

You can modify the code (of the code listing below or of the example C# project in the API Examples folder) in any way you like and run it.

Compiling and running the example

In the API Examples folder, double-click the file AutomateStyleVision_VS2008.sln or the file AutomateStyleVision_VS2010.sln (to open in Visual Studio 2010/2012/2013/2015/2017/2019). Alternatively the file can be opened from within Visual Studio (with File | Open | Project/Solution). To compile and run the example, select Debug | Start Debugging or Debug | Start Without Debugging.

Code listing of the example

Given below is the C# code listing of the basic functionality of the form (Form1.cs) created in the AutomateStyleVision example. Note that the code listed below might differ slightly from the code in the API Examples form. The listing below is commented for ease of understanding. Parts of the code are also presented separately in the sub-sections of this section, according to the Application API functionality they access.
The code essentially consists of a series of handlers for the buttons in the user interface shown in the screenshot above.

namespace WindowsFormsApplication2
{
    public partial class Form1 : Form
    {
        public Form1()
        {
            InitializeComponent();
        }

        // An instance of StyleVision is accessed via its automation interface.
        StyleVisionLib.Application StyleVision;

        // Location of examples installed with StyleVision
        String strExamplesFolder;

        private void Form1_Load(object sender, EventArgs e)
        {
            // Locate examples installed with StyleVision.
            // REMARK: You might need to adapt this if you have a different major version of the product.
            strExamplesFolder = Environment.GetEnvironmentVariable("USERPROFILE") + "\My Documents\Altova\StyleVision2012\StyleVisionExamples\";
            }

        // Handler for the "Start StyleVision" button
        private void StartStyleVision_Click(object sender, EventArgs e)
        {
            if (StyleVision == null)
            {
            Cursor.Current = Cursors.WaitCursor;

            // If there is no StyleVision instance, create one and make it visible.
            StyleVision = new StyleVisionLib.Application();
            StyleVision.Visible = true;

            Cursor.Current = Cursors.Default;
            }
            else
            {
                // If a StyleVision instance is already running, make sure it's visible.
                if (!StyleVision.Visible)
                StyleVision.Visible = true;
            }
        }

        // Handler for the "Open OrgChart.pxf" button
        private void openOrgChart_Click(object sender, EventArgs e)
        { 
            // Make sure there's a running StyleVision instance, and that it's visible
            StartStyleVision_Click(null, null);
// Open a sample files installed with the product.
StyleVision.Documents.OpenDocument(strExamplesFolder + "OrgChart.pxf");
updateListBox();
}

// Handler for the "Open MultiFileOutput.sps" button
private void openMultiFileOutput_Click(object sender, EventArgs e)
{
    // Make sure there's a running StyleVision instance, and that it's visible
    StartStyleVision_Click(null, null);

    // Open one of the sample files installed with the product.
    updateListBox();
}

// Handler for the "Shutdown StyleVision" button
// Shut down the application instance by explicitly releasing the COM object.
private void shutdownStyleVision_Click(object sender, EventArgs e)
{
    if (StyleVision != null)
    {
        // Allow shut-down of StyleVision by releasing UI
        StyleVision.Visible = false;

        // Explicitly release the COM object
        try
        {
            int i =
            System.Runtime.InteropServices.Marshal.ReleaseComObject(StyleVision);
            while
            (System.Runtime.InteropServices.Marshal.ReleaseComObject(StyleVision) > 0) ;
        }
        finally
        {
            // Disallow subsequent access to this object.
            StyleVision = null;
        }
    }
}

delegate void addListBoxItem_delegate(string sText);
// Called from the UI thread
private void addListBoxItem(string sText)
{
    listBoxMessages.Items.Add(sText);
}

// Wrapper method to call UI control methods from a worker thread
void syncWithUIthread(Control ctrl, addListBoxItem_delegate methodToInvoke, String
sText)
{
    // Control.Invoke: Executes on the UI thread, but calling thread waits for
    completion before continuing.
    // Control.BeginInvoke: Executes on the UI thread, and calling thread doesn't
    wait for completion.
    if (ctrl.InvokeRequired)
ctrl.BeginInvoke(methodToInvoke, new Object[] { sText });

// Event handler for OnDocumentClosed event
private void handleOnDocumentClosed(StyleVisionLib.Document i_ipDocument)
{
    String sText = "";

    if (i_ipDocument.Name.Length > 0)
        sText = "Document " + i_ipDocument.Name + " was closed!";

    // Synchronize the calling thread with the UI thread because
    // COM events are triggered from a working thread
    addListItem_delegate methodToInvoke = new
    addListItem_delegate(addListItem);

    // Call syncWithUIThread with the following arguments:
    // 1 - listBoxMessages - list box control to display messages from COM events
    // 2 - methodToInvoke - a C# delegate which points to the method which will be
    // called from the UI thread
    // 3 - sText - the text to be displayed in the list box
    syncWithUIThread(listBoxMessages, methodToInvoke, sText);
}

private void updateListBox()
{
    // Iterate through all open documents
    listBoxMessages.Items.Clear();

    for (int i = 1; i <= StyleVision.Documents.Count; i++)
    {
        StyleVisionLib.Document doc = StyleVision.Documents[i];

        if (doc != null)
            if (checkBoxEventOnOff.Checked)
                doc.OnDocumentClosed += new
                StyleVisionLib._IDocumentEvents_OnDocumentClosedEventHandler(handleOnDocumentClosed);
            else
                doc.OnDocumentClosed -= new
                StyleVisionLib._IDocumentEvents_OnDocumentClosedEventHandler(handleOnDocumentClosed);

        listBoxMessages.Items.Add(doc.Name);
        StyleVisionLib.SchemaSources sources = doc.SchemaSources;

        for (int j = 1; j <= sources.Count; j++)
        {
            StyleVisionLib.SchemaSource source = sources[j];

            if (source != null)
                listBoxMessages.Items.Add("\tSchema file name : " + source.SchemaFileName + "\n");
        }
    }
}
Add the application's type library as a reference in a .NET project as follows: With the .NET project open, click **Project | Add Reference**. Then browse for the type library, which is called **StyleVision.tlb** and is located in the StyleVision application folder.

Then declare a variable to access the StyleVision API:

```csharp
// An instance of StyleVision is accessed via its automation interface.
StyleVisionLib.Application StyleVision;
```

**Application Startup and Shutdown**

In the code snippets below, the methods **StartStyleVision_Click** and **ShutdownStyleVision_Click** are those assigned to buttons in the **AutomateStyleVision example** that, respectively, start up and shut down the application. This example is located in the C# subfolder of the API Examples folder *(see the file Form1.cs)*:

```csharp
// Handler for the "Start StyleVision" button
private void StartStyleVision_Click(object sender, EventArgs e)
{
    if (StyleVision == null)
    {
        Cursor.Current = Cursors.WaitCursor;

        // If there is no StyleVision instance, create one and make it visible.
        StyleVision = new StyleVisionLib.Application();
        StyleVision.Visible = true;
    }
}
```
## Shutting down StyleVision

The following code snippet from the [AutomateStyleVision example](#) shows how to shut down the application.

```csharp
// Handler for the "Shutdown StyleVision" button
// Shut down the application instance by explicitly releasing the COM object.
private void shutdownStyleVision_Click(object sender, EventArgs e)
{
    if (StyleVision != null)
    {
        // Allow shut-down of StyleVision by releasing UI
        StyleVision.Visible = false;

        // Explicitly release the COM object
        try
        {
            int i =
            System.Runtime.InteropServices.Marshal.ReleaseComObject(StyleVision);
            while
            (System.Runtime.InteropServices.Marshal.ReleaseComObject(StyleVision) > 0) ;
        }
        finally
        {
            // Disallow subsequent access to this object.
            StyleVision = null;
        }
    }
}
```

### 17.2.1.2.2.3 Opening Documents

The code snippets below (from the [AutomateStyleVision example](#)) show how two files are opened via two separate methods assigned to two buttons in the user interface. Both methods use the same Application API access mechanism: `Documents.OpenDocument(string)`.

The [AutomateStyleVision example](#) ([see the file Form1.cs](#)) is located in the C# subfolder of the API Examples folder:

| Windows 7, Windows 8, Windows 10 | C:\Users\<username>\Documents\Altova\StyleVision\2022\%APPNAME%>Examples |
You can compile and run the project from within Visual Studio 2010/2012/2013/2015/2017/2019.

**Code snippet**

```csharp
// Handler for the "Open OrgChart.pxf" button
private void openOrgChart_Click(object sender, EventArgs e)
{
    // Make sure there's a running StyleVision instance, and that it's visible
    StartStyleVision_Click(null, null);

    // Open a sample files installed with the product.
    StyleVision.Documents.OpenDocument(strExamplesFolder + "OrgChart.pxf");
    updateListBox();
}

// Handler for the "Open MultiFileOutput.sps" button
private void openMultiFileOutput_Click(object sender, EventArgs e)
{
    if (StyleVision == null)
        StartStyleVision_Click(null, null);

    // Open one of the sample files installed with the product.
    updateListBox();
}
```

The file opened last will be the active file.

### 17.2.1.2.2.4 Events

The code snippet below (from the [AutomateStyleVision example](#)) lists the code for two event handlers. The [AutomateStyleVision example](#) (see the file Form1.cs) is located in the C# subfolder of the API Examples folder:

| Windows 7, Windows 8, Windows 10 | C:\Users\<username>\Documents\Altova\StyleVision\2022\%APPNAME%\Examples |

You can compile and run the project from within Visual Studio 2010/2012/2013/2015/2017/2019.

**Code snippet**

```csharp
delegate void addListBoxItem_delegate(string sText);
// Called from the UI thread
private void addListBoxItem(string sText)
{
    listBoxMessages.Items.Add(sText);
}
```
// Wrapper method to call UI control methods from a worker thread
void syncWithUIthread(Control ctrl, addListBoxItem_delegate methodToInvoke, String sText)
{
    // Control.Invoke: Executes on the UI thread, but calling thread waits for completion before continuing.
    // Control.BeginInvoke: Executes on the UI thread, and calling thread doesn't wait for completion.
    if (ctrl.InvokeRequired)
    {
        ctrl.BeginInvoke(methodToInvoke, new Object[ ] { sText });
    }
}

// Event handler for OnDocumentClosed event
private void handleOnDocumentClosed(StyleVisionLib.Document i_ipDocument)
{
    String sText = "";
    if (i_ipDocument.Name.Length > 0)
    {
        sText = "Document " + i_ipDocument.Name + " was closed!";
    }

    // Synchronize the calling thread with the UI thread because COM events are triggered from a working thread
    addListBoxItem_delegate methodToInvoke = new addListBoxItem_delegate(addListBoxItem);
    // Call syncWithUIthread with the following arguments:
    // 1 - listBoxMessages - list box control to display messages from COM events
    // 2 - methodToInvoke - a C# delegate which points to the method which will be called from the UI thread
    // 3 - sText - the text to be displayed in the list box
    syncWithUIthread(listBoxMessages, methodToInvoke, sText);
}

private void updateListBox()
{
    // Iterate through all open documents
    listBoxMessages.Items.Clear();

    for (int i = 1; i <= StyleVision.Documents.Count; i++)
    {
        StyleVisionLib.Document doc = StyleVision.Documents[i];
        if (doc != null)
        {
            if (checkBoxEventOnOff.Checked)
            {
            }
            else
            {
            }
            listBoxMessages.Items.Add(doc.Name);
            StyleVisionLib.SchemaSources sources = doc.SchemaSources;
        }
    }
}
for (int j = 1; j <= sources.Count; j++)
{
    StyleVisionLib.SchemaSource source = sources[j];
    if (source != null)
    {
        listBoxMessages.Items.Add("\tSchema file name : " + source.SchemaFileName + 
        listBoxMessages.Items.Add("\tWorking XML file name : " + source.WorkingXMLFileName + 
        listBoxMessages.Items.Add("\tIs main schema source : " + source.IsMainSchemaSource + 
        listBoxMessages.Items.Add("\tType name : " + source.TypeName + 
    }
}
}

17.2.1.2.3  Java

The Application API can be accessed from Java code. To allow accessing the StyleVision automation server directly from Java code, the libraries listed below must reside in the classpath. They are installed in the folder: JavaAPI in the StyleVision application folder.

- AltovaAutomation.dll: a JNI wrapper for Altova automation servers (AltovaAutomation_x64.dll in the case of 64-bit versions)
- AltovaAutomation.jar: Java classes to access Altova automation servers
- StyleVisionAPI.jar: Java classes that wrap the StyleVision automation interface
- StyleVisionAPI_JavaDoc.zip: a Javadoc file containing help documentation for the Java API

**Note:** In order to use the Java API, the DLL and Jar files must be on the Java Classpath.

**Example Java project**

An example Java project is supplied with your product installation. You can test the Java project and modify and use it as you like. For more details of the example Java project, see the section, Example Java Project.

**Rules for mapping the Application API names to Java**

The rules for mapping between the Application API and the Java wrapper are as follows:

- **Classes and class names**
  For every interface of the StyleVision automation interface a Java class exists with the name of the interface.

- **Method names**
  Method names on the Java interface are the same as used on the COM interfaces but start with a small letter to conform to Java naming conventions. To access COM properties, Java methods that prefix the property name with `get` and `set` can be used. If a property does not support write-access, no setter method is available. Example: For the `Name` property of the `Document` interface, the Java methods `setName` and `setName` are available.
**Enumerations**
For every enumeration defined in the automation interface, a Java enumeration is defined with the same name and values.

**Events and event handlers**
For every interface in the automation interface that supports events, a Java interface with the same name plus 'Event' is available. To simplify the overloading of single events, a Java class with default implementations for all events is provided. The name of this Java class is the name of the event interface plus 'DefaultHandler'. For example:

- **Application**: Java class to access the application
- **ApplicationEvents**: Events interface for the Application
- **ApplicationEventsDefaultHandler**: Default handler for ApplicationEvents

### Exceptions to mapping rules
There are some exceptions to the rules listed above. These are listed below:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Java name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document, method SetEncoding</td>
<td>setFileEncoding</td>
</tr>
<tr>
<td>AuthenticView, method Goto</td>
<td>gotoElement</td>
</tr>
<tr>
<td>AuthenticRange, method Goto</td>
<td>gotoElement</td>
</tr>
<tr>
<td>AuthenticRange, method Clone</td>
<td>cloneRange</td>
</tr>
</tbody>
</table>

### This section
This section explains how some basic StyleVision functionality can be accessed from Java code. It is organized into the following sub-sections:

- **Example Java Project**
- **Application Startup and Shutdown**
- **Simple Document Access**
- **Iterations**
- **Event Handlers**

### 17.2.1.2.3.1 Example Java Project
The StyleVision installation package contains an example Java project, located in the the API\Java subfolder of the Examples folder:

```
Windows 7, Windows 8,  C:\Users\<username>\Documents\%APPNAME%\Examples
Windows 10          Altova\StyleVision\2022\%APPNAME%\Examples
```

This folder contains Java examples for the StyleVision API. You can test it directly from the command line using the batch file BuildAndRun.bat, or you can compile and run the example project from within Eclipse. See below for instructions on how to use these procedures.
File list
The Java examples folder contains all the files required to run the example project. These files are listed below. If you are using a 64-bit version of the application, some filenames contain _x64 in the name. These filenames are indicated with (_x64).

- AltovaAutomation(_x64).dll: Java-COM bridge: DLL part
- AltovaAutomation.jar: Java-COM bridge: Java library part
- StyleVisionAPI.jar: Java classes of the StyleVision API
- RunStyleVision.java: Java example source code
- BuildAndRun.bat: Batch file to compile and run example code from the command line prompt. Expects folder where Java Virtual Machine resides as parameter.
- .classpath: Eclipse project helper file
- .project: Eclipse project file
- StyleVision_JavaDoc.zip: Javadoc file containing help documentation for the Java API

What the example does
The example starts up StyleVision and performs a few operations, including opening and closing documents. When done, StyleVision stays open. You must close it manually.

- **Start StyleVision**: Starts StyleVision, which is registered as an automation server, or activates StyleVision if it is already running.
- **Open OrgChart.pxf**: Locates one of the example documents installed with StyleVision and opens it.
- **Iteration and Changing the View Mode**: Shows how to iterate through open documents.
- **Event Handling**: Shows how to handle StyleVision events.
- **Shut down StyleVision**: Shuts down StyleVision.

You can modify the example in any way you like and run it.

Running the example from the command line
To run the example from the command line, open a command prompt window, go to the Java folder of the API Examples folder (see above for location), and then type:

```
buildAndRun.bat "<Path-to-the-Java-bin-folder>"
```

The Java binary folder must be that of a JDK 1.5 or later installation on your computer. Press the Return key. The Java source in RunStyleVision.java will be compiled and then executed.

Loading the example in Eclipse
Open Eclipse and use the **Import | Existing Projects into Workspace** command to add the Eclipse project file (.project) located in the Java folder of the API Examples folder (see above for location). The project RunStyleVision will then appear in your Package Explorer or Navigator. Select the project and then the command **Run as | Java Application** to execute the example.
Note: You can select a class name or method of the Java API and press F1 to get help for that class or method.

Java source code listing
The Java source code in the example file RunStyleVision.java is listed below with comments.

01 // Access general JAVA-COM bridge classes
02 import com.altova.automation.libs.*;
03
04 // Access StyleVision Java-COM bridge
05 import com.altova.automation.StyleVision.);
06 import com.altova.automation.StyleVision.Enums.ENUMApplicationStatus;
07
08 /**
09 * A simple example that starts the COM server and performs a View operations on it.
10 * Feel free to extend.
11 */
12 public class RunStyleVision
13 {
14   public static void main(String[] args)
15   {
16     // An instance of the application.
17     Application stylevision = null;
18
19     // Instead of COM error-handling, use Java exception mechanism.
20     try
21     {
22       // Start StyleVision as COM server.
23       stylevision = new Application();
24
25       ENUMApplicationStatus status = ENUMApplicationStatus.eApplicationRunning;
26       do{
27         // Check the application status
28         status = stylevision.getStatus();
29         System.out.println("status : " + status + "\n");
30       } while (status != ENUMApplicationStatus.eApplicationRunning);
31
32       // COM servers start up invisible, so we make the server visible
33       stylevision.setVisible(true);
34
35       // Locate samples installed with the product.
36       String strExamplesFolder = System.getenv("USERPROFILE") + "\My Documents\Altova\StyleVision2012\StyleVisionExamples\"");
37
38       // Open two files from the product samples.
39       stylevision.getDocuments().openDocument(strExamplesFolder + "OrgChart.pxf");
40       stylevision.getDocuments().openDocument(strExamplesFolder + "BiggestCitiesPerContinent.sps");
41
42       // Iterate through all open documents
43       for (Document doc:stylevision.getDocuments())
44       {
45         System.out.println("Document name : " + doc.getName() + "\n");
46         SchemaSources sources = doc.getSchemaSources();
for (int i = 1; i <= sources.getCount(); i++)
{
    SchemaSource source = sources.getItem(i);
    System.out.println("\tSchema file name : " + source.getSchemaFileName() + "\n");
    System.out.println("\tWorking XML file name : " + source.getWorkingXMLFileName() + "\n");
    System.out.println("\tIs main schema source : " + source.getIsMainSchemaSource() + "\tType name : " + source.getTypeName() + "\n");
}
// The following lines attach to the document events using a default implementation
// for the events and override one of its methods.
// If you want to override all document events it is better to derive your listener class
// from DocumentEvents and implement all methods of this interface.
Document doc = stylevision.getActiveDocument();
doc.addListener(new DocumentEventsDefaultHandler()
{
    @Override
    public void onDocumentClosed(Document i_ipDoc) throws AutomationException
    {
        System.out.println("Document " + i_ipDoc.getName() + " requested closing.");
    }
});
    doc.close();
    doc = null;
    System.out.println("Watch StyleVision!");
}
catch (AutomationException e)
{
    e.printStackTrace();
}
finally
{
    // Make sure that StyleVision can shut down properly.
    if (stylevision != null)
        stylevision.dispose();
    // Since the COM server was made visible and still is visible, it will keep running
    // and needs to be closed manually.
    System.out.println("Now close StyleVision!");
}
17.2.1.2.3.2  Application Startup and Shutdown

The code listings below show how the application can be started up and shut down.

Application startup

Before starting up the application, the appropriate classes must be imported (see below).

```java
01 // Access general JAVA-COM bridge classes
02 import com.altova.automation.libs.*;
03
04 // Access StyleVision Java-COM bridge
05 import com.altova.automation.StyleVision.*;
06 import com.altova.automation.StyleVision.Enums.ENUMApplicationStatus;
07
08 /**
09 * A simple example that starts the COM server and performs a View operations on it.
10 * Feel free to extend.
11 */
12 public class RunStyleVision
13 {
14   public static void main(String[] args)
15   {
16     // An instance of the application.
17     Application stylevision = null;
18
19     // Instead of COM error-handling, use Java exception mechanism.
20     try
21     {
22       // Start StyleVision as COM server.
23       stylevision = new Application();
24
25       ENUMApplicationStatus status = ENUMApplicationStatus.eApplicationRunning;
26       do{
27         // Check the application status
28         status = stylevision.getStatus();
29         System.out.println("status : " + status + "\n");
30       } while (status != ENUMApplicationStatus.eApplicationRunning);
31
32       // COM servers start up invisible, so we make the server visible
33       stylevision.setVisible(true);
34
35     }...
36   }
37 }
38 }
```

Application shutdown

The application can be shut down as shown below.

```java
1 {
2   // Make sure that StyleVision can shut down properly.
3   if (stylevision != null)
```
7.2.1.2.3.3  Simple Document Access

The code listing below shows how to open a document.

```java
// Locate samples installed with the product.
String strExamplesFolder = System.getenv("USERPROFILE") + "\My Documents\Altova\StyleVision2012\StyleVisionExamples\";

// We open two files form the product samples.
styleTypevision.getDocuments().openDocument(strExamplesFolder + "OrgChart.pxf");
styleTypevision.getDocuments().openDocument(strExamplesFolder + "BiggestCitiesPerContinent.sps");
```

7.2.1.2.3.4  Iterations

The listing below shows how to iterate through open documents.

```java
// Iterate through all open documents
for (Document doc : stylevision.getDocuments()) {
    System.out.println("Document name : " + doc.getName() + "\n");
    SchemaSources sources = doc.getSchemaSources();
    for (int i = 1; i <= sources.getCount(); i++) {
        SchemaSource source = sources.getItem(i);
        System.out.println("\tSchema file name : " + source.getSchemaFileName() + "\n");
        System.out.println("\tWorking XML file name : " + source.getWorkingXMLFileName() + "\n");
        System.out.println("\tIs main schema source : " + source.getIsMainSchemaSource() + "\n");
        System.out.println("\tType name : " + source.getTypeName() + "\n");
    }
}
```

7.2.1.2.3.5  Event Handlers

The listing below shows how to listen for and use events.
// The following lines attach to the document events using a default implementation
// for the events and override one of its methods.
// If you want to override all document events it is better to derive your listener class
// from DocumentEvents and implement all methods of this interface.
Document doc = stylevision.getActiveDocument();
doc.addListener(new DocumentEventsDefaultHandler()
{
    @Override
    public void onDocumentClosed(Document i_ipDoc) throws AutomationException
    {
        System.out.println("Document " + i_ipDoc.getName() + " requested closing.");
    }
});
doc.close();
doc = null;

17.2.2 Interfaces

This chapter contains the reference of the StyleVision Type Library.

17.2.2.1 Application

Methods

Quit 862

Properties

Application  862
Parent  862

ActiveDocument  862
Documents  862

Status  862
MajorVersion  862
MinorVersion  862
Edition  862
IsAPISupported  862
ServicePackVersion  862

Description
Application is the root for all other objects. It is the only object you can create by CreateObject (VisualBasic) or other similar COM related functions.

Example

Dim objSpy As Application
Set objSpy = CreateObject("XMLSpy.Application")

17.2.2.1.1  Events

17.2.2.1.1  OnShutDown

*Event:* OnShutDown()

*Description*
Sent just before StyleVision shuts down.

17.2.2.1.2  ActiveDocument

*Property:* ActiveDocument as *Document* (read-only)

*Description*
Reference to the active document. If no document is open, ActiveDocument is null (nothing).

*Errors*
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.

17.2.2.1.3  Application

*Property:* Application as *Application* (read-only)

*Description*
Accesses the StyleVision application object.

*Errors*
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.

17.2.2.1.4  Documents

*Property:* Documents as *Documents*

*Description*
Collection of all open documents.

*Errors*
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.
17.2.2.1.5 **Edition**

*Property:* Edition as String

**Description**
Returns the edition of the application, for example *Altova StyleVision Enterprise Edition for the Enterprise edition.*

**Errors**

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>The application object is no longer valid.</td>
</tr>
<tr>
<td>1100</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>

17.2.2.1.6 **IsAPISupported**

*Property:* IsAPISupported as Boolean

**Description**
Returns whether the API is supported in this version or not.

**Errors**

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>The application object is no longer valid.</td>
</tr>
<tr>
<td>1100</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>

17.2.2.1.7 **MajorVersion**

*Property:* MajorVersion as Integer

**Description**
Returns the application version's major number, for example 15 for 2013 versions, and 16 for 2014 versions.

**Errors**

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>The application object is no longer valid.</td>
</tr>
<tr>
<td>1100</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>

17.2.2.1.8 **MinorVersion**

*Property:* MinorVersion as Integer

**Description**
Returns the application version's minor number.

**Errors**

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1111</td>
<td>The application object is no longer valid.</td>
</tr>
<tr>
<td>1100</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>
17.2.2.1.9  NewDocument

*Method:* NewDocument as Document

**Return Value**
None

**Description**
Creates a new empty document based on the previous template.

**Errors**
- 1000   The application object is invalid.
- 1005   Error when creating a new document
- 1006   Cannot create document

17.2.2.1.10  OpenDocument

*Method:* OpenDocument(strFileName as String) as Document

**Return Value**
None

**Description**
Opens an existing SPS file.

**Errors**
- 1000   The application object is invalid.
- 1002   Invalid file extension.
- 1003   Error when opening document.
- 1004   Cannot open document.

17.2.2.1.11  Parent

*Property:* Parent as Application (read-only)

**Description**
Accesses the StyleVision application object.

**Errors**
- 1111   The application object is no longer valid.
- 1100   Invalid address for the return parameter was specified.
17.2.2.1.12  Quit

**Method:** Quit()

**Return Value**
None

**Description**
This method terminates StyleVision. All modified documents will be closed without saving the changes. This is also true for an open project.

If StyleVision was automatically started as an automation server by a client program, the application will not shut down automatically when your client program shuts down if a project or any document is still open. Use the Quit method to ensure automatic shut-down.

**Errors**
- 1111  The application object is no longer valid.

17.2.2.1.13  ServicePackVersion

**Property:** ServicePackVersion as Long

**Description**
Returns the Service Pack version number of the application. Eg: 1 for 2010 R2 SP1

**Errors**
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.

17.2.2.1.14  Status

**Property:** Status as ENUMApplicationStatus

**Description**
Returns the current status of the running application.

**Errors**
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.

17.2.2.1.15  Visible

**Property:** Visible as VARIANT_BOOL

**Description**
Sets or gets the visibility attribute of StyleVision.
Errors
1110 The application object is no longer valid.
1100 Invalid address for the return parameter was specified.

17.2.2.2 AppOutputLine

Represents a message line. Its structure is more detailed and can contain a collection of child lines, thereby forming a tree of message lines.

Properties and Methods
Properties to navigate the object model:

- Application
- Parent

Line access:

- GetLineSeverity
- GetLineSymbol
- GetLineText
- GetLineTextEx
- GetLineTextWithChildren
- GetLineTextWithChildrenEx

A single AppOutputLine consists of one or more sub-lines.

Sub-line access:

- GetLineCount

A sub-line consists of one or more cells.

Cell access:

- GetCellCountInLine
- GetCellIcon
- GetCellStyle
- GetCellText
- GetCellTextDecoration
- GetIsCellText

Below an AppOutputLine there can be zero, one, or more child lines which themselves are of type AppOutputLine, which thus form a tree structure.

Child lines access:

- ChildLines
17.2.2.2.1 Application

Property: Application as Application (read-only)

Description
Retrieves the application's top-level object.

Errors
- 4100 The object is no longer valid.
- 4101 Invalid address for the return parameter was specified.

17.2.2.2 ChildLines

Property: ChildLines as AppOutputLines (read-only)

Description
Returns a collection of the current line's direct child lines.

Errors
- 4100 The application object is no longer valid.
- 4101 Invalid address for the return parameter was specified.

17.2.2.3 GetCellCountInLine

Method: GetCellCountInLine (nLine as Long) as Long

Description
Gets the number of cells in the sub-line indicated by nLine in the current AppOutputLine.

Errors
- 4100 The object is no longer valid.
- 4101 Invalid address for the return parameter was specified.

17.2.2.4 GetCellIcon

Method: GetCellIcon (nLine as Long, nCell as Long) as Long

Description
Gets the icon of the cell indicated by nCell in the current AppOutputLine's sub-line indicated by nLine.

Errors
- 4100 The object is no longer valid.
- 4101 Invalid address for the return parameter was specified.
17.2.2.2.5  GetCellSymbol

**Method:** GetCellSymbol (nLine as Long, nCell as Long) as AppOutputLineSymbol

**Description**
Gets the symbol of the cell indicated by nCell in the current AppOutputLine's sub-line indicated by nLine.

**Errors**
- 4100  The object is no longer valid.
- 4101  Invalid address for the return parameter was specified.

17.2.2.2.6  GetCellText

**Method:** GetCellText (nLine as Long, nCell as Long) as String

**Description**
Gets the text of the cell indicated by nCell in the current AppOutputLine's sub-line indicated by nLine.

**Errors**
- 4100  The object is no longer valid.
- 4101  Invalid address for the return parameter was specified.

17.2.2.2.7  GetCellTextDecoration

**Method:** GetCellTextDecoration (nLine as Long, nCell as Long) as Long

**Description**
Gets the decoration of the text cell indicated by nCell in the current AppOutputLine's sub-line indicated by nLine.
It can be one of the ENUMAppOutputLine_TextDecoration values.

**Errors**
- 4100  The object is no longer valid.
- 4101  Invalid address for the return parameter was specified.

17.2.2.2.8  GetIsCellText

**Method:** GetIsCellText (nLine as Long, nCell as Long) as String

**Description**
Gets the text of the cell indicated by nCell in the current AppOutputLine's sub-line indicated by nLine.

**Errors**
- 4100  The object is no longer valid.
4101 Invalid address for the return parameter was specified.

17.2.2.2.9 GetLineCount

*Method:* GetLineCount () as Long

*Description*
Gets the number of sub-lines the current line consists of.

*Errors*
- 4100 The object is no longer valid.
- 4101 Invalid address for the return parameter was specified.

17.2.2.2.10 GetLineSeverity

*Method:* GetLineSeverity () as Long

*Description*
Gets the severity of the line. It can be one of the ENUMAppOutputLine_Severity values:

*Errors*
- 4100 The object is no longer valid.
- 4101 Invalid address for the return parameter was specified.

17.2.2.2.11 GetLineSymbol

*Method:* GetLineSymbol () as AppOutputLineSymbol

*Description*
Gets the symbol assigned to the whole line.

*Errors*
- 4100 The object is no longer valid.
- 4101 Invalid address for the return parameter was specified.

17.2.2.2.12 GetLineText

*Method:* GetLineText () as String

*Description*
 Gets the contents of the line as text.

*Errors*
17.2.2.2.13 GetLineTextEx

**Method:** GetLineTextEx (psTextPartSeparator as String, psLineSeparator as String) as String

**Description**
Gets the contents of the line as text using the specified part and line separators.

**Errors**
- 4100: The object is no longer valid.
- 4101: Invalid address for the return parameter was specified.

17.2.2.2.14 GetLineTextWithChildren

**Method:** GetLineTextWithChildren () as String

**Description**
Gets the contents of the line including all child and descendant lines as text.

**Errors**
- 4100: The object is no longer valid.
- 4101: Invalid address for the return parameter was specified.

17.2.2.2.15 GetLineTextWithChildrenEx

**Method:** GetLineTextWithChildrenEx (psPartSep as String, psLineSep as String, psTabSep as String, psItemSep as String) as String

**Description**
Gets the contents of the line including all child and descendant lines as text using the specified part, line, tab and item separators.

**Errors**
- 4100: The object is no longer valid.
- 4101: Invalid address for the return parameter was specified.

17.2.2.2.16 Parent

**Property:** Parent as AppOutputLines (read-only)

**Description**
The parent object according to the object model.

**Errors**
- 4100 The object is no longer valid.
- 4101 Invalid address for the return parameter was specified.

### 17.2.2.3 AppOutputLines

Represents a collection of AppOutputLine message lines.

**Properties and Methods**
Properties to navigate the object model:

- **Application**
- **Parent**

Iterating through the collection:

- **Count**
- **Item**

#### 17.2.2.3.1 Application

**Property:** Application as Application (read-only)

**Description**
Retrieves the application's top-level object.

**Errors**
- 4000 The object is no longer valid.
- 4001 Invalid address for the return parameter was specified.

#### 17.2.2.3.2 Count

**Property:** Count as Integer (read-only)

**Description**
Retrieves the number of lines in the collection.

**Errors**
- 4000 The object is no longer valid.
- 4001 Invalid address for the return parameter was specified.
17.2.2.3.3  Item

Property: Item (nIndex as Integer) as AppOutputLine (read-only)

Description
Retrieves the line at nIndex from the collection. Indices start with 1.

Errors
4000  The object is no longer valid.
4001  Invalid address for the return parameter was specified.

17.2.2.3.4  Parent

Property: Parent as AppOutputLine (read-only)

Description
The parent object according to the object model.

Errors
4000  The object is no longer valid.
4001  Invalid address for the return parameter was specified.

17.2.2.4  AppOutputLineSymbol

An AppOutputLineSymbol represents a link in an AppOutputLine message line which can be clicked in the StyleVision Messages window. It is applied to a cell of an AppOutputLine or to the whole line itself.

Properties and Methods
Properties to navigate the object model:

Application
Parent

Access to AppOutputLineSymbol methods:

GetSymbolHREF
GetSymbolID
IsSymbolHREF

17.2.2.4.1  Application

Property: Application as Application (read-only)
Description
Retrieves the application's top-level object.

Errors
- 4200 The object is no longer valid.
- 4201 Invalid address for the return parameter was specified.

17.2.2.4.2 GetSymbolHREF

Method: GetSymbolHREF () as String

Description
If the symbol is of type URL, returns the URL as a string.

Errors
- 4200 The object is no longer valid.
- 4201 Invalid address for the return parameter was specified.

17.2.2.4.3 GetSymbolID

Method: GetSymbolHREF () as Long

Description
Gets the ID of the symbol.

Errors
- 4200 The object is no longer valid.
- 4201 Invalid address for the return parameter was specified.

17.2.2.4.4 IsSymbolHREF

Method: IsSymbolHREF () as Boolean

Description
Indicates if the symbol is of kind URL.

Errors
- 4200 The object is no longer valid.
- 4201 Invalid address for the return parameter was specified.
17.2.2.4.5 Parent

Property: Parent as Application (read-only)

Description
The parent object according to the object model.

Errors
4200 The object is no longer valid.
4201 Invalid address for the return parameter was specified.

17.2.2.5 AuthenticContextMenu

The context menu interface provides the means for the user to customize the context menus shown in Authentic. The interface has the methods listed in this section.

17.2.2.5.1 CountItems

Method: CountItems() nItems as long

Return Value
Returns the number of menu items.

Errors
2501 Invalid object.

17.2.2.5.2 DeleteItem

Method: DeleteItem(IndexPosition as long)

Return Value
Deletes the menu item that has the index position submitted in the first parameter.

Errors
2501 Invalid object
2502 Invalid index
17.2.2.5.3 GetItemText

Method: GetItemText(IndexPosition as long) MenuItemName as string

Return Value
Gets the name of the menu item located at the index position submitted in the first parameter.

Errors
2501 Invalid object
2502 Invalid index

17.2.2.5.4 InsertItem

Method: InsertItem(IndexPosition as long, MenuItemName as string, MacroName as string)

Return Value
Inserts a user-defined menu item at the position in the menu specified in the first parameter and having the name submitted in the second parameter. The menu item will start a macro, so a valid macro name must be submitted.

Errors
2501 Invalid object
2502 Invalid index
2503 No such macro
2504 Internal error

17.2.2.5.5 SetItemText

Method: SetItemText(IndexPosition as long, MenuItemName as string)

Return Value
Sets the name of the menu item located at the index position submitted in the first parameter.

Errors
2501 Invalid object
2502 Invalid index

17.2.2.6 AuthenticEventContext

The EventContext interface gives access to many properties of the context in which a macro is executed.
17.2.2.6.1 EvaluateXPath

Method: EvaluateXPath (strExpression as string) as strValue as string

Return Value
The method evaluates the XPath expression in the context of the node within which the event was triggered and returns a string.

Description
EvaluateXPath() executes an XPath expression with the given event context. The result is returned as a string, in the case of a sequence it is a space-separated string.

Errors
2201 Invalid object.
2202 No context.
2209 Invalid parameter.
2210 Internal error.
2211 XPath error.

17.2.2.6.2 GetEventContextType

Method: GetEventContextType () Type as AuthenticEventContextType enumeration

Return Value
Returns the context node type.

Description
GetEventContextType allows the user to determine whether the macro is in an XML node or in an XPath atomic item context. The enumeration AuthenticEventContextType is defined as follows:

authenticEventContextXML,
authenticEventContextAtomicItem,
authenticEventContextOther

If the context is a normal XML node, the GetXMLNode() function gives access to it (returns NULL if not).

Errors
2201 Invalid object.
2202 No context.
2209 Invalid parameter.

17.2.2.6.3 GetNormalizedTextValue

Method: GetNormalizedTextValue () strValue as string

Return Value
Returns the value of the current node as string

Errors
2201 Invalid object.
2202 No context.
2203 Invalid context
2209 Invalid parameter.

17.2.2.6.4 GetVariableValue

Method: GetVariableValue (strName as string) strValue as string

Return Value
Gets the value of the variable submitted as the parameter.

Description
GetVariableValue gets the variable's value in the scope of the context.

nZoom = parseInt( AuthenticView.EventContext.GetVariableValue(’Zoom’));
if (nZoom > 1 )
{
    AuthenticView.EventContext.SetVariableValue( ’Zoom’, nZoom - 1 );
}

Errors
2201 Invalid object.
2202 No context.
2204 No such variable in scope
2205 Variable cannot be evaluated
2206 Variable returns sequence
2209 Invalid parameter

17.2.2.6.5 GetXMLNode

Method: GetXMLNode () Node as XMLData object

Return Value
Returns the context XML node or NULL

Errors
2201 Invalid object.
2202 No context.
2203 Invalid context
2209 Invalid parameter.
17.2.2.6.6  IsAvailable

**Method:** IsAvailable() as Boolean

**Return Value**
Returns true if EventContext is set, false otherwise.

**Errors**
- 2201  Invalid object.

17.2.2.6.7  SetVariableValue

**Method:** SetVariableValue(strName as string, strValue as string)

**Return Value**
Sets the value (second parameter) of the variable submitted in the first parameter.

**Description**
SetVariableValue sets the variable's value in the scope of the context.

```plaintext
nZoom = parseInt( AuthenticView.EventContext.GetVariableValue( 'Zoom' ) );
if ( nZoom > 1 )
{
    AuthenticView.EventContext.SetVariableValue( 'Zoom', nZoom - 1 );
}
```

**Errors**
- 2201  Invalid object.
- 2202  No context.
- 2204  No such variable in scope
- 2205  Variable cannot be evaluated
- 2206  Variable returns sequence
- 2207  Variable read-only
- 2208  No modification allowed

17.2.2.7  AuthenticRange

The first table lists the properties and methods of AuthenticRange that can be used to navigate through the document and select specific portions.

<table>
<thead>
<tr>
<th>Properties</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application</td>
<td>Clone</td>
</tr>
<tr>
<td></td>
<td>MoveBegin</td>
</tr>
</tbody>
</table>
The following table lists the content modification methods, most of which can be found on the right/button mouse menu.

<table>
<thead>
<tr>
<th>Properties</th>
<th>Edit operations</th>
<th>Dynamic table operations</th>
</tr>

</tbody>
</table>
**SetElementAttributeValue**

**Description**

AuthenticRange objects are the ‘cursor’ selections of the automation interface. You can use them to point to any cursor position in the Authentic view, or select a portion of the document. The operations available for AuthenticRange objects then work on this selection in the same way, as the corresponding operations of the user interface do with the current user interface selection. The main difference is that you can use an arbitrary number of AuthenticRange objects at the same time, whereas there is exactly one cursor selection in the user interface.

To get to an initial range object use **AuthenticView.Selection** to obtain a range corresponding with the current cursor selection in the user interface. Alternatively, some trivial ranges are accessible via the read-only properties **AuthenticView.DocumentBegin**, **AuthenticView.DocumentEnd**, and **AuthenticView.WholeDocument**. The most flexible method is **AuthenticView.Goto**, which allows navigation to a specific portion of the document within one call. For more complex selections, combine the above with the various navigation methods on range objects listed in the first table on this page.

Another method to select a portion of the document is to use the position properties of the range object. Two positioning systems are available and can be combined arbitrarily:

- **Absolute** text cursor positions, starting with position 0 at the document beginning, can be set and retrieved for the beginning and end of a range. For more information see **FirstTextPosition** and **LastTextPosition**. This method requires complex internal calculations and should be used with care.

- The **XMLData** element and a text position inside this element, can be set and retrieved for the beginning and end of a range. For more information see **FirstXMLData**, **FirstXMLDataOffset**, **LastXMLData**, and **LastXMLDataOffset**. This method is very efficient but requires knowledge of the underlying document structure. It can be used to locate XMLData objects and perform operations on them otherwise not accessible through the user interface.

Modifications to the document content can be achieved by various methods:

- The **Text** property allows you to retrieve the document text selected by the range object. If set, the selected document text gets replaced with the new text.
- The standard document edit functions **Cut**, **Copy**, **Paste** and **Delete**.
- Table operations for tables that can grow dynamically.
- Methods that map the functionality of the Authentic entry helper windows.
- Access to the **XMLData** objects of the underlying document to modify them directly.

**17.2.2.7.1 AppendRow**

**Method:** AppendRow() as Boolean

**Description**

If the beginning of the range is inside a dynamic table, this method inserts a new row at the end of the selected table. The selection of the range is modified to point to the beginning of the new row. The function returns **true** if the append operation was successful, otherwise **false**.
Errors

2001    The authentic range object or its related view object is no longer valid.
2005    Invalid address for the return parameter was specified.

Examples

' ---------------------------------------------------------
' Scripting environment - VBScript
' Append row at end of current dynamically growable table
' ---------------------------------------------------------
Dim objRange
' we assume that the active document is open in authentic view mode
Set objRange = Application.ActiveDocument.AuthenticView.Selection

' check if we can insert something
If objRange.IsInDynamicTable Then
    objRange.AppendRow
    ' objRange points to beginning of new row
    objRange.Select
End If

17.2.2.7.2 Application

Property: Application as Application (read-only)

Description
Accesses the StyleVision application object.

Errors

2001    The authentic range object or its related view object is no longer valid.
2005    Invalid address for the return parameter was specified.

17.2.2.7.3 CanPerformAction

Method: CanPerformAction (eAction as SPYAuthenticActions, strElementName as String) as Boolean

Description
CanPerformAction and its related methods enable access to the entry-helper functions of Authentic. This function allows easy and consistent modification of the document content, without having to know exactly where the modification will take place. The beginning of the range object is used to locate the next valid location where the specified action can be performed. If the location can be found, the method returns True, otherwise it returns False.

HINT: To find out all valid element names for a given action, use CanPerformActionWith.

Errors

2001    The authentic range object or its related view object is no longer valid.
2005    Invalid address for the return parameter was specified.
2007    Invalid action was specified.

Examples
See PerformAction.

17.2.2.7.4  CanPerformActionWith

Method: CanPerformActionWith (eAction as SPYAuthenticActions, out_arrElementNames as Variant)

Description
PerformActionWith and its related methods, enable access to the entry-helper functions of Authentic. This function allows easy and consistent modification of the document content without having to know exactly where the modification will take place.

This method returns an array of those element names that the specified action can be performed with.

HINT: To apply the action use CanPerformActionWith.

Errors
2001 The authentic range object, or its related view object is no longer valid.
2005 Invalid address for the return parameter was specified.
2007 Invalid action was specified.

Examples
See PerformAction.

17.2.2.7.5  Clone

Method: Clone() as AuthenticRange

Description
Returns a copy of the range object.

Errors
2001 The authentic range object, or its related view object is no longer valid.
2005 Invalid address for the return parameter was specified.

17.2.2.7.6  CollapsToBegin

Method: CollapsToBegin() as AuthenticRange

Description
Sets the end of the range object to its begin. The method returns the modified range object.

Errors
2001 The authentic range object, or its related view object is no longer valid.
2005 Invalid address for the return parameter was specified.
17.2.2.7.7  CollapsToEnd

Method:  CollapsToEnd() as AuthenticRange

Description
Sets the beginning of the range object to its end. The method returns the modified range object.

Errors
2001  The authentic range object, or its related view object is no longer valid.
2005  Invalid address for the return parameter was specified.

17.2.2.7.8  Copy

Method:  Copy() as Boolean

Description
Returns False if the range contains no portions of the document that may be copied.
Returns True if text, and in case of fully selected XML elements the elements as well, has been copied to the copy/paste buffer.

Errors
2001  The authentic range object or its related view object is no longer valid.
2005  Invalid address for the return parameter was specified.

17.2.2.7.9  Cut

Method:  Cut() as Boolean

Description
Returns False if the range contains portions of the document that may not be deleted.
Returns True after text, and in case of fully selected XML elements the elements as well, has been deleted from the document and saved in the copy/paste buffer.

Errors
2001  The authentic range object, or its related view object is no longer valid.
2005  Invalid address for the return parameter was specified.

17.2.2.7.10  Delete

Method:  Delete() as Boolean

Description
Returns False if the range contains portions of the document that may not be deleted.
Returns True after text, and in case of fully selected XML elements the elements as well, has been deleted from the document.
Errors
2001 The authentic range object or its related view object is no longer valid.
2005 Invalid address for the return parameter was specified.

17.2.2.7.11  DeleteRow

*Method:* DeleteRow() as Boolean

*Description*
If the beginning of the range is inside a dynamic table, this method deletes the selected row. The selection of
the range gets modified to point to the next element after the deleted row. The function returns *true*, if the delete
operation was successful, otherwise *false*.

Errors
2001 The authentic range object, or its related view object is no longer valid.
2005 Invalid address for the return parameter was specified.

*Examples*
' ---------------------------------------------------------
' Scripting environment - VBScript
' Delete selected row from dynamically growing table
' ---------------------------------------------------------
Dim objRange
' we assume that the active document is open in authentic view mode
Set objRange = Application.ActiveDocument.AuthenticView.Selection

' check if we are in a table
If objRange.IsInDynamicTable Then
    objRange.DeleteRow
End If

17.2.2.7.12  DuplicateRow

*Method:* DuplicateRow() as Boolean

*Description*
If the beginning of the range is inside a dynamic table, this method inserts a duplicate of the current row after
the selected one. The selection of the range gets modified to point to the beginning of the new row. The function
returns *true* if the duplicate operation was successful, otherwise *false*.

Errors
2001 The authentic range object, or its related view object is no longer valid.
2005 Invalid address for the return parameter was specified.

*Examples*
' ---------------------------------------------------------
' Scripting environment - VBScript
' duplicate row in current dynamically growable table
' ---------------------------------------------------------
Dim objRange
' we assume that the active document is open in authentic view mode
Set objRange = Application.ActiveDocument.AuthenticView.Selection

' check if we can insert something
If objRange.InDynamicTable Then
    objRange.DuplicateRow
    ' objRange points to beginning of new row
    objRange.Select
End If

17.2.2.7.13  EvaluateXPath

Method: EvaluateXPath (strExpression as string) strValue as string

Return Value
The method returns a string

Description
EvaluateXPath() executes an XPath expression with the context node being the beginning of the range selection. The result is returned as a string, in the case of a sequence it is a space-separated string. If XML context node is irrelevant, the user may provide any node, like AuthenticView.XMLDataRoot.

Errors
   2001  Invalid object
   2005  Invalid parameter
   2008  Internal error
   2202  Missing context node
   2211  XPath error

17.2.2.7.14  ExpandTo

Method: ExpandTo (eKind as SPYAuthenticElementKind), as AuthenticRange

Description
Selects the whole element of type eKind, that starts at, or contains, the first cursor position of the range. The method returns the modified range object.

Errors
   2001  The authentic range object, or its related view object is no longer valid.
   2003  Range expansion would be beyond end of document.
   2005  Invalid address for the return parameter was specified.

17.2.2.7.15  FirstTextPosition

Property: FirstTextPosition as Long

Description
Set or get the left-most text position index of the range object. This index is always less or equal to `LastTextPosition`. Indexing starts with 0 at document beginning, and increments with every different position that the text cursor can occupy. Incrementing the test position by 1, has the same effect as the cursor-right key. Decrementing the test position by 1 has the same effect as the cursor-left key.

If you set `FirstTextPosition` to a value greater than the current `LastTextPosition`, `LastTextPosition` gets set to the new `FirstTextPosition`.

**HINT:** Use text cursor positions with care, since this is a costly operation compared to XMLData based cursor positioning.

### Errors

- **2001** The authentic range object, or its related view object is not valid.
- **2005** Invalid address for the return parameter was specified.
- **2006** A text position outside the document was specified.

### Examples

```
' ---------------------------------------
' Scripting environment - VBScript
' ---------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView
nDocEndPosition = objAuthenticView.DocumentEnd.FirstTextPosition

' let's create a range that selects the whole document
' in an inefficient way
Dim objRange
' we need to get a (any) range object first
Set objRange = objAuthenticView.DocumentBegin
objRange.FirstTextPosition = nDocStartPosition
objRange.LastTextPosition = nDocEndPosition

' let's check if we got it right
If objRange.isEqual(objAuthenticView.WholeDocument) Then
    MsgBox "Test using direct text cursor positioning was ok"
Else
    MsgBox "Ooops!"
End If
```

### 17.2.2.7.16 FirstXMLData

**Property:** `FirstXMLData` as `XMLData`<sup>896</sup>

**Description**
Set or get the first XMLData element in the underlying document that is partially, or completely selected by the range. The exact beginning of the selection is defined by the `FirstXMLDataOffset` attribute.
Whenever you set FirstXMLData to a new data object, FirstXMLDataOffset gets set to the first cursor position inside this element. Only XMLData objects that have a cursor position may be used. If you set FirstXMLData / FirstXMLDataOffset selects a position greater than the current LastXMLData / LastXMLDataOffset, the latter gets moved to the new start position.

HINT: You can use the FirstXMLData and LastXMLData properties to directly access and manipulate the underlying XML document in those cases where the methods available with the AuthenticRange object are not sufficient.

Errors

- 2001 The authentic range object, or its related view object is not valid.
- 2005 Invalid address for the return parameter was specified.
- 2008 Internal error
- 2009 The XMLData object cannot be accessed.

Examples

```vbs
' _______________________________________________________
' Scripting environment - VBScrip
' show name of currently selected XMLData element
' _______________________________________________________
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

Dim objXMLData
Set objXMLData = objAuthenticView.Selection.FirstXMLData
' authentic view adds a "text" child element to elements
' of the document which have content. So we have to go one
' element up.
Set objXMLData = objXMLData.Parent
MsgBox "Current selection selects element " & objXMLData.Name
```

17.2.7.17 FirstXMLDataOffset

**Property:** FirstXMLDataOffset as Long

**Description**
Set or get the cursor position offset inside FirstXMLData element for the beginning of the range. Offset positions are based on the characters returned by the Text property, and start with 0. When setting a new offset, use -1 to set the offset to the last possible position in the element. The following cases require specific attention:

- The textual form of entries in Combo Boxes, Check Boxes and similar controls can be different from what you see on screen. Although the data offset is based on this text, there only two valid offset positions, one at the beginning and one at the end of the entry. An attempt to set the offset to somewhere in the middle of the entry, will result in the offset being set to the end.

- The textual form of XML Entities might differ in length from their representation on the screen. The offset is based on this textual form.
If `FirstXMLData` / `FirstXMLDataOffset` selects a position after the current `LastXMLData` / `LastXMLDataOffset`, the latter gets moved to the new start position.

**Errors**

- **2001** The authentic range object, or its related view object is not valid.
- **2005** Invalid offset was specified.
  - Invalid address for the return parameter was specified.

**Examples**

```vbscript
' Scripting environment - VBScript
' Select the complete text of an XMLData element
' using XMLData based selection and ExpandTo
' ---------------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

' first we use the XMLData based range properties
' to select all text of the first XMLData element
' in the current selection
Dim objRange
Set objRange = objAuthenticView.Selection
objRange.FirstXMLDataOffset = 0 ' start at beginning of element text
objRange.LastXMLData = objRange.FirstXMLData ' select only one element
objRange.LastXMLDataOffset = -1 ' select till its end

' the same can be achieved with the ExpandTo method
Dim objRange2
Set objRange2 = objAuthenticView.Selection.ExpandTo(spyAuthenticTag)

' were we successful?
If objRange.IsEqual(objRange2) Then
  objRange.Select()
Else
  MsgBox "Oops"
End If
```

**17.2.2.7.18 GetElementAttributeNames**

**Method:** GetElementAttributeNames (strAttributeName as String, out_arrAttributeNames as Variant)

**Description**
Retrieve the names of all attributes for the enclosing element with the specified name. Use the element/attribute pairs, to set or get the attribute value with the methods `GetElementAttributeValue` and `SetElementAttributeValue`.

**Errors**

- **2001** The authentic range object, or its related view object is no longer valid.
- **2005** Invalid element name was specified.
  - Invalid address for the return parameter was specified.
Examples
See SetElementAttributeValue.

17.2.2.7.19  GetElementAttributeValue

Method: GetElementAttributeValue (strElementName as String, strAttributeName as String) as String

Description
Retrieve the value of the attribute specified in strAttributeName, for the element identified with strElementName. If the attribute is supported but has no value assigned, the empty string is returned. To find out the names of attributes supported by an element, use GetElementAttributeNames, or HasElementAttribute.

Errors
2001  The authentic range object, or its related view object is no longer valid.
2005  Invalid element name was specified.
       Invalid attribute name was specified.
       Invalid address for the return parameter was specified.

Examples
See SetElementAttributeValue.

17.2.2.7.20  GetElementHierarchy

Method: GetElementHierarchy (out_arrElementNames as Variant)

Description
Retrieve the names of all XML elements that are parents of the current selection. Inner elements get listed before enclosing elements. An empty list is returned whenever the current selection is not inside a single XMLData element.

The names of the element hierarchy, together with the range object uniquely identify XMLData elements in the document. The attributes of these elements can be directly accessed by GetElementAttributeNames, and related methods.

Errors
2001  The authentic range object, or its related view object is no longer valid.
2005  Invalid address for the return parameter was specified.

17.2.2.7.21  GetEntityNames

Method: GetEntityNames (out_arrEntityNames as Variant)

Description
Retrieve the names of all defined entities. The list of retrieved entities is independent of the current selection, or location. Use one of these names with the InsertEntity function.

Errors
2001 The authentic range object, or its related view object is no longer valid.
2005 Invalid address for the return parameter was specified.

Examples
See: GetElementHierarchy and InsertEntity.

17.2.2.7.22 GetVariableValue

Method: GetVariableValue(strName as string) strVal as string

Return Value
Gets the value of the variable named as the method's parameter.

Errors
2001 Invalid object.
2202 No context.
2204 No such variable in scope
2205 Variable cannot be evaluated
2206 Variable returns sequence
2209 Invalid parameter

17.2.2.7.23 Goto

Method: Goto (eKind as SPYAuthenticElementKind, nCount as Long, eFrom as SPYAuthenticDocumentPosition) as AuthenticRange

Description
Sets the range to point to the beginning of the nCount element of type eKind. The start position is defined by the parameter eFrom.

Use positive values for nCount to navigate to the document end. Use negative values to navigate to the beginning of the document. The method returns the modified range object.

Errors
2001 The authentic range object, or its related view object is no longer valid.
2003 Target lies after end of document.
2004 Target lies before begin of document.
2005 Invalid element kind specified.
Invalid start position specified.
Invalid address for the return parameter was specified.
17.2.2.7.24  GotoNext

Method: GotoNext (eKind as SPYAuthenticElementKind) as AuthenticRange

Description
Sets the range to the beginning of the next element of type eKind. The method returns the modified range object.

Errors
2001  The authentic range object, or its related view object is no longer valid.
2003  Target lies after end of document.
2005  Invalid element kind specified.
Invalid address for the return parameter was specified.

Examples
'  ---------------------------------------------------------------------
'  Scripting environment - VBScript
'  Scan through the whole document word-by-word
'  ---------------------------------------------------------------------
Dim objAuthenticView
'  we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

Dim objRange
Set objRange = objAuthenticView.DocumentBegin
Dim bEndOfDocument
bEndOfDocument = False
On Error Resume Next
While Not bEndOfDocument
    objRange.GotoNext(spyAuthenticWord).Select
    If ((Err.number - vbObjecterror) = 2003) Then
        bEndOfDocument = True
        Err.Clear
    ElseIf (Err.number <> 0) Then
        Err.Raise ' forward error
    End If
Wend

17.2.2.7.25  GotoNextCursorPosition

Method: GotoNextCursorPosition() as AuthenticRange

Description
Sets the range to the next cursor position after its current end position. Returns the modified object.

Errors
2001  The authentic range object, or its related view object is no longer valid.
2003  Target lies after end of document.
2005  Invalid address for the return parameter was specified.
17.2.2.7.26  GotoPrevious

Method: GotoPrevious (eKind as SPYAuthenticElementKind) as AuthenticRange

Description
Sets the range to the beginning of the element of type eKind which is before the beginning of the current range. The method returns the modified range object.

Errors
- 2001  The authentic range object, or its related view object is no longer valid.
- 2004  Target lies before beginning of document.
- 2005  Invalid element kind specified.
- Invalid address for the return parameter was specified.

Examples
' --------------------------------------------
' Scripting environment - VBScript
' Scan through the whole document tag-by-tag
' --------------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

Dim objRange
Set objRange = objAuthenticView.DocumentEnd
Dim bBeginOfDocument
bBeginOfDocument = False
On Error Resume Next
While Not bBeginOfDocument
    objRange.GotoPrevious(spyAuthenticTag).Select
    If ((Err.number - vbObjecterror) = 2004) Then
        bBeginOfDocument = True
        Err.Clear
    ElseIf (Err.number <> 0) Then
        Err.Raise  ' forward error
    End If
Wend

17.2.2.7.27  GotoPreviousCursorPosition

Method: GotoPreviousCursorPosition() as AuthenticRange

Description
Set the range to the cursor position immediately before the current position. Returns the modified object.

Errors
- 2001  The authentic range object, or its related view object is no longer valid.
- 2004  Target lies before begin of document.
2005  Invalid address for the return parameter was specified.

17.2.2.7.28  HasElementAttribute

*Method:* HasElementAttribute *strElementName* as String, *strAttributeName* as String) as Boolean

*Description*
Tests if the enclosing element with name *strElementName*, supports the attribute specified in *strAttributeName*.

*Errors*
- 2001  The authentic range object, or its related view object is no longer valid.
- 2005  Invalid element name was specified.
- Invalid address for the return parameter was specified.

17.2.2.7.29  InsertEntity

*Method:* InsertEntity (strEntityName as String)

*Description*
Replace the ranges selection with the specified entity. The specified entity must be one of the entity names returned by GetEntityNames.

*Errors*
- 2001  The authentic range object, or its related view object is no longer valid.
- 2005  Unknown entry name was specified.

*Examples*
```vbscript
' ---------------------------------------------------------
' Scripting environment - VBScript
' Insert the first entity in the list of available entities
' ---------------------------------------------------------
Dim objRange
' we assume that the active document is open in authentic view mode
Set objRange = Application.ActiveDocument.AuthenticView.Selection

' first we get the names of all available entities as they
' are shown in the entry helper of XMLSpy
Dim arrEntities
objRange.GetEntityNames arrEntities

' we insert the first one of the list
If UBound(arrEntities) >= 0 Then
    objRange.InsertEntity arrEntities(0)
Else
    MsgBox "Sorry, no entities are available for this document"
End If
```
17.2.2.7.30    InsertRow

*Method:* InsertRow() as Boolean

*Description*
If the beginning of the range is inside a dynamic table, this method inserts a new row before the current one. The selection of the range gets modified to point to the beginning of the newly inserted row. The function returns *true* if the insert operation was successful, otherwise *false*.

*Errors*
- 2001   The authentic range object, or its related view object is no longer valid.
- 2005   Invalid address for the return parameter was specified.

*Examples*

```
' -------------------------------------------------------------
' Scripting environment - VBScript
' Insert row at beginning of current dynamically growing table
' -------------------------------------------------------------
Dim objRange
' we assume that the active document is open in authentic view mode
Set objRange = Application.ActiveDocument.AuthenticView.Selection

' check if we can insert something
If objRange.IsInDynamicTable Then
    objRange.InsertRow
    ' objRange points to beginning of new row
    objRange.Select
End If
```

17.2.2.7.31    IsCopyEnabled

*Property:* IsCopyEnabled as Boolean (read-only)

*Description*
Checks if the copy operation is supported for this range.

*Errors*
- 2001   The authentic range object, or its related view object is no longer valid.
- 2005   Invalid address for the return parameter was specified.

17.2.2.7.32    IsCutEnabled

*Property:* IsCutEnabled as Boolean (read-only)

*Description*
Checks if the cut operation is supported for this range.

*Errors*
The authentic range object, or its related view object is no longer valid.
Invalid address for the return parameter was specified.

17.2.2.7.33  IsDeleteEnabled

Property: IsDeleteEnabled as Boolean (read-only)

Description
Checks if the delete operation is supported for this range.

Errors
The authentic range object, or its related view object is no longer valid.
Invalid address for the return parameter was specified.

17.2.2.7.34  isEmpty

Method: isEmpty() as Boolean

Description
Tests if the first and last position of the range are equal.

Errors
The authentic range object, or its related view object is no longer valid.
Invalid address for the return parameter was specified.

17.2.2.7.35  isEqual

Method: isEqual (objCmpRange as AuthenticRange) as Boolean

Description
Tests if the start and end of both ranges are the same.

Errors
One of the two range objects being compared, is invalid.
Invalid address for a return parameter was specified.

17.2.2.7.36  IsFirstRow

Property: IsFirstRow as Boolean (read-only)

Description
Test if the range is in the first row of a table. Which table is taken into consideration depends on the extent of
the range. If the selection exceeds a single row of a table, the check is if this table is the first element in an
embedding table. See the entry helpers of the user manual for more information.

Errors
The authentic range object, or its related view object is no longer valid.
2005  Invalid address for the return parameter was specified.

17.2.2.7.37  IsInDynamicTable

**Method:** IsInDynamicTable() as Boolean

**Description**
Test if the whole range is inside a table that supports the different row operations like 'insert', 'append', duplicate, etc.

**Errors**
- 2001  The authentic range object, or its related view object is no longer valid.
- 2005  Invalid address for the return parameter was specified.

17.2.2.7.38  IsLastRow

**Property:** IsLastRow as Boolean (read-only)

**Description**
Test if the range is in the last row of a table. Which table is taken into consideration depends on the extent of the range. If the selection exceeds a single row of a table, the check is if this table is the last element in an embedding table. See the entry helpers of the user manual for more information.

**Errors**
- 2001  The authentic range object, or its related view object is no longer valid.
- 2005  Invalid address for the return parameter was specified.

17.2.2.7.39  IsPasteEnabled

**Property:** IsPasteEnabled as Boolean (read-only)

**Description**
Checks if the paste operation is supported for this range.

**Errors**
- 2001  The authentic range object, or its related view object is no longer valid.
- 2005  Invalid address for the return parameter was specified.

17.2.2.7.40  IsSelected

**Property:** IsSelected as Boolean

**Description**
Returns true() if selection is present. The selection range still can be empty: that happens when e.g. only the cursor is set.

### 17.2.2.7.41 IsTextStateApplied

**Method:** IsTextStateApplied (i_strElementName as String) as Boolean

**Description**
Checks if all the selected text is embedded into an XML Element with name i_strElementName. Common examples for the parameter i_strElementName are "strong", "bold" or "italic".

**Errors**
- 2001 The authentic range object, or its related view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

### 17.2.2.7.42 LastTextPosition

**Property:** LastTextPosition as Long

**Description**
Set or get the rightmost text position index of the range object. This index is always greater or equal to FirstTextPosition. Indexing starts with 0 at the document beginning, and increments with every different position that the text cursor can occupy. Incrementing the test position by 1, has the same effect as the cursor-right key. Decreasing the test position by 1 has the same effect as the cursor-left key.

If you set LastTextPosition to a value less then the current FirstTextPosition, FirstTextPosition gets set to the new LastTextPosition.

HINT: Use text cursor positions with care, since this is a costly operation compared to XMLData based cursor positioning.

**Errors**
- 2001 The authentic range object, or its related view object is not valid.
- 2005 Invalid address for the return parameter was specified.
- 2006 A text position outside the document was specified.

**Examples**

```
' ---------------------------------------
' Scripting environment - VBScript
' ---------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

nDocEndPosition = objAuthenticView.DocumentEnd.FirstTextPosition

' let's create a range that selects the whole document
' in an inefficient way
```
Dim objRange
' we need to get a (any) range object first
Set objRange = objAuthenticView.DocumentBegin
objRange.FirstTextPosition = nDocStartPosition
objRange.LastTextPosition = nDocEndPosition

' let's check if we got it right
If objRange.isEqual(objAuthenticView.WholeDocument) Then
    MsgBox "Test using direct text cursor positioning was ok"
Else
    MsgBox "Oops!"
End If

17.2.2.7.43 LastXMLData

Property: LastXMLData as XMLData

Description
Set or get the last XMLData element in the underlying document that is partially or completely selected by the range. The exact end of the selection is defined by the LastXMLDataOffset attribute.

Whenever you set LastXMLData to a new data object, LastXMLDataOffset gets set to the last cursor position inside this element. Only XMLData objects that have a cursor position may be used. If you set LastXMLData / LastXMLDataOffset, select a position less then the current FirstXMLData / FirstXMLDataOffset, the latter gets moved to the new end position.

HINT: You can use the FirstXMLData and LastXMLData properties to directly access and manipulate the underlying XML document in those cases, where the methods available with the AuthenticRange object are not sufficient.

Errors
2001 The authentic range object, or its related view object is not valid.
2005 Invalid address for the return parameter was specified.
2008 Internal error
2009 The XMLData object cannot be accessed.

17.2.2.7.44 LastXMLDataOffset

Property: LastXMLDataOffset as Long

Description
Set or get the cursor position inside LastXMLData element for the end of the range.

Offset positions are based on the characters returned by the Text property and start with 0. When setting a new offset, use -1 to set the offset to the last possible position in the element. The following cases require specific attention:

- The textual form of entries in Combo Boxes, Check Boxes and similar controls can be different from what you see on the screen. Although, the data offset is based on this text, there only two valid offset positions,
one at the beginning and one at the end of the entry. An attempt to set the offset to somewhere in the middle of the entry, will result in the offset being set to the end.

- The textual form of XML Entities might differ in length from their representation on the screen. The offset is based on this textual form.

If \texttt{LastXMLData} \atabl{LastXMLDataOffset} selects a position before \texttt{FirstXMLData} \atabl{FirstXMLDataOffset}, the latter gets moved to the new end position.

**Errors**

- 2001: The authentic range object, or its related view object is not valid.
- 2005: Invalid offset was specified.
- Invalid address for the return parameter was specified.

**Examples**

' ---------------------------------------------
' Scripting environment - VBScript
' Select the complete text of an XMLData element
' using XMLData based selection and ExpandTo
' ---------------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

' first we use the XMLData based range properties
' to select all text of the first XMLData element
' in the current selection
Dim objRange
Set objRange = objAuthenticView.Selection
objRange.FirstXMLDataOffset = 0 ' start at beginning of element text
objRange.LastXMLData = objRange.FirstXMLData ' select only one element
objRange.LastXMLDataOffset = -1 ' select till its end

' the same can be achieved with the ExpandTo method
Dim objRange2
Set objRange2 = objAuthenticView.Selection.ExpandTo(spyAuthenticTag)

' were we successful?
If objRange.IsEqual(objRange2) Then
  objRange.Select()
Else
  MsgBox "Ooops"
End If

**17.2.2.7.45 MoveBegin**

*Method:* MoveBegin (\texttt{eKind} as \texttt{SPYAuthenticElementKind}, \texttt{nCount} as \texttt{Long}) as \texttt{AuthenticRange}

*Description*

Move the beginning of the range to the beginning of the \texttt{nCount} element of type \texttt{eKind}. Counting starts at the current beginning of the range object.
Use positive numbers for nCount to move towards the document end, use negative numbers to move towards document beginning. The end of the range stays unmoved, unless the new beginning would be larger than it. In this case, the end is moved to the new beginning. The method returns the modified range object.

**Errors**
- 2001 The authentic range object, or its related view object is no longer valid.
- 2003 Target lies after end of document.
- 2004 Target lies before beginning of document.
- 2005 Invalid element kind specified.
  Invalid address for the return parameter was specified.

### 17.2.2.7.46 MoveEnd

**Method:** `MoveEnd (eKind as SPYAuthenticElementKind, nCount as Long) as AuthenticRange`

**Description**
Move the end of the range to the begin of the nCount element of type eKind. Counting starts at the current end of the range object.

Use positive numbers for nCount to move towards the document end, use negative numbers to move towards document beginning. The beginning of the range stays unmoved, unless the new end would be less than it. In this case, the beginning gets moved to the new end. The method returns the modified range object.

**Errors**
- 2001 The authentic range object, or its related view object is no longer valid.
- 2003 Target lies after end of document.
- 2004 Target lies before begin of document.
- 2005 Invalid element kind specified.
  Invalid address for the return parameter was specified.

### 17.2.2.7.47 MoveRowDown

**Method:** `MoveRowDown() as Boolean`

**Description**
If the beginning of the range is inside a dynamic table and selects a row which is not the last row in this table, this method swaps this row with the row immediately below. The selection of the range moves with the row, but does not otherwise change. The function returns `true` if the move operation was successful, otherwise `false`.

**Errors**
- 2001 The authentic range object or its related view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

### 17.2.2.7.48 MoveRowUp

**Method:** `MoveRowUp() as Boolean`

**Description**
If the beginning of the range is inside a dynamic table and selects a row which is not the first row in this table, this method swaps this row with the row above. The selection of the range moves with the row, but does not change otherwise. The function returns true if the move operation was successful, otherwise false.

Errors

- 2001 The authentic range object, or its related view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

17.2.2.7.49 Parent

*Property:* Parent as AuthenticView (read-only)

*Description*
Access the view that owns this range object.

Errors

- 2001 The authentic range object, or its related view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

17.2.2.7.50 Paste

*Method:* Paste() as Boolean

*Description*
Returns False if the copy/paste buffer is empty, or its content cannot replace the current selection. Otherwise, deletes the current selection, inserts the content of the copy/paste buffer, and returns True.

Errors

- 2001 The authentic range object, or its related view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

17.2.2.7.51 PerformAction

*Method:* PerformAction (eAction as SPYAuthenticActions, strElementName as String) as Boolean

*Description*
PerformAction and its related methods, give access to the entry-helper functions of Authentic. This function allows easy and consistent modification of the document content without a need to know exactly where the modification will take place. The beginning of the range object is used to locate the next valid location where the specified action can be performed. If no such location can be found, the method returns False. Otherwise, the document gets modified and the range points to the beginning of the modification.

HINT: To find out element names that can be passed as the second parameter use CanPerformActionWith.

Errors

- 2001 The authentic range object, or its related view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.
Invalid action was specified.

Examples

' ---------------------------------------------
' Scripting environment - VBScript
' Insert the innermost element
' ---------------------------------------------
Dim objRange
' we assume that the active document is open in authentic view mode
Set objRange = Application.ActiveDocument.AuthenticView.Selection

' we determine the elements that can be inserted at the current position
Dim arrElements()
objRange.CanPerformActionWith spyAuthenticInsertBefore, arrElements

' we insert the first (innermost) element
If UBound(arrElements) >= 0 Then
    objRange.PerformAction spyAuthenticInsertBefore, arrElements(0)
    ' objRange now points to the beginning of the inserted element
    ' we set a default value and position at its end
    objRange.Text = "Hello"
    objRange.ExpandTo(spyAuthenticTag).CollapsToEnd().Select
Else
    MsgBox "Can't insert any elements at current position"
End If

17.2.2.7.52  Select

Method: Select()

Description
Makes this range the current user interface selection. You can achieve the same result using:
'objRange.Parent.Selection = objRange'

Errors
2001  The authentic range object or its related view object is no longer valid.

Examples

' ---------------------------------------------
' Scripting environment - VBScript
' ---------------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

' set current selection to end of document
objAuthenticView.DocumentEnd.Select()
17.2.2.7.53  SelectNext

**Method:** SelectNext (eKind as [SPYAuthenticElementKind](#) as AuthenticRange)

**Description**
Selects the element of type eKind after the current end of the range. The method returns the modified range object.

**Errors**
- 2001  The authentic range object, or its related view object is no longer valid.
- 2003  Target lies after end of document.
- 2005  Invalid element kind specified.
- Invalid address for the return parameter was specified.

**Examples**

```
' --------------------------------------------
' Scripting environment - VBScript
' Scan through the whole document word-by-word
' --------------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

Dim objRange
Set objRange = objAuthenticView.DocumentBegin
Dim bEndOfDocument
bEndOfDocument = False
On Error Resume Next
While Not bEndOfDocument
    objRange.SelectNext(spyAuthenticWord).Select
    If ((Err.number - vbObjecterror) = 2003) Then
        bEndOfDocument = True
        Err.Clear
    ElseIf (Err.number <> 0) Then
        Err.Raise "forward error"
    End If
Wend
```

17.2.2.7.54  SelectPrevious

**Method:** GotoPrevious (eKind as [SPYAuthenticElementKind](#) as AuthenticRange)

**Description**
Selects the element of type eKind before the current beginning of the range. The method returns the modified range object.

**Errors**
- 2001  The authentic range object, or its related view object is no longer valid.
2004 Target lies before begin of document.
2005 Invalid element kind specified.
    Invalid address for the return parameter was specified.

Examples
' ________________________________
' Scripting environment - VBScript
' Scan through the whole document tag-by-tag
' ________________________________
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

Dim objRange
Set objRange = objAuthenticView.DocumentEnd
Dim bBeginOfDocument
bBeginOfDocument = False
On Error Resume Next
While Not bBeginOfDocument
    objRange.SelectPrevious(spyAuthenticTag).Select
    If ((Err.number - vbObjecterror) = 2004) Then
        bBeginOfDocument = True
        Err.Clear
    ElseIf (Err.number <> 0) Then
        Err.Raise ' forward error
    End If
End If
Wend

17.2.2.7.55 SetElementAttributeValue

Method: SetElementAttributeValue (strElementName as String, strAttributeName as String, strAttributeValue as String)

Description
Set the value of the attribute specified in strAttributeName for the element identified with strElementName. If the attribute is supported but has no value assigned, the empty string is returned. To find out the names of attributes supported by an element, use GetElementAttributeNames or HasElementAttribute.

Errors
2001 The authentic range object or its related view object is no longer valid.
2005 Invalid element name was specified.
    Invalid attribute name was specified.
    Invalid attribute value was specified.

Examples
' ________________________________
' Scripting environment - VBScript
' Get and set element attributes
' _--------------------------------------------
Dim objRange
' we assume that the active document is open in authentic view mode
Set objRange = Application.ActiveDocument.AuthenticView.Selection

' first we find out all the elements below the beginning of the range
Dim arrElements
objRange.GetElementHierarchy arrElements

If IsArray(arrElements) Then
    If UBound(arrElements) >= 0 Then
        ' we use the top level element and find out its valid attributes
        Dim arrAttrNames()
        objRange.GetElementAttributeNames arrElements(0), arrAttrNames

        If UBound(arrAttrNames) >= 0 Then
            ' we retrieve the current value of the first valid attribute
            Dim strAttrVal
            strAttrVal = objRange.GetElementAttributeValue(arrElements(0), arrAttrNames(0))
            msgbox "current value of " & arrElements(0) & "/" & arrAttrNames(0) & ": " & strAttrVal

            ' we change this value and read it again
            strAttrVal = "Hello"
            objRange.SetElementAttributeValue arrElements(0), arrAttrNames(0), strAttrVal
            strAttrVal = objRange.GetElementAttributeValue(arrElements(0), arrAttrNames(0))
            msgbox "new value of " & arrElements(0) & "/" & arrAttrNames(0) & ": " & strAttrVal
        End If
    End If
End If

17.2.2.7.56    SetFromRange

Method: SetFromRange (objSrcRange as AuthenticRange)

Description
Sets the range object to the same beginning and end positions as objSrcRange.

Errors
  2001  One of the two range objects, is invalid.
  2005  Null object was specified as source object.

17.2.2.7.57    SetVariableValue

Method: SetVariableValue(strName as string, strValue as string)

Return Value
Sets the value (second parameter) of the variable named in the first parameter.
Errors
2201  Invalid object.
2202  No context.
2204  No such variable in scope
2205  Variable cannot be evaluated
2206  Variable returns sequence
2207  Variable read-only
2208  No modification allowed

17.2.2.7.58  Text

Property: Text as String

Description
Set or get the textual content selected by the range object.

The number of characters retrieved are not necessarily identical, as there are text cursor positions between the
beginning and end of the selected range. Most document elements support an end cursor position different to
the beginning cursor position of the following element. Drop-down lists maintain only one cursor position, but
can select strings of any length. In the case of radio buttons and check boxes, the text property value holds the
string of the corresponding XML element.

If the range selects more then one element, the text is the concatenation of the single texts. XML entities are
expanded so that '&' is expected as '&amp;'.

Setting the text to the empty string, does not delete any XML elements. Use Cut, Delete or
PerformAction instead.

Errors
2001  The authentic range object or its related view object is no longer valid.
2005  Invalid address for a return parameter was specified.

17.2.2.8  AuthenticView

Properties
Application
AsXMLString
DocumentBegin
DocumentEnd
Event
MarkupVisibility
Parent
Selection
XMLDataRoot
WholeDocument

Methods
Goto
IsRedoEnabled
IsUndoEnabled
Print
Redo
Undo
UpdateXMLInstanceEntities

Events
OnBeforeCopy
OnBeforeCut
OnBeforeDelete
OnBeforeDrop
OnBeforePaste

OnMouseEvent
OnSelectionChanged
Description

AuthenticateView and its child objects AuthenticRange and AuthenticDataTransfer provide you with an interface for Authentic View, which allow easy and consistent modification of document contents. These interfaces replace the following interfaces which are marked now as obsolete:

OldAuthenticateView (old name was DocEditView)
AuthenticateSelection (old name was DocEditSelection, superseded by AuthenticRange)
AuthenticateEvent (old name was DocEditEvent)

AuthenticateView gives you easy access to specific features such as printing, the multi-level undo buffer, and the current cursor selection, or position.

AuthenticateView uses objects of type AuthenticRange to make navigation inside the document straightforward, and to allow for the flexible selection of logical text elements. Use the properties DocumentBegin, DocumentEnd, or WholeDocument for simple selections, while using the Goto method for more complex selections. To navigate relative to a given document range, see the methods and properties of the AuthenticRange object.

17.2.2.8.1 Events

17.2.2.8.1.1 OnBeforeCopy

Event: OnBeforeCopy() as Boolean

Scripting environment - VBScript:
Function On_AuthenticBeforeCopy()
    ' On_AuthenticBeforeCopy = False ' to disable operation
End Function

Scripting environment - JScript:
function On_AuthenticBeforeCopy()
{
    // return false; /* to disable operation */
}

17.2.2.8.1.2 OnBeforeCut

Event: OnBeforeCut() as Boolean

Scripting environment - VBScript:
Function On_AuthenticBeforeCut()
    ' On_AuthenticBeforeCut = False ' to disable operation
End Function

Scripting environment - JScript:
function On_AuthenticBeforeCut()
17.2.2.8.1.3 OnBeforeDelete

**Event:** OnBeforeDelete() as Boolean

**Scripting environment - VBScript:**
Function On_AuthenticBeforeDelete()
    ' On_AuthenticBeforeDelete = False ' to disable operation
End Function

**Scripting environment - JScript:**
function On_AuthenticBeforeDelete()
{
    // return false; /* to disable operation */
}

17.2.2.8.1.4 OnBeforeDrop

**Event:** OnBeforeDrop (i_nXPos as Long, i_nYPos as Long, i_ipRange as AuthenticRange, i_ipData as cancelBoolean)

**Scripting environment - VBScript:**
Function On_AuthenticBeforeDrop(nXPos, nYPos, objRange, objData)
    ' On_AuthenticBeforeDrop = False ' to disable operation
End Function

**Scripting environment - JScript:**
function On_AuthenticBeforeDrop(nXPos, nYPos, objRange, objData)
{
    // return false; /* to disable operation */
}

**Description**
This event gets triggered whenever a previously dragged object gets dropped inside the application window. All event related information gets passed as parameters.

The first two parameters specify the mouse position at the time when the event occurred. The parameter `objRange` passes a range object that selects the XML element below the mouse position. The value of this parameter might be `NULL`. Be sure to check before you access the range object. The parameter `objData` allows to access information about the object being dragged.

Return `False` to cancel the drop operation. Return `True` (or nothing) to continue normal operation.
17.2.2.8.1.5  OnBeforePaste

**Event:** OnBeforePaste (objData as Variant, strType as String) as Boolean

**Scripting environment - VBScript:**
Function On_AuthenticBeforePaste(objData, strType)
    ' On_AuthenticBeforePaste = False  ' to disable operation
End Function

**Scripting environment - JScript:**
function On_AuthenticBeforePaste(objData, strType)
{
    // return false;  /* to disable operation */
}

**Description**
This event gets triggered before a paste operation gets performed on the document. The parameter strType is one of "TEXT", "UNICODETEXT" or "UNKNOWN". In the first two cases objData contains a string representation of the object that will be pasted. In the later case, objData contains a pointer to an IUnknown COM interface.

Return True (or nothing) to allow paste operation. Return False to disable operation.

17.2.2.8.1.6  OnBeforeSave

**Event:** OnBeforeSave (SaveAs flag) as Boolean

**Description:** OnBeforeSave gives the opportunity to e.g. warn the user about overwriting the existing XML document, or to make the document read-only when specific circumstances are not met. The event will be fired before the file dialog is shown. (Please note, that the event fires when saving the XML document, and not when saving the SPS design in StyleVision.)

17.2.2.8.1.7  OnLoad

**Event:** OnLoad ()

**Description:** OnLoad can be used e.g. to restrict some AuthenticView functionality, as shown in the example below:

function On_AuthenticLoad( )
{
    // We are disabling all entry helpers in order to prevent user from manipulating XML tree
    AuthenticView.DisableElementEntryHelper();
    AuthenticView.DisableAttributeEntryHelper();
    
    // We are also disabling the markup buttons for the same purpose
    AuthenticView.SetToolbarButtonState( 'AuthenticMarkupSmall', authenticToolbarButtonDisabled );
AuthenticView.SetToolBarButtonState( 'AuthenticMarkupLarge', authenticToolbarButtonDisabled );
AuthenticView.SetToolBarButtonState( 'AuthenticMarkupMixed', authenticToolbarButtonDisabled );
}

In the example the status of the Markup Small, Markup Large, Markup Mixed toolbar buttons are manipulated with the help of button identifiers. See complete list.

17.2.2.8.1.8 OnMouseEvent

_Event:_ OnMouseEvent (nXPos as Long, nYPos as Long, eMouseEvent as SPYMouseEvent, objRange as AuthenticRange) as Boolean

**Scripting environment - VBScript:**
Function On_AuthenticMouseEvent(nXPos, nYPos, eMouseEvent, objRange)
   ' On_AuthenticMouseEvent = True  ' to cancel bubbling of event
End Function

**Scripting environment - JScript:**
function On_AuthenticMouseEvent(nXPos, nYPos, eMouseEvent, objRange)
{
   // return true; /* to cancel bubbling of event */
}

**Description**
This event gets triggered for every mouse movement and mouse button Windows message.

The actual message type and the mouse buttons status, is available in the _eMouseEvent_ parameter. Use the bit-masks defined in the enumeration datatype SPYMouseEvent to test for the different messages, button status, and their combinations.

The parameter _objRange_ identifies the part of the document found at the current mouse cursor position. The range object always selects a complete tag of the document. (This might change in future versions, when a more precise positioning mechanism becomes available). If no selectable part of the document is found at the current position, the range object is null.

17.2.2.8.1.9 OnSelectionChanged

_Event:_ OnSelectionChanged (objNewSelection as AuthenticRange)

**Scripting environment - VBScript:**
Function On_AuthenticSelectionChanged(objNewSelection)
   End Function

**Scripting environment - JScript:**
function On_AuthenticSelectionChanged(objNewSelection)
{
}

**Description**
This event gets triggered whenever the selection in the user interface changes.
17.2.2.8.1.10  **OnToolBarButtonClicked**

**Event:** OnToolBarButtonClicked (Button identifier)

**Description:** *OnToolBarButtonClicked* is fired when a toolbar button was clicked by user. The parameter button identifier helps to determine which button was clicked. The list of predefined button identifiers is below:

- AuthenticPrint
- AuthenticPrintPreview
- AuthenticUndo
- AuthenticRedo
- AuthenticCut
- AuthenticCopy
- AuthenticPaste
- AuthenticClear
- AuthenticMarkupHide
- AuthenticMarkupLarge
- AuthenticMarkupMixed
- AuthenticMarkupSmall
- AuthenticValidate
- AuthenticChangeWorkingDBXMLCell
- AuthenticSave
- AuthenticSaveAs
- AuthenticReload
- AuthenticTableInsertRow
- AuthenticTableAppendRow
- AuthenticTableDeleteRow
- AuthenticTableInsertCol
- AuthenticTableAppendCol
- AuthenticTableDeleteCol
- AuthenticTableJoinCellRight
- AuthenticTableJoinCellLeft
- AuthenticTableJoinCellAbove
- AuthenticTableJoinCellBelow
- AuthenticTableSplitCellHorizontally
- AuthenticTableSplitCellVertically
- AuthenticTableAlignCellContentTop
- AuthenticTableCenterCellVertically
- AuthenticTableAlignCellContentBottom
- AuthenticTableAlignCellContentLeft
- AuthenticTableCenterCellContent
- AuthenticTableAlignCellContentRight
- AuthenticTableJustifyCellContent
- AuthenticTableInsertTable
- AuthenticTableDeleteTable
- AuthenticTableProperties
- AuthenticAppendRow
- AuthenticInsertRow
- AuthenticDuplicateRow
- AuthenticMoveRowUp
- AuthenticMoveRowDown
For custom buttons the user might add his own identifiers. Please, note that the user must take care, as the identifiers are not checked for uniqueness. The same identifiers can be used to identify buttons in the Set/GetToolBarState() COM API calls. By adding code for different buttons, the user is in the position to completely redefine the AuthenticView toolbar behavior, adding own methods for table manipulation, etc.

17.2.2.8.1.11   On TOOLBAR Button Executed

**Event:** OnToolBarButtonExecuted (Button identifier)

**Description:** OnToolBarButtonClicked is fired when a toolbar button was clicked by user. The parameter button identifier helps to determine which button was clicked. See the list of predefined button identifiers [here](#).

OnToolBarButtonExecuted is fired after the toolbar action was executed. It is useful e.g. to add update code, as shown in the example below:

```javascript
//event fired when a toolbar button action was executed
function On_AuthenticToolbarButtonExecuted( varBtnIdentifier )
{
    // After whatever command user has executed - make sure to update toolbar button states
    UpdateOwnToolbarButtonStates();
}
```

In this case UpdateOwnToolbarButtonStates is a user function defined in the Global Declarations.

17.2.2.8.1.12   On USER Added XML Node

**Event:** OnUserAddedXMLNode (XML node)

**Description:** OnUserAddedXMLNode will be fired when the user adds an XML node as a primary action. This happens in the situations, where the user clicks on

- auto-add hyperlinks (see example OnUserAddedXMLNode.sps)
- the Insert…, Insert After…, Insert Before… context menu items
- Append row, Insert row toolbar buttons
- Insert After…, Insert Before… actions in element entry helper (outside StyleVision)

The event doesn’t get fired on Duplicate row, or when the node was added externally (e.g. via COM API), or on Apply (e.g. Text State Icons), or when in XML table operations or in DB operations.

The event parameter is the XML node object, which was added giving the user an opportunity to manipulate the XML node added. An elaborate example for an event handler can be found in the OnUserAddedXMLNode.sps file.
17.2.2.8.2 Application

**Property:** Application as Application (read-only)

**Description**
Accesses the StyleVision application object.

**Errors**
- 2000 The authentic view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

17.2.2.8.3 AsXMLString

**Property:** AsXMLString as String

**Description**
Returns or sets the document content as an XML string. Setting the content to a new value does not change the schema file or sps file in use. If the new XMLString does not match the actual schema file error 2011 gets returned.

**Errors**
- 2000 The authentic view object is no longer valid.
- 2011 AsXMLString was set to a value which is no valid XML for the current schema file.

17.2.2.8.4 ContextMenu

**Property:** ContextMenu() as ContextMenu

**Description**
The property `ContextMenu` gives access to customize the context menu. The best place to do it is in the event handler `OnContextMenuActivated`.

**Errors**
- 2000 Invalid object.
- 2005 Invalid parameter.

17.2.2.8.5 CreateXMLNode

**Method:** CreateXMLNode (nKind as SPYXMLDataKind) as XMLData

**Return Value**
The method returns the new XMLData object.

**Description**
To create a new XMLData object use the CreateXMLNode() method.
Errors
2000  Invalid object.
2012  Cannot create XML node.

17.2.2.8.6  DisableAttributeEntryHelper

*Method:* DisableAttributeEntryHelper()

*Description*
DisableAttributeEntryHelper() disables the attribute entry helper in XMLSpy, Authentic Desktop and Authentic Browser plug-in.

Errors
2000  Invalid object.

17.2.2.8.7  DisableElementEntryHelper

*Method:* DisableElementEntryHelper()

*Description*
DisableElementEntryHelper() disables the element entry helper in XMLSpy, Authentic Desktop and Authentic Browser plug-in.

Errors
2000  Invalid object.

17.2.2.8.8  DisableEntityEntryHelper

*Method:* DisableEntityEntryHelper()

*Description*
DisableEntityEntryHelper() disables the entity entry helper in XMLSpy, Authentic Desktop and Authentic Browser plug-in.

Errors
2000  Invalid object.

17.2.2.8.9  DocumentBegin

*Property:* DocumentBegin as AuthenticRange (read-only)
**Description**  
Retrieve a range object that points to the beginning of the document.

**Errors**  
<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>The authentic view object is no longer valid.</td>
</tr>
<tr>
<td>2005</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>

17.2.2.8.10   **DocumentEnd**

**Property:** DocumentEnd as AuthenticRange (read-only)

**Description**  
Retrieve a range object that points to the end of the document.

**Errors**  
<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>The authentic view object is no longer valid.</td>
</tr>
<tr>
<td>2005</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>

17.2.2.8.11   **DoNotPerformStandardAction**

**Method:** DoNotPerformStandardAction ()

**Description**  
DoNotPerformStandardAction() serves as cancel bubble for macros, and stops further execution after macro has finished.

**Errors**  
<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Invalid object.</td>
</tr>
</tbody>
</table>

17.2.2.8.12   **EvaluateXPath**

**Method:** EvaluateXPath (XMLData as XMLData, strExpression as string) strValue as string

**Return Value**  
The method returns a string

**Description**  
EvaluateXPath() executes an XPath expression with the given XML context node. The result is returned as a string, in the case of a sequence it is a space-separated string.

**Errors**  
<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Invalid object.</td>
</tr>
<tr>
<td>2005</td>
<td>Invalid parameter.</td>
</tr>
<tr>
<td>2008</td>
<td>Internal error.</td>
</tr>
<tr>
<td>2013</td>
<td>XPath error.</td>
</tr>
</tbody>
</table>
17.2.2.8.13  Event

Property: Event as AuthenticEvent (read-only)

Description
This property gives access to parameters of the last event in the same way as OldAuthenticView.event does. Since all events for the scripting environment and external clients are now available with parameters this Event property should only be used from within IDE-Plugins.

Errors
- 2000  The authentic view object is no longer valid.
- 2005  Invalid address for the return parameter was specified.

17.2.2.8.14  EventContext

Property: EventContext() as EventContext

Description
EventContext property gives access to the running macros context. See the EventContext interface description for more details.

Errors
- 2000  Invalid object.

17.2.2.8.15  GetToolbarButtonState

Method: GetToolbarButtonState (ButtonIdentifier as string) as AuthenticToolbarButtonState

Return Value
The method returns AuthenticToolbarButtonState

Description
Get/SetToolbarButtonState queries the status of a toolbar button, and lets the user disable or enable the button, identified via its button identifier (see list above). One usage is to disable toolbar buttons permanently. Another usage is to put SetToolbarButtonState in the OnSelectionChanged event handler, as toolbar buttons are updated regularly when the selection changes in the document.

Toolbar button states are given by the listed enumerations.

The default state means that the enable/disable of the button is governed by AuthenticView. When the user sets the button state to enable or disable, the button remains in that state as long as the user does not change it.

Errors
- 2000  Invalid object.
17.2.2.8.16  Goto

**Method:** Goto (eKind as SPYAuthenticElementKind, nCount as Long, eFrom as SPYAuthenticDocumentPosition) as AuthenticRange

**Description**
Retrieve a range object that points to the beginning of the nCount element of type eKind. The start position is defined by the parameter eFrom. Use positive values for nCount to navigate to the document end. Use negative values to navigate towards the beginning of the document.

**Errors**
- 2000  The authentic view object is no longer valid.
- 2003  Target lies after end of document.
- 2004  Target lies before beginning of document.
- 2005  Invalid element kind specified.
  The document position to start from is not one of spyAuthenticDocumentBegin or spyAuthenticDocumentEnd.
  Invalid address for the return parameter was specified.

**Examples**
```
' ---------------------------------------
' Scripting environment - VBScript
' ---------------------------------------
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

On Error Resume Next
Dim objRange
' goto beginning of first table in document
Set objRange = objAuthenticView.Goto (spyAuthenticTable, 1, spyAuthenticDocumentBegin)
If (Err.number = 0) Then
    objRange.Select()
Else
    MsgBox "No table found in document"
End If
```

17.2.2.8.17  IsRedoEnabled

**Property:** IsRedoEnabled as Boolean (read-only)

**Description**
True if redo steps are available and Redo is possible.

**Errors**
2000 The authentic view object is no longer valid.
2005 Invalid address for the return parameter was specified.

17.2.2.8.18 IsUndoEnabled

Property: IsUndoEnabled as Boolean (read-only)

Description
True if undo steps are available and Undo is possible.

Errors
2000 The authentic view object is no longer valid.
2005 Invalid address for the return parameter was specified.

17.2.2.8.19 MarkupVisibility

Property: MarkupVisibility as SPYAuthenticMarkupVisibility

Description
Set or get current visibility of markup.

Errors
2000 The authentic view object is no longer valid.
2005 Invalid enumeration value was specified.
Invalid address for the return parameter was specified.

17.2.2.8.20 Parent

Property: Parent as Document (read-only)

Description
Access the document shown in this view.

Errors
2000 The authentic view object is no longer valid.
2005 Invalid address for the return parameter was specified.

17.2.2.8.21 Print

Method: Print (bWithPreview as Boolean, bPromptUser as Boolean)

Description
Print the document shown in this view. If `bWithPreview` is set to `True`, the print preview dialog pops up. If `bPromptUser` is set to `True`, the print dialog pops up. If both parameters are set to `False`, the document gets printed without further user interaction.

**Errors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>The authentic view object is no longer valid.</td>
</tr>
</tbody>
</table>

### 17.2.2.8.22 Redo

**Method:** Redo() as Boolean

**Description**

Redo the modification undone by the last undo command.

**Errors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>The authentic view object is no longer valid.</td>
</tr>
<tr>
<td>2005</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>

### 17.2.2.8.23 Selection

**Property:** Selection as AuthenticRange

**Description**

Set or get current text selection in user interface.

**Errors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>The authentic view object is no longer valid.</td>
</tr>
<tr>
<td>2002</td>
<td>No cursor selection is active.</td>
</tr>
<tr>
<td>2005</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
</tbody>
</table>

**Examples**

```vbscript
' ______________________________________
' Scripting environment - VBScript
' ______________________________________
Dim objAuthenticView
' we assume that the active document is open in authentic view mode
Set objAuthenticView = Application.ActiveDocument.AuthenticView

' if we are the end of the document, re-start at the beginning
If (objAuthenticView.Selection.IsEqual(objAuthenticView.DocumentEnd)) Then
    objAuthenticView.Selection = objAuthenticView.DocumentBegin
Else
    objAuthenticView.Selection = objAuthenticView.Selection.GotoNextCursorPosition()
    ' or shorter:
    objAuthenticView.Selection.GotoNextCursorPosition().Select
End If
```
17.2.2.8.24 SetToolbarButtonState

**Method:** SetToolbarButtonState (ButtonIdentifier as string, AuthenticToolbarButtonState state)

**Description**
Get/SetToolbarButtonState queries the status of a toolbar button, and lets the user disable or enable the button, identified via its button identifier (see list above). One usage is to disable toolbar buttons permanently. Another usage is to put SetToolbarButtonState in the OnSelectionChanged event handler, as toolbar buttons are updated regularly when the selection changes in the document.

Toolbar button states are given by the listed enumerations.

The default state means that the enable/disable of the button is governed by AuthenticView. When the user sets the button state to enable or disable, the button remains in that state as long as the user does not change it.

**Errors**
- 2000 Invalid object.
- 2008 Internal error.
- 2014 Invalid button identifier.

17.2.2.8.25 Undo

**Method:** Undo() as Boolean

**Description**
Undo the last modification of the document from within this view.

**Errors**
- 2000 The authentic view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

17.2.2.8.26 UpdateXMLInstanceEntities

**Method:** UpdateXMLInstanceEntities()

**Description**
Updates the internal representation of the declared entities, and refills the entry helper. In addition, the validator is reloaded, allowing the XML file to validate correctly. Please note that this may also cause schema files to be reloaded.

**Errors**
The method never returns an error.

**Example**
// -----------------------------
// Scripting environment - JavaScript
// ----------------------------------------
{
    var objDocType;
    objDocType = Application.ActiveDocument.DocEditView.XMLRoot.GetFirstChild(10);

    if(objDocType)
    {
        var objEntity = Application.ActiveDocument.CreateChild(14);
        objEntity.Name = "child";
        objEntity.TextValue = "SYSTEM \"child.xml\"";
        objDocType.AppendChild(objEntity);

        Application.ActiveDocument/AuthenticView.UpdateXMLInstanceEntities();
    }
}

17.2.2.8.27 WholeDocument

*Property:* WholeDocument as [AuthenticRange](#) (read-only)

**Description**
Retrieve a range object that selects the whole document.

**Errors**
- 2000 The authentic view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

17.2.2.8.28 XMLDataRoot

*Property:* XMLDataRoot as [XMLData](#) (read-only)

**Description**
Returns or sets the top-level XMLData element of the current document. This element typically describes the
document structure and would be of kind spyXMLDataXMLDocStruct, spyXMLDataXMLEntityDocStruct or
spyXMLDataDTDDocStruct.

**Errors**
- 2000 The authentic view object is no longer valid.
- 2005 Invalid address for the return parameter was specified.

17.2.2.9 Document

The **Document** interface has the following methods and properties:

**Methods**
17.2.2.9.1 Events

17.2.2.9.1.1 OnDocumentClosed

**Event:** OnDocumentClosed(Document as Document)

**Description**
This event gets fired as a result of closing a document.
### 17.2.2.9.1.2 OnModifiedFlagChanged

**Event:** OnModifiedFlagChanged(as Boolean)

**Description**
Returns true if the Modified flag has been changed.

### 17.2.2.9.2 Activate

**Method:** Activate()

**Description**
Activate document frame.

**Errors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1200</td>
<td>Document object is invalid.</td>
</tr>
<tr>
<td>1201</td>
<td>Invalid input parameter.</td>
</tr>
</tbody>
</table>

### 17.2.2.9.3 Application

**Property:** Application as Application (read-only)

**Description**
Accesses the StyleVision application object.

**Errors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>140011</td>
<td>The object is no longer valid.</td>
</tr>
<tr>
<td>11</td>
<td></td>
</tr>
<tr>
<td>140711</td>
<td>Invalid address for the return parameter was specified.</td>
</tr>
<tr>
<td>00</td>
<td></td>
</tr>
</tbody>
</table>

### 17.2.2.9.4 AssignWorkingXMLFile

**Method:** AssignWorkingXMLFile (strWorkingXMLFileName as String, strSchemaSourceName as String)

**Description**
Assigns the Working XML File by supplying its URI as a string and the Schema Source Name as a string. The Schema Source Name is the name assigned to the schema in the SPS; (the default schema name in an SPS created new in StyleVision is: XML).

**Errors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1200</td>
<td>The document object is invalid.</td>
</tr>
<tr>
<td>1201</td>
<td>Invalid input parameter.</td>
</tr>
</tbody>
</table>
17.2.2.9.5  Close

**Method:** Close *(bDiscardChanges as Boolean)*

**Description**
To close the document call this method. If bDiscardChanges is true and the document is modified, the document will be closed but not saved.

**Errors**
- 1400  The object is no longer valid.
- 1401  Document needs to be saved first.

17.2.2.9.6  FullName

**Property:** FullName as String

**Description**
This property can be used to get or set the full file name - including the path - to where the document gets saved. The validity of the name is not verified before the next save operation.

This property makes the methods **GetPathName** and **SetPathName** obsolete.

**Errors**
- 1400  The document object is no longer valid.
- 1402  Empty string has been specified as full file name.

17.2.2.9.7  GetPathName (obsolete)

```javascript
// ----- javascript sample -----  
// instead of:                  
// strPathName = Application.ActiveDocument.GetPathName();  
// use now:                      
strPathName = Application.ActiveDocument.FullName;
```

**Method:** GetPathName() as String

**Description**
The method GetPathName gets the path of the active document.

See also **Document.SetPathName** (obsolete).
17.2.2.9.8  Name

**Property:** Name as String (read-only)

**Description**
Use this property to retrieve the name - not including the path - of the document file. To change the file name for a document use the property `FullName`.

**Errors**
- 1400  The document object is no longer valid.
- 1407  Invalid address for the return parameter was specified.

17.2.2.9.9  Parameters

**Property:** Parameters as Parameters (read-only)

**Description**
Reference to the current Parameters object.

**Errors**
- 1200  Document object is invalid.
- 1201  Invalid input parameter.

17.2.2.9.10  Parent

**Property:** Parent as Documents (read-only)

**Description**
Access the parent of the document object.

**Errors**
- 1400  The document object is no longer valid.
- 1407  Invalid address for the return parameter was specified.

**Property:** Parent as Application (read-only)

**Description**
Access the StyleVision application object.

**Errors**
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.
17.2.2.9.11 Path

*Property:* Path as String (read-only)

**Description**
Use this property to retrieve the path - not including the file name - of the document file. To change the file name and path for a document use the property [FullName](#).

**Errors**
- 1400  The document object is no longer valid.
- 1407  Invalid address for the return parameter was specified.

17.2.2.9.12 Save

*Method:* Save()

**Description**
The method writes any modifications of the document to the associated file.

**Errors**
- 1400  The document object is no longer valid.
- 1407  An empty file name has been specified.
- 1403  Error when saving file, probably the file name is invalid.

17.2.2.9.13 SaveAs

*Method:* SaveAs (strFileName as String)

**Description**
Save the document to the file specified.

**Errors**
- 1400  The document object is no longer valid.
- 1407  An empty file name has been specified.
- 1403  Error when saving file, probably the file name is invalid.

17.2.2.9.14 Saved

*Property:* Saved as Boolean (read-only)

**Description**
This property can be used to check if the document has been saved after the last modifications.

**Errors**
- 1400  The document object is no longer valid.
- 1407  Invalid address for the return parameter was specified.
17.2.2.9.15  SaveGeneratedFOFile

*Method:* SaveGeneratedFOFile *(strFileName as String)*

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.16  SaveGeneratedFOFileEx

*Method:* SaveGeneratedFOFileEx *(strFileName as String, pbError as Variant) as AppOutputLines*

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.17  SaveGeneratedHTMLFile

*Method:* SaveGeneratedHTMLFile *(strFileName as String)*

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.18  SaveGeneratedHTMLFileEx

*Method:* SaveGeneratedHTMLFileEx *(strFileName as String, pbError as Variant) as AppOutputLines*

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.
17.2.2.9.19  SaveGeneratedPDFFile

*Method:* SaveGeneratedPDFFile (*strFileName* as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.20  SaveGeneratedPDFFileEx

*Method:* SaveGeneratedPDFFileEx (*strFileName* as String, *pbError* as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.21  SaveGeneratedRTFFile

*Method:* SaveGeneratedRTFFile (*strFileName* as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.22  SaveGeneratedRTFFileEx

*Method:* SaveGeneratedRTFFileEx (*strFileName* as String, *pbError* as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.
17.2.2.9.23  SaveGeneratedWord2007File

*Method:* SaveGeneratedWord2007File (*strFileName* as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.24  SaveGeneratedWord2007FileEx

*Method:* SaveGeneratedWord2007FileEx (*strFileName* as String, *pbError* as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.25  SaveGeneratedTextFile

*Method:* SaveGeneratedTextFile (*strFileName* as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.26  SaveGeneratedTextFileEx

*Method:* SaveGeneratedTextFileEx (*strFileName* as String, *pbError* as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.
17.2.2.9.27  SaveGeneratedXSLTFOFile

*Method:* SaveGeneratedXSLTFOFile (strFileName as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.28  SaveGeneratedXSLTFOFileEx

*Method:* SaveGeneratedXSLTFOFileEx (strFileName as String, pbError as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.29  SaveGeneratedXSLTHTMLFile

*Method:* SaveGeneratedXSLTHTMLFile (strFileName as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.30  SaveGeneratedXSLTHTMLFileEx

*Method:* SaveGeneratedXSLTHTMLFileEx (strFileName as String, pbError as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
17.2.2.9.31  SaveGeneratedXSLTRTFFile

*Method:* SaveGeneratedXSLTRTFFile (*strFileName* as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.32  SaveGeneratedXSLTRTFFileEx

*Method:* SaveGeneratedXSLTRTFFileEx (*strFileName* as String, *pbError* as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.33  SaveGeneratedXSLTWord2007File

*Method:* SaveGeneratedXSLTWord2007File (*strFileName* as String)

*Description*
Saves the generated file to the location specified.

*Errors*
- 1201  Invalid document object.
- 1204  Cannot generate output file.

17.2.2.9.34  SaveGeneratedXSLTWord2007FileEx

*Method:* SaveGeneratedXSLTWord2007FileEx (*strFileName* as String, *pbError* as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.
Errors
1201  Invalid document object.
1204  Cannot generate output file.

17.2.2.9.35  SaveGeneratedXSLTTextFile

*Method:* SaveGeneratedXSLTTextFile (*strFileName* as String)

*Description*
Saves the generated file to the location specified.

Errors
1201  Invalid document object.
1204  Cannot generate output file.

17.2.2.9.36  SaveGeneratedXSLTTextFileEx

*Method:* SaveGeneratedXSLTTextFileEx (*strFileName* as String, *pbError* as Variant) as AppOutputLines

*Description*
Saves the generated file to the location specified and gives error description.

Errors
1201  Invalid document object.
1204  Cannot generate output file.

17.2.2.9.37  SchemaSources

*Property:* SchemaSources as SchemaSources (read-only)

*Description*
Reference to the current SchemaSources object.

Errors
1200  Document object is invalid.
1201  Invalid input parameter.

17.2.2.9.38  SetPathName (obsolete)

Superseded by [Document.FullName](#)
// ----- javascript sample -----  
// instead of:  
// Application.ActiveDocument.SetPathName("C:\myXMLFiles\test.xml");  
// use now:  
Application.ActiveDocument.FullName = "C:\myXMLFiles\test.xml";

**Method:** SetPathName *(strPath as String)*

**Description**
The method SetPathName sets the path of the active document. SetPathName only copies the string and does not check if the path is valid. All succeeding save operations are done into this file.

### 17.2.2.10 Documents

The `Documents` interface has the following methods and properties:

**Methods**

- `ActiveDocument`
- `Item`
- `NewDocument`
- `OpenDocument`

**Properties**

- `Application`
- `Count`
- `Parent`

#### 17.2.2.10.1 ActiveDocument

**Property:** ActiveDocument as `Document`

**Description**
Reference to the active document. If no document is open, `ActiveDocument` is null (nothing).

**Errors**

- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.
- 1600  Invalid `Documents` object
- 1601  Invalid input parameter
17.2.2.10.2 Application

Property: Application as Application (read-only)

Description
Access the StyleVision application object.

Errors
1111 The application object is no longer valid.
1100 Invalid address for the return parameter was specified.

17.2.2.10.3 Count

Property: Count as long

Description
Count of open documents.

Errors
1600 Invalid Documents object
1601 Invalid input parameter

17.2.2.10.4 Item

Method: Item (n as long) as Document

Description
Gets the document with the index n in this collection. Index is 1-based.

Errors
1600 Invalid Documents object
1601 Invalid input parameter

17.2.2.10.5 NewDocument

Method: NewDocument() as Document

Return Value
None

Description
Creates a new empty document based on the previous template.

**Errors**
- 1000  The application object is invalid.
- 1005  Error when creating a new document
- 1006  Cannot create document
- 1600  Invalid `Documents` object
- 1601  Invalid input parameter

17.2.2.10.6  OpenDocument

**Method:** OpenDocument(strFileName as `String`) as `Document`

**Return Value**
None

**Description**
Opens an existing SPS file.

**Errors**
- 1000  The application object is invalid.
- 1002  Invalid file extension.
- 1003  Error when opening document.
- 1004  Cannot open document.
- 1600  Invalid `Documents` object
- 1601  Invalid input parameter

17.2.2.10.7  Parent

**Property:** Parent as `Application` (read-only)

**Description**
Access the StyleVision application object.

**Errors**
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.

17.2.2.11  Parameter

The `Parameter` interface has the following properties:
- **Application**
- **Name**
- **Parent**
- **Value**

### 17.2.2.11.1 Application

**Property:** Application as `Application` (read-only)

**Description**
Access the StyleVision application object.

**Errors**
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.

### 17.2.2.11.2 Name

**Property:** Name as String (read-only)

**Errors**
- 1600  Invalid `Documents` object
- 1601  Invalid input parameter

### 17.2.2.11.3 Parent

**Property:** Parent as `Application` (read-only)

**Description**
Access the StyleVision application object.

**Errors**
- 1111  The application object is no longer valid.
- 1100  Invalid address for the return parameter was specified.

### 17.2.2.11.4 Value

**Property:** Value as String (read-only)

**Errors**
- 1600  Invalid `Documents` object
- 1601  Invalid input parameter
17.2.2.12 Parameters

The Parameters interface has the following properties:

Properties

- Application
- Count
- Item
- Parent

17.2.2.12.1 Application

**Property:** Application as Application (read-only)

**Description**
Access the StyleVision application object.

**Errors**

- 1111 The application object is no longer valid.
- 1100 Invalid address for the return parameter was specified.

17.2.2.12.2 Count

**Property:** Count as long

**Description**
Count of parameters.

**Errors**

- 1600 Invalid Parameters object
- 1601 Invalid input parameter

17.2.2.12.3 Item

**Method:** Item (n as long) as Document

**Description**
Gets the document with the index n in this collection. Index is 1-based.
17.2.2.12.4  Parent

**Property:** Parent as Application (read-only)

**Description**
Access the StyleVision application object.

**Errors**
- 1111 The application object is no longer valid.
- 1100 Invalid address for the return parameter was specified.

17.2.2.13  SchemaSource

The SchemaSource interface has the following properties:

**Properties**
- Application
- IsMainSchemaSource
- Name
- Parent
- SchemaFileName
- TemplateFileName
- Type
- TypeName
- WorkingXMLFileName

17.2.2.13.1  Application

**Property:** Application as Application (read-only)

**Description**
Access the StyleVision application object.

**Errors**
- 1111 The application object is no longer valid.
- 1100 Invalid address for the return parameter was specified.
17.2.2.13.2  IsMainSchemaSource

Property:  IsMainSchemaSource as Boolean (read-only)

Description
Returns true if schema source is the main schema source.

Errors
  1400  Invalid schema source object.
  1401  Invalid parameter.

17.2.2.13.3  Name

Property:  Name as String (read-only)

Description
Use this property to retrieve the name of the schema source.

Errors
  1400  The schema source object is not valid.
  1401  Invalid parameter.

17.2.2.13.4  Parent

Property:  Parent as SchemaSource (read-only)

Description
The parent object according to the object model.

Errors
  1111  The application object is no longer valid.
  1100  Invalid address for the return parameter was specified.

17.2.2.13.5  SchemaFileName

Property:  SchemaFileName as String

Description
Use this property to retrieve the name of the Schema File.

Errors
  1400  Invalid schema source object.
  1401  Invalid parameter.
17.2.2.13.6  **TemplateName**

*Property:*  TemplateFileName as String

**Description**
Use this property to retrieve the name of the Working XML File.

**Errors**
- 1400  Invalid schema source object.
- 1401  Invalid parameter.
- 1403  Missing XMLSchema or DTD
- 1407  Error assigning Template XML File

17.2.2.13.7  **Type**

*Property:*  Type as ENUMSchemaSourceType (read-only)

**Description**
Use this property to retrieve the type of the schema source.

**Errors**
- 1400  Invalid schema source object.
- 1401  Invalid parameter.

17.2.2.13.8  **TypeName**

*Property:*  TypeName as String (read-only)

**Description**
Use this property to retrieve the type of the schema source.

**Errors**
- 1400  Invalid schema source object.
- 1401  Invalid parameter.
17.2.2.13.9 WorkingXMLFileName

Property: WorkingXMLFileName as String

Description
Use this property to retrieve the name of the Working XML File.

Errors
1400 Invalid schema source object.
1401 Invalid parameter.
1403 Missing XMLSchema or DTD
1203 Error assigning Working XML File

17.2.2.14 SchemaSources

The SchemaSources interface has the following properties:

Properties
- Application
- MainSchemaSource
- Parent

17.2.2.14.1 Application

Property: Application as Application (read-only)

Description
Access the StyleVision application object.

Errors
1111 The application object is no longer valid.
1100 Invalid address for the return parameter was specified.

17.2.2.14.2 Count

Property: Count as long (read-only)

Description
Count of schema sources.

Errors
1300 Invalid SchemaSources object
1301 Invalid input parameter

17.2.2.14.3 Item

Method: Item (n as long) as Document

Description
Gets the document with the index n in this collection. Index is 1-based.

Errors
  1300 Invalid SchemaSources object
  1301 Invalid input parameter

17.2.2.14.4 MainSchemaSource

Property: MainSchemaSource as SchemaSource (read-only)

Errors
  1300 Invalid SchemaSources object
  1301 Invalid input parameter

17.2.2.14.5 Parent

Property: Parent as SchemaSources (read-only)

Description
The parent object according to the object model.

Errors
  1111 The application object is no longer valid.
  1100 Invalid address for the return parameter was specified.

17.2.2.15 XMLData

Properties
  Kind
  Name
  TextValue
  HasChildren
MayHaveChildren
Parent

Methods
GetFirstChild
GetNextChild
GetCurrentChild

InsertChild
InsertChildAfter
InsertChildBefore
AppendChild

EraseAllChildren
EraseChild
EraseCurrentChild

IsSameNode

CountChildren
CountChildrenKind

GetChild
GetChildAttribute
GetChildElement
GetChildKind
GetNamespacePrefixForURI

HasChildrenKind
SetTextValueXMLEncoded

Description
The XMLData interface provides direct XML-level access to a document. You can read and directly modify the
XML representation of the document. However, please, note the following restrictions:

- The XMLData representation is only valid when the document is shown in grid view or authentic view.
- When in authentic view, additional XMLData elements are automatically inserted as parents of each visible
document element. Typically this is an XMLData of kind spyXMLDataElement with the Name property set
to 'Text'.
- When you use the XMLData interface while in a different view mode you will not receive errors, but changes
are not reflected to the view and might get lost during the next view switch.

Note also:

- Setting a new text value for an XML element is possible if the element does not have non-text children.
  A text value can be set even if the element has attributes.
- When setting a new text value for an XML element which has more than one text child, the latter will be
deleted and replaced by one new text child.
- When reading the text value of an XML element which has more than one text child, only the value of
the first text child will be returned.
17.2.2.15.1 AppendChild

**Declaration:** AppendChild (pNewData as XMLData)

**Description**
AppendChild appends pNewData as last child to the XMLData object.

**Errors**
- 1500  The XMLData object is no longer valid.
- 1505  Invalid XMLData kind was specified.
- 1506  Invalid address for the return parameter was specified.
- 1507  Element cannot have Children
- 1512  Cyclic insertion - new data element is already part of document
- 1514  Invalid XMLData kind was specified for this position.
- 1900  Document must not be modified

**Example**
```vba
Dim objCurrentParent As XMLData
Dim objNewChild As XMLData

Set objNewChild = objSpy.ActiveDocument.CreateChild(spyXMLDataElement)

objCurrentParent.AppendChild objNewChild

Set objNewChild = Nothing
```

17.2.2.15.2 CountChildren

**Declaration:** CountChildren as long

**Description**
CountChildren gets the number of children.

Available with TypeLibrary version 1.5

**Errors**
- 1500  The XMLData object is no longer valid.

17.2.2.15.3 CountChildrenKind

**Declaration:** CountChildrenKind (nKind as SPYXMLDataKind) as long

**Description**
CountChildrenKind gets the number of children of the specific kind.
Errors
1500  The XMLData object is no longer valid.

17.2.2.15.4  EraseAllChildren

Declaration: EraseAllChildren

Description
EraseAllChildren deletes all associated children of the XMLData object.

Errors
1500  The XMLData object is no longer valid.
1900  Document must not be modified

Example
The sample erases all elements of the active document.

Dim objCurrentParent As XMLData

objCurrentParent.EraseAllChildren

17.2.2.15.5  EraseChild

Method: EraseChild (Child as XMLData)

Description
Deletes the given child node.

Errors
1500  Invalid object.
1506  Invalid input xml
1510  Invalid parameter.

17.2.2.15.6  EraseCurrentChild

Declaration: EraseCurrentChild

Description
EraseCurrentChild deletes the current XMLData child object. Before you call EraseCurrentChild you must initialize an internal iterator with XMLData.GetFirstChild. After deleting the current child, EraseCurrentChild increments the internal iterator of the XMLData element. No error is returned when the last child gets erased.
and the iterator is moved past the end of the child list. The next call to EraseCurrentChild however, will return error 1503.

Errors

1500  The XMLData object is no longer valid.
1503  No iterator is initialized for this XMLData object, or the iterator points past the last child.
1900  Document must not be modified

Examples

// ---------------------------------------
// XMLSpy scripting environment - JScript
// erase all children of XMLData
// ---------------------------------------
// let's get an XMLData element, we assume that the
// cursor selects the parent of a list in grid view

// the following line would be shorter, of course
// objList.EraseAllChildren();

// but we want to demonstrate the usage of EraseCurrentChild
if ((objList !== null) && (objList.HasChildren))
{
    try
    {
        objEle = objList.GetFirstChild(-1);
        while (objEle !== null)
        {
            objList.EraseCurrentChild();
            // no need to call GetNextChild
        }
    }
    catch (err)
    {
        if ((err.number & 0xffff) !== 1503)
            throw (err);
    }
}

17.2.2.15.7 GetChild

Declaration: GetChild (position as long) as XMLData

Return Value
Returns an XML element as XMLData object.

Description
GetChild() returns a reference to the child at the given index (zero-based).

Available with TypeLibrary version 1.5

Errors

1500  The XMLData object is no longer valid.
1510  Invalid address for the return parameter was specified.
17.2.2.15.8  GetChildAttribute

**Method:** GetChildAttribute (strName as string) child as XMLElement object (NULL on error)

**Description**
Retrieves the attribute having the given name.

**Errors**
1500  Invalid object.
1510  Invalid parameter.

17.2.2.15.9  GetChildElement

**Method:** GetChildElement (strName as string, nIndex as long) child as XMLElement object (NULL on error)

**Description**
Retrieves the Nth child element with the given name.

**Errors**
1500  Invalid object.
1510  Invalid parameter.

17.2.2.15.10  GetChildKind

**Declaration:** GetChildKind (position as long, nKind as SPYXMLElementKind) as XMLElement

**Return Value**
Returns an XMLElement as XMLElement object.

**Description**
GetChildKind() returns a reference to a child of this kind at the given index (zero-based). The position parameter is relative to the number of children of the specified kind and not to all children of the object.

Available with TypeLibrary version 1.5

**Errors**
1500  The XMLElement object is no longer valid.
1510  Invalid address for the return parameter was specified.
17.2.2.15.11  GetCurrentChild

**Declaration:** GetCurrentChild as XMLData

**Return Value**
Returns an XML element as XMLData object.

**Description**
GetCurrentChild gets the current child. Before you call GetCurrentChild you must initialize an internal iterator with XMLData.GetFirstChild.

**Errors**
- 1500: The XMLData object is no longer valid.
- 1503: No iterator is initialized for this XMLData object.
- 1510: Invalid address for the return parameter was specified.

17.2.2.15.12  GetFirstChild

**Declaration:** GetFirstChild (nKind as SPYXMLDataKind) as XMLData

**Return Value**
Returns an XML element as XMLData object.

**Description**
GetFirstChild initializes a new iterator and returns the first child. Set nKind = -1 to get an iterator for all kinds of children.

REMARK: The iterator is stored inside the XMLData object and gets destroyed when the XMLData object gets destroyed. Be sure to keep a reference to this object as long as you want to use GetCurrentChild, GetNextChild or EraseCurrentChild.

**Errors**
- 1500: The XMLData object is no longer valid.
- 1501: Invalid XMLData kind was specified.
- 1504: Element has no children of specified kind.
- 1510: Invalid address for the return parameter was specified.

**Example**
See the example at XMLData.GetNextChild.

17.2.2.15.13  GetNamespacePrefixForURI

**Method:** GetNamespacePrefixForURI (strURI as string) strNS as string

**Description**
Returns the namespace prefix of the supplied URI.
Errors
  1500  Invalid object.
  1510  Invalid parameter.

17.2.2.15.14  GetNextChild

Declaration: GetNextChild as XMLData

Return Value
Returns an XML element as XMLData object.

Description
GetNextChild steps to the next child of this element. Before you call GetNextChild you must initialize an
internal iterator with XMLData.GetFirstChild.

Check for the last child of the element as shown in the sample below.

Errors
  1500  The XMLData object is no longer valid.
  1503  No iterator is initialized for this XMLData object.
  1510  Invalid address for the return parameter was specified.

Examples
' ----------------------------------------------
' VBA code snippet - iterate XMLData children
' ----------------------------------------------
On Error Resume Next
Set objParent = objSpy.ActiveDocument.RootElement

'get elements of all kinds
Set objCurrentChild = objParent.GetFirstChild(-1)

Do
  'do something useful with the child

  'step to next child
  Set objCurrentChild = objParent.GetNextChild
Loop Until (Err.Number - vbObjectError = 1503)

// ---------------------------------------
// XMLSpy scripting environment - JScript
// iterate through children of XMLData
// ---------------------------------------
try
{
  var objXMLData = ... // initialize somehow
  var objChild = objXMLData.GetFirstChild(-1);
while (true) {
    // do something useful with objChild
    objChild = objXMLData.GetNextChild();
}

catch (err) {
    if ((err.number & 0xffff) == 1504) {
        // element has no children
    } else if ((err.number & 0xffff) == 1503) {
        // last child reached
    } else {
        throw (err);
    }
}

17.2.2.15.15 GetTextValueXMLDecoded

Method: GetTextValueXMLDecoded () as string

Description
Gets the decoded text value of the XML.

Errors
1500 Invalid object.
1510 Invalid parameter.

17.2.2.15.16 HasChildren

Declaration: HasChildren as Boolean

Description
The property is true if the object is the parent of other XMLData objects. This property is read-only.

Errors
1500 The XMLData object is no longer valid.
1510 Invalid address for the return parameter was specified.

17.2.2.15.17 HasChildrenKind

Declaration: HasChildrenKind (nKind as SPYXMLDataKind) as Boolean

Description
The method returns true if the object is the parent of other XMLData objects of the specific kind.
Available with TypeLibrary version 1.5

Errors
1500  The XMLData object is no longer valid.
1510  Invalid address for the return parameter was specified.

17.2.2.15.18  InsertChild

Declaration: InsertChild (pNewData as XMLData)

Description
InsertChild inserts the new child before the current child (see also XMLData.GetFirstChild, XMLData.GetNextChild to set the current child).

Errors
1500  The XMLData object is no longer valid.
1503  No iterator is initialized for this XMLData object.
1505  Invalid XMLData kind was specified.
1506  Invalid address for the return parameter was specified.
1507  Element cannot have Children
1512  Cyclic insertion - new data element is already part of document
1514  Invalid XMLData kind was specified for this position.
1900  Document must not be modified

17.2.2.15.19  InsertChildAfter

Method: InsertChildAfter (Node as XMLData, NewData as XMLData)

Description
Inserts a new XML node (supplied with the second parameter) after the specified node (first parameter).

Errors
1500  Invalid object.
1506  Invalid input xml
1507  No children allowed
1510  Invalid parameter.
1512  Child is already added
1514  Invalid kind at position

17.2.2.15.20  InsertChildBefore

Method: InsertChildBefore (Node as XMLData, NewData as XMLData)
Description
Inserts a new XML node (supplied with the second parameter) before the specified node (first parameter).

Errors
- 1500 Invalid object.
- 1506 Invalid input xml
- 1507 No children allowed
- 1510 Invalid parameter.
- 1512 Child is already added
- 1514 Invalid kind at position

17.2.2.15.21 IsSameNode

Declaration: IsSameNode (pNodeToCompare as XMLData) as Boolean

Description
Returns true if pNodeToCompare references the same node as the object itself.

Errors
- 1500 The XMLData object is no longer valid.
- 1506 Invalid address for the return parameter was specified.

17.2.2.15.22 Kind

Declaration: Kind as SPYXMLDataKind

Description
Kind of this XMLData object. This property is read-only.

Errors
- 1500 The XMLData object is no longer valid.
- 1510 Invalid address for the return parameter was specified.

17.2.2.15.23 MayHaveChildren

Declaration: MayHaveChildren as Boolean

Description
Indicates whether it is allowed to add children to this XMLData object. This property is read-only.

Errors
- 1500 The XMLData object is no longer valid.
- 1510 Invalid address for the return parameter was specified.
17.2.2.15.24   Name

Declaration: Name as String

Description
Used to modify and to get the name of the XMLData object.

Errors
1500  The XMLData object is no longer valid.
1510  Invalid address for the return parameter was specified.

17.2.2.15.25   Parent

Declaration: Parent as XMLData

Return value
Parent as XMLData object. Nothing (or NULL) if there is no parent element.

Description
Parent of this element. This property is read-only.

Errors
1500  The XMLData object is no longer valid.
1510  Invalid address for the return parameter was specified.

17.2.2.15.26   SetTextValueXMLEncoded

Method: SetTextValueXMLEncoded ( strVal as String)

Description
Sets the encoded text value of the XML.

Errors
1500  Invalid object.
1513  Modification not allowed.

17.2.2.15.27   TextValue

Declaration: TextValue as String

Description
Used to modify and to get the text value of this XMLData object.

Errors
1500  The XMLData object is no longer valid.
17.2.3 Enumerations

This is a list of all enumerations used by the StyleVision API. If your scripting environment does not support enumerations use the number-values instead.

17.2.3.1 ENUMApplicationStatus

Description
Enumeration to specify the current Application status.

Possible values:

- eApplicationRunning = 0
- eApplicationAfterLicenseCheck = 1
- eApplicationBeforeLicenseCheck = 2
- eApplicationConcurrentLicenseCheckFailed = 3
- eApplicationProcessingCommandLine = 4

17.2.3.2 ENUMAppOutputLine_Severity

Description
Enumeration values to identify the severity of an AppOutputLine.

Possible values:

- eSeverity_Undefined = -1
- eSeverity_Info = 0
- eSeverity_Warning = 1
- eSeverity_Error = 2
- eSeverity_CriticalError = 3
- eSeverity_Success = 4
- eSeverity_Summary = 5
- eSeverity_Progress = 6
- eSeverity_DataEdit = 7
- eSeverity_ParserInfo = 8
- eSeverity_PossibleInconsistencyWarning = 9
- eSeverity_Message = 10
- eSeverity_Document = 11
- eSeverity_Rest = 12
- eSeverity_NoSelect = 13
- eSeverity_Select = 14
- eSeverity_Autoinsertion = 15
- eSeverity_GlobalResources_DefaultWarning = 16
17.2.3.3 ENUMAppOutputLine_TextDecoration

**Description**
Enumeration values for the different kinds of text decoration of an AppOutputLine.

**Possible values:**
- `eTextDecorationDefault` = 0
- `eTextDecorationBold` = 1
- `eTextDecorationDebugValues` = 2
- `eTextDecorationDB_ObjectName` = 3
- `eTextDecorationDB_ObjectLink` = 4
- `eTextDecorationDB_ObjectKind` = 5
- `eTextDecorationDB_TimeoutValue` = 6
- `eTextDecorationFind_MatchingString` = 7
- `eTextDecorationValidation_Speclink` = 8
- `eTextDecorationValidation_ErrorPosition` = 9
- `eTextDecorationValidation_UnknownParam` = 10

17.2.3.4 ENUMSchemaSourceType

**Description**
Enumeration to specify the source schema type: XML Schema, DTD, DB, DB cell, User-Defined, or XBRL.

**Possible values:**
- `eSchemaSourceType_XSDorDTD` = 0
- `eSchemaSourceType_DB` = 1
- `eSchemaSourceType_DBCell` = 2
- `eSchemaSourceType_User` = 3
- `eSchemaSourceType_XBRL` = 4

17.2.3.5 ENUMSchemaType

**Description**
Enumeration to specify the schema type: W3C XML Schema or DTD.

**Possible values:**
- `eSchemaTypeW3CSchema` = 0
- `eSchemaTypeDTD` = 1
17.2.3.6 SPYAuthenticActions

**Description**
Actions that can be performed on AuthenticRange objects.

**Possible values:**
- spyAuthenticInsertAt = 0
- spyAuthenticApply = 1
- spyAuthenticClearSurr = 2
- spyAuthenticAppend = 3
- spyAuthenticInsertBefore = 4
- spyAuthenticRemove = 5

17.2.3.7 SPYAuthenticDocumentPosition

**Description**
Relative and absolute positions used for navigating with AuthenticRange objects.

**Possible values:**
- spyAuthenticDocumentBegin = 0
- spyAuthenticDocumentEnd = 1
- spyAuthenticRangeBegin = 2
- spyAuthenticRangeEnd = 3

17.2.3.8 SPYAuthenticElementKind

**Description**
Enumeration of the different kinds of elements used for navigation and selection within the AuthenticRange and AuthenticView objects.

**Possible values:**
- spyAuthenticChar = 0
- spyAuthenticWord = 1
- spyAuthenticLine = 3
- spyAuthenticParagraph = 4
- spyAuthenticTag = 6
- spyAuthenticDocument = 8
- spyAuthenticTable = 9
- spyAuthenticTableRow = 10
- spyAuthenticTableColumn = 11
17.2.3.9  SPYAuthenticMarkupVisibility

Description
Enumeration values to customize the visibility of markup with MarkupVisibility.

Possible values:
- spyAuthenticMarkupHidden  = 0
- spyAuthenticMarkupSmall   = 1
- spyAuthenticMarkupLarge   = 2
- spyAuthenticMarkupMixed   = 3

17.2.3.10  SPYAuthenticToolbarButtonState

Description
Authentic toolbar button states are given by the following enumeration:

Possible values:
- authenticToolbarButtonDefault  = 0
- authenticToolbarButtonEnabled  = 1
- authenticToolbarButtonDisabled = 2

17.2.3.11  SPYMouseEvent

Description
Enumeration type that defines the mouse status during a mouse event. Use the enumeration values as bitmasks rather than directly comparing with them.

Examples

' to check for ctrl-leftbutton-down in VB
If (i_eMouseEvent = (XMLSpyLib.spyLeftButtonDownMask Or XMLSpyLib.spyCtrlKeyDownMask)) Then
    ' react on ctrl-leftbutton-down
End If

' to check for double-click with any button in VBScript
If (((i_eMouseEvent And spyDoubleClickMask) <> 0) Then
    ' react on double-click
End If

Possible values:
- spyNoButtonMask               = 0
- spyMouseMoveMask              = 1
- spyLeftButtonMask             = 2
- spyMiddleButtonMask           = 4
- spyRightButtonMask            = 8
- spyButtonUpMask               = 16
spyButtonDownMask = 32
spyDoubleClickMask = 64
spyShiftKeyDownMask = 128
spyCtrlKeyDownMask = 256
spyLeftButtonDownMask = 34 // spyLeftButtonMask | spyButtonDownMask
spyMiddleButtonDownMask = 36 // spyMiddleButtonMask | spyButtonDownMask
spyRightButtonDownMask = 40 // spyRightButtonMask | spyButtonDownMask
spyLeftButtonUpMask = 18 // spyLeftButtonMask | spyButtonUpMask
spyMiddleButtonUpMask = 20 // spyMiddleButtonMask | spyButtonUpMask
spyRightButtonUpMask = 24 // spyRightButtonMask | spyButtonUpMask
spyLeftDoubleClickMask = 66 // spyRightButtonMask | spyButtonUpMask
spyMiddleDoubleClickMask = 68 // spyMiddleButtonMask | spyDoubleClickMask
spyRightDoubleClickMask = 72 // spyRightButtonMask | spyDoubleClickMask

17.2.3.12 SPYValidateXSDVersion

**Description**
Enumeration values that select what XSD version to use. The XSD version that is selected depends on both (i) the presence/absence—and, if present, the value—of the /xs:schema/@vc:minVersion attribute of the XSD document, and (ii) the value of this enumeration.

spyValidateXSDVersion_1_0 selects XSD 1.0 if vc:minVersion is absent, or is present with any value.
spyValidateXSDVersion_1_1 selects XSD 1.1 if vc:minVersion is absent, or is present with any value.
spyValidateXSDVersion_AutoDetect selects XSD 1.1 if vc:minVersion=1.1. If the vc:minVersion attribute is absent, or is present with a value other than 1.1, then XSD 1.0 is selected.

**Possible values**
spyValidateXSDVersion_AutoDetect = 0
spyValidateXSDVersion_1_1 = 1
spyValidateXSDVersion_1_0 = 2

17.2.3.13 SPYValidateErrorFormat

**Description**
Enumeration values that select the format of the error message.

**Possible values**
spyValidateErrorFormat_Text = 0
spyValidateErrorFormat_ShortXML = 1
spyValidateErrorFormat_LongXML = 2
17.2.3.14 SPYXMLDataKind

**Description**
The different types of XMLData elements available for XML documents.

**Possible values:**

- `spyXMLDataXMLDocStruct` = 0
- `spyXMLDataXMLEntityDocStruct` = 1
- `spyXMLDataDTDDocStruct` = 2
- `spyXMLDataXML` = 3
- `spyXMLDataElement` = 4
- `spyXMLDataAttr` = 5
- `spyXMLDataText` = 6
- `spyXMLDataCDATA` = 7
- `spyXMLDataComment` = 8
- `spyXMLDataPI` = 9
- `spyXMLDataDefDoctype` = 10
- `spyXMLDataDefExternalID` = 11
- `spyXMLDataDefElement` = 12
- `spyXMLDataDefAttlist` = 13
- `spyXMLDataDefEntity` = 14
- `spyXMLDataDefNotation` = 15
- `spyXMLDataKindsCount` = 16
17.3 ActiveX Integration

The StyleVision user interface and the functionality described in this section can be integrated into custom applications that can consume ActiveX controls. ActiveX technology enables a wide variety of languages to be used for integration, such as C++, C#, VB.NET, HTML. (Note that ActiveX components integrated in HTML must be run with Microsoft Internet Explorer versions and platforms that support ActiveX). All components are full OLE Controls. Integration into Java is provided through wrapper classes.

To integrate the ActiveX controls into your custom code, the StyleVision Integration Package must be installed (see https://www.altova.com/components/download). Ensure that you install StyleVision first, and then the StyleVision Integration Package. Other prerequisites apply, depending on language and platform (see Prerequisites).

You can flexibly choose between two different levels of integration: application level and document level.

Integration at application level means embedding the complete interface of StyleVision (including its menus, toolbars, panes, etc) as an ActiveX control into your custom application. For example, in the most simple scenario, your custom application could consist of only one form that embeds the StyleVision graphical user interface. This approach is easier to implement than integration at document level but may not be suitable if you need flexibility to configure the StyleVision graphical user interface according to your custom requirements.

Integration at document level means embedding StyleVision into your own application piece-by-piece. This includes implementing not only the main StyleVision control but also the main document editor window, and, optionally, any additional windows. This approach provides greater flexibility to configure the GUI, but requires advanced interaction with ActiveX controls in your language of choice.

The sections Integration at the Application Level and Integration at Document Level describe the key steps at these respective levels. The ActiveX Integration Examples section provides examples in C#, HTML, and Java. Looking through these examples will help you to make the right decisions quickly. The Object Reference section describes all COM objects that can be used for integration, together with their properties and methods.

For information about using StyleVision as a Visual Studio plug-in, see StyleVision in Visual Studio.

17.3.1 Prerequisites

To integrate the StyleVision ActiveX control into a custom application, the following must be installed on your computer:

- StyleVision
- The StyleVision Integration Package, available for download at https://www.altova.com/components/download

To integrate the 64-bit ActiveX control, install the 64-bit versions of StyleVision and StyleVision Integration Package. For applications developed under Microsoft .NET platform with Visual Studio, both the 32-bit and 64-bit versions of StyleVision and StyleVision Integration Package must be installed, as explained below.
**Microsoft .NET (C#, VB.NET) with Visual Studio**

To integrate the StyleVision ActiveX control into a 32-bit application developed under Microsoft .NET, the following must be installed on your computer:

- Microsoft .NET Framework 4.0 or later
- Visual Studio 2010/2012/2013/2015/2017/2019
- StyleVision 32-bit and StyleVision Integration Package 32-bit
- The ActiveX controls must be added to the Visual Studio toolbox (see [Adding the ActiveX Controls to the Toolbox](#)).

If you want to integrate the 64-bit ActiveX control, the following prerequisites apply in addition to the ones above:

- StyleVision 32-bit and StyleVision Integration Package 32-bit must still be installed (this is required to provide the 32-bit ActiveX control to the Visual Studio designer, since Visual Studio runs on 32-bit)
- StyleVision 64-bit and StyleVision Integration Package 64-bit must be installed (provides the actual 64-bit ActiveX control to your custom application at runtime)
- In Visual Studio, create a 64-bit build configuration and build your application using this configuration. For an example, see [Running the Sample C# Solution](#).

**Java**

To integrate the StyleVision ActiveX control into Java application using the Eclipse development environment, the following must be installed on your computer:

- Java Runtime Environment (JRE) or Java Development Kit (JDK) 7 or later
- Eclipse
- StyleVision and StyleVision Integration Package

**Note:** To run the 64-bit version of the StyleVision ActiveX control, use a 64-bit version of Eclipse, as well as the 64-bit version of StyleVision and the StyleVision Integration Package.

**StyleVision integration and deployment on client computers**

If you create a .NET application and intend to distribute it to other clients, you will need to install the following on the client computer(s):

- StyleVision
- The StyleVision Integration Package
- The custom integration code or application.

### 17.3.2 Adding the ActiveX Controls to the Toolbox

To use the StyleVision ActiveX controls in an application developed with Visual Studio, the controls must first be added to the Visual Studio Toolbox, as follows:

1. On the **Tools** menu of Visual Studio, click **Choose Toolbox Items**.
2. On the **COM Components** tab, select the check boxes next to the StyleVisionControl, StyleVisionControl Document, and StyleVisionControl Placeholder.
In case the controls above are not available, follow the steps below:

1. On the **COM Components** tab, click **Browse**, and select the **StyleVisionControl.ocx** file from the StyleVision installation folder. Remember that the StyleVision Integration Package must be installed; otherwise, this file is not available, see Prerequisites.
2. If prompted to restart Visual Studio with elevated permissions, click **Restart under different credentials**.

If the steps above were successful, the StyleVision ActiveX controls become available in the Visual Studio Toolbox.
17.3.3 Integration at Application Level

Integration at application level allows you to embed the complete interface of StyleVision into a window of your application. With this type of integration, you get the whole user interface of StyleVision, including all menus, toolbars, the status bar, document windows, and helper windows. Customization of the application's user interface is restricted to what StyleVision provides. This includes rearrangement and resizing of helper windows and customization of menus and toolbars.

The only ActiveX control you need to integrate is **StyleVisionControl**. Do not instantiate or access **StyleVisionControlDocument** or **StyleVisionControlPlaceholder** ActiveX controls when integrating at application-level.

If you have any initialization to do or if you want to automate some behaviour of StyleVision, use the properties, methods, and events described for **StyleVisionControl**. Consider using **StyleVisionControl.Application** for more complex access to StyleVision functionality.

**Note:** For an application-level integration, only the **StyleVisionControl** ActiveX control is used (see **Integration at Application Level**). The **StyleVisionControl Document** and **StyleVisionControl Placeholder** controls are used for document-level integration (see **Integration at Document Level**).
For an example that shows how the StyleVision application can be embedded in an HTML page, see HTML Integration at Application Level.

In C# or VB.NET with Visual Studio, the steps to create a basic, one-form application which integrates the StyleVision ActiveX controls at application level are as follows:

1. Check that all prerequisites are met (see Prerequisites).
2. Create a new Visual Studio Windows Forms project with a new empty form.
3. If you have not done that already, add the ActiveX controls to the toolbox (see Adding the ActiveX Controls to the Toolbox).
4. Drag the StyleVisionControl from the toolbox onto your new form.
5. Select the StyleVisionControl on the form, and, in the Properties window, set the IntegrationLevel property to ICAcativeXIntegrationOnApplicationLevel.

6. Create a build platform configuration that matches the platform under which you want to build (x86, x64). Here is how you can create the build configuration:
   a. Right-click the solution in Visual Studio, and select Configuration Manager.
   b. Under Active solution platform, select New... and then select the x86 or x64 configuration (in this example, x86).
You are now ready to build and run the solution in Visual Studio. Remember to build using the configuration that matches your target platform (x86, x64).

### 17.3.4 Integration at Document Level

Compared to integration at application level, integration at document level is a more complex, yet more flexible way to embed StyleVision functionality into your application by means of ActiveX controls. With this approach, your code can access selectively the following parts of the StyleVision user interface:

- Document editing window
- Project window
- Design Overview window
- Schema Tree window
- Design Tree window
- Styles window
- Style Repository window
- Properties window
- Messages window

As mentioned in Integration at Application Level, for an ActiveX integration at application level, only one control is required, namely the StyleVisionControl. However, for an ActiveX integration at document level, StyleVision functionality is provided by the following ActiveX controls:

- StyleVisionControl
- StyleVisionControl Document
- StyleVisionControl Placeholder

These controls are supplied by the StyleVisionControl.ocx file available in the application installation folder of StyleVision. When you develop the ActiveX integration with Visual Studio, you will need to add these controls to the Visual Studio toolbox (see Adding the ActiveX Controls to the Toolbox).

The basic steps to integrate the ActiveX controls at document level into your application are as follows:

1. First, instantiate StyleVisionControl in your application. Instantiating this control is mandatory; it enables support for the StyleVisionControl Document and StyleVisionControl Placeholder controls mentioned above. It is important to set the IntegrationLevel property to
ICActiveXIntegrationOnDocumentLevel (or "1"). To hide the control from the user, set its Visible property to False.

Note: When integrating at document level, do not use the Open method of the StyleVisionControl; this might lead to unexpected results. Use the corresponding open methods of StyleVisionControl Document and StyleVisionControl PlaceHolder instead.

2. Create at least one instance of StyleVisionControl Document in your application. This control supplies the document editing window of StyleVision to your application and can be instantiated multiple times if necessary.

Use the method Open to load any existing file. To access document-related functionality, use the Path and Save or methods and properties accessible via the property Document.

Note: The control does not support a read-only mode. The value of the property ReadOnly is ignored.

3. Optionally, add to your application the StyleVisionControl Placeholder control for each additional window (other than the document window) that must be available to your application.

Instances of StyleVisionControl PlaceHolder allow you to selectively embed additional windows of StyleVision into your application. The window kind (for example, Project window) is defined by the property PlaceholderWindowID. Therefore, to set the window kind, set the property PlaceholderWindowID. For valid window identifiers, see StyleVisionControlPlaceholderWindow.

Note: Use only one StyleVisionControl PlaceHolder for each window identifier.

For placeholder controls that select the StyleVision project window, additional methods are available. Use OpenProject to load a StyleVision project. Use the property Project and the methods and properties from the StyleVision automation interface to perform any other project related operations.

For example, in C# or VB.NET with Visual Studio, the steps to create a basic, one-form application which integrates the StyleVision ActiveX controls at document level could be similar to those listed below. Note that your application may be more complex if necessary; however, the instructions below are important to understand the minimum requirements for an ActiveX integration at document level.

1. Create a new Visual Studio Windows Forms project with a new empty form.
2. If you have not done that already, add the ActiveX controls to the toolbox (see Adding the ActiveX Controls to the Toolbox).
3. Drag the StyleVisionControl from the toolbox onto your new form.
4. Set the IntegrationLevel property of the StyleVisionControl to ICAActiveXIntegrationOnDocumentLevel, and the Visible property to False. You can do this either from code or from the Properties window.
5. Drag the StyleVisionControl Document from the toolbox onto the form. This control provides the main document window of StyleVision to your application, so you may need to resize it to a reasonable size for a document.
6. Optionally, add one or more StyleVisionControl Placeholder controls to the form (one for each additional window type that your application needs, for example, the Project window). You will typically want to place such additional placeholder controls either below or to the right or left of the main document control, for example:
7. Set the **PlaceholderWindowID** property of each **StyleVisionControl Placeholder** control to a valid window identifier. For the list of valid values, see [StyleVisionControlPlaceholderWindow](#).

8. Add commands to your application (at minimum, you will need to open, save and close documents), as shown below.

### Querying StyleVision Commands

When you integrate at document level, no StyleVision menu or toolbar is available to your application. Instead, you can retrieve the required commands, view their status, and execute them programmatically, as follows:

- To retrieve all available commands, use the **CommandsList** property of the **StyleVisionControl**.
- To retrieve commands organized according to their menu structure, use the **MainMenu** property.
- To retrieve commands organized by the toolbar in which they appear, use the **Toolbars** property.
- To send commands to StyleVision, use the **Exec** method.
- To query if a command is currently enabled or disabled, use the **QueryStatus** method.

This enables you to flexibly integrate StyleVision commands into your application's menus and toolbars.

Your installation of StyleVision also provides you with command label images used within StyleVision. See the folder `<ApplicationFolder>\Examples\ActiveX\Images` of your StyleVision installation for icons in GIF format. The file names correspond to the command names as they are listed in the [Command Reference](#) section.
General considerations
To automate the behaviour of StyleVision, use the properties, methods, and events described for the
StyleVisionControl, StyleVisionControlDocument, and StyleVisionControlPlaceholder.

For more complex access to StyleVision functionality, consider using the following properties:

- StyleVisionControl.Application
- StyleVisionControlDocument.Document
- StyleVisionControlPlaceHolder.Project

These properties give you access to the StyleVision automation interface (StyleVisionAPI)

Note: To open a document, always use StyleVisionControlDocument.Open or
StyleVisionControlDocument.New on the appropriate document control. To open a project,
always use StyleVisionControlPlaceHolder.OpenProject on a placeholder control embedding
a StyleVision project window.

For examples that show how to instantiate and access the necessary controls in different programming
environments, see ActiveX Integration Examples.

17.3.5 ActiveX Integration Examples

This section contains examples of StyleVision document-level integration using different container environments
and programming languages. (The HTML section additionally contains examples of integration at application
level.) Source code for all examples is available in the folder <ApplicationFolder>\Examples\ActiveX of your
StyleVision installation.

17.3.5.1 C#

A basic ActiveX integration example solution for C# and Visual Studio is available in the folder
 <ApplicationFolder>\Examples\ActiveX\C# Before you compile the source code and run the sample,
make sure that all prerequisites are met (see Running the Sample C# Solution).

17.3.5.1.1 Running the Sample C# Solution

The sample Visual Studio solution available in the folder <ApplicationFolder>\Examples\ActiveX\C#
illustrates how to consume the StyleVision ActiveX controls. Before attempting to build and run this solution,
note the following steps:

Step 1: Check the prerequisites
Visual Studio 2010 or later is required to open the sample solution. For the complete list of prerequisites, see
Prerequisites.
Step 2: Copy the sample to a directory where you have write permissions
To avoid running Visual Studio as an Administrator, copy the source code to a directory where you have write permissions, instead of running it from the default location.

Step 3: Check and set all required control properties
The sample application contains one instance of StyleVisionControlDocument and several instances of StyleVisionControlPlaceHolder controls. Double-check that the following properties of these controls are set as shown in the table below:

<table>
<thead>
<tr>
<th>Control name</th>
<th>Property</th>
<th>Property value</th>
</tr>
</thead>
<tbody>
<tr>
<td>axStyleVisionControl</td>
<td>IntegrationLevel</td>
<td>I CActiveX IntegrationOnDocumentLevel</td>
</tr>
<tr>
<td>axStyleVisionControlHelperWndSchemaSource</td>
<td>PlaceholderWindowID</td>
<td>2</td>
</tr>
<tr>
<td>axStyleVisionControlHelperWndStyleRepository</td>
<td>PlaceholderWindowID</td>
<td>4</td>
</tr>
<tr>
<td>axStyleVisionControlHelperWndContextStyle</td>
<td>PlaceholderWindowID</td>
<td>6</td>
</tr>
<tr>
<td>axStyleVisionControlHelperWndContextProperties</td>
<td>PlaceholderWindowID</td>
<td>5</td>
</tr>
<tr>
<td>axStyleVisionControlHelperWndProject</td>
<td>PlaceholderWindowID</td>
<td>0</td>
</tr>
<tr>
<td>axStyleVisionControlHelperWndDesignOverview</td>
<td>PlaceholderWindowID</td>
<td>1</td>
</tr>
<tr>
<td>axStyleVisionControlHelperWndDesignTree</td>
<td>PlaceholderWindowID</td>
<td>3</td>
</tr>
</tbody>
</table>

Here is how you can view or set the properties of an ActiveX control:

1. Open the MDIMain.cs form in the designer window.

Note: On 64-bit Windows, it may be necessary to change the build configuration of the Visual Studio solution to "x86" before opening the designer window. If you need to build the sample as a 64-bit application, see Prerequisites.

3. Click an ActiveX control in the **Document Outline** window, and edit its required property in the **Properties** window, for example:
Step 4: Set the build platform

- Create a build platform configuration that matches the platform under which you want to build (x86, x64). Here is how you can create the build configuration:

  a. Right-click the solution in Visual Studio, and select Configuration Manager.
  b. Under Active solution platform, select New... and then select the x86 or x64 configuration (in this example, x86).
You are now ready to build and run the solution in Visual Studio. Remember to build using the configuration that matches your target platform (x86, x64); otherwise, runtime errors might occur.

17.3.5.2 HTML

The code listings in this section show how to integrate the StyleVisionControl at application level and document level. Source code for all examples is available in the folder `<ApplicationFolder>\Examples\ActiveX\HTML` of your StyleVision installation.

Note: ActiveX controls in an HTML page are supported only by Internet Explorer when it runs as a 32-bit application. When Internet Explorer 10 or 11 runs in 64-bit mode, it does not load ActiveX controls. The default browser security settings will normally block ActiveX, so you will need to explicitly allow blocked content to run on the page when prompted by Internet Explorer.

17.3.5.2.1 HTML Integration at Application Level

This example shows a simple integration of the StyleVision control at application-level into a HTML page. The integration is described in the following sections:

- Instantiate a StyleVisionControl in HTML code.
- Implement buttons to load documents and automate code-generation tasks.
- Define actions for some application events.

The code for this example is available at the following location in your StyleVision installation:

`<ApplicationFolder>\Examples\ActiveX\HTML\StyleVisionActiveX_ApplicationLevel.htm`

17.3.5.2.1.1 Instantiate the Control

The HTML `Object` tag is used to create an instance of the StyleVisionControl. The `Classid` is that of StyleVisionControl. Width and height specify the window size. No additional parameters are necessary, since application-level is the default.

```html
<OBJECT id="objStyleVisionControl" Classid="clsid:559db547-71fc-435d-aa8e-7faa321d0c6e" width="1000" height="700" VIEWASTEXT>
</OBJECT>
```

17.3.5.2.1.2 Add Button to Open Default Document

As a simple example of how to automate some tasks, we add a button to the page:

```html
<input type="button" value="Open File" onclick="BtnOpen()"/>
```
When clicked, a predefined document will be opened in the StyleVisionControl. The `MakeAbsolutePath` method creates an absolute path using the location of the script as a base path.

```javascript
function BtnOpen()
{
    if(strPath.value.length > 0)
    {
        var absolutePath = MakeAbsolutePath(strPath.value);
        var objDoc = objStyleVisionControl.Open(absolutePath);
        if (objDoc == null)
            alert("Unable to locate " + absolutePath);
    }
    else
    {
        alert("Please give the document name to open from StyleVisionExamples folder!");
        strPath.focus();
    }
}
```

### 17.3.5.2.1.3 Check Validity of Current Document

The validity of the current document is checked using the following script:

```javascript
// check validity of current document.
// if validation fails, show validation result in alert box .
function BtnTest()
{
    // get top-level object of automation interface
    var objApp = objStyleVisionControl.Application;

    // get the active document
    var objDocument = objApp.ActiveDocument;

    if ( objDocument == null )
        alert( "no active document found" );
    else
    {
        // define as arrays to support their usage as return parameters
        var errorText = new Array(1);
        var errorPos = new Array(1);
        var badData = new Array(1);

        var valid = objDocument.IsValid(errorText, errorPos, badData);

        if (! valid)
        {
            // compose the error description
            var text = errorText;

            // access that XMLData object only if filled in
            if (badData[0] != null)
```
text += "(" + badData[0].Name + "/" + badData[0].TextValue + ")";

    alert("Validation error[" + errorPos + "]: " + text);
  } else
    alert("Document is valid");
}

### 17.3.5.2.1.4 Connect to Custom Events

The example implements two event callbacks for StyleVisionControl custom events to show the principle:

```html
<!-- ----------------------------------------------------------- -->
<!-- custom event 'OnDocumentOpened' of StyleVisionControl object -->
<SCRIPT FOR="objStyleVisionControl" event="OnDocumentOpened( objDocument )"
LANGUAGE="javascript">
  // alert("Document '" + objDocument.Name + '" opened!");
</SCRIPT>
<!-- ----------------------------------------------------------- -->
<!-- custom event 'OnDocumentClosed' of StyleVisionControl object -->
<SCRIPT FOR="objStyleVisionControl" event="OnDocumentClosed( objDocument )"
LANGUAGE="javascript">
  // alert("Document '" + objDocument.Name + '" closed!");
</SCRIPT>
```

### 17.3.5.2.2 HTML Integration at Document Level

This example shows an integration of the StyleVision control at document-level into a HTML page. The following topics are covered:

- Instantiate a StyleVisionControl ActiveX control object in HTML code
- Instantiate a StyleVisionControlDocument ActiveX control to allow editing a StyleVision file
- Instantiate one StyleVisionControlPlaceHolder for a StyleVisionControl project window
- Instantiate one StyleVisionControlPlaceHolder to alternatively host one of the StyleVision helper windows
- Use event handlers to update command buttons

This example is available in its entirety in the file `StyleVisionActiveX_DocumentLevel.htm` within the `<ApplicationFolder>\Examples\ActiveX\HTML\` folder of your StyleVision installation.

### 17.3.5.2.2.1 Instantiate the StyleVisionControl

The HTML `OBJECT` tag is used to create an instance of the StyleVisionControl. The Classid is that of `StyleVisionControl`. Width and height are set to 0 since we use this control as manager control without use for its user interface. The integration level is specified as a parameter within the `OBJECT` tag.
17.3.5.2.2.2  Create Editor Window

The HTML OBJECT tag is used to embed an editing window. The additional custom parameter specifies that the control is to be initialized with a new empty document.

```
<object id="objStyleVisionControl" classid="clsid:559db547-71fc-435d-aa8e-7faa321d0c6e"
       width="0" height="0" VIEWASTEXT>
  <param name="IntegrationLevel" value="1">
</object>
```

17.3.5.2.2.3  Create Project Window

The HTML OBJECT tag is used to create a StyleVisionControlPlaceHolder window. The parameter defines the placeholder to show the StyleVision project window.

```
<object id="objDoc1" classid="clsid:8EE4E77E-C793-468B-A0D8-5D6334CD6986" width="800"
       height="500" VIEWASTEXT>
  <param name="NewDocument">
</object>
```

17.3.5.2.2.4  Create Placeholder for Helper Windows

The StyleVisionControlPlaceHolder control is required to host an application helper window, see also Integration at Document Level. For example, in the code listing below, the HTML object tag is used to instantiate a control that will host the Message window.

```
<object id="objProjectWindow" classid="clsid:E6ECBA9C-0E01-4FD5-98C3-C08B3D4824BC"
        width="200" height="250" VIEWASTEXT>
  <param name="PlaceholderWindowID" value="-1">
</object>
```

```
<object id="objMessageWindow" classid="clsid:E6ECBA9C-0E01-4FD5-98C3-C08B3D4824BC"
        width="400" height="200" VIEWASTEXT>
  <param name="PlaceholderWindowID" value="-1">
</object>
```
Notice that the `PlaceholderWindowID` parameter is set to -1, which means that, initially, no helper window is shown. Whenever a file is open, the method `DisplayHelperWindowsContent()` is invoked. This method assigns the appropriate `PlaceholderWindowID` to each control. For the list of possible values of `PlaceholderWindowID`, see `StyleVisionControlPlaceholderWindow`.

### 17.3.5.2.2.5 Mandatory Event Handlers

A mandatory event handler, such as for an already opened file:

```xml
<-- custom event 'OnOpenedOrFocused' of StyleVisionControl object -->
function objStyleVisionControl::OnOpenedOrFocused( strFilePath, bOpenWithThisControl, bFileAlreadyOpened)
{
    if (!bFileAlreadyOpened)
        DoOpenFile(objDoc1, strFilePath);
    msgtext.innerText = "Opened document: " + strFilePath;
}
```

### 17.3.5.3 Java

StyleVision ActiveX components can be accessed from Java code. Java integration is provided by the libraries listed below. These libraries are available in the folder `<ApplicationFolder>\Examples\JavaAPI` of your StyleVision installation, after you have installed both StyleVision and the StyleVision Integration Package (see also Prerequisites).

- `AltovaAutomation.dll`: a JNI wrapper for Altova automation servers (in case of the 32-bit installation of StyleVision)
- `AltovaAutomation_x64.dll`: a JNI wrapper for Altova automation servers (in case of the 64-bit installation of StyleVision)
- `AltovaAutomation.jar`: Java classes to access Altova automation servers
- `StyleVisionActiveX.jar`: Java classes that wrap the StyleVision ActiveX interface
- `StyleVisionActiveX_JavaDoc.zip`: a Javadoc file containing help documentation for the Java interface

**Note:** In order to use the Java ActiveX integration, the .dll and .jar files must be included in the Java class search path.

**Example Java project**

An example Java project is supplied with your product installation. You can test the Java project and modify and use it as you like. For more details, see Example Java Project.

**Rules for mapping the ActiveX Control names to Java**

For the documentation of ActiveX controls, see Object Reference. Note that the object naming conventions are slightly different in Java compared to other languages. Namely, the rules for mapping between the ActiveX controls and the Java wrapper are as follows:
Programmers' Reference

- **Classes and class names**
  For every component of the StyleVision ActiveX interface a Java class exists with the name of the component.

- **Method names**
  Method names on the Java interface are the same as used on the COM interfaces but start with a small letter to conform to Java naming conventions. To access COM properties, Java methods that prefix the property name with get and set can be used. If a property does not support write-access, no setter method is available. Example: For the IntegrationLevel property of the StyleVisionControl, the Java methods `getIntegrationLevel` and `setIntegrationLevel` are available.

- **Enumerations**
  For every enumeration defined in the ActiveX interface, a Java enumeration is defined with the same name and values.

- **Events and event handlers**
  For every interface in the automation interface that supports events, a Java interface with the same name plus 'Event' is available. To simplify the overloading of single events, a Java class with default implementations for all events is provided. The name of this Java class is the name of the event interface plus 'DefaultHandler'. For example:
  - `StyleVisionControl`: Java class to access the application
  - `StyleVisionControlEvents`: Events interface for the StyleVisionControl
  - `StyleVisionControlEventsDefaultHandler`: Default handler for `StyleVisionControlEvents`

**Exceptions to mapping rules**
There are some exceptions to the rules listed above. These are listed below:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Java name</th>
</tr>
</thead>
<tbody>
<tr>
<td>StyleVisionControlDocument, method New</td>
<td><code>newDocument</code></td>
</tr>
<tr>
<td>AuthenticView, method Goto</td>
<td><code>gotoElement</code></td>
</tr>
<tr>
<td>AuthenticRange, method Goto</td>
<td><code>gotoElement</code></td>
</tr>
<tr>
<td>AuthenticRange, method Clone</td>
<td><code>cloneRange</code></td>
</tr>
</tbody>
</table>

**This section**
This section shows how some basic StyleVision ActiveX functionality can be accessed from Java code. It is organized into the following sub-sections:

- **Example Java Project**
- **Creating the ActiveX Controls**
- **Loading Data in the Controls**
- **Basic Event Handling**
- **Menus**
- **UI Update Event Handling**
- **Creating a StyleVision Node Tree**
17.3.5.3.1  Example Java Project

The StyleVision installation package contains an example Java project, located in the ActiveX Examples folder of the application folder: `<ApplicationFolder>\Examples\ActiveX\Java`.

The Java example shows how to integrate the StyleVisionControl in a common desktop application created with Java. You can test it directly from the command line using the batch file `BuildAndRun.bat`, or you can compile and run the example project from within Eclipse. See below for instructions on how to use these procedures.

File list

The Java examples folder contains all the files required to run the example project. These files are listed below:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.classpath</td>
<td>Eclipse project helper file</td>
</tr>
<tr>
<td>.project</td>
<td>Eclipse project file</td>
</tr>
<tr>
<td>AltovaAutomation.dll</td>
<td>Java-COM bridge: DLL part (for the 32-bit installation)</td>
</tr>
<tr>
<td>AltovaAutomation_x64.dll</td>
<td>Java-COM bridge: DLL part (for the 64-bit installation)</td>
</tr>
<tr>
<td>AltovaAutomation.jar</td>
<td>Java-COM bridge: Java library part</td>
</tr>
<tr>
<td>BuildAndRun.bat</td>
<td>Batch file to compile and run example code from the command line prompt. Expects folder where Java Virtual Machine resides as parameter.</td>
</tr>
<tr>
<td>StyleVisionActiveX.jar</td>
<td>Java classes of the StyleVision ActiveX control</td>
</tr>
<tr>
<td>StyleVisionActiveX_JavaDoc.zip</td>
<td>Javadoc file containing help documentation for the Java API</td>
</tr>
<tr>
<td>StyleVisionContainer.java</td>
<td>Java example source code</td>
</tr>
<tr>
<td>StyleVisionContainerEventHandler.java</td>
<td>Java example source code</td>
</tr>
<tr>
<td>StyleVisionDialog.java</td>
<td>Java example source code</td>
</tr>
</tbody>
</table>

What the example does

The example places one StyleVision document editor window, the StyleVision project window, the StyleVision schema tree window and the StyleVision design overview window in an AWT frame window. It reads out the main menu defined for StyleVision and creates an AWT menu with the same structure. You can use this menu or the project window to open and work with files in the document editor.

You can modify the example in any way you like.

The following specific features are described in code listings:

- **Creating the ActiveX Controls**: Starts StyleVision, which is registered as an automation server, or activates StyleVision if it is already running.
- **Loading Data in the Controls**: Locates one of the example documents installed with StyleVision and opens it.
### Basic Event Handling
Changes the view of all open documents to Text View. The code also shows how to iterate through open documents.

### Menus
Validates the active document and shows the result in a message box. The code shows how to use output parameters.

### UI Update Event Handling
Shows how to handle StyleVision events.

### Creating a StyleVision Node Tree
Shows how to create a StyleVision node tree and prepare it for modal activation.

#### Updating the path to the Examples folder
Before running the provided sample, you may need to edit the `StyleVisionContainer.java` file. Namely, check that the following path refers to the actual folder where the StyleVision example files are stored on your operating system:

```java
// Locate samples installed with the product.
final String strExamplesFolder = System.getenv("USERPROFILE") + "\Documents\Altova\StyleVision2022\StyleVisionExamples\";
```

#### Running the example from the command line
To run the example from the command line:

1. Check that all prerequisites are met (see [Prerequisites](#)).
2. Open a command prompt window, change the current directory to the sample Java project folder, and type:

   ```
   buildAndRun.bat "<Path-to-the-Java-bin-folder>"
   ```

3. Press Enter.

The Java source in `StyleVisionContainer.java` will be compiled and then executed.

#### Compiling and running the example in Eclipse
To import the sample Java project into Eclipse:

1. Check that all prerequisites are met (see [Prerequisites](#)).
2. On the File menu, click Import.
3. Select Existing Projects into Workspace, and browse for the Eclipse project file located at `<ApplicationFolder>\Examples\ActiveX\Java`. Since you may not have write-access in this folder, it is recommended to select the Copy projects into workspace check box on the Import dialog box.

To run the example application, right-click the project in Package Explorer and select the command Run as | Java Application.

Help for Java API classes is available through comments in code as well as the Javadoc view of Eclipse. To enable the Javadoc view in Eclipse, select the menu command Window | Show View | JavaDoc.
17.3.5.3.2 Creating the ActiveX Controls

The code listing below show how ActiveX controls can be created. The constructors will create the Java wrapper objects. Adding these Canvas-derived objects to a panel or to a frame will trigger the creation of the wrapped ActiveX object.

```
/**
 * StyleVision manager control - always needed
 */
public static StyleVisionControl styleVisionControl = null;

/**
 * StyleVisionDocument editing control
 */
public static StyleVisionControlDocument styleVisionDocument = null;

/**
 * Tool windows - StyleVision place-holder controls
 */
private static StyleVisionControlPlaceHolder styleVisionProjectToolWindow = null;
private static StyleVisionControlPlaceHolder styleVisionDesignToolWindow = null;
private static StyleVisionControlPlaceHolder styleVisionSchemaTreeToolWindow = null;

// Create the StyleVision ActiveX controls. First should be StyleVisionControl
// determining that we want to place document controls and place-holder
// controls individually. It gives us full control over the menu, as well.
styleVisionControl = new StyleVisionControl(
    ICActorXIntegrationLevel.ICActiveXIntegrationOnDocumentLevel.getValue() );
styleVisionDocument = new StyleVisionControlDocument();
frame.add( styleVisionDocument, BorderLayout.CENTER );

// Create a project window and open the sample project in it
styleVisionProjectToolWindow = new StyleVisionPlaceHolder(StyleVisionControlPlaceholderWindow.StyleVisionControlProjectWindowToolWnd.getValue() );
styleVisionProjectToolWindow.setPreferredSize( new Dimension( 200, 200 ) );
```

17.3.5.3.3 Loading Data in the Controls

The code listing below show how data can be loaded in the ActiveX controls.

```
// Locate samples installed with the product.
final String strExamplesFolder = System.getenv( "USERPROFILE" ) +
    "\Documents\Altova\StyleVision2021\StyleVisionExamples\";
stylenessVisionProjectToolWindow.openProject( strExamplesFolder + "Examples.svp" );
```
17.3.5.3.4 Basic Event Handling

The code listing below shows how basic events can be handled. When calling the StyleVisionControl's `open` method, or when trying to open a file via the menu or Project tree, the `onOpenedOrFocused` event is sent to the attached event handler. The basic handling for this event is opening the file by calling the StyleVisionDocumentControl's `open` method.

```java
01    // Open the PXF file when button is pressed
02    btnOpenPxf.addActionListener( new ActionListener() {
03        public void actionPerformed(ActionEvent e) {
04            try {
05                styleVisionControl.open( strExamplesFolder + "OrgChart.pxf" );
06            } catch (AutomationException e1) {
07                e1.printStackTrace();
08            }
09        }
10    } );
11
12    public void onOpenedOrFocused( String i_strFileName,
13            boolean i_bOpenWithThisControl,
14            boolean i_bFileAlreadyOpened ) throws AutomationException
15    {
16        // Handle the New/Open events coming from the Project tree or from the menus
17        if ( !i_bFileAlreadyOpened )
18            // This is basically an SDI interface, so open the file in the already existing document control
19            try {
20                StyleVisionContainer.initStyleVisionDocument();
21                StyleVisionContainer.styleVisionDocument.open( i_strFileName );
22            } catch (Exception e) {
23                e.printStackTrace();
24            }
```

17.3.5.3.5 Menus

The code listing below shows how menu items can be created. Each `StyleVisionCommand` object gets a corresponding `MenuItem` object, with the `ActionCommand` set to the ID of the command. The actions generated by all menu items are handled by the same function, which can perform specific handlings (like reinterpreting the closing mechanism) or can delegate the execution to the `StyleVisionControl` object by calling its `exec` method. The `menuMap` object that is filled during menu creation is used later (see section UI Update Event Handling).

```java
01    // Load the file menu when the button is pressed
02    btnMenu.addActionListener( new ActionListener() {
03        public void actionPerformed(ActionEvent e) {
04            try {
05                // Create the menubar that will be attached to the frame
06                MenuBar mb = new MenuBar();
07                // Load the main menu's first item - the File menu
```
StyleVisionCommand xmlSpyMenu = styleVisionControl.getMainMenue().getSubCommands().getItem(0);

// Create Java menu items from the Commands objects
Menu fileMenu = new Menu();
handlerObject.fillMenu( fileMenu, xmlSpyMenu.getSubCommands() );
fileMenu.setLabel( xmlSpyMenu.getLabel().replace( "&", "" ) );
mb.add( fileMenu );
frame.setMenuBar( mb );
frame.validate();
}
} catch (AutomationException e1) {
  e1.printStackTrace();
}

// Disable the button when the action has been performed
((AbstractButton) e.getSource()).setEnabled( false );
}

/**
 * Populates a menu with the commands and submenus contained in a StyleVisionCommands object
 */
public void fillMenu(Menu newMenu, StyleVisionCommands styleVisionMenu) throws AutomationException {
  // For each command/submenu in the xmlSpyMenu
  for ( int i = 0 ; i < styleVisionMenu.getCount() ; ++i ) {
    StyleVisionCommand styleVisionCommand = styleVisionMenu.getItem( i );
    if ( styleVisionCommand.getIsSeparator() )
      newMenu.addSeparator();
    else {
      StyleVisionCommands subCommands = styleVisionCommand.getSubCommands();
      // Is it a command (leaf), or a submenu?
      if ( subCommands.isNull() || subCommands.getCount() == 0 )
        // Command -> add it to the menu, set its ActionCommand to its ID and store it in the menuMap
        MenuItem mi = new MenuItem( styleVisionCommand.getLabel().replace( "&", "" ) );
        mi.setActionCommand( "" + styleVisionCommand.getID() );
        mi.addActionListener( this );
        newMenu.add( mi );
        menuMap.put( styleVisionCommand.getID(), mi );
      }
    else {
      // Submenu -> create submenu and repeat recursively
      Menu newSubMenu = new Menu();
      fillMenu( newSubMenu, subCommands );
      newSubMenu.setLabel( styleVisionCommand.getLabel().replace( "&", "" ) );
      newMenu.add( newSubMenu );
    }
  }
}

/**
 * Action handler for the menu items
 * Called when the user selects a menu item; the item's action command corresponds to the command table for XMLSpy
17.3.5.3.6  UI Update Event Handling

The code listing below shows how a UI-Update event handler can be created.

```java
/**
 * Call-back from the StyleVisionControl.
 * Usually called while enabling/disabling commands due to UI updates
 */
@Override
public boolean onIsActiveEditor( String i_strFilePath ) throws AutomationException
{
    try {
        return StyleVisionContainer.styleVisionDocument.getDocument().getFullName().equalsIgnoreCase( i_strFilePath );
    } catch ( Exception e ) {
        return false;
    }
}
```
17.3.5.3.7 Listing the Properties of a StyleVision Document

The listing below shows the properties of a StyleVision document (schemas, parameters, etc) can be loaded as nodes in a tree.

```java
Return false;
}
}

Listing the Properties of a StyleVision Document

The listing below shows the properties of a StyleVision document (schemas, parameters, etc) can be loaded as nodes in a tree.

```
046    myTree.expandRow( i );
047    myTree.setRootVisible( false );
048 }
049
050 /**<
051 * Loads the nodes of an XML element under a given tree node
052 * @param node  Target tree node
053 * @param doc  Source XML element
054 */
055 private void fillTree( DefaultMutableTreeNode node, Document doc)
056 {
057     try
058     {
059         DefaultMutableTreeNode titleNode = new
060             DefaultMutableTreeNode( "SchemaSources" ) ;
061             for (SchemaSource schema : doc.getSchemaSources())
062             {
063                 String nodeText = "$" + schema.getName() ;
064                     if ( schema.getIsMainSchemaSource() )
065                         nodeText += " (main)";
066                 DefaultMutableTreeNode newNode = new DefaultMutableTreeNode(nodeText ) ;
067                 node.add( titleNode ) ;
068                 titleNode.add( newNode );
069                 String attribute = schema.getSchemaFileName() ;
070                     if ( attribute.length() > 0 )
071                     {
072                         DefaultMutableTreeNode subNode = new DefaultMutableTreeNode( "SchemaFile" ) ;
073                             subNode.add( new DefaultMutableTreeNode( attribute ) ) ;
074                             newNode.add( subNode );
075                     }
076                     attribute = schema.getWorkingXMLFileName() ;
077                     if ( attribute.length() > 0 )
078                     {
079                         DefaultMutableTreeNode subNode = new DefaultMutableTreeNode( "Working
080                             XML" ) ;
081                             subNode.add( new DefaultMutableTreeNode( attribute ) ) ;
082                             newNode.add( subNode );
083                     }
084                     attribute = schema.getTemplateFileName() ;
085                     if ( attribute.length() > 0 )
086                     {
087                         DefaultMutableTreeNode subNode = new DefaultMutableTreeNode( "Template" ) ;
088                         subNode.add( new DefaultMutableTreeNode( attribute ) ) ;
089                         newNode.add( subNode );
090                     }
091         titleNode = new DefaultMutableTreeNode( "Parameters" ) ;
092             for (Parameter param : doc.getParameters())
093             {
094                 DefaultMutableTreeNode newNode = new DefaultMutableTreeNode( "$" +
095                     param.getName() ) ;
096                 node.add( titleNode ) ;
097                 titleNode.add( newNode );
098                 DefaultMutableTreeNode subNode = new DefaultMutableTreeNode( "Value" ) ;
099                 subNode.add( new DefaultMutableTreeNode( param.getValue() ) ) ;
100             }
101         }
102     catch {Exception e}
17.3.6 Command Reference

This section lists the names and identifiers of all menu commands that are available within StyleVision. Every sub-section lists the commands from the corresponding top-level menu of StyleVision. The command tables are organized as follows:

- The "Menu Item" column shows the command's menu text as it appears in StyleVision, to make it easier for you to identify the functionality behind the command.
- The "Command Name" column specifies the string that can be used to get an icon with the same name from ActiveXImages folder of the StyleVision installation directory.
- The "ID" column shows the numeric identifier of the column that must be supplied as argument to methods which execute or query this command.

To execute a command, use the StyleVisionControl.Exec or the StyleVisionControlDocument.Exec methods. To query the status of a command, use the StyleVisionControl.QueryStatus or StyleVisionControlDocument.QueryStatus methods.

Depending on the edition of StyleVision you have installed, some of these commands might not be supported.

### 17.3.6.1 "File" Menu

The "File" menu has the following commands:

<table>
<thead>
<tr>
<th>Menu item</th>
<th>Command name</th>
<th>ID</th>

</tbody>
</table>
### 17.3.7 Object Reference

#### Objects:
- **StyleVisionCommand**
- **StyleVisionCommands**
- **StyleVisionControl**
- **StyleVisionControlDocument**
- **StyleVisionControlPlaceHolder**

To give access to standard StyleVision functionality, objects of the *StyleVision automation interface* can be accessed as well. See [StyleVisionControl.Application](#) and [StyleVisionControlDocument.Document](#) and [StyleVisionControlPlaceHolder.Project](#) for more information.

#### 17.3.7.1 StyleVisionCommand

**Properties:**
- **ID**
- **Label**
- **Name**
- **IsSeparator**
- **ToolTip**
- **StatusText**
- **Accelerator**
- **SubCommands**

**Description:**
A command object can be one of the following: an executable command, a command container (for example, a menu, submenu, or toolbar), or a menu separator. To determine what kind of information is stored in the current Command object, query its ID, IsSeparator, and SubCommands properties, as follows.

<table>
<thead>
<tr>
<th>The Command object is...</th>
<th>When...</th>
</tr>
</thead>
</table>
| An executable command    | • ID is greater than zero  
                          | • IsSeparator is false  
                          | • SubCommands is empty |
The Command object is...

<table>
<thead>
<tr>
<th>A command container</th>
<th>When...</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• ID is zero</td>
</tr>
<tr>
<td></td>
<td>• IsSeparator is false</td>
</tr>
<tr>
<td></td>
<td>• SubCommands contains a collection of</td>
</tr>
<tr>
<td></td>
<td>Command objects.</td>
</tr>
<tr>
<td>Separator</td>
<td>• ID is zero</td>
</tr>
<tr>
<td></td>
<td>• IsSeparator is true</td>
</tr>
</tbody>
</table>

### 17.3.7.1.1 Accelerator

**Property:** `Accelerator as string`

**Description:**
Returns the accelerator key defined for the command. If the command has no accelerator key assigned, this property returns the empty string. The string representation of the accelerator key has the following format:

```
[ALT+] [CTRL+] [SHIFT+] key
```

Where `key` is converted using the Windows Platform SDK function `GetKeyNameText`.

### 17.3.7.1.2 ID

**Property:** `ID as long`

**Description:**
This property gets the unique identifier of the command. A command's ID is required to execute the command (using `Exec`) or query its status (using `QueryStatus`). If the command is a container for other commands (for example, a top-level menu), or a separator, the ID is 0.

### 17.3.7.1.3 IsSeparator

**Property:** `IsSeparator as boolean`

**Description:**
The property returns `true` if the command object is a menu separator; `false` otherwise. See also `Command`.

### 17.3.7.1.4 Label

**Property:** `Label as string`

**Description:**
This property gets the text of the command as it is displayed in the graphical user interface of StyleVision. If the command is a separator, "Label" is an empty string. This property may also return an empty string for some toolbar commands that do not have any GUI text associated with them.

17.3.7.1.5 Name

Property: Name as string

Description:
This property gets the unique name of the command. This value can be used to get the icon file of the command, where it is available. The available icon files can be found in the folder `<ApplicationFolder>\Examples\ActiveX\Images` of your StyleVision installation.

17.3.7.1.6 StatusText

Property: Label as string

Description:
The status text is the text shown in the status bar of StyleVision when the command is selected. It applies only to command objects that are not separators or containers of other commands; otherwise, the property is an empty string.

17.3.7.1.7 SubCommands

Property: SubCommands as Commands

Description:
The `SubCommands` property gets the collection of `Command` objects that are sub-commands of the current command. The property is applicable only to commands that are containers for other commands (menus, submenus, or toolbars). Such container commands have the `ID` set to 0, and the `IsSeparator` property set to false.

17.3.7.1.8 ToolTip

Property: ToolTip as string

Description:
This property gets the text that is shown as a tool-tip for each command. If the command does not have a tooltip text, the property returns an empty string.

17.3.7.2 StyleVisionCommands

Properties:
- `Count`
- `Item`
Description:
Collection of Command objects to get access to command labels and IDs of the StyleVisionControl. Those commands can be executed with the Exec method and their status can be queried with QueryStatus.

17.3.7.2.1 Count

Property: Count as long

Description:
Number of Command objects on this level of the collection.

17.3.7.2.2 Item

Property: Item (n as long) as Command

Description:
Gets the command with the index n in this collection. Index is 1-based.

17.3.7.3 StyleVisionControl

Properties:
IntegrationLevel
Appearance
Application
BorderStyle
CommandsList
EnableUserPrompts
MainMenu
Toolbars

Methods:
Open
Exec
QueryStatus

Events:
OnUpdateCmdUI
OnOpenedOrFocused
OnCloseEditingWindow
OnFileChangedAlert
OnContextChanged
OnDocumentOpened
OnValidationWindowUpdated

This object is a complete ActiveX control and should only be visible if the StyleVision library is used in the Application Level mode.
17.3.7.3.1  Properties

The following properties are defined:

IntegrationLevel
EnableUserPrompts
Appearance
BorderStyle

Command related properties:
CommandsList
MainMenu
Toolbars

Access to StyleVision API:
Application

17.3.7.3.1.1  Appearance

Property: Appearance as short

Dispatch Id: -520

Description:
A value not equal to 0 displays a client edge around the control. Default value is 0.

17.3.7.3.1.2  Application

Property: Application as Application

Dispatch Id: 1

Description:
The Application property gives access to the Application object of the complete StyleVision automation server API. The property is read-only.

17.3.7.3.1.3  BorderStyle

Property: BorderStyle as short

Dispatch Id: -504

Description:
A value of 1 displays the control with a thin border. Default value is 0.
17.3.7.3.1.4  **CommandsList**

**Property:** CommandList as `Commands` (read-only)

**Dispatch Id:** 1004

**Description:**
This property returns a flat list of all commands defined available with StyleVisionControl. To get commands organized according to their menu structure, use `MainMenu`. To get toolbar commands, use `Toolbars`.

```csharp
public void GetAllStyleVisionCommands()
{
    // Get all commands from the StyleVision ActiveX control assigned to the current form
    StyleVisionControlLib.StyleVisionCommands commands =
        this.axStyleVisionControl1.CommandList;
    // Iterate through all commands
    for (int i = 0; i < commands.Count; i++)
    {
        // Get each command by index and output it to the console
        StyleVisionControlLib.StyleVisionCommand cmd =
            axStyleVisionControl1.CommandList[i];
        Console.WriteLine("{0} {1} {2}", cmd.ID, cmd.Name, cmd.Label.Replace("&", ""));
    }
}
```

C# example

17.3.7.3.1.5  **EnableUserPrompts**

**Property:** EnableUserPrompts as `boolean`

**Dispatch Id:** 1006

**Description:**
Setting this property to `false`, disables user prompts in the control. The default value is `true`.

17.3.7.3.1.6  **IntegrationLevel**

**Property:** IntegrationLevel as `ICActiveXIntegrationLevel`

**Dispatch Id:** 1000

**Description:**
The `IntegrationLevel` property determines the operation mode of the control. See also Integration at Application Level and Integration at Document Level for more information.
Programmers' Reference

ActiveX Integration 1005

Note: It is important to set this property immediately after the creation of the StyleVisionControl object.

17.3.7.3.1.7

MainMenu

Property: MainMenu as C ommand 999 (read-only)
Dispatch Id: 1003
Description:
This property provides information about the structure and commands available in the StyleVisionControl main
menu, as a Command object. The Command object contains all available submenus of StyleVision (for example
"File", "Edit", "View" etc.). To access the submenu objects, use the SubCommands property of the MainMenu
property. Each submenu is also a Command object. For each submenu, you can then further iterate through their
SubCommands property in order to get their corresponding child commands and separators (this technique may
be used, for example, to create the application menu programmatically). Note that some menu commands act
as containers ("parents") for other menu commands, in which case they also have a SubCommands property. To
get the structure of all menu commands programmatically, you will need a recursive function.

public void GetStyleVisionMenus()
{
// Get the main menu from the StyleVision ActiveX control assigned to the current
form
StyleVisionControlLib.StyleVisionCommand mainMenu =
this.axStyleVisionControl1.MainMenu;
// Loop through entries of the main menu (e.g. File, Edit, etc.)
for (int i = 0; i < mainMenu.SubCommands.Count; i++)
{
StyleVisionControlLib.StyleVisionCommand menu = mainMenu.SubCommands[i];
Console.WriteLine("{0} menu has {1} children items (including separators)",
menu.Label.Replace("&", ""), menu.SubCommands.Count);
}
}

C# example

17.3.7.3.1.8

Toolbars

Property: Toolbars as C ommands 1001 (read-only)
Dispatch Id: 1005
Description:
This property provides information about the structure of StyleVisionControl toolbars, as a Command object. The
Command object contains all available toolbars of StyleVision. To access the toolbars, use the SubCommands
property of the Toolbars property. Each toolbar is also a Command object. For each toolbar, you can then
further iterate through their SubCommands property in order to get their commands (this technique may be used,
for example, to create the application's toolbars programmatically).

© 2015-2021 Altova GmbH

Altova StyleVision 2022 Professional Edition


public void GetStyleVisionToolbars()
{
    // Get the application toolbars from the StyleVision ActiveX control assigned to the current form
    StyleVisionControlLib.StyleVisionCommands toolbars =
        this.axStyleVisionControl1.Toolbars;

    // Iterate through all toolbars
    for (int i = 0; i < toolbars.Count; i++)
    {
        StyleVisionControlLib.StyleVisionCommand toolbar = toolbars[i];
        Console.WriteLine();
        Console.WriteLine("The toolbar "{0}" has the following commands:",
            toolbar.Label);

        // Iterate through all commands of this toolbar
        for (int j = 0; j < toolbar.SubCommands.Count; j++)
        {
            StyleVisionControlLib.StyleVisionCommand cmd = toolbar.SubCommands[j];
            // Output only command objects that are not separators
            if (!cmd.IsSeparator)
            {
                Console.WriteLine("{0}, {1}, {2}",
                    cmd.ID, cmd.Name, cmd.Label.Replace("&", ""));
            }
        }
    }
}

C# example

17.3.7.3.2 Methods

The following methods are defined:
Open Exec QueryStatus

17.3.7.3.2.1 Exec

Method: Exec (nCmdID as long) as boolean

Dispatch Id: 6

Description:
This method calls the StyleVision command with the ID nCmdID. If the command can be executed, the method returns true. To get a list of all available commands, use CommandsList. To retrieve the status of any command, use QueryStatus.
17.3.7.3.2.2  Open

Method: Open (strFilePath as string) as boolean

Dispatch Id: 5

Description:
The result of the method depends on the extension passed in the argument strFilePath. If the file extension is .sps, a new document is opened. If the file extension is .svp, the corresponding project is opened. If a different file extension is passed into the method, the control tries to load the file as a new component into the active document.

Do not use this method to load documents or projects when using the control in document-level integration mode. Instead, use StyleVisionControlDocument.Open and StyleVisionControlPlaceHolder.OpenProject.

17.3.7.3.2.3  QueryStatus

Method: QueryStatus (nCmdID as long) as long

Dispatch Id: 7

Description:
QueryStatus returns the enabled/disabled and checked/unchecked status of the command specified by nCmdID. The status is returned as a bit mask.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Supported</td>
<td>Set if the command is supported.</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Enabled</td>
<td>Set if the command is enabled (can be executed).</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Checked</td>
<td>Set if the command is checked.</td>
</tr>
</tbody>
</table>

This means that if QueryStatus returns 0 the command ID is not recognized as a valid StyleVision command. If QueryStatus returns a value of 1 or 5, the command is disabled.

17.3.7.3.3  Events

The StyleVisionControl ActiveX control provides the following connection point events:

- OnUpdateCmdUI
- OnOpenedOrFocused
- OnCloseEditingWindow
- OnFileChangedAlert
- OnContextChanged
- OnDocumentOpened
- OnValidationWindowUpdated
17.3.7.3.3.1  OnCloseEditingWindow

**Event:** OnCloseEditingWindow (i_strFilePath as String) as boolean

**Dispatch Id:** 1002

**Description:**
This event is triggered when StyleVision needs to close an already open document. As an answer to this event, clients should close the editor window associated with `i_strFilePath`. Returning `true` from this event indicates that the client has closed the document. Clients can return `false` if no specific handling is required and StyleVisionControl should try to close the editor and destroy the associated document control.

17.3.7.3.3.2  OnContextChanged

**Event:** OnContextChanged (i_strContextName as String, i_bActive as bool) as bool

**Dispatch Id:** 1004

**Description:**
This event is not used in StyleVision

17.3.7.3.3.3  OnDocumentOpened

**Event:** OnDocumentOpened (objDocument as Document)

**Dispatch Id:** 1

**Description:**
This event is triggered whenever a document is opened. The argument `objDocument` is a `Document` object from the StyleVision automation interface and can be used to query for more details about the document, or perform additional operations. When integrating on document-level, it is often better to use the event `StyleVisionControlDocument.OnDocumentOpened` instead.

17.3.7.3.3.4  OnFileChangedAlert

**Event:** OnFileChangedAlert (i_strFilePath as String) as bool

**Dispatch Id:** 1001

**Description:**
This event is triggered when a file loaded with StyleVisionControl is changed on the hard disk by another application. Clients should return `true`, if they handled the event, or `false`, if StyleVision should handle it in its customary way, i.e. prompting the user for reload.
17.3.7.3.5  **OnLicenseProblem**

*Event:* `OnLicenseProblem(i_strLicenseProblemText as String)`

*Dispatch Id:* 1005

*Description:*
This event is triggered when `StyleVisionControl` detects that no valid license is available for this control. In case of restricted user licenses this can happen some time after the control has been initialized. Integrators should use this event to disable access to this control's functionality. After returning from this event, the control will block access to its functionality (e.g. show empty windows in its controls and return errors on requests).

17.3.7.3.6  **OnOpenedOrFocused**

*Event:* `OnOpenedOrFocused(i_strFilePath as String, i_bOpenWithThisControl as bool)`

*Dispatch Id:* 1000

*Description:*
When integrating at application level, this event informs clients that a document has been opened, or made active by `StyleVision`.

When integrating at document level, this event instructs the client to open the file `i_strFilePath` in a document window. If the file is already open, the corresponding document window should be made the active window.

If `i_bOpenWithThisControl` is true, the document must be opened with `StyleVisionControl`, since internal access is required. Otherwise, the file can be opened with different editors.

17.3.7.3.7  **OnToolWindowUpdated**

*Event:* `OnToolWindowUpdated(pToolWnd as long)`

*Dispatch Id:* 1006

*Description:*
This event is triggered when the tool window is updated.

17.3.7.3.8  **OnUpdateCmdUI**

*Event:* `OnUpdateCmdUI()`

*Dispatch Id:* 1003

*Description:*
Called frequently to give integrators a good opportunity to check status of `StyleVision` commands using `StyleVisionControl.QueryStatus`. Do not perform long operations in this callback.
17.3.7.3.9  **OnValidationWindowUpdated**

**Event:** OnValidationWindowUpdated()

**Dispatch Id:** 3

**Description:**
This event is triggered whenever the validation output window is updated with new information.

17.3.7.4  **StyleVisionControlDocument**

**Properties:**
- Appearance
-BorderStyle
-Document
-IsModified
-Path
-ReadOnly

**Methods:**
- Exec
- New
- Open
- QueryStatus
- Reload
- Save
- SaveAs

**Events:**
- OnDocumentOpened
- OnDocumentClosed
- OnModifiedFlagChanged
- OnContextChanged
- OnFileChangedAlert
- OnActivate

If the StyleVisionControl is integrated in the Document Level mode each document is displayed in an own object of type StyleVisionControlDocument. The StyleVisionControlDocument contains only one document at the time but can be reused to display different files one after another.

This object is a complete ActiveX control.

17.3.7.4.1  **Properties**

The following properties are defined:
- ReadOnly
- IsModified
- Path
Access to StyleVision API:

**Appearance**

**Property:** Appearance as short  
**Dispatch Id:** -520  
**Description:** A value not equal to 0 displays a client edge around the document control. Default value is 0.

**BorderStyle**

**Property:** BorderStyle as short  
**Dispatch Id:** -504  
**Description:** A value of 1 displays the control with a thin border. Default value is 0.

**Document**

**Property:** Document as Document  
**Dispatch Id:** 1  
**Description:** The Document property gives access to the Document object of the StyleVision automation server API. This interface provides additional functionality which can be used with the document loaded in the control. The property is read-only.

**IsModified**

**Property:** IsModified as boolean (read-only)  
**Dispatch Id:** 1006  
**Description:** IsModified is true if the document content has changed since the last open, reload or save operation. It is false, otherwise.
17.3.7.4.1.5  Path

**Property:** Path as string

**Dispatch Id:** 1005

**Description:**
Sets or gets the full path name of the document loaded into the control.

17.3.7.4.1.6  ReadOnly

**Property:** ReadOnly as boolean

**Dispatch Id:** 1007

**Description:**
Using this property you can turn on and off the read-only mode of the document. If `ReadOnly` is true it is not possible to do any modifications.

17.3.7.4.2  Methods

The following methods are defined:

Document handling:
- `New`
- `Open`
- `Reload`
- `Save`
- `SaveAs`

Command Handling:
- `Exec`
- `QueryStatus`

17.3.7.4.2.1  Exec

**Method:** Exec (nCmdID as long) as boolean

**Dispatch Id:** 8

**Description:**
Exec calls the StyleVision command with the ID `nCmdID`. If the command can be executed, the method returns true. This method should be called only if there is currently an active document available in the application.

To get commands organized according to their menu structure, use the `MainMenu` property of StyleVisionControl. To get toolbar commands, use the `Toolbars` property of the StyleVisionControl.
17.3.7.4.2.2  New

Method: New () as boolean

Dispatch Id: 1000

Description:
This method initializes a new document inside the control.

17.3.7.4.2.3  Open

Method: Open (strFileName as string) as boolean

Dispatch Id: 1001

Description:
Open loads the file strFileName as the new document into the control.

17.3.7.4.2.4  QueryStatus

Method: QueryStatus (nCmdID as long) as long

Dispatch Id: 9

Description:
QueryStatus returns the enabled/disabled and checked/unchecked status of the command specified by nCmdID. The status is returned as a bit mask.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Supported</td>
<td>Set if the command is supported.</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Enabled</td>
<td>Set if the command is enabled (can be executed).</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Checked</td>
<td>Set if the command is checked.</td>
</tr>
</tbody>
</table>

This means that if QueryStatus returns 0 the command ID is not recognized as a valid StyleVision command. If QueryStatus returns a value of 1 or 5 the command is disabled. The client should call the QueryStatus method of the document control if there is currently an active document available in the application.

17.3.7.4.2.5  Reload

Method: Reload () as boolean

Dispatch Id: 1002

Description:
Reload updates the document content from the file system.

17.3.7.4.2.6  Save

*Method:* Save () as *boolean*

*Dispatch Id:* 1003

*Description:* 
Save saves the current document at the location Path.

17.3.7.4.2.7  SaveAs

*Method:* SaveAs (strFileName as *string*) as *boolean*

*Dispatch Id:* 1004

*Description:* 
SaveAs sets Path to strFileName and then saves the document to this location.

17.3.7.4.3  Events

The StyleVisionControlDocument ActiveX control provides following connection point events:

- **OnDocumentOpened**
- **OnDocumentClosed**
- **OnModifiedFlagChanged**
- **OnContextChanged**
- **OnFileChangedAlert**
- **OnActivate**
- **OnSetEditorTitle**

17.3.7.4.3.1  OnActivate

*Event:* OnActivate ()

*Dispatch Id:* 1005

*Description:* 
This event is triggered when the document control is activated, has the focus, and is ready for user input.

17.3.7.4.3.2  OnContextChanged

*Event:* OnContextChanged (i_strContextName as *String*, i_bActive as *bool*) as *bool*

*Dispatch Id:* 1004
Description: None

17.3.7.4.3.3  OnDocumentClosed

Event: OnDocumentClosed (objDocument as Document)

Dispatch Id: 1001

Description: This event is triggered whenever the document loaded into this control is closed. The argument objDocument is a Document object from the StyleVision automation interface and should be used with care.

17.3.7.4.3.4  OnDocumentOpened

Dispatch Id: 1000

Description: This event is triggered whenever a document is opened in this control. The argument objDocument is a Document object from the StyleVision automation interface, and can be used to query for more details about the document, or perform additional operations.

17.3.7.4.3.5  OnDocumentSaveAs

Event: OnContextDocumentSaveAs (i_strFileName as String)

Dispatch Id: 1007

Description: This event is triggered when this document gets internally saved under a new name.

17.3.7.4.3.6  OnFileChangedAlert

Event: OnFileChangedAlert () as bool

Dispatch Id: 1003

Description: This event is triggered when the file loaded into this document control is changed on the hard disk by another application. Clients should return true, if they handled the event, or false, if StyleVision should handle it in its customary way, i.e. prompting the user for reload.
17.3.7.4.3.7  **OnModifiedFlagChanged**

*Event:* OnModifiedFlagChanged(i_bIsModified as boolean)

*Dispatch Id:* 1002

*Description:* This event gets triggered whenever the document changes between modified and unmodified state. The parameter *i_bIsModified* is true if the document contents differs from the original content, and *false*, otherwise.

17.3.7.4.3.8  **OnSetEditorTitle**

*Event:* OnSetEditorTitle()

*Dispatch Id:* 1006

*Description:* This event is being raised when the contained document is being internally renamed.

17.3.7.5  **StyleVisionControlPlaceHolder**

Properties available for all kinds of placeholder windows:

- **PlaceholderWindowID**

Properties for project placeholder window:

- **Project**

Methods for project placeholder window:

- **OpenProject**
- **CloseProject**

The `StyleVisionControlPlaceHolder` control is used to show the additional StyleVision windows like Overview, Library or Project window. It is used like any other ActiveX control and can be placed anywhere in the client application.

17.3.7.5.1  **Properties**

The following properties are defined:

- **PlaceholderWindowID**

Access to StyleVisionAPI:

- **Project**
17.3.7.5.1.1  Label

Property: Label as String (read-only)

Dispatch Id: 1001

Description:
This property gives access to the title of the placeholder. The property is read-only.

17.3.7.5.1.2  PlaceholderWindowID

Property: PlaceholderWindowID as StyleVisionControlPlaceholderWindow

Dispatch Id: 1

Description:
This property specifies which StyleVision window should be displayed in the client area of the control. The PlaceholderWindowID can be set at any time to any valid value of the StyleVisionControlPlaceholderWindow enumeration. The control changes its state immediately and shows the new StyleVision window.

17.3.7.5.1.3  Project

Property: Project as Project (read-only)

Dispatch Id: 2

Description:
The Project property gives access to the Project object of the StyleVision automation server API. This interface provides additional functionality which can be used with the project loaded into the control. The property will return a valid project interface only if the placeholder window has PlaceholderWindowID with a value of StyleVisionXProjectWindow (=3). The property is read-only.

17.3.7.5.2  Methods

The following method is defined:

OpenProject
CloseProject

17.3.7.5.2.1  OpenProject

Method: OpenProject (strFileName as string) as boolean
Dispatch Id: 3

Description:
OpenProject loads the file strFileName as the new project into the control. The method will fail if the placeholder window has a PlaceholderWindowID different to StyleVisionXProjectWindow (=3).

17.3.7.5.2.2 CloseProject

Method: CloseProject()

Dispatch Id: 4

Description:
CloseProject closes the project loaded by the control. The method will fail if the placeholder window has a PlaceholderWindowID different to StyleVisionXProjectWindow (=3).

17.3.7.5.3 Events

The StyleVisionControlPlaceholder ActiveX control provides following connection point events:

OnModifiedFlagChanged

17.3.7.5.3.1 OnModifiedFlagChanged

Event: OnModifiedFlagChanged(i_bIsModified as boolean)

Dispatch Id: 1

Description:
This event gets triggered only for placeholder controls with a PlaceholderWindowID of StyleVisionXProjectWindow (=3). The event is fired whenever the project content changes between modified and unmodified state. The parameter i_bIsModified is true if the project contents differs from the original content, and false, otherwise.

17.3.7.5.3.2 OnSetLabel

Event: OnSetLabel(i_strNewLabel as string)

Dispatch Id: 1000

Description:
Raised when the title of the placeholder window is changed.
17.3.7.6 Enumerations

The following enumerations are defined:

- **ICActiveXIntegrationLevel**: 1019
- **StyleVisionControlPlaceholderWindow**: 1016

### 17.3.7.6.1 ICActiveXIntegrationLevel

Possible values for the `IntegrationLevel` property of the StyleVisionControl.

- `ICActiveXIntegrationOnApplicationLevel` = 0
- `ICActiveXIntegrationOnDocumentLevel` = 1

### 17.3.7.6.2 StyleVisionControlPlaceholderWindow

This enumeration contains the list of the supported additional StyleVision windows.

- `StyleVisionControlNoToolWnd` = -1
- `StyleVisionControlProjectWnd` = 0
- `StyleVisionControlDesignOverviewWnd` = 1
- `StyleVisionControlSchemaSourcesWnd` = 2
- `StyleVisionControlDesignTreeWnd` = 3
- `StyleVisionControlStyleRepositoryWnd` = 4
- `StyleVisionControlContextPropertiesWnd` = 5
- `StyleVisionControlContextStylesWnd` = 6
- `StyleVisionControlMessageWnd` = 7
- `StyleVisionControlDBQueryWnd` = 8
18 Appendices

These appendices contain (i) information about the XSLT Engines used in StyleVision; (ii) information about the conversion of DB datatypes to XML Schema datatypes; (iii) technical information about StyleVision; and (iv) licensing information for StyleVision. Each appendix contains the sub-sections listed below:

**XSLT Engine Information**
Provides implementation-specific information about the Altova XSLT Engines, which are used by StyleVision to generate output.

- Altova XSLT 1.0 Engine
- Altova XSLT 2.0 Engine
- Altova XSLT 3.0 Engine
- XSLT and XPath/XQuery Functions

**DatatypesDB2XSD**
When DB fields are converted to XML nodes, the DB datatypes are converted to XML Schema datatypes. This appendix lists the mappings for the following source DBs.

- MS Access
- MS SQL Server
- MySQL
- Oracle
- ODBC
- ADO
- Sybase

**Technical Data**
Provides technical information about StyleVision.

- OS and memory requirements
- Altova XML Parser
- Altova XSLT and XQuery Engines
- Unicode support
- Internet usage

**License Information**
Contains information about the way StyleVision is distributed and about its licensing.

- Electronic software distribution
- License metering
- Copyright
- End User License Agreement
18.1 XSLT and XQuery Engine Information

The XSLT and XQuery engines of StyleVision follow the W3C specifications closely and are therefore stricter than previous Altova engines—such as those in previous versions of XMLSpy. As a result, minor errors that were ignored by previous engines are now flagged as errors by StyleVision.

For example:

- It is a type error (err:XPTY0018) if the result of a path operator contains both nodes and non-nodes.
- It is a type error (err:XPTY0019) if $E_1$ in a path expression $E_1/E_2$ does not evaluate to a sequence of nodes.

If you encounter this kind of error, modify either the XSLT/XQuery document or the instance document as appropriate.

This section describes implementation-specific features of the engines, organized by specification:

- XSLT 1.0
- XSLT 2.0
- XSLT 3.0
- XQuery 1.0
- XQuery 3.1

18.1.1 XSLT 1.0

The XSLT 1.0 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XSLT 1.0 Recommendation of 16 November 1999 and XPath 1.0 Recommendation of 16 November 1999. Note the following information about the implementation.

Notes about the implementation

When the method attribute of xsl:output is set to HTML, or if HTML output is selected by default, then special characters in the XML or XSLT file are inserted in the HTML document as HTML character references in the output. For instance, the character U+00A0 (the hexadecimal character reference for a non-breaking space) is inserted in the HTML code either as a character reference (&#160; or &nbsp;) or as an entity reference, &amp;#160;.

18.1.2 XSLT 2.0

This section:

- Engine conformance
- Backward compatibility
- Namespaces
- Schema awareness
- Implementation-specific behavior
Conformance

Backwards Compatibility
The XSLT 2.0 engine is backwards compatible. The only time the backwards compatibility of the XSLT 2.0 engine comes into effect is when using the XSLT 2.0 engine to process an XSLT 1.0 stylesheet. Note that there could be differences in the outputs produced by the XSLT 1.0 Engine and the backwards-compatible XSLT 2.0 engine.

Namespaces
Your XSLT 2.0 stylesheet should declare the following namespaces in order for you to be able to use the type constructors and functions available in XSLT 2.0. The prefixes given below are conventionally used; you could use alternative prefixes if you wish.

<table>
<thead>
<tr>
<th>Namespace Name</th>
<th>Prefix</th>
<th>Namespace URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML Schema types</td>
<td>xs</td>
<td><a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a></td>
</tr>
<tr>
<td>XPath 2.0 functions</td>
<td>fn</td>
<td><a href="http://www.w3.org/2005/xpath-functions">http://www.w3.org/2005/xpath-functions</a></td>
</tr>
</tbody>
</table>

Typically, these namespaces will be declared on the xsl:stylesheet or xsl:transform element, as shown in the following listing:

```xml
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    ...
</xsl:stylesheet>
```

The following points should be noted:

- The XSLT 2.0 engine uses the XPath 2.0 and XQuery 1.0 Functions namespace (listed in the table above) as its default functions namespace. So you can use XPath 2.0 and XSLT 2.0 functions in your stylesheet without any prefix. If you declare the XPath 2.0 Functions namespace in your stylesheet with a prefix, then you can additionally use the prefix assigned in the declaration.
- When using type constructors and types from the XML Schema namespace, the prefix used in the namespace declaration must be used when calling the type constructor (for example, xs:date).
- Some XPath 2.0 functions have the same name as XML Schema datatypes. For example, for the XPath functions fn:string and fn:boolean there exist XML Schema datatypes with the same local names: xs:string and xs:boolean. So if you were to use the XPath expression string('Hello'), the expression evaluates as fn:string('Hello')—not as xs:string('Hello').

Schema-awareness
The XSLT 2.0 engine is schema-aware. So you can use user-defined schema types and the xsl:validate instruction.
Implementation-specific behavior
Given below is a description of how the XSLT 2.0 engine handles implementation-specific aspects of the behavior of certain XSLT 2.0 functions.

**xsl:result-document**
Additionally supported encodings are (the Altova-specific): x-base16tobinary and x-base64tobinary.

**function-available**
The function tests for the availability of in-scope functions (XSLT, XPath, and extension functions).

**unparsed-text**
The `href` attribute accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the `file:///` protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64.

**unparsed-text-available**
The `href` attribute accepts (i) relative paths for files in the base-uri folder, and (ii) absolute paths with or without the `file:///` protocol. Additionally supported encodings are (the Altova-specific): x-binarytobase16 and x-binarytobase64.

**Note:** The following encoding values, which were implemented in earlier versions of RaptorXML's predecessor product, AltovaXML, are now deprecated: base16tobinary, base64tobinary, binarytobase16 and binarytobase64.

### 18.1.3 XSLT 3.0

The XSLT 3.0 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XSLT 3.0 Recommendation of 8 June 2017 and XPath 3.1 Recommendation of 21 March 2017.

The XSLT 3.0 engine has the same implementation-specific characteristics as the XSLT 2.0 engine. Additionally, it includes support for a number of new XSLT 3.0 features: XPath/XQuery 3.1 functions and operators, and the XPath 3.1 specification.

**Note:** The optional streaming feature is not supported currently. The entire document will be loaded into memory regardless of the value of the streamable attribute. If enough memory is available, then: (i) the entire document will be processed—without streaming, (ii) guaranteed-streamable constructs will be processed correctly, as if the execution used streaming, and (iii) streaming errors will not be detected. In 64-bit apps, non-streaming execution should not be a problem. If memory does turn out to be an issue, a solution would be to add more memory to the system.

### 18.1.4 XQuery 1.0

*This section:*
- Engine conformance
- Schema awareness
Conformance
The XQuery 1.0 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XQuery 1.0 Recommendation of 14 December 2010. The XQuery standard gives implementations discretion about how to implement many features. Given below is a list explaining how the XQuery 1.0 Engine implements these features.

Schema awareness
The XQuery 1.0 Engine is schema-aware.

Encoding
The UTF-8 and UTF-16 character encodings are supported.

Namespaces
The following namespace URIs and their associated bindings are pre-defined.

<table>
<thead>
<tr>
<th>Namespace Name</th>
<th>Prefix</th>
<th>Namespace URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML Schema types</td>
<td>xs:</td>
<td><a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a></td>
</tr>
<tr>
<td>Schema instance</td>
<td>xsi:</td>
<td><a href="http://www.w3.org/2001/XMLSchema-instance">http://www.w3.org/2001/XMLSchema-instance</a></td>
</tr>
<tr>
<td>Built-in functions</td>
<td>fn:</td>
<td><a href="http://www.w3.org/2005/xpath-functions">http://www.w3.org/2005/xpath-functions</a></td>
</tr>
<tr>
<td>Local functions</td>
<td>local:</td>
<td><a href="http://www.w3.org/2005/xquery-local-functions">http://www.w3.org/2005/xquery-local-functions</a></td>
</tr>
</tbody>
</table>

The following points should be noted:

- The XQuery 1.0 Engine recognizes the prefixes listed above as being bound to the corresponding namespaces.
- Since the built-in functions namespace listed above is the default functions namespace in XQuery, the fn: prefix does not need to be used when built-in functions are invoked (for example, string("Hello") will call the fn:string function). However, the prefix fn: can be used to call a built-in function without having to declare the namespace in the query prolog (for example: fn:string("Hello")).
- You can change the default functions namespace by declaring the default function namespace expression in the query prolog.
- When using types from the XML Schema namespace, the prefix xs: may be used without having to explicitly declare the namespaces and bind these prefixes to them in the query prolog. (Example: xs:date and xs:yearMonthDuration.) If you wish to use some other prefix for the XML Schema
namespace, this must be explicitly declared in the query prolog. (Example: declare namespace alt = "http://www.w3.org/2001/XMLSchema"; alt:date("2004-10-04").)

Note that the untypedAtomic, dayTimeDuration, and yearMonthDuration datatypes have been moved, with the CRs of 23 January 2007, from the XPath Datatypes namespace to the XML Schema namespace, so: xs:yearMonthDuration.

If namespaces for functions, type constructors, node tests, etc are wrongly assigned, an error is reported. Note, however, that some functions have the same name as schema datatypes, e.g. fn:string and fn:boolean. (Both xs:string and xs:boolean are defined.) The namespace prefix determines whether the function or type constructor is used.

XML source document and validation
XML documents used in executing an XQuery document with the XQuery 1.0 Engine must be well-formed. However, they do not need to be valid according to an XML Schema. If the file is not valid, the invalid file is loaded without schema information. If the XML file is associated with an external schema and is valid according to it, then post-schema validation information is generated for the XML data and will be used for query evaluation.

Static and dynamic type checking
The static analysis phase checks aspects of the query such as syntax, whether external references (e.g. for modules) exist, whether invoked functions and variables are defined, and so on. If an error is detected in the static analysis phase, it is reported and the execution is stopped.

Dynamic type checking is carried out at run-time, when the query is actually executed. If a type is incompatible with the requirement of an operation, an error is reported. For example, the expression xs:string("1") + 1 returns an error because the addition operation cannot be carried out on an operand of type xs:string.

Library Modules
Library modules store functions and variables so they can be reused. The XQuery 1.0 Engine supports modules that are stored in a single external XQuery file. Such a module file must contain a module declaration in its prolog, which associates a target namespace. Here is an example module:

```xml
module namespace libns="urn:module-library";
declare variable $libns:company := "Altova";
declare function libns:webaddress() { "http://www.altova.com" };
```

All functions and variables declared in the module belong to the namespace associated with the module. The module is used by importing it into an XQuery file with the import module statement in the query prolog. The import module statement only imports functions and variables declared directly in the library module file. As follows:

```xml
import module namespace modlib = "urn:module-library" at "modulefilename.xq";
if ($modlib:company = "Altova")
then modlib:webaddress()
else error("No match found.")
```

External functions
External functions are not supported, i.e. in those expressions using the external keyword, as in:
Collations
The default collation is the Unicode-codepoint collation, which compares strings on the basis of their Unicode codepoint. Other supported collations are the ICU collations listed here. To use a specific collation, supply its URI as given in the list of supported collations. Any string comparisons, including for the fn:max and fn:min functions, will be made according to the specified collation. If the collation option is not specified, the default Unicode-codepoint collation is used.

Precision of numeric types

- The xs:integer datatype is arbitrary-precision, i.e. it can represent any number of digits.
- The xs:decimal datatype has a limit of 20 digits after the decimal point.
- The xs:float and xs:double datatypes have limited-precision of 15 digits.

XQuery Instructions Support
The Pragma instruction is not supported. If encountered, it is ignored and the fallback expression is evaluated.

18.1.5 XQuery 3.1

The XQuery 3.1 Engine of StyleVision conforms to the World Wide Web Consortium's (W3C's) XQuery 3.1 Recommendation of 21 March 2017 and includes support for XPath and XQuery Functions 3.1. The XQuery 3.1 specification is a superset of the 3.0 specification. The XQuery 3.1 engine therefore supports XQuery 3.0 features.

Implementation-specific characteristics are the same as for XQuery 1.0.
18.2 XSLT and XPath/XQuery Functions

This section lists Altova extension functions and other extension functions that can be used in XPath and/or XQuery expressions. Altova extension functions can be used with Altova's XSLT and XQuery engines, and provide functionality additional to that available in the function libraries defined in the W3C standards.

General points
The following general points should be noted:

- Functions from the core function libraries defined in the W3C specifications can be called without a prefix. That's because the XSLT and XQuery engines read non-prefixed functions as belonging to a default functions namespace which is that specified in the XPath/XQuery functions specifications http://www.w3.org/2005/xpath-functions. If this namespace is explicitly declared in an XSLT or XQuery document, the prefix used in the namespace declaration can also optionally be used on function names.
- In general, if a function expects a sequence of one item as an argument, and a sequence of more than one item is submitted, then an error is returned.
- All string comparisons are done using the Unicode codepoint collation.
- Results that are QNames are serialized in the form [prefix:]localname.

Precision of xs:decimal
The precision refers to the number of digits in the number, and a minimum of 18 digits is required by the specification. For division operations that produce a result of type xs:decimal, the precision is 19 digits after the decimal point with no rounding.

Implicit timezone
When two date, time, or dateTime values need to be compared, the timezones of the values being compared need to be known. When the timezone is not explicitly given in such a value, the implicit timezone is used. The implicit timezone is taken from the system clock, and its value can be checked with the implicit-timezone() function.

Collations
The default collation is the Unicode codepoint collation, which compares strings on the basis of their Unicode codepoint. The engine uses the Unicode Collation Algorithm. Other supported collations are the ICU collations listed below; to use one of these, supply its URI as given in the table below. Any string comparisons, including for the max and min functions, will be made according to the specified collation. If the collation option is not specified, the default Unicode-codepoint collation is used.

Appendices

18.2.1 Altova Extension Functions

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

Functions defined in the W3C's XPath/XQuery Functions specifications can be used in: (i) XPath expressions in an XSLT context, and (ii) in XQuery expressions in an XQuery document. In this documentation we indicate the functions that can be used in the former context (XPath in XSLT) with an xp symbol and call them XPath functions; those functions that can be used in the latter (XQuery) context are indicated with an xq symbol; they work as XQuery functions. The W3C's XSLT specifications—not XPath/XQuery Functions specifications—also define functions that can be used in XPath expressions in XSLT documents. These functions are marked with an xslt symbol and are called XSLT functions. The XPath/XQuery and XSLT versions in which a function can be used are indicated in the description of the function (see symbols below). Functions from the XPath/XQuery and XSLT function libraries are listed without a prefix. Extension functions from other libraries, such as Altova extension functions, are listed with a prefix.

### Namespace axis

The namespace axis is deprecated in XPath 2.0. Use of the namespace axis is, however, supported. To access namespace information with XPath 2.0 mechanisms, use the `in-scope-prefixes()`, `namespace-uri()` and `namespace-uri-for-prefix()` functions.
XSLT functions

XSLT functions can only be used in XPath expressions in an XSLT context (similarly to XSLT 2.0's current-group() or key() functions). These functions are not intended for, and will not work in, a non-XSLT context (for instance, in an XQuery context). Note that XSLT functions for XBRL can be used only with editions of Altova products that have XBRL support.

XPath/XQuery functions

XPath/XQuery functions can be used both in XPath expressions in XSLT contexts as well as in XQuery expressions:

- Date/Time
- Geolocation
- Image-related
- Numeric
- Sequence
- String
- Miscellaneous

Barcode functions

Altova's barcode extension functions enable barcodes to be generated and placed in output generated via XSLT stylesheets.

18.2.1.1 XSLT Functions

XSLT extension functions can be used in XPath expressions in an XSLT context. They will not work in a non-XSLT context (for instance, in an XQuery context).

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.
**XQuery functions (used in XQuery expressions in XQuery):**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>altova:distinct-nodes()</code></td>
<td>Takes a set of one or more nodes as its input and returns the same set minus nodes with duplicate values. The comparison is done using the XPath/XQuery function <code>fn:deep-equal</code>.</td>
</tr>
<tr>
<td><code>altova:evaluate(XPathExpression as xs:string[, ValueOf$p1, ... ValueOf$pN])</code></td>
<td>Takes an XPath expression, passed as a string, as its mandatory argument. It returns the output of the evaluated expression. For example: <code>altova:evaluate('//Name[1]')</code> returns the contents of the first Name element in the document. Note that the expression '//Name[1]' is passed as a string by enclosing it in single quotes.</td>
</tr>
</tbody>
</table>

### General functions

**distinct-nodes [altova:]**

```
altova:distinct-nodes(node()*) as node()* XSLT1 XSLT2 XSLT3
```

Takes a set of one or more nodes as its input and returns the same set minus nodes with duplicate values. The comparison is done using the XPath/XQuery function `fn:deep-equal`.

- **Examples**
  - `altova:distinct-nodes(country)` returns all child country nodes less those having duplicate values.

**evaluate [altova:]**

```
altova:evaluate(XPathExpression as xs:string[, ValueOf$p1, ... ValueOf$pN]) XSLT1 XSLT2 XSLT3
```

Takes an XPath expression, passed as a string, as its mandatory argument. It returns the output of the evaluated expression. For example: `altova:evaluate('//Name[1]')` returns the contents of the first Name element in the document. Note that the expression `//Name[1]` is passed as a string by enclosing it in single quotes.

The `altova:evaluate` function can optionally take additional arguments. These arguments are the values of in-scope variables that have the names p1, p2, p3... pN. Note the following points about usage: (i) The variables must be defined with names of the form pX, where X is an integer; (ii) the `altova:evaluate` function's arguments (see signature above), from the second argument onwards, provide the values of the variables, with the sequence of the arguments corresponding to the numerically ordered sequence of variables: p1 to pN: The second argument will be the value of the variable p1, the third argument that of the variable p2, and so on; (iii) The variable values must be of type `item*`.

- **Example**
  ```
  <xs1:variable name="xpath" select="'$p3, $p2, $p1'" />
  <xs1:value-of select="altova:evaluate($xpath, 10, 20, 'hi')" />
  Outputs "hi 20 10"
  ```

  In the listing above, notice the following:
  
  - The second argument of the `altova:evaluate` expression is the value assigned to the variable $p1, the third argument that assigned to the variable $p2, and so on.
  - Notice that the fourth argument of the function is a string value, indicated by its being enclosed in quotes.
  - The `select` attribute of the `xs:variable` element supplies the XPath expression. Since this expression must be of type `xs:string`, it is enclosed in single quotes.

- **Examples to further illustrate the use of variables**
  ```
  <xs1:variable name="xpath" select="'$p1'" />
  <xs1:value-of select="altova:evaluate($xpath, //Name[1])" />
  Outputs value of the first Name element.
  ```
The \texttt{altova:evaluate()} extension function is useful in situations where an XPath expression in the XSLT stylesheet contains one or more parts that must be evaluated dynamically. For example, consider a situation in which a user enters his request for the sorting criterion and this criterion is stored in the attribute UserReq/@sortkey. In the stylesheet, you could then have the expression:

\begin{verbatim}
<xsl:sort select="altova:evaluate(../UserReq/@sortkey)" order="ascending"/>
\end{verbatim}

The \texttt{altova:evaluate()} function reads the \texttt{sortkey} attribute of the UserReq child element of the parent of the context node. Say the value of the \texttt{sortkey} attribute is Price, then Price is returned by the \texttt{altova:evaluate()} function and becomes the value of the \texttt{select} attribute:

\begin{verbatim}
<xsl:sort select="Price" order="ascending"/>
\end{verbatim}

If this sort instruction occurs within the context of an element called Order, then the Order elements will be sorted according to the values of their Price children. Alternatively, if the value of @sortkey were, say, Date, then the Order elements would be sorted according to the values of their Date children. So the sort criterion for Order is selected from the \texttt{sortkey} attribute at runtime. This could not have been achieved with an expression like:

\begin{verbatim}
<xsl:sort select="../UserReq/@sortkey" order="ascending"/>
\end{verbatim}

In the case shown above, the sort criterion would be the \texttt{sortkey} attribute itself, not Price or Date (or any other current content of \texttt{sortkey}).

\textbf{Note:} The static context includes namespaces, types, and functions—but not variables—from the calling environment. The base URI and default namespace are inherited.

\begin{itemize}
\item Static variables:
\begin{verbatim}
<xsl:value-of select="$i3, $i2, $i1"/>
\end{verbatim}
\end{itemize}

\begin{itemize}
\item Dynamic XPath expression with dynamic variables:
\begin{verbatim}
<xsl:variable name="xpath" select="'.$p3, $p2, $p1'" />
<xsl:value-of select="altova:evaluate($xpath, 10, 20, 30)"/>
\end{verbatim}
\end{itemize}

\begin{itemize}
\item Dynamic XPath expression with no dynamic variable:
\begin{verbatim}
<xsl:variable name="xpath" select="'.$p3, $p2, $p1'"/>
<xsl:value-of select="altova:evaluate($xpath)"/>
\end{verbatim}
\end{itemize}

\begin{verbatim}
encode-for-rtf [altova:]
\end{verbatim}

\texttt{altova:encode-for-rtf(input as xs:string, preserveallwhitespace as xs:boolean, preservenewlines as xs:boolean) as xs:string XSLT2 XSLT3}

Converts the input string into code for RTF. Whitespace and new lines will be preserved according to the boolean value specified for their respective arguments.
XBRL functions
Altova XBRL functions can be used only with editions of Altova products that have XBRL support.

▼ xbrl-footnotes [altova:]
\[
\text{altova:xbrl-footnotes}(\text{node()} ) \text{ as node()* XSLT2 XSLT3}
\]
Takes a node as its input argument and returns the set of XBRL footnote nodes referenced by the input node.

▼ xbrl-labels [altova:]
\[
\text{altova:xbrl-labels}(\text{xs:QName}, \text{xs:string} ) \text{ as node()* XSLT2 XSLT3}
\]
Takes two input arguments: a node name and the taxonomy file location containing the node. The function returns the XBRL label nodes associated with the input node.

[ Top ]

18.2.1.2 XPath/XQuery Functions: Date and Time
Altova's date/time extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data held as XML Schema's various date and time datatypes. The functions in this section can be used with Altova's XPath 3.0 and XQuery 3.0 engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability
Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

▼ Grouped by functionality
- Add a duration to xs:dateTime and return xs:dateTime
- Add a duration to xs:dateTime and return xs:date
- Add a duration to xs:time and return xs:time
- Format and retrieve durations
- Remove timezone from functions that generate current date/time
Appendices

XSLT and XPath/XQuery Functions

- Return days, hours, minutes, and seconds from durations
- Return weekday as integer from date
- Return week number as integer from date
- Build date, time, or duration type from lexical components of each type
- Construct date, dateTime, or time type from string input
- Age-related functions
- Epoch time (Unix time) functions

Listed alphabetically

- altova:add-days-to-date

- altova:weekday-from-dateTime
- altova:weeknumber-from-date
- altova:weeknumber-from-dateTime
Add a duration to *xs:dateTime* XP3.1 XQ3.1

These functions add a duration to *xs:dateTime* and return *xs:dateTime*. The *xs:dateTime* type has a format of CCYY-MM-DDThh:mm:ss.sss. This is a concatenation of the *xs:date* and *xs:time* formats separated by the letter T. A timezone suffix (+01:00, for example) is optional.

**add-years-to-dateTime** [altova:]

```xml
altova:add-years-to-dateTime(DateTime as xs:dateTime, Years as xs:integer) as xs:dateTime
```

Add a duration in years to an *xs:dateTime* (see examples below). The second argument is the number of years to be added to the *xs:dateTime* supplied as the first argument. The result is of type *xs:dateTime*.

**Examples**

- `altova:add-years-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10)` returns 2024-01-15T14:00:00
- `altova:add-years-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -4)` returns 2010-01-15T14:00:00

**add-months-to-dateTime** [altova:]

```xml
altova:add-months-to-dateTime(DateTime as xs:dateTime, Months as xs:integer) as xs:dateTime
```

Add a duration in months to an *xs:dateTime* (see examples below). The second argument is the number of months to be added to the *xs:dateTime* supplied as the first argument. The result is of type *xs:dateTime*.

**Examples**

- `altova:add-months-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10)` returns 2014-11-15T14:00:00
- `altova:add-months-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -2)` returns 2013-11-15T14:00:00

**add-days-to-dateTime** [altova:]

```xml
altova:add-days-to-dateTime(DateTime as xs:dateTime, Days as xs:integer) as xs:dateTime
```

Add a duration in days to an *xs:dateTime* (see examples below). The second argument is the number of days to be added to the *xs:dateTime* supplied as the first argument. The result is of type *xs:dateTime*.

**Examples**

- `altova:add-days-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10)` returns 2014-01-25T14:00:00
- `altova:add-days-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -8)` returns 2014-01-07T14:00:00

**add-hours-to-dateTime** [altova:]

```xml
altova:add-hours-to-dateTime(DateTime as xs:dateTime, Hours as xs:integer) as xs:dateTime
```

Add a duration in hours to an *xs:dateTime* (see examples below). The second argument is the number of hours to be added to the *xs:dateTime* supplied as the first argument. The result is of type *xs:dateTime*.

**Examples**

- `altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), 10)` returns 2014-01-15T16:00:00
- `altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T14:00:00"), -8)` returns 2014-01-15T06:00:00
hours to be added to the \texttt{xs:dateTime} supplied as the first argument. The result is of type \texttt{xs:dateTime}.

\section*{Examples}
\begin{itemize}
  \item \texttt{altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T13:00:00"), 10)} returns \texttt{2014-01-15T23:00:00}
  \item \texttt{altova:add-hours-to-dateTime(xs:dateTime("2014-01-15T13:00:00"), -8)} returns \texttt{2014-01-15T05:00:00}
\end{itemize}

\section*{Add a duration to \texttt{xs:date}} \XP3.1 \XQ3.1
These functions add a duration to \texttt{xs:date} and return \texttt{xs:date}. The \texttt{xs:date} type has a format of CCYY-MM-DD.

\section*{add-years-to-date [altova:]}
\texttt{altova:add-years-to-date(Date as xs:date, Years as xs:integer) as xs:date} \XP3.1 \XQ3.1
Adds a duration in years to a date. The second argument is the number of years to be added to the \texttt{xs:date} supplied as the first argument. The result is of type \texttt{xs:date}.

\section*{Examples}
\begin{itemize}
  \item \texttt{altova:add-years-to-date(xs:date("2014-01-15"), 10)} returns \texttt{2024-01-15}
\end{itemize}
• **`altova:add-years-to-date`**(xs:date("2014-01-15"), -4) returns 2010-01-15

**add-months-to-date** [altova:]

`altova:add-months-to-date(Date as xs:date, Months as xs:integer) as xs:date` XP3.1 XQ3.1

Adds a duration in months to a date. The second argument is the number of months to be added to the `xs:date` supplied as the first argument. The result is of type `xs:date`.

**Examples**

• `altova:add-months-to-date(xs:date("2014-01-15"), 10)` returns 2014-11-15
• `altova:add-months-to-date(xs:date("2014-01-15"), -2)` returns 2013-11-15

**add-days-to-date** [altova:]

`altova:add-days-to-date(Date as xs:date, Days as xs:integer) as xs:date` XP3.1 XQ3.1

Adds a duration in days to a date. The second argument is the number of days to be added to the `xs:date` supplied as the first argument. The result is of type `xs:date`.

**Examples**

• `altova:add-days-to-date(xs:date("2014-01-15"), 10)` returns 2014-01-25
• `altova:add-days-to-date(xs:date("2014-01-15"), -8)` returns 2014-01-07

**Format and retrieve durations** XP3.1 XQ3.1

These functions parse an input `xs:duration` or `xs:string` and return, respectively, an `xs:string` or `xs:duration`.

**format-duration** [altova:]

`altova:format-duration(Duration as xs:duration, Picture as xs:string) as xs:string` XP3.1 XQ3.1

Formats a duration, which is submitted as the first argument, according to a picture string submitted as the second argument. The output is a text string formatted according to the picture string.

**Examples**

• `altova:format-duration(xs:duration("P2DT2H53M11.7S"), "Days:[D01] Hours:[H01] Minutes:[m01] Seconds:[s01] Fractions:[f0]") returns "Days:02 Hours:02 Minutes:53 Seconds:11 Fractions:7"
• `altova:format-duration(xs:duration("P3M2DT2H53M11.7S"), "Months:[M01] Days:[D01] Hours:[H01] Minutes:[m01]") returns "Months:03 Days:02 Hours:02 Minutes:53"

**parse-duration** [altova:]

`altova:parse-duration(InputString as xs:string, Picture as xs:string) as xs:duration` XP3.1 XQ3.1

Takes a patterned string as the first argument, and a picture string as the second argument. The input
string is parsed on the basis of the picture string, and an \textit{xs:duration} is returned.

\begin{itemize}
  \item \texttt{altova:parse-duration} ("Days:02 Hours:02 Minutes:53 Seconds:11 Fractions:7") returns \texttt{"P2DT2H53M11.7S"}
  \item \texttt{altova:parse-duration} ("Days:[D01] Hours:[H01] Minutes:[m01] Seconds:[s01] Fractions:[f0]") returns \texttt{"P2DT2H53M11.7S"}
\end{itemize}

**Add a duration to \textit{xs:time}** \texttt{XP3.1 XQ3.1}

These functions add a duration to \textit{xs:time} and return \textit{xs:time}. The \textit{xs:time} type has a lexical form of \texttt{hh:mm:ss.sss}. An optional time zone may be suffixed. The letter \texttt{Z} indicates Coordinated Universal Time (UTC). All other time zones are represented by their difference from UTC in the format +hh:mm, or −hh:mm. If no time zone value is present, it is considered unknown; it is not assumed to be UTC.

\begin{itemize}
  \item \texttt{add-hours-to-time [altova:]}
    \texttt{altova:add-hours-to-time(Time as \textit{xs:time}, Hours as \textit{xs:integer}) as \textit{xs:time} XP3.1 XQ3.1}
    Adds a duration in hours to a time. The second argument is the number of hours to be added to the \textit{xs:time} supplied as the first argument. The result is of type \textit{xs:time}.
    \begin{itemize}
      \item \texttt{altova:add-hours-to-time(xs:time("11:00:00"), 10) returns 21:00:00}
      \item \texttt{altova:add-hours-to-time(xs:time("11:00:00"), -7) returns 04:00:00}
    \end{itemize}
  \item \texttt{add-minutes-to-time [altova:]
    \texttt{altova:add-minutes-to-time(Time as \textit{xs:time}, Minutes as \textit{xs:integer}) as \textit{xs:time} XP3.1 XQ3.1}
    Adds a duration in minutes to a time. The second argument is the number of minutes to be added to the \textit{xs:time} supplied as the first argument. The result is of type \textit{xs:time}.
    \begin{itemize}
      \item \texttt{altova:add-minutes-to-time(xs:time("14:10:00"), 45) returns 14:55:00}
      \item \texttt{altova:add-minutes-to-time(xs:time("14:10:00"), -5) returns 14:05:00}
    \end{itemize}
  \item \texttt{add-seconds-to-time [altova:]
    \texttt{altova:add-seconds-to-time(Time as \textit{xs:time}, Minutes as \textit{xs:integer}) as \textit{xs:time} XP3.1 XQ3.1}
    Adds a duration in seconds to a time. The second argument is the number of seconds to be added to the \textit{xs:time} supplied as the first argument. The result is of type \textit{xs:time}. The Seconds component can be in the range of 0 to 59.999.
    \begin{itemize}
      \item \texttt{altova:add-seconds-to-time(xs:time("14:00:00"), 20) returns 14:00:20}
      \item \texttt{altova:add-seconds-to-time(xs:time("14:00:00"), 20.895) returns 14:00:20.895}
    \end{itemize}
\end{itemize}
Remove the timezone part from date/time datatypes

These functions remove the timezone from the current `xs:dateTime`, `xs:date`, or `xs:time` values, respectively. Note that the difference between `xs:dateTime` and `xs:dateTimeStamp` is that in the case of the latter the timezone part is required (while it is optional in the case of the former). So the format of an `xs:dateTimeStamp` value is: `CCYY-MM-DDThh:mm:ss.sss±hh:mm` or `CCYY-MM-DDThh:mm:ss.sssZ`. If the date and time is read from the system clock as `xs:dateTimeStamp`, the `current-dateTime-no-TZ()` function can be used to remove the timezone if so required.

**current-date-no-TZ [altova:]**

```
altova:current-date-no-TZ() as xs:date
```

This function takes no argument. It removes the timezone part of `current-date()` (which is the current date according to the system clock) and returns an `xs:date` value.

**Examples**

If the current date is `2014-01-15+01:00`:

- `altova:current-date-no-TZ()` returns `2014-01-15`

**current-dateTime-no-TZ [altova:]**

```
altova:current-dateTime-no-TZ() as xs:dateTime
```

This function takes no argument. It removes the timezone part of `current-dateTime()` (which is the current date-and-time according to the system clock) and returns an `xs:dateTime` value.

**Examples**

If the current dateTime is `2014-01-15T14:00:00+01:00`:

- `altova:current-dateTime-no-TZ()` returns `2014-01-15T14:00:00`

**current-time-no-TZ [altova:]**

```
altova:current-time-no-TZ() as xs:time
```

This function takes no argument. It removes the timezone part of `current-time()` (which is the current time according to the system clock) and returns an `xs:time` value.

**Examples**

If the current time is `14:00:00+01:00`:

- `altova:current-time-no-TZ()` returns `14:00:00`

**date-no-TZ [altova:]**

```
altova:date-no-TZ(InputDate as xs:date)
```

This function takes an `xs:date` argument, removes the timezone part from it, and returns an `xs:date` value. Note that the date is not modified.

**Examples**
• `altova:dateTime-no-TZ(xs:dateTime("2014-01-15T14:00:00+01:00"))` returns 2014-01-15T14:00:00

**dateTime-no-TZ [altova:]**

`altova:dateTime-no-TZ(InputDateTime as xs:dateTime) as xs:dateTime XP3.1 XQ3.1`  
This function takes an `xs:dateTime` argument, removes the timezone part from it, and returns an `xs:dateTime` value. Note that neither the date nor the time is modified.

**Examples**

• `altova:dateTime-no-TZ(xs:dateTime("2014-01-15T14:00:00+01:00"))` returns 2014-01-15T14:00:00

**time-no-TZ [altova:]**

`altova:time-no-TZ(InputTime as xs:time) as xs:time XP3.1 XQ3.1`  
This function takes an `xs:time` argument, removes the timezone part from it, and returns an `xs:time` value. Note that the time is not modified.

**Examples**

• `altova:time-no-TZ(xs:time("14:00:00+01:00"))` returns 14:00:00

[ Top ]

Return the number of days, hours, minutes, seconds from durations  
XP3.1 XQ3.1

These functions return the number of days in a month, and the number of hours, minutes, and seconds, respectively, from durations.

**days-in-month [altova:]**

`altova:days-in-month(Year as xs:integer, Month as xs:integer) as xs:integer XP3.1 XQ3.1`  
Returns the number of days in the specified month. The month is specified by means of the `Year` and `Month` arguments.

**Examples**

• `altova:days-in-month(2018, 10)` returns 31
• `altova:days-in-month(2018, 2)` returns 28
• `altova:days-in-month(2020, 2)` returns 29

**hours-from-dayTimeDuration-accumulated**

`altova:hours-from-dayTimeDuration-accumulated(DayAndTime as xs:duration) as xs:integer XP3.1 XQ3.1`  
Returns the total number of hours in the duration submitted by the `DayAndTime` argument (which is of type `xs:duration`). The hours in the `Day` and `Time` components are added together to give a result that is an integer. A new hour is counted only for a full 60 minutes. Negative durations result in a negative hour value.

**Examples**

• `altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5D"))` returns 120, which
is the total number of hours in 5 days.

- \texttt{altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H"))} returns 122, which is the total number of hours in 5 days plus 2 hours.
- \texttt{altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H60M"))} returns 123, which is the total number of hours in 5 days plus 2 hours and 60 mins.
- \texttt{altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H119M"))} returns 123, which is the total number of hours in 5 days plus 2 hours and 119 mins.
- \texttt{altova:hours-from-dayTimeDuration-accumulated(xs:duration("P5DT2H120M"))} returns 124, which is the total number of hours in 5 days plus 2 hours and 120 mins.
- \texttt{altova:hours-from-dayTimeDuration-accumulated(xs:duration("-P5DT2H"))} returns -122

\paragraph*{minutes-from-dayTimeDuration-accumulated}

\texttt{altova:minutes-from-dayTimeDuration-accumulated(DayAndTime as xs:duration) as xs:integer}

XP3.1 XQ3.1

Returns the total number of minutes in the duration submitted by the DayAndTime argument (which is of type \texttt{xs:duration}). The minutes in the Day and Time components are added together to give a result that is an integer. Negative durations result in a negative minute value.

\textbf{Examples}

- \texttt{altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT60M"))} returns 60
- \texttt{altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT1H"))} returns 60, which is the total number of minutes in 1 hour.
- \texttt{altova:minutes-from-dayTimeDuration-accumulated(xs:duration("PT2H40M"))} returns 100
- \texttt{altova:minutes-from-dayTimeDuration-accumulated(xs:duration("P1D") as xs:integer)} returns 1440, which is the total number of minutes in 1 day.
- \texttt{altova:minutes-from-dayTimeDuration-accumulated(xs:duration("-P1DT60M"))} returns -1500

\paragraph*{seconds-from-dayTimeDuration-accumulated}

\texttt{altova:seconds-from-dayTimeDuration-accumulated(DayAndTime as xs:duration) as xs:integer}

XP3.1 XQ3.1

Returns the total number of seconds in the duration submitted by the DayAndTime argument (which is of type \texttt{xs:duration}). The seconds in the Day and Time components are added together to give a result that is an integer. Negative durations result in a negative seconds value.

\textbf{Examples}

- \texttt{altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT1M"))} returns 60, which is the total number of seconds in 1 minute.
- \texttt{altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT1H"))} returns 3600, which is the total number of seconds in 1 hour.
- \texttt{altova:seconds-from-dayTimeDuration-accumulated(xs:duration("PT2H2M"))} returns 3720
- \texttt{altova:seconds-from-dayTimeDuration-accumulated(xs:duration("P1D") as xs:integer)} returns 86400, which is the total number of seconds in 1 day.
- \texttt{altova:seconds-from-dayTimeDuration-accumulated(xs:duration("-P1DT1M"))} returns -86460
Return the weekday from xs:dateTime or xs:date  XP3.1 XQ3.1

These functions return the weekday (as an integer) from xs:dateTime or xs:date. The days of the week are numbered (using the American format) from 1 to 7, with Sunday=1. In the European format, the week starts with Monday (=1). The American format, where Sunday=1, can be set by using the integer 0 where an integer is accepted to indicate the format.

weekday-from-dateTime [altova:]

altova:weekday-from-dateTime(DateTime as xs:dateTime) as xs:integer  XP3.1 XQ3.1

Takes a date-with-time as its single argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with Sunday=1. If the European format is required (where Monday=1), use the other signature of this function (see next signature below).

Examples
• altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00")) returns 2, which would indicate a Monday.

altova:weekday-from-dateTime(DateTime as xs:dateTime, Format as xs:integer) as xs:integer  XP3.1 XQ3.1

Takes a date-with-time as its first argument and returns the day of the week of this date as an integer. If the second (integer) argument is 0, then the weekdays are numbered 1 to 7 starting with Sunday=1. If the second argument is an integer other than 0, then Monday=1. If there is no second argument, the function is read as having the other signature of this function (see previous signature).

Examples
• altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00"), 1) returns 1, which would indicate a Monday
• altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00"), 4) returns 1, which would indicate a Monday
• altova:weekday-from-dateTime(xs:dateTime("2014-02-03T09:00:00"), 0) returns 2, which would indicate a Monday

weekday-from-date [altova:]

altova:weekday-from-date(Date as xs:date) as xs:integer  XP3.1 XQ3.1

Takes a date as its single argument and returns the day of the week of this date as an integer. The weekdays are numbered starting with Sunday=1. If the European format is required (where Monday=1), use the other signature of this function (see next signature below).

Examples
• altova:weekday-from-date(xs:date("2014-02-03+01:00")) returns 2, which would indicate a Monday.

altova:weekday-from-date(Date as xs:date, Format as xs:integer) as xs:integer  XP3.1 XQ3.1

Takes a date as its first argument and returns the day of the week of this date as an integer. If the second (Format) argument is 0, then the weekdays are numbered 1 to 7 starting with Sunday=1. If the second argument is an integer other than 0, then Monday=1. If there is no second argument, the function is read as having the other signature of this function (see previous signature).

Examples
• altova:weekday-from-date(xs:date("2014-02-03"), 1) returns 1, which would indicate a
Monday

- **altova:weekday-from-date** (xs:date("2014-02-03"), 4) returns 1, which would indicate a Monday
- **altova:weekday-from-date** (xs:date("2014-02-03"), 0) returns 2, which would indicate a Monday.

**Return the week number from xs:dateTime or xs:date**

These functions return the week number (as an integer) from xs:dateTime or xs:date. Week-numbering is available in the US, ISO/European, and Islamic calendar formats. Week-numbering is different in these calendar formats because the week is considered to start on different days (on Sunday in the US format, Monday in the ISO/European format, and Saturday in the Islamic format).

- **weeknumber-from-date** [altova:]

  **altova:weeknumber-from-date** (Date as xs:date, Calendar as xs:integer) as xs:integer

  Returns the week number of the submitted Date argument as an integer. The second argument (Calendar) specifies the calendar system to follow. Supported Calendar values are:

  - 0 = US calendar (week starts Sunday)
  - 1 = ISO standard, European calendar (week starts Monday)
  - 2 = Islamic calendar (week starts Saturday)

  Default is 0.

- **Examples**

  - **altova:weeknumber-from-date** (xs:date("2014-03-23"), 0) returns 13
  - **altova:weeknumber-from-date** (xs:date("2014-03-23"), 1) returns 12
  - **altova:weeknumber-from-date** (xs:date("2014-03-23"), 2) returns 13
  - **altova:weeknumber-from-date** (xs:date("2014-03-23")) returns 13

  The day of the date in the examples above (2014-03-23) is Sunday. So the US and Islamic calendars are one week ahead of the European calendar on this day.

- **weeknumber-from-dateTime** [altova:]

  **altova:weeknumber-from-dateTime** (DateTime as xs:dateTime, Calendar as xs:integer) as xs:integer

  Returns the week number of the submitted DateTime argument as an integer. The second argument (Calendar) specifies the calendar system to follow. Supported Calendar values are:

  - 0 = US calendar (week starts Sunday)
• 1 = ISO standard, European calendar (week starts Monday)
• 2 = Islamic calendar (week starts Saturday)

Default is 0.

Examples

- \texttt{altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"), 0)} returns 13
- \texttt{altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"), 1)} returns 12
- \texttt{altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"), 2)} returns 13
- \texttt{altova:weeknumber-from-dateTime(xs:dateTime("2014-03-23T00:00:00"))} returns 13

The day of the dateTime in the examples above (2014-03-23T00:00:00) is Sunday. So the US and Islamic calendars are one week ahead of the European calendar on this day.

Build date, time, and duration datatypes from their lexical components

The functions take the lexical components of the \( \text{xs:dateTime}, \text{xs:time}, \) or \( \text{xs:duration} \) datatype as input arguments and combine them to build the respective datatype.

\textbf{build-date [altova:]}

\begin{verbatim}
altova:build-date(Year as xs:integer, Month as xs:integer, Date as xs:integer) as xs:date
\end{verbatim}

The first, second, and third arguments are, respectively, the year, month, and date. They are combined to build a value of \( \text{xs:date} \) type. The values of the integers must be within the correct range of that particular date part. For example, the second argument (for the month part) should not be greater than 12.

Examples

- \texttt{altova:build-date(2014, 2, 03)} returns 2014-02-03

\textbf{build-time [altova:]}

\begin{verbatim}
altova:build-time(Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer) as xs:time
\end{verbatim}

The first, second, and third arguments are, respectively, the hour (0 to 23), minutes (0 to 59), and seconds (0 to 59) values. They are combined to build a value of \( \text{xs:time} \) type. The values of the integers must be within the correct range of that particular time part. For example, the second (minutes) argument should not be greater than 59. To add a timezone part to the value, use the other signature of this function (see next signature).

Examples

- \texttt{altova:build-time(23, 4, 57)} returns 23:04:57

\begin{verbatim}
altova:build-time(Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer, TimeZone as xs:string) as xs:time
\end{verbatim}

The first, second, and third arguments are, respectively, the hour (0 to 23), minutes (0 to 59), and seconds (0 to 59) values. The fourth argument is a string that provides the timezone part of the value. The four arguments are combined to build a value of \( \text{xs:time} \) type. The values of the integers must be within the
correct range of that particular time part. For example, the second (Minutes) argument should not be greater than 59.

**Examples**

- altova:build-time(23, 4, 57, '+1') returns 23:04:57+01:00

### build-duration [altova:]

```
altova:build-duration(Years as xs:integer, Months as xs:integer) as xs:yearMonthDuration
```

Takes two arguments and builds a value of type xs:yearMonthDuration. The first argument provides the Years part of the duration value while the second argument provides the Months part. If the second (Months) argument is greater than or equal to 12, then the integer is divided by 12; the quotient is added to the first argument to provide the Years part of the duration value while the remainder (of the division) provides the Months part. To build a duration of type xs:dayTimeDuration, see the next signature.

**Examples**

- altova:build-duration(2, 10) returns P2Y10M
- altova:build-duration(14, 27) returns P16Y3M
- altova:build-duration(2, 24) returns P4Y

```
altova:build-duration(Days as xs:integer, Hours as xs:integer, Minutes as xs:integer, Seconds as xs:integer) as xs:dayTimeDuration
```

Takes four arguments and combines them to build a value of type xs:dayTimeDuration. The first argument provides the Days part of the duration value, the second, third, and fourth arguments provide, respectively, the Hours, Minutes, and Seconds parts of the duration value. Each of the three Time arguments is converted to an equivalent value in terms of the next higher unit and the result is used for calculation of the total duration value. For example, 72 seconds is converted to 1M+12S (1 minute and 12 seconds), and this value is used for calculation of the total duration value. To build a duration of type xs:yearMonthDuration, see the previous signature.

**Examples**

- altova:build-duration(2, 10, 3, 56) returns P2DT10H3M56S
- altova:build-duration(1, 0, 100, 0) returns P1DT1H40M
- altova:build-duration(1, 0, 0, 3600) returns P1DT1H

---

### Construct date, dateTime, and time datatypes from string input [XP2 XQ1 XP3.1 XQ3.1]

These functions take strings as arguments and construct xs:date, xs:dateTime, or xs:time datatypes. The string is analyzed for components of the datatype based on a submitted pattern argument.

#### parse-date [altova:]

```
altova:parse-date(Date as xs:string, DatePattern as xs:string) as xs:date
```

Returns the input string Date as an xs:date value. The second argument DatePattern specifies the pattern (sequence of components) of the input string. DatePattern is described with the component specifiers listed below and with component separators that can be any character. See the examples below.
The pattern in **DatePattern** must match the pattern in **Date**. Since the output is of type **xs:date**, the output will always have the lexical format `YYYY-MM-DD`.

### Examples

- `altova:parse-date(xs:string("09-12-2014"), ",[D]-[M]-[Y]")` returns `2014-12-09`
- `altova:parse-date(xs:string("09-12-2014"), ",[M]-[D]-[Y]")` returns `2014-09-12`
- `altova:parse-date("06/03/2014", ",[M]/[D]/[Y]")` returns `2014-06-03`
- `altova:parse-date("06 03 2014", ",[M] [D] [Y]")` returns `2014-06-03`
- `altova:parse-date("6 3 2014", ",[M] [D] [Y]")` returns `2014-06-03`

### parse-dateTime [altova:]

`altova:parse-dateTime(DateTime as xs:string, DateTimePattern as xs:string) as xs:dateTime`<br>
`XP2 XQ1 XP3.1 XQ3.1`

Returns the input string **DateTime** as an **xs:dateTime** value. The second argument **DateTimePattern** specifies the pattern (sequence of components) of the input string. **DateTimePattern** is described with the component specifiers listed below and with component separators that can be any character. See the examples below.

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Date</td>
</tr>
<tr>
<td>M</td>
<td>Month</td>
</tr>
<tr>
<td>Y</td>
<td>Year</td>
</tr>
<tr>
<td>H</td>
<td>Hour</td>
</tr>
<tr>
<td>m</td>
<td>minutes</td>
</tr>
<tr>
<td>s</td>
<td>seconds</td>
</tr>
</tbody>
</table>

The pattern in **DateTimePattern** must match the pattern in **DateTime**. Since the output is of type **xs:dateTime**, the output will always have the lexical format `YYYY-MM-DDTHH:mm:ss`.

### Examples

- `altova:parse-dateTime(xs:string("09-12-2014 13:56:24"), ",[M]-[D]-[Y] [H]:[m]:[s]")` returns `2014-09-12T13:56:24`
- `altova:parse-dateTime("time=13:56:24; date=09-12-2014", "time=[H]:[m]:[s]; date=[D]-[M]-[Y]")` returns `2014-12-09T13:56:24`

### parse-time [altova:]

`altova:parse-time(Time as xs:string, TimePattern as xs:string) as xs:time`<br>
`XP2 XQ1 XP3.1 XQ3.1`

Returns the input string **Time** as an **xs:time** value. The second argument **TimePattern** specifies the pattern (sequence of components) of the input string. **TimePattern** is described with the component specifiers listed below and with component separators that can be any character. See the examples below.
Appendices XSLT and XPath/XQuery Functions

H  Hour
m  minutes
s  seconds

The pattern in TimePattern must match the pattern in Time. Since the output is of type xs:time, the output will always have the lexical format HH:mm:ss.

Examples

- `altova:parse-time("13-56-24", "[H]-[m]")` returns 13:56:00
- `altova:parse-time("time=13h56m24s", "time=[H]h[m]m[s]s")` returns 13:56:24
- `altova:parse-time("time=24s56m13h", "time=[s]s[m]m[H]h")` returns 13:56:24

Age-related functions

These functions return the age as calculated (i) between one input argument date and the current date, or (ii) between two input argument dates. The `altova:age` function returns the age in terms of years, the `altova:age-details` function returns the age as a sequence of three integers giving the years, months, and days of the age.

age [altova:]

`altova:age(StartDate as xs:date) as xs:integer`  XP3.1  XQ3.1

Returns an integer that is the age in years of some object, counting from a start-date submitted as the argument and ending with the current date (taken from the system clock). If the input argument is a date anything greater than or equal to one year in the future, the return value will be negative.

Examples

If the current date is 2014-01-15:

- `altova:age(xs:date("2013-01-15"))` returns 1
- `altova:age(xs:date("2013-01-16"))` returns 0
- `altova:age(xs:date("2015-01-15"))` returns -1
- `altova:age(xs:date("2015-01-14"))` returns 0

`altova:age(StartDate as xs:date, EndDate as xs:date) as xs:integer`  XP3.1  XQ3.1

Returns an integer that is the age in years of some object, counting from a start-date that is submitted as the first argument up to an end-date that is the second argument. The return value will be negative if the first argument is one year or more later than the second argument.

Examples

If the current date is 2014-01-15:

- `altova:age(xs:date("2000-01-15"), xs:date("2010-01-15"))` returns 10
- `altova:age(xs:date("2000-01-15"), current-date())` returns 14 if the current date is 2014-01-15
- `altova:age(xs:date("2014-01-15"), xs:date("2010-01-15"))` returns -4
age-details [altova:]

\[
\text{altova:age-details}(\text{InputDate as xs:date}) \text{ as } \text{xs:integer}^* \text{ XP3.1 XP3.1}
\]

Returns three integers that are, respectively, the years, months, and days between the date that is submitted as the argument and the current date (taken from the system clock). The sum of the returned \( \text{years+months+days} \) together gives the total time difference between the two dates (the input date and the current date). The input date may have a value earlier or later than the current date, but whether the input date is earlier or later is not indicated by the sign of the return values; the return values are always positive.

\text{Examples}

If the current date is 2014-01-15:

- \text{altova:age-details}(\text{xs:date("2014-01-16")}) \text{ returns (0 0 1)}
- \text{altova:age-details}(\text{xs:date("2014-01-14")}) \text{ returns (0 0 1)}
- \text{altova:age-details}(\text{xs:date("2013-01-16")}) \text{ returns (1 0 1)}
- \text{altova:age-details}(\text{current-date()}) \text{ returns (0 0 0)}

\[
\text{altova:age-details}(\text{Date-1 as xs:date, Date-2 as xs:date}) \text{ as } \text{xs:integer}^* \text{ XP3.1 XP3.1}
\]

Returns three integers that are, respectively, the years, months, and days between the two argument dates. The sum of the returned \( \text{years+months+days} \) together gives the total time difference between the two input dates; it does not matter whether the earlier or later of the two dates is submitted as the first argument. The return values do not indicate whether the input date occurs earlier or later than the current date. Return values are always positive.

\text{Examples}

- \text{altova:age-details}(\text{xs:date("2014-01-16"), xs:date("2014-01-15")}) \text{ returns (0 0 1)}
- \text{altova:age-details}(\text{xs:date("2014-01-15"), xs:date("2014-01-16")}) \text{ returns (0 0 1)}

Epoch time (Unix time) functions \text{ XP3.1 XP3.1}

Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. Altova's Epoch time extension functions convert \text{xs:dateTime} values to Epoch time values and vice versa.

dateTime-from-epoch [altova:]

\[
\text{altova:dateTime-from-epoch}(\text{Epoch as xs:decimal as xs:dateTime} \text{ XP3.1 XP3.1}
\]

Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. The \text{dateTime-from-epoch} function returns the \text{xs:dateTime} equivalent of an Epoch time, adjusts it for the local timezone, and includes the timezone information in the result.

The function takes an \text{xs:decimal} argument and returns an \text{xs:dateTime} value that includes a \text{TZ} (timezone) part. The result is obtained by calculating the UTC \text{dateTime} equivalent of the Epoch time, and adding to it the local timezone (taken from the system clock). For example, if the function is executed on a machine that has been set to be in a timezone of +01:00 (relative to UTC), then after the UTC \text{dateTime}
equivalent has been calculated, one hour will be added to the result. The timezone information, which is an optional lexical part of the xs:dateTime result, is also reported in the dateTime result. Compare this result with that of dateTime-from-epoch-no-TZ, and also see the function epoch-from-dateTime.

**Examples**
The examples below assume a local timezone of UTC +01:00. Consequently, the UTC dateTime equivalent of the submitted Epoch time will be incremented by one hour. The timezone is reported in the result.

- `altova:dateTime-from-epoch(34)` returns `1970-01-01T01:00:34+01:00`
- `altova:dateTime-from-epoch(62)` returns `1970-01-01T01:01:02+01:00`

**dateTime-from-epoch-no-TZ [altova:]**

```
altova:dateTime-from-epoch-no-TZ(Epoch as xs:decimal as xs:dateTime XP3.1 XQ3.1
```

Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. The dateTime-from-epoch-no-TZ function returns the xs:dateTime equivalent of an Epoch time, adjusts it for the local timezone, but does not include the timezone information in the result.

The function takes an xs:decimal argument and returns an xs:dateTime value that does not include a TZ (timezone) part. The result is obtained by calculating the UTC dateTime equivalent of the Epoch time, and adding to it the local timezone (taken from the system clock). For example, if the function is executed on a machine that has been set to be in a timezone of +01:00 (relative to UTC), then after the UTC dateTime equivalent has been calculated, one hour will be added to the result. The timezone information, which is an optional lexical part of the xs:dateTime result, is not reported in the dateTime result. Compare this result with that of dateTime-from-epoch, and also see the function epoch-from-dateTime.

**Examples**
The examples below assume a local timezone of UTC +01:00. Consequently, the UTC dateTime equivalent of the submitted Epoch time will be incremented by one hour. The timezone is not reported in the result.

- `altova:dateTime-from-epoch(34)` returns `1970-01-01T01:00:34`
- `altova:dateTime-from-epoch(62)` returns `1970-01-01T01:01:02`

**epoch-from-dateTime [altova:]**

```
altova:epoch-from-dateTime(dateTimeValue as xs:dateTime) as xs:decimal XP3.1 XQ3.1
```

Epoch time is a time system used on Unix systems. It defines any given point in time as being the number of seconds that have elapsed since 00:00:00 UTC on 1 January 1970. The epoch-from-dateTime function returns the Epoch time equivalent of the xs:dateTime that is submitted as the argument of the function. Note that you might have to explicitly construct the xs:dateTime value. The submitted xs:dateTime value may or may not contain the optional TZ (timezone) part.

Whether the timezone part is submitted as part of the argument or not, the local timezone offset (taken from the system clock) is subtracted from the submitted dateTimeValue argument. This produces the equivalent UTC time, from which the equivalent Epoch time is calculated. For example, if the function is
executed on a machine that has been set to be in a timezone of +01:00 (relative to UTC), then one hour is subtracted from the submitted dateTimeValue before the Epoch value is calculated. Also see the function dateTime-from-epoch.

Examples

The examples below assume a local timezone of UTC +01:00. Consequently, one hour will be subtracted from the submitted dateTime before the Epoch time is calculated.

- `altova:epoch-from-dateTime(xs:dateTime("1970-01-01T01:00:34+01:00"))` returns 34
- `altova:epoch-from-dateTime(xs:dateTime("1970-01-01T01:00:34"))` returns 34
- `altova:epoch-from-dateTime(xs:dateTime("2021-04-01T11:22:33"))` returns 1617272553

18.2.1.3 XPath/XQuery Functions: Geolocation

The following geolocation XPath/XQuery extension functions are supported in the current version of StyleVision and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix `altova:`, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

format-geolocation [altova:]

`altova:format-geolocation(Latitude as xs:decimal, Longitude as xs:decimal, GeolocationOutputStringFormat as xs:integer) as xs:string` XP3.1 XQ3.1

Takes the latitude and longitude as the first two arguments, and outputs the geolocation as a string. The third argument, `GeolocationOutputStringFormat`, is the format of the geolocation output string; it uses integer values from 1 to 4 to identify the output string format (see ‘Geolocation output string formats’ below). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

Note: The image-exif-data function and the Exif metadata's attributes can be used to supply the input strings.
**Appendices XSLT and XPath/XQuery Functions**

### Examples

- `altova:format-geolocation(33.33, -22.22, 4)` returns the `xs:string` "33.33 -22.22"
- `altova:format-geolocation(33.33, -22.22, 2)` returns the `xs:string` "33.33N 22.22W"
- `altova:format-geolocation(-33.33, 22.22, 2)` returns the `xs:string` "33.33S 22.22E"
- `altova:format-geolocation(33.33, -22.22, 1)` returns the `xs:string` "33°19'48.00"S 22°13'12.00"E"

### Geolocation output string formats:

The supplied latitude and longitude is formatted in one of the output formats given below. The desired format is identified by its integer ID (1 to 4). Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

1. **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)**
   
   $D^\circ M^\prime S^\prime\prime N/S$  $D^\circ M^\prime S^\prime\prime E/W$

   *Example:* $33^\circ 55'11.11"N$  $22^\circ 44'66.66"W$

2. **Decimal degrees, with suffixed orientation (N/S, E/W)**
   
   $D.DD N/S$  $D.DD E/W$

   *Example:* $33.33\text{N}$  $22.22\text{W}$

3. **Degrees, minutes, decimal seconds, with prefixed sign (+/-); plus sign for (N/E) is optional**

   $+/D^\circ M^\prime S^\prime\prime$  $+/D^\circ M^\prime S^\prime\prime$

   *Example:* $33^\circ 55'11.11"$  $-22^\circ 44'66.66"$

4. **Decimal degrees, with prefixed sign (+/-); plus sign for (N/E) is optional**

   $+/D.DD$  $+/D.DD$

   *Example:* $33.33$  $-22.22$

### Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute `Geolocation` from standard Exif metadata tags. `Geolocation` is a concatenation of four Exif tags: `GPSLatitude`, `GPSLatitudeRef`, `GPSLongitude`, `GPSLongitudeRef`, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>$33^\circ 51'21.91&quot;S$  $151^\circ 13'11.73&quot;E$</td>
</tr>
</tbody>
</table>
**parse-geolocation [altova:]**

```
altova:parse-geolocation(GeolocationInputString as xs:string) as xs:decimal+
```

Parses the supplied `GeolocationInputString` argument and returns the geolocation's latitude and longitude (in that order) as a sequence two `xs:decimal` items. The formats in which the geolocation input string can be supplied are listed below.

**Note:** The `image-exif-data` function and the Exif metadata's `@Geolocation` attribute can be used to supply the geolocation input string (see example below).

### Examples

- `altova:parse-geolocation("33.33  -22.22")` returns the sequence of two `xs:decimals` (33.33, 22.22)
- `altova:parse-geolocation("48°51'29.6"N  24°17'40.2"W")` returns the sequence of two `xs:decimals` (48.858222222222, 24.2945)
- `altova:parse-geolocation("48°51'29.6"N  24°17'40.2")` returns the sequence of two `xs:decimals` (48.858222222222, 24.2945)
- `altova:parse-geolocation(image-exif-data(//MyImages/Image20141130.01)/@Geolocation)` returns a sequence of two `xs:decimals`

### Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to −90 (N to S). Longitude values range from +180 to −180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow ("), while unit indicators that are escaped are highlighted in blue ("').

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)**
  
  \[D{\text{°}}M'^{\prime}S\text{.SS}"N/S\]

  **Example:** 33°55'11.11"N  22°44'55.25"W

- **Degrees, minutes, decimal seconds, with prefix sign (+/-); the plus sign for (N/E) is optional**
  
  \[\pm D{\text{°}}M'^{\prime}S\text{.SS}"\]

  **Example:** 33°55'11.11"  -22°44'55.25"W

- **Degrees, decimal minutes, with suffixed orientation (N/S, E/W)**
  
  \[D{\text{°}}M.M'M.E/W\]

  **Example:** 33°55.55'N  22°44.44'W

- **Degrees, decimal minutes, with prefix sign (+/-); the plus sign for (N/E) is optional**
Appendices XSLT and XPath/XQuery Functions

Example: 

$+/D°M.MM' +/D°M.MM'$

Example: $+33°55.55' -22°44.44'$

- **Decimal degrees, with suffixed orientation** ($N/S$ $E/W$)
  - **D.DDN/S** $D.DDW/E$
  - Example: $33.33N 22.22W$

- **Decimal degrees, with prefixed sign** ($+/-$); the plus sign for ($N/S$ $E/W$) is optional
  - $+/D.DD$ $+/D.DD$  $+/D.DD$ $+/D.DD$
  - Example: $33.33 -22.22$

**Examples of format-combinations:**

- $33.33$ $-22°44'55.25''$
- $33.33$ $22°44'55.25''W$
- $33.33$ $22.45$

**Altova Exif Attribute: Geolocation**

The Altova XPath/XQuery Engine generates the custom attribute **Geolocation** from standard Exif metadata tags. **Geolocation** is a concatenation of four Exif tags: **GPSLatitude**, **GPSLatitudeRef**, **GPSLongitude**, **GPSLongitudeRef**, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>$33°51'21.91&quot;S 151°13'11.73&quot;E$</td>
</tr>
</tbody>
</table>

**Note:** The **image-exif-data** function and the Exif metadata's **@Geolocation** attribute can be used to supply geolocation input strings.

**Examples**

- **altova:geolocation-distance-km**

  ```xml
  altova:geolocation-distance-km(GeolocationInputString-1 as xs:string,
  GeolocationInputString-2 as xs:string) as xs:decimal XP3.1 XQ3.1
  ```

  Calculates the distance between two geolocations in kilometers. The formats in which the geolocation input string can be supplied are listed below. Latitude values range from $+90$ to $-90$ ($N$ to $S$). Longitude values range from $+180$ to $-180$ ($E$ to $W$).

  **Examples**

  - **altova:geolocation-distance-km**

    ```xml
    "$33.33 -22.22", "48°51'29.6MN 24°17'40.2MM"
    ```

    returns the **xs:decimal** $4183.0813273292$

  **Geolocation input string formats:**

  The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from $+90$ to $-90$ ($N$ to $S$). Longitude values range from $+180$ to $-180$ ($E$ to $W$).
Note: If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (""), while unit indicators that are escaped are highlighted in blue (\"\").

- Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)
  \(D^\circ M^{\prime}.SS^\prime\)N/S \(D^\circ M^{\prime}.SS^\prime\)W/E
  Example: \(33^\circ 55'11.11"\)N \(22^\circ 44'55.25"\)W

- Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional
  +/-\(D^\circ M^{\prime}.SS^\prime\) +/-\(D^\circ M^{\prime}.SS^\prime\)
  Example: \(33^\circ 55'11.11"\) -\(22^\circ 44'55.25"\)

- Degrees, decimal minutes, with suffixed orientation (N/S, E/W)
  \(D^\circ M.MM^{\prime}\)N/S \(D^\circ M.MM^{\prime}\)W/E
  Example: \(33^\circ 55.55'\)N \(22^\circ 44.44'\)W

- Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional
  +/-\(D^\circ M.MM^{\prime}\) +/-\(D^\circ M.MM^{\prime}\)
  Example: \(+33^\circ 55.55'\) -\(22^\circ 44.44'\)

- Decimal degrees, with suffixed orientation (N/S, E/W)
  \(D.DD\)N/S \(D.DD\)W/E
  Example: \(33.33\)N \(22.22\)W

- Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional
  +/-\(D.DD\) +/-\(D.DD\)
  Example: \(33.33\) -\(22.22\)

Examples of format-combinations:

| 33.33N | -22°44'55.25" |
| 33.33 | 22°44'55.25"W |
| 33.33 | 22.45 |

Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>33°51'21.91&quot;S 151°</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>13°11.73&quot;E</td>
</tr>
</tbody>
</table>
geolocation-distance-mi [altova:]

```
altova:geolocation-distance-mi(GeolocationInputString-1 as xs:string,
GeolocationInputString-2 as xs:string) as xs:decimal XP3.1 XQ3.1
```

Calculates the distance between two geolocations in miles. The formats in which a geolocation input string can be supplied are listed below. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** The `image-exif-data` function and the Exif metadata's `@Geolocation` attribute can be used to supply geolocation input strings.

**Examples**

- `altova:geolocation-distance-mi("33.33  -22.22", "48°51'29.6"N  24°17'40.2"W")`
  
  returns the `xs:decimal 2599.40652340653`

**Geolocation input string formats:**

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow ("), while unit indicators that are escaped are highlighted in blue ("').

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)**
  
  `D°M'.SS"N/S  D°M'.SS"W/E`

  **Example:** 33°55'11.11"N  22°44'55.25"W

- **Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional**
  
  `+/-D°M'.SS"  +/-D°M'.SS"`

  **Example:** 33°55'11.11"  -22°44'55.25"W

- **Degrees, decimal minutes, with suffixed orientation (N/S, E/W)**
  
  `D°M.MM"N/S  D°M.MM"W/E`

  **Example:** 33°55.55"N  22°44.44"W

- **Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional**
  
  `+/-D°M.MM"  +/-D°M.MM"

  **Example:** +33°55.55'  -22°44.44'

- **Decimal degrees, with suffixed orientation (N/S, E/W)**
  
  `D.DDN/S  D.DDW/E`

  **Example:** 33.33N  22.22W
• Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional
  \(+/-\text{D.DD}\)

  \textbf{Example:} \(33.33\ -22.22\)

\textbf{Examples of format-combinations:}
\begin{itemize}
  \item \(33.33N\ -22°44'55.25''\)
  \item \(33.33\ 22°44'55.25''W\)
  \item \(33.33\ 22.45\)
\end{itemize}

\textbf{Altova Exif Attribute: Geolocation}

The Altova XPath/XQuery Engine generates the custom attribute \textit{Geolocation} from standard Exif metadata tags. \textit{Geolocation} is a concatenation of four Exif tags: \textit{GPSLatitude}, \textit{GPSLatitudeRef}, \textit{GPSLongitude}, \textit{GPSLongitudeRef}, with units added (see \textbf{table below}).

\begin{table}[!h]
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
\textbf{GPSLatitude} & \textbf{GPSLatitudeRef} & \textbf{GPSLongitude} & \textbf{GPSLongitudeRef} & \textbf{Geolocation} \\
\hline
33 & 51 & 21.91 & S & 151 & 13 & 11.73 & E & 33°51'21.91"\textit{S} & 151°13'11.73"\textit{E} \\
\hline
\end{tabular}
\end{table}

\textbf{Geolocation input string formats:}

\begin{itemize}
  \item \textbf{Example 1:} \texttt{altova:geolocations-bounding-rectangle(\texttt{("48.2143531 16.3707266", "51.50939 -0.11832"}), 1)} returns the sequence \texttt{("51°30'33.804"N 0°7'5.952"W", "48°12'51.67116"N 16°22'14.61576"W")}
  \item \textbf{Example 2:} \texttt{altova:geolocations-bounding-rectangle(\texttt{("48.2143531 16.3707266", "51.50939 -0.11832", "42.5584577 -70.8893334"), 4}) returns the sequence \texttt{("51.50939 -70.8893334", "42.5584577 16.3707266")}}
\end{itemize}
The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to −90 (N to S). Longitude values range from +180 to −180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (“”) while unit indicators that are escaped are highlighted in blue (“”).

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)**
  
  \[D°M'S.SS''N/S\]
  
  \[D°M'S.SS''W/E\]

  **Example:** 33°55'11.11"N  22°44'55.25"W

- **Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional**

  \[+/-D°M'S.SS''\]
  
  \[+/-D°M'S.SS''\]

  **Example:** 33°55'11.11"  -22°44'55.25"

- **Degrees, decimal minutes, with suffixed orientation (N/S, E/W)**

  \[D°M.MM'M/S\]
  
  \[D°M.MM'M/W\]

  **Example:** 33°55.55'N  22°44.44'W

- **Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional**

  \[+/-D°M.MM'M\]
  
  \[+/-D°M.MM'M\]

  **Example:** +33°55.55'  -22°44.44'

- **Decimal degrees, with suffixed orientation (N/S, E/W)**

  \[D.DDN/S\]
  
  \[D.DDW/E\]

  **Example:** 33.33N  22.22W

- **Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional**

  \[+/-D.DD\]
  
  \[+/-D.DD\]

  **Example:** 33.33  -22.22

**Examples of format-combinations:**

- 33.33N  -22°44'55.25"
- 33.33  22°44'55.25"W
- 33.33  22.45

**Geolocation output string formats:**

The supplied latitude and longitude is formatted in one of the output formats given below. The desired format is identified by its integer ID (1 to 4). Latitude values range from +90 to −90 (N to S). Longitude values range from +180 to −180 (E to W).
Example: 33°55’11.11”N  22°44’66.66”W

Example: 33.33N  22.22W

Example: 33°55’11.11”  -22°44’66.66”

Example: 33.33 -22.22

Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>33°51’21.91”S 151°13’11.73”E</td>
</tr>
</tbody>
</table>

Note: The image-exif-data function and the Exif metadata’s @Geolocation attribute can be used to supply geolocation input strings.
**Examples**

- `altova:geolocation-within-polygon("33 -22", ("58 -32", "-78 -55", "48°51'29.6"N 24°17'40.2"W"))` returns `true()`

**Geolocation input string formats:**

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

**Note:** If single quotes or double quotes are used to delimit the input string argument, this will create a mismatch with the single quotes or double quotes that are used, respectively, to indicate minute-values and second-values. In such cases, the quotes that are used for indicating minute-values and second-values must be escaped by doubling them. In the examples in this section, quotes used to delimit the input string are highlighted in yellow (`"`) while unit indicators that are escaped are highlighted in blue (`"`).

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)**
  
  D°M'S.SS"N/S  D°M'S.SS"W/E
  
  *Example:* 33°55'11.11"N  22°44'55.25"W

- **Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional**
  
  +/-D°M'S.SS"  +/-D°M'S.SS"
  
  *Example:* 33°55'11.11"  -22°44'55.25"

- **Degrees, decimal minutes, with suffixed orientation (N/S, E/W)**
  
  D°M.MM'N/S  D°M.MM'W/E
  
  *Example:* 33°55.55'N  22°44.44'W

- **Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional**
  
  +/-D°M.MM'  +/-D°M.MM'
  
  *Example:* +33°55.55'  -22°44.44'

- **Decimal degrees, with suffixed orientation (N/S, E/W)**
  
  D.DDN/S  D.DDW/E
  
  *Example:* 33.33N  22.22W

- **Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional**
  
  +/-D.DD  +/-D.DD
  
  *Example:* 33.33  -22.22

**Examples of format-combinations:**

33.33N  -22°44'55.25"

33.33  22°44'55.25"W
Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute **Geolocation** from standard Exif metadata tags. **Geolocation** is a concatenation of four Exif tags: **GPSLatitude**, **GPSLatitudeRef**, **GPSLongitude**, **GPSLongitudeRef**, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>33°51'21.91&quot;S 151°13'11.73&quot;E</td>
</tr>
</tbody>
</table>

Note: The `image-exif-data` function and the Exif metadata's `@Geolocation` attribute can be used to supply geolocation input strings.

Examples

- `altova:geolocation-within-rectangle("33 -22", "58 -32", "48 24")` returns `true()`
- `altova:geolocation-within-rectangle("33 -22", "58 -32", "48 24")` returns `false()`
- `altova:geolocation-within-rectangle("33 -22", "58 -32", "48°51'29.6"S 24°17'40.2"E")` returns `true()`

Geolocation input string formats:

The geolocation input string must contain latitude and longitude (in that order) separated by whitespace. Each can be in any of the following formats. Combinations are allowed. So latitude can be in one format and longitude can be in another. Latitude values range from +90 to -90 (N to S). Longitude values range from +180 to -180 (E to W).

- **Degrees, minutes, decimal seconds, with suffixed orientation (N/S, E/W)**
- Degrees, minutes, decimal seconds, with prefixed sign (+/-); the plus sign for (N/E) is optional
  \[+/-D^{°}M^{\prime}S^{\prime\prime}\]  \[+/-D^{°}M^{\prime}S^{\prime\prime}\]
  Example: \[33^{°}55^{\prime}11.11^{\prime\prime}N\ 22^{°}44^{\prime}55.25^{\prime\prime}W\]

- Degrees, decimal minutes, with suffixed orientation (N/S, E/W)
  \[D^{°}M^{.MM}N/S\ D^{°}M^{.MM}W/E\]
  Example: \[33^{°}55.55^{\prime}N\ 22^{°}44.44^{\prime}W\]

- Degrees, decimal minutes, with prefixed sign (+/-); the plus sign for (N/E) is optional
  \[+/-D^{°}M^{.MM}\]  \[+/-D^{°}M^{.MM}\]
  Example: \[+33^{°}55.55^{\prime}\ -22^{°}44.44^{\prime}\]

- Decimal degrees, with suffixed orientation (N/S, E/W)
  \[D.DD\]  \[D.DDW/E\]
  Example: \[33.33N\ 22.22W\]

- Decimal degrees, with prefixed sign (+/-); the plus sign for (N/S E/W) is optional
  \[+/-D.DD\]  \[+/-D.DD\]
  Example: \[33.33\ -22.22\]

**Examples of format-combinations:**
- \[33.33N\ -22^{°}44^{\prime}55.25^{\prime\prime}\]
- \[33.33\ 22^{°}44^{\prime}55.25^{\prime\prime}W\]
- \[33.33\ 22.45\]

**Altova Exif Attribute: Geolocation**

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51.21.91</td>
<td>S</td>
<td>151 11.73</td>
<td>E</td>
<td>33°51'21.91&quot;S 151°13'11.73&quot;E</td>
</tr>
</tbody>
</table>
18.2.1.4 XPath/XQuery Functions: Image-Related

The following image-related XPath/XQuery extension functions are supported in the current version of StyleVision and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

</tr>
</tbody>
</table>

suggested-image-file-extension [altova:]

altova:suggested-image-file-extension(Base64String as string) as string? XP3.1 XQ3.1

Takes the Base64 encoding of an image file as its argument and returns the file extension of the image as recorded in the Base64-encoding of the image. The returned value is a suggestion based on the image type information available in the encoding. If this information is not available, then an empty string is returned. This function is useful if you wish to save a Base64 image as a file and wish to dynamically retrieve an appropriate file extension.

Examples

- `altova:suggested-image-file-extension(/MyImages/MobilePhone/Image20141130.01)` returns 'jpg'
- `altova:suggested-image-file-extension($XML1/Staff/Person/@photo)` returns ''

In the examples above, the nodes supplied as the argument of the function are assumed to contain a Base64-encoded image. The first example retrieves jpg as the file's type and extension. In the second example, the submitted Base64 encoding does not provide usable file extension information.

image-exif-data [altova:]

altova:image-exif-data(Base64BinaryString as string) as element? XP3.1 XQ3.1

Takes a Base64-encoded JPEG image as its argument and returns an element called Exif that contains the Exif metadata of the image. The Exif metadata is created as attribute-value pairs of the Exif element. The attribute names are the Exif data tags found in the Base64 encoding. The list of Exif-specification tags is given below. If a vendor-specific tag is present in the Exif data, this tag and its value will also be returned as an attribute-value pair. Additional to the standard Exif metadata tags (see list below), Altova-specific attribute-value pairs are also generated. These Altova Exif attributes are listed below.
Examples

- To access any one attribute, use the function like this:
  ```xml
  image-exif-data(//MyImages/Image20141130.01)/@GPSLatitude
  image-exif-data(//MyImages/Image20141130.01)/@Geolocation
  ```

- To access all the attributes, use the function like this:
  ```xml
  image-exif-data(//MyImages/Image20141130.01)/@*
  ```

- To access the names of all the attributes, use the following expression:
  ```xml
  for $i in image-exif-data(//MyImages/Image20141130.01)/@* return name($i)
  ```
  This is useful to find out the names of the attributes returned by the function.

Altova Exif Attribute: Geolocation

The Altova XPath/XQuery Engine generates the custom attribute Geolocation from standard Exif metadata tags. Geolocation is a concatenation of four Exif tags: GPSLatitude, GPSLatitudeRef, GPSLongitude, GPSLongitudeRef, with units added (see table below).

<table>
<thead>
<tr>
<th>GPSLatitude</th>
<th>GPSLatitudeRef</th>
<th>GPSLongitude</th>
<th>GPSLongitudeRef</th>
<th>Geolocation</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 51 21.91</td>
<td>S</td>
<td>151 13 11.73</td>
<td>E</td>
<td>33°51'21.91&quot;S 151°13'11.73&quot;E</td>
</tr>
</tbody>
</table>

Altova Exif Attribute: OrientationDegree

The Altova XPath/XQuery Engine generates the custom attribute OrientationDegree from the Exif metadata tag Orientation.

OrientationDegree translates the standard Exif tag Orientation from an integer value (1, 8, 3, or 6) to the respective degree values of each (0, 90, 180, 270), as shown in the figure below. Note that there are no translations of the Orientation values of 2, 4, 5, 7. (These orientations are obtained by flipping image 1 across its vertical center axis to get the image with a value of 2, and then rotating this image in 90-degree jumps clockwise to get the values of 7, 4, and 5, respectively).

18.2.1.5 XPath/XQuery Functions: Numeric

Altova’s numeric extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova’s XPath 3.0 and XQuery 3.0 engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability
Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the **Altova extension functions namespace**, [http://www.altova.com/xslt-extensions](http://www.altova.com/xslt-extensions), and are indicated in this section with the prefix `altova:`, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

### Auto-numbering functions

#### `generate-auto-number` [altova:]

```xml
altova:generate-auto-number(ID as xs:string, StartsWith as xs:double, Increment as xs:double, ResetOnChange as xs:string) as xs:integer
```

Generates a number each time the function is called. The first number, which is generated the first time the function is called, is specified by the `StartsWith` argument. Each subsequent call to the function generates a new number, this number being incremented over the previously generated number by the value specified in the `Increment` argument. In effect, the `altova:generate-auto-number` function creates a counter having a name specified by the `ID` argument, with this counter being incremented each time the function is called. If the value of the `ResetOnChange` argument changes from that of the previous function call, then the value of the number to be generated is reset to the `StartsWith` value. Auto-numbering can also be reset by using the `altova:reset-auto-number` function.

**Examples**

- `altova:generate-auto-number("ChapterNumber", 1, 1, "SomeString")` will return one number each time the function is called, starting with 1, and incrementing by 1 with each call to the function. As long as the fourth argument remains "SomeString" in each subsequent call, the incrementing will continue. When the value of the fourth argument changes, the counter (called `ChapterNumber`) will reset to 1. The value of `ChapterNumber` can also be reset by a call to the `altova:reset-auto-number` function, like this: `altova:reset-auto-number("ChapterNumber")`.

#### `reset-auto-number` [altova:]

```xml
altova:reset-auto-number(ID as xs:string) as xs:integer
```

This function resets the number of the auto-numbering counter named in the `ID` argument. The number is reset to the number specified by the `StartsWith` argument of the `altova:generate-auto-number` function that created the counter named in the `ID` argument.

**Examples**

- `altova:reset-auto-number("ChapterNumber")` resets the number of the auto-numbering counter named `ChapterNumber` that was created by the `altova:generate-auto-number` function. The number is reset to the value of the `StartsWith` argument of the `altova:generate-auto-number` function that created `ChapterNumber`.

---

**Note:**

In future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.
Numeric functions

hex-string-to-integer [altova:]

**altova:hex-string-to-integer(HexString as xs:string) as xs:integer**

Takes a string argument that is the Base-16 equivalent of an integer in the decimal system (Base-10), and returns the decimal integer.

- **Examples**
  - `altova:hex-string-to-integer('1')` returns `1`
  - `altova:hex-string-to-integer('9')` returns `9`
  - `altova:hex-string-to-integer('A')` returns `10`
  - `altova:hex-string-to-integer('B')` returns `11`
  - `altova:hex-string-to-integer('F')` returns `15`
  - `altova:hex-string-to-integer('G')` returns an error
  - `altova:hex-string-to-integer('10')` returns `16`
  - `altova:hex-string-to-integer('01')` returns `1`
  - `altova:hex-string-to-integer('20')` returns `32`
  - `altova:hex-string-to-integer('21')` returns `33`
  - `altova:hex-string-to-integer('5A')` returns `90`
  - `altova:hex-string-to-integer('USA')` returns an error

integer-to-hex-string [altova:]

**altova:integer-to-hex-string(Integer as xs:integer) as xs:string**

Takes an integer argument and returns its Base-16 equivalent as a string.

- **Examples**
  - `altova:integer-to-hex-string(1)` returns `'1'`
  - `altova:integer-to-hex-string(9)` returns `'9'`
  - `altova:integer-to-hex-string(10)` returns `'A'`
  - `altova:integer-to-hex-string(11)` returns `'B'`
  - `altova:integer-to-hex-string(15)` returns `'F'`
  - `altova:integer-to-hex-string(16)` returns `'10'`
  - `altova:integer-to-hex-string(32)` returns `'20'`
  - `altova:integer-to-hex-string(33)` returns `'21'`
  - `altova:integer-to-hex-string(90)` returns `'5A'`
18.2.1.6 XPath/XQuery Functions: Schema

The Altova extension functions listed below return schema information. Given below are descriptions of the functions, together with (i) examples and (ii) a listing of schema components and their respective properties. They can be used with Altova's XPath 3.0 and XQuery 3.0 engines and are available in XPath/XQuery contexts.

Schema information from schema documents
The function `altova:schema` has two arguments: one with zero arguments and the other with two arguments. The zero-argument function returns the whole schema. You can then, from this starting point, navigate into the schema to locate the schema components you want. The two-argument function returns a specific component kind that is identified by its QName. In both cases, the return value is a function. To navigate into the returned component, you must select a property of that specific component. If the property is a non-atomic item (that is, if it is a component), then you can navigate further by selecting a property of this component. If the selected property is an atomic item, then the value of the item is returned and you cannot navigate any further.

Note: In XPath expressions, the schema must be imported into the processing environment (for example, into XSLT) with the `xslt:import-schema` instruction. In XQuery expressions, the schema must be explicitly imported using a schema import.

Schema information from XML nodes
The function `altova:type` submits the node of an XML document and returns the node's type information from the PSVI.

Note about naming of functions and language applicability
Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, `http://www.altova.com/xslt-extensions`, and are indicated in this section with the prefix `altova:`, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

- **Schema (zero arguments)**

  `altova:schema()` as (function(xs:string) as item())? XP3.1 XQ3.1

  Returns the `schema` component as a whole. You can navigate further into the `schema` component by selecting one of the `schema` component's properties.

  - If this property is a component, you can navigate another step deeper by selecting one of this component's properties. This step can be repeated to navigate further into the schema.
  - If the component is an atomic value, the atomic value is returned and you cannot navigate any deeper.
The properties of the schema component are:

"type definitions"
"attribute declarations"
"element declarations"
"attribute group definitions"
"model group definitions"
"notation declarations"
"identity-constraint definitions"

The properties of all other component kinds (besides schema) are listed below.

Note: In XQuery expressions, the schema must be explicitly imported. In XPath expressions, the schema must have been imported into the processing environment, for example, into XSLT with the xslt:import instruction.

Examples

- import schema "" at "C:\Test\ExpReport.xsd"; for $typedef in altova:schema() ("type definitions")
  return $typedef ("name") returns the names of all simple types or complex types in the schema

- import schema "" at "C:\Test\ExpReport.xsd";
  altova:schema() ("type definitions")[1]("name") returns the name of the first of all simple types or complex types in the schema

### Schema (two arguments)
altova:schema(\texttt{ComponentKind} \texttt{as xs:string}, \texttt{Name} \texttt{as xs:QName}) \texttt{as (function(xs:string) as item()*)? XP3.1 XP3.1}

Returns the component kind that is specified in the first argument which has a name that is the same as the name supplied in the second argument. You can navigate further by selecting one of the component's properties.

- If this property is a component, you can navigate another step deeper by selecting one of this component's properties. This step can be repeated to navigate further into the schema.
- If the component is an atomic value, the atomic value is returned and you cannot navigate any deeper.

\textbf{Note:} In XQuery expressions, the schema must be explicitly imported. In XPath expressions, the schema must have been imported into the processing environment, for example, into XSLT with the \texttt{xslt:import} instruction.

\textbf{Examples}

- \texttt{import schema "" at "C:\Test\ExpReport.xsd"; altova:schema("element declaration", xs:QName("OrgChart"))("type definition")
  ("content type")("particles")[3].("term")("kind")}
  returns the kind property of the term of the third particles component. This particles component is a descendant of the element declaration having a QName of OrgChart

- \texttt{import schema "" at "C:\Test\ExpReport.xsd"; let $typedef := altova:schema("type definition", xs:QName("emailType"))
  for $facet in $typedef ("facets")
  return [$facet ("kind"), $facet("value")]
  returns, for each facet of each emailType component, an array containing that facet's kind and value}

scope & A function with properties ("class":"Scope", "variety": "global" or "local", "parent": the containing & \\
\hline
\end{tabular}
The document contains tables describing attributes, attribute uses, and attribute wildcards for different types, such as Complex Type or Attribute Group. The tables include columns for Property name, Property type, and Property value, detailing specific properties and constraints. The tables are structured to show how different properties are defined and their corresponding values or constraints. For instance, the `value constraint` property indicates the presence of a function with specific properties, while the `inheritable` property is boolean, indicating whether the property is inheritable or not.

Type

\texttt{altova:type(Node as item?) as (function(xs:string) as item()*)?} XP3.1 XQ3.1

The function \texttt{altova:type} submits an element or attribute node of an XML document and returns the node's type information from the PSVI.

\textbf{Note:} The XML document must have a schema declaration so that the schema can be referenced.

\textbf{Examples}

- \texttt{for $element in //Email}
  \hspace{1em} \texttt{let $type := altova:type($element)}
  \hspace{1em} \texttt{return $type}

  returns a function that contains the Email node's type information

- \texttt{for $element in //Email}
  \hspace{1em} \texttt{let $type := altova:type($element)}
  \hspace{1em} \texttt{return $type ("kind")}

  takes the Email node's type component (Simple Type or Complex Type) and returns the value of the component's kind property

The "\_props" parameter returns the properties of the selected component. For example:

- \texttt{for $element in //Email}
  \hspace{1em} \texttt{let $type := altova:type($element)}
  \hspace{1em} \texttt{return ($type ("kind"), $type ("\_props"))}

  takes the Email node's type component (Simple Type or Complex Type) and returns (i) the value of the component's kind property, and then (ii) the properties of that component.

\textit{Components and their properties}

18.2.1.7 XPath/XQuery Functions: Sequence

Altova’s sequence extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova’s XPath 3.0 and XQuery 3.0 engines. They are available in XPath/XQuery contexts.

Note about naming of functions and language applicability

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

`altova:attributes [altova:]`

`altova:attributes(AttributeName as xs:string) as attribute() * XP3.1 XQ3.1`

Returns all attributes that have a local name which is the same as the name supplied in the input argument, AttributeName. The search is case-sensitive and conducted along the attribute:: axis. This means that the context node must be the parent element node.

**Examples**

- `altova:attributes("MyAttribute")` returns `MyAttribute()` *

`altova:attributes(AttributeName as xs:string, SearchOptions as xs:string) as attribute() * XP3.1 XQ3.1`

Returns all attributes that have a local name which is the same as the name supplied in the input argument, AttributeName. The search is case-sensitive and conducted along the attribute:: axis. The context node must be the parent element node. The second argument is a string containing option flags. Available flags are:

- `r` = switches to a regular-expression search; AttributeName must then be a regular-expression search string;
- `f` = If this option is specified, then AttributeName provides a full match; otherwise AttributeName need only partially match an attribute name to return that attribute. For example: if `f` is not specified, then `MyAtt` will return `MyAttribute`;
- `i` = switches to a case-insensitive search;
- `p` = includes the namespace prefix in the search; AttributeName should then contain the namespace prefix, for example: `altova:MyAttribute`.

The flags can be written in any order. Invalid flags will generate errors. One or more flags can be omitted. The empty string is allowed, and will produce the same effect as the function having only one argument.
Appendices X SLT and X Path/X Query Functions

然而，一个空序列不被允许作为第二个参数。

**Examples**
- `altova:attributes("MyAttribute", "rfip")` returns `MyAttribute()`*
- `altova:attributes("MyAttribute", "pri")` returns `MyAttribute()`*
- `altova:attributes("MyAtt", "rip")` returns `MyAttribute()`*
- `altova:attributes("MyAttributes", "rfip")` returns no match
- `altova:attributes("MyAttribute", "")` returns `MyAttribute()`*
- `altova:attributes("MyAttribute", "Rip")` returns an unrecognized-flag error.
- `altova:attributes("MyAttribute", )` returns a missing-second-argument error.

**elements [altova:]**

`altova:elements(ElementName as xs:string) as element()*` XP3.1 XQ3.1

返回所有拥有与输入参数相同局部名称的元素。搜索是区分大小写的，并沿着 `child::` 轴进行。上下文节点必须是被搜索元素的父节点。

**Examples**
- `altova:elements("MyElement")` returns `MyElement()`*
- `altova:elements("MyElement", "rip")` returns `MyElement()`*
- `altova:elements("MyElement", ")` returns `MyElement()`*
- `altova:elements("MyElement", "Rip")` returns an unrecognized-flag error.

**find-first [altova:]**
altova:find-first((Sequence as item()*) , (Condition (Sequence-Item as xs:boolean)) as item())? XP3.1 XQ3.1

This function takes two arguments. The first argument is a sequence of one or more items of any datatype. The second argument, Condition, is a reference to an XPath function that takes one argument (has an arity of 1) and returns a boolean. Each item of sequence is submitted, in turn, to the function referenced in Condition. *(Remember: This function takes a single argument.) The first Sequence item that causes the function in Condition to evaluate to true() is returned as the result of altova:find-first, and the iteration stops.

**Examples**

- altova:find-first(5 to 10, function($a) { $a mod 2 = 0}) returns xs:integer 6
  The Condition argument references the XPath 3.0 inline function, function(), which declares an inline function named $a and then defines it. Each item in the Sequence argument of altova:find-first is passed, in turn, to $a as its input value. The input value is tested on the condition in the function definition ($a mod 2 = 0). The first input value to satisfy this condition is returned as the result of altova:find-first (in this case 6).

- altova:find-first((1 to 10), (function($a) { $a+3=7})) returns xs:integer 4

**Further examples**

If the file C:\Temp\Customers.xml exists:

- altova:find-first( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1) ) returns xs:string C:\Temp\Customers.xml

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html exists:

If the file C:\Temp\Customers.xml does not exist, and http://www.altova.com/index.html also does not exist:

- altova:find-first( ("C:\Temp\Customers.xml", "http://www.altova.com/index.html"), (doc-available#1) ) returns no result

**Notes about the examples given above**

- The XPath 3.0 function, doc-available, takes a single string argument, which is used as a URI, and returns true if a document node is found at the submitted URI. (The document at the submitted URI must therefore be an XML document.)
- The doc-available function can be used for Condition, the second argument of altova:find-first, because it takes only one argument (arity=1), because it takes an item() as input (a string which is used as a URI), and returns a boolean value.
- Notice that the doc-available function is only referenced, not called. The #1 suffix that is attached to it indicates a function with an arity of 1. In its entirety doc-available#1 simply means: *Use the doc-available() function that has arity=1, passing to it as its single argument, in turn, each of the items in the first sequence.* As a result, each of the two strings will be passed
to \texttt{doc-available()}, which uses the string as a URI and tests whether a document node exists at the URI. If one does, the \texttt{doc-available()} evaluates to \texttt{true()} and that string is returned as the result of the \texttt{altova:find-first} function. \textit{Note about the \texttt{doc-available()} function: Relative paths are resolved relative to the current base URI, which is by default the URI of the XML document from which the function is loaded.}

\begin{itemize}
  \item The first two arguments, Seq-01 and Seq-02, are sequences of one or more items of any datatype.
  \item The third argument, Condition, is a reference to an X Path function that takes two arguments (has an arity of 2) and returns a boolean.
\end{itemize}

The items of Seq-01 and Seq-02 are passed in ordered pairs (one item from each sequence making up a pair) as the arguments of the function in Condition. The pairs are ordered as follows.

\begin{itemize}
  \item \textbf{If} Seq-01 = X1, X2, X3 \ldots Xn
  \item \textbf{And} Seq-02 = Y1, Y2, Y3 \ldots Yn
  \item \textbf{Then} (X1 Y1), (X1 Y2), (X1 Y3) \ldots (X1 Yn), (X2 Y1), (X2 Y2) \ldots (Xn Yn)
\end{itemize}

The first ordered pair that causes the Condition function to evaluate to \texttt{true()} is returned as the result of \texttt{altova:find-first-combination}. Note that: (i) If the Condition function iterates through the submitted argument pairs and does not once evaluate to \texttt{true()}, then \texttt{altova:find-first-combination} returns \texttt{No results}; (ii) The result of \texttt{altova:find-first-combination} will always be a pair of items (of any datatype) or no item at all.

\textbf{Examples}

\begin{itemize}
  \item \texttt{altova:find-first-combination(11 to 20, 21 to 30, function($a, $b) {$a+$b = 32})} returns the sequence of \texttt{xs:integers} (11, 21)
  \item \texttt{altova:find-first-combination(11 to 20, 21 to 30, function($a, $b) {$a+$b = 33})} returns the sequence of \texttt{xs:integers} (11, 22)
  \item \texttt{altova:find-first-combination(11 to 20, 21 to 30, function($a, $b) {$a+$b = 34})} returns the sequence of \texttt{xs:integers} (11, 23)
\end{itemize}

\begin{itemize}
  \item The first two arguments, Seq-01 and Seq-02, are sequences of one or more items of any datatype.
  \item The third argument, Condition, is a reference to an X Path function that takes two arguments (has an arity of 2) and returns a boolean.
\end{itemize}
The items of Seq-01 and Seq-02 are passed in ordered pairs as the arguments of the function in Condition. The pairs are ordered as follows.

If Seq-01 = X1, X2, X3 ... Xn
And Seq-02 = Y1, Y2, Y3 ... Yn
Then (X1 Y1), (X2 Y2), (X3 Y3) ... (Xn Yn)

The first ordered pair that causes the condition function to evaluate to true() is returned as the result of altova:find-first-pair. Note that: (i) If the condition function iterates through the submitted argument pairs and does not once evaluate to true(), then altova:find-first-pair returns No results; (ii) The result of altova:find-first-pair will always be a pair of items (of any datatype) or no item at all.

Examples

- altova:find-first-pair(11 to 20, 21 to 30, function($a, $b) {$a+$b = 32}) returns the sequence of xs: integers (11, 21)
- altova:find-first-pair(11 to 20, 21 to 30, function($a, $b) {$a+$b = 33}) returns No results

Notice from the two examples above that the ordering of the pairs is: (11, 21) (12, 22) (13, 23) ... (20, 30). This is why the second example returns No results (because no ordered pair gives a sum of 33).

find-first-pair-pos [altova:]

altova:find-first-pair-pos((Seq-01 as item()*) , (Seq-02 as item()*) , (Condition( Seq-01-Item, Seq-02-Item as xs:boolean))) as xs: integer

XP3.1 XQ3.1

This function takes three arguments:

- The first two arguments, Seq-01 and Seq-02, are sequences of one or more items of any datatype.
- The third argument, Condition, is a reference to an XPath function that takes two arguments (has an arity of 2) and returns a boolean.

The items of Seq-01 and Seq-02 are passed in ordered pairs as the arguments of the function in Condition. The pairs are ordered as follows.

If Seq-01 = X1, X2, X3 ... Xn
And Seq-02 = Y1, Y2, Y3 ... Yn
Then (X1 Y1), (X2 Y2), (X3 Y3) ... (Xn Yn)

The index position of the first ordered pair that causes the Condition function to evaluate to true() is returned as the result of altova:find-first-pair-pos. Note that if the Condition function iterates through the submitted argument pairs and does not once evaluate to true(), then altova:find-first-pair-pos returns No results.

Examples

- altova:find-first-pair-pos(11 to 20, 21 to 30, function($a, $b) {$a+$b = 32}) returns 1
- altova:find-first-pair-pos(11 to 20, 21 to 30, function($a, $b) {$a+$b = 33}) returns No results
returns *No results*

Notice from the two examples above that the ordering of the pairs is: (11, 21) (12, 22) (13, 23) ... (20, 30). In the first example, the first pair causes the condition function to evaluate to `true()`, and so its index position in the sequence, 1, is returned. The second example returns *No results* because no pair gives a sum of 33.

### `find-first-pos [altova:]`

```
altova:find-first-pos((Sequence as item())*), (Condition( Sequence-Item as xs:boolean))
as xs:integer
```

This function takes two arguments. The first argument is a sequence of one or more items of any datatype. The second argument, `Condition`, is a reference to an XPath function that takes one argument (has an arity of 1) and returns a boolean. Each item of `Sequence` is submitted, in turn, to the function referenced in `Condition`. *(Remember: This function takes a single argument.)* The first `Sequence` item that causes the function in `Condition` to evaluate to `true()` has its index position in `Sequence` returned as the result of `altova:find-first-pos`, and the iteration stops.

### Examples

- `altova:find-first-pos(5 to 10, function($a) {$a mod 2 = 0}) returns xs:integer 2`

  The `Condition` argument references the XPath 3.0 inline function, `function()`, which declares an inline function named `$a` and then defines it. Each item in the `Sequence` argument of `altova:find-first-pos` is passed, in turn, to `$a` as its input value. The input value is tested on the condition in the function definition (`$a mod 2 = 0`). The index position in the sequence of the first input value to satisfy this condition is returned as the result of `altova:find-first-pos` (in this case 2, since 6, the first value in the sequence) to satisfy the condition, is at index position 2 in the sequence).

- `altova:find-first-pos((2 to 10), (function($a) {$a+3=7})) returns xs:integer 3`

### Further examples

If the file `C:\Temp\Customers.xml` exists:

- `altova:find-first-pos("C:\Temp\Customers.xml", 
  "http://www.altova.com/index.html"), (doc-available#1) returns 1`

If the file `C:\Temp\Customers.xml` does not exist, and `http://www.altova.com/index.html` exists:

- `altova:find-first-pos("C:\Temp\Customers.xml", 
  "http://www.altova.com/index.html"), (doc-available#1) returns 2`

If the file `C:\Temp\Customers.xml` does not exist, and `http://www.altova.com/index.html` also does not exist:

- `altova:find-first-pos("C:\Temp\Customers.xml", 
  "http://www.altova.com/index.html"), (doc-available#1) returns no result`

**Notes about the examples given above**
• The XPath 3.0 function, `doc-available`, takes a single string argument, which is used as a URI, and returns `true` if a document node is found at the submitted URI. (The document at the submitted URI must therefore be an XML document.)

• The `doc-available` function can be used for `Condition`, the second argument of `altova:find-first-pos`, because it takes only one argument (arity=1), because it takes an `item()` as input (a string which is used as a URI), and returns a boolean value.

• Notice that the `doc-available` function is only referenced, not called. The `#1` suffix that is attached to it indicates a function with an arity of 1. In its entirety `doc-available#1` simply means: Use the `doc-available()` function that has arity=1, passing to it as its single argument, in turn, each of the items in the first sequence. As a result, each of the two strings will be passed to `doc-available()`, which uses the string as a URI and tests whether a document node exists at the URI. If one does, the `doc-available()` function evaluates to `true()` and the index position of that string in the sequence is returned as the result of the `altova:find-first-pos` function. Note about the `doc-available()` function: Relative paths are resolved relative to the the current base URI, which is by default the URI of the XML document from which the function is loaded.

▼ `for-each-attribute-pair` [altova:]

```xml
altova:for-each-attribute-pair(Seq1 as element()?, Seq2 as element()?, Function as function()) as item()*
```

The first two arguments identify two elements, the attributes of which are used to build attribute pairs, where one attribute of a pair is obtained from the first element and the other attribute is obtained from the second element. Attribute pairs are selected on the basis of having the same name, and the pairs are ordered alphabetically (on their names) into a set. If, for one attribute no corresponding attribute on the other element exists, then the pair is "disjoint", meaning that it consists of one member only. The function item (third argument `Function`) is applied separately to each pair in the sequence of pairs (joint and disjoint), resulting in an output that is a sequence of items.

**Examples**

• `altova:for-each-attribute-pair(/Example/Test-A, /Example/Test-B, function($a, $b) {+$a+$b})` returns ...

  (2, 4, 6) if
  <Test-A att1="1" att2="2" att3="3" />
  <Test-B att1="1" att2="2" att3="3" />

  (2, 4, 6) if
  <Test-A att2="2" att1="1" att3="3" />
  <Test-B att3="3" att2="2" att1="1" />

  (2, 6) if
  <Test-A att4="4" att1="1" att3="3" />
  <Test-B att3="3" att2="2" att1="1" />

  **Note:** The result (2, 6) is obtained by way of the following action: (1+1, ()+2, 3+3, 4+()). If one of the operands is the empty sequence, as in the case of items 2 and 4, then the result of the addition is an empty sequence.

• `altova:for-each-attribute-pair(/Example/Test-A, /Example/Test-B, concat#2)` returns
... (11, 22, 33) if
<Test-A att1="1" att2="2" att3="3" />
<Test-B att1="1" att2="2" att3="3" />

(11, 2, 33, 4) if
<Test-A att4="4" att1="1" att3="3" />
<Test-B att3="3" att2="2" att1="1" />

\[\text{for-each-combination} \] [altova:]
\begin{verbatim}
altova:for-each-combination(FirstSequence as item(), SecondSequence as item(),
Function($i,$j)({$i || $j}) as item()* \text{XP3.1 XQ3.1}
\end{verbatim}

The items of the two sequences in the first two arguments are combined so that each item of the first
sequence is combined, in order, once with each item of the second sequence. The function given as the
third argument is applied to each combination in the resulting sequence, resulting in an output that is a
sequence of items (\textit{see example}).

\begin{itemize}
\item \textit{altova:for-each-combination} ( ('a', 'b', 'c'), ('1', '2', '3'), function($i, $j) 
{si || $j} ) returns ('a1', 'a2', 'a3', 'b1', 'b2', 'b3', 'c1', 'c2', 'c3')
\end{itemize}

\[\text{for-each-matching-attribute-pair} \] [altova:]
\begin{verbatim}
altova:for-each-matching-attribute-pair(Seq1 as element()?, Seq2 as element()?,
Function as function()) as item()* \text{XP3.1 XQ3.1}
\end{verbatim}

The first two arguments identify two elements, the attributes of which are used to build attribute pairs,
where one attribute of a pair is obtained from the first element and the other attribute is obtained from
the second element. Attribute pairs are selected on the basis of having the same name, and the pairs are
ordered alphabetically (on their names) into a set. If, for one attribute no corresponding attribute on the
other element exists, then no pair is built. The function item (third argument \textit{Function}) is applied
separately to each pair in the sequence of pairs, resulting in an output that is a sequence of items.

\begin{itemize}
\item \textit{altova:for-each-matching-attribute-pair} (/Example/Test-A, /Example/Test-B,
function($a, $b)($a+$b)) returns ...
\end{itemize}
• **altova:for-each-matching-attribute-pair** (/Example/Test-A, /Example/Test-B, concat#2) returns ...

   (11, 22, 33) if
   <Test-A att1="1" att2="2" att3="3" />
   <Test-B att1="1" att2="2" att3="3" />

   (11, 33) if
   <Test-A att4="4" att1="1" att3="3" />
   <Test-B att3="3" att2="2" att1="1" />

▼ **substitute-empty** [altova:]

   **altova:substitute-empty** (FirstSequence as item()*, SecondSequence as item()) as item()*

   **XP3.1**  **XQ3.1**
   If FirstSequence is empty, returns SecondSequence. If FirstSequence is not empty, returns FirstSequence.
   **Examples**

   • **altova:substitute-empty** ( (1,2,3), (4,5,6) ) returns (1,2,3)
   • **altova:substitute-empty** ( (), (4,5,6) ) returns (4,5,6)

### 18.2.1.8 XPath/XQuery Functions: String

Altova's string extension functions can be used in XPath and XQuery expressions and provide additional functionality for the processing of data. The functions in this section can be used with Altova's **XPath 3.0** and **XQuery 3.0** engines. They are available in XPath/XQuery contexts.

**Note about naming of functions and language applicability**

Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the **Altova extension functions namespace**, [http://www.altova.com/xslt-extensions](http://www.altova.com/xslt-extensions), and are indicated in this section with the prefix **altova:**, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

</tbody>
</table>

▼ **camel-case** [altova:]

   **altova:camel-case** (InputString as xs:string) as xs:string **XP3.1** **XQ3.1**
Returns the input string \texttt{InputString} in CamelCase. The string is analyzed using the regular expression `\s` (which is a shortcut for the whitespace character). The first non-whitespace character after a whitespace or sequence of consecutive whitespaces is capitalized. The first character in the output string is capitalized.

\textbf{Examples}

- \texttt{altova:camel-case("max") returns Max}
- \texttt{altova:camel-case("max max") returns Max Max}
- \texttt{altova:camel-case("file01.xml") returns File01.xml}
- \texttt{altova:camel-case("file01.xml file02.xml") returns File01.xml File02.xml}
- \texttt{altova:camel-case("file01.xml file02.xml") returns File01.xml File02.xml}
- \texttt{altova:camel-case("file01.xml -file02.xml") returns File01.xml -file02.xml}

\texttt{altova:camel-case(InputString as xs:string, SplitChars as xs:string, IsRegex as xs:boolean) as xs:string XP3.1 XQ3.1}

Converts the input string \texttt{InputString} to camel case by using \texttt{SplitChars} to determine the character/s that trigger the next capitalization. \texttt{SplitChars} is used as a regular expression when \texttt{IsRegex = true()}, or as plain characters when \texttt{IsRegex = false()}. The first character in the output string is capitalized.

\textbf{Examples}

- \texttt{altova:camel-case("setname getname", "set|get", true()) returns setName getName}
- \texttt{altova:camel-case("altova\documents\testcases", "\", false()) returns Altova\Documents\Testcases}

\texttt{char [altova:]}

\texttt{altova:char(Position as xs:integer) as xs:string XP3.1 XQ3.1}

Returns a string containing the character at the position specified by the \texttt{Position} argument, in the string obtained by converting the value of the context item to \texttt{xs:string}. The result string will be empty if no character exists at the index submitted by the \texttt{Position} argument.

\textbf{Examples}

If the context item is 1234ABCD:

- \texttt{altova:char(2) returns 2}
- \texttt{altova:char(5) returns A}
- \texttt{altova:char(9) returns the empty string.}
- \texttt{altova:char(-2) returns the empty string.}

\texttt{altova:char(InputString as xs:string, Position as xs:integer) as xs:string XP3.1 XQ3.1}

Returns a string containing the character at the position specified by the \texttt{Position} argument, in the string submitted as the \texttt{InputString} argument. The result string will be empty if no character exists at the index submitted by the \texttt{Position} argument.

\textbf{Examples}

- \texttt{altova:char("2014-01-15", 5) returns -}
- \texttt{altova:char("USA", 1) returns U}
- \texttt{altova:char("USA", 10) returns the empty string.}
- \texttt{altova:char("USA", -2) returns the empty string.}
create-hash-from-string[altova:]

altova:create-hash-from-string(InputString as xs:string) as xs:string

Generates a hash string from InputString by using the hashing algorithm specified by the HashAlgo argument. The following hashing algorithms may be specified (in upper or lower case): MD5, SHA-1, SHA-224, SHA-256, SHA-384, SHA-512. If the second argument is not specified (see the first signature above), then the SHA-256 hashing algorithm is used.

Examples

- altova:create-hash-from-string('abc') returns a hash string generated by using the SHA-256 hashing algorithm.
- altova:create-hash-from-string('abc', 'md5') returns a hash string generated by using the MD5 hashing algorithm.
- altova:create-hash-from-string('abc', 'MD5') returns a hash string generated by using the MD5 hashing algorithm.

first-chars [altova:]

altova:first-chars(X-Number as xs:integer) as xs:string

Returns a string containing the first X-Number of characters of the string obtained by converting the value of the context item to xs:string.

Examples

- If the context item is 1234ABCD:
  - altova:first-chars(2) returns 12
  - altova:first-chars(5) returns 1234A
  - altova:first-chars(9) returns 1234ABCD

altova:first-chars(InputString as xs:string, X-Number as xs:integer) as xs:string

Returns a string containing the first X-Number of characters of the string submitted as the InputString argument.

Examples

- altova:first-chars("2014-01-15", 5) returns 2014-
- altova:first-chars("USA", 1) returns U

format-string [altova:]

altova:format-string(InputString as xs:string, FormatSequence as item()) as xs:string

The input string (first argument) contains positional parameters (%1, %2, etc). Each parameter is replaced by the string item that is located at the corresponding position in the format sequence (submitted as the second argument). So the first item in the format sequence replaces the positional parameter %1, the second item replaces %2, and so on. The function returns this formatted string that contains the replacements. If no string exists for a positional parameter, then the positional parameter itself is returned. This happens when the index of a positional parameter is greater than the number of items in the format sequence.
Examples

- `altova:format-string('Hello %1, %2, %3', ('Jane', 'John', 'Joe'))` returns "Hello Jane, John, Joe"
- `altova:format-string('Hello %1, %2, %3', ('Jane', 'John', 'Joe', 'Tom'))` returns "Hello Jane, John, Tom"
- `altova:format-string('Hello %1, %2, %4', ('Jane', 'John', 'Joe'))` returns "Hello Jane, John, %4"

last-chars [altova:]

### `altova:last-chars(X-Number as xs:integer) as xs:string XP3.1 XQ3.1`

Returns a string containing the last X-Number of characters of the string obtained by converting the value of the context item to xs:string.

**Examples**

- `altova:last-chars(2)` returns CD
- `altova:last-chars(5)` returns 4ABCD
- `altova:last-chars(9)` returns 1234ABCD

### `altova:last-chars(InputString as xs:string, X-Number as xs:integer) as xs:string XP3.1 XQ3.1`

Returns a string containing the last X-Number of characters of the string submitted as the InputString argument.

**Examples**

- `altova:last-chars("2014-01-15", 5)` returns 01-15
- `altova:last-chars("USA", 10)` returns USA

pad-string-left [altova:]

### `altova:pad-string-left(StringToPad as xs:string, StringLength as xs:integer, PadCharacter as xs:string) as xs:string XP3.1 XQ3.1`

The PadCharacter argument is a single character. It is padded to the left of the string to increase the number of characters in StringToPad so that this number equals the integer value of the StringLength argument. The StringLength argument can have any integer value (positive or negative), but padding will occur only if the value of StringLength is greater than the number of characters in StringToPad. If StringToPad has more characters than the value of StringLength, then StringToPad is left unchanged.

**Examples**

- `altova:pad-string-left('AP', 1, 'Z')` returns 'AP'
- `altova:pad-string-left('AP', 2, 'Z')` returns 'AP'
- `altova:pad-string-left('AP', 3, 'Z')` returns 'ZAP'
- `altova:pad-string-left('AP', 4, 'Z')` returns 'ZZAP'
- `altova:pad-string-left('AP', -3, 'Z')` returns 'AP'
- `altova:pad-string-left('AP', 3, 'YZ')` returns a pad-character-too-long error
pad-string-right [altova:]

```
altova:pad-string-right(StringToPad as xs:string, StringLength as xs:integer, PadCharacter as xs:string) as xs:string
```

The PadCharacter argument is a single character. It is padded to the right of the string to increase the number of characters in StringToPad so that this number equals the integer value of the StringLength argument. The StringLength argument can have any integer value (positive or negative), but padding will occur only if the value of StringLength is greater than the number of characters in StringToPad. If StringToPad has more characters than the value of StringLength, then StringToPad is left unchanged.

**Examples**

- `altova:pad-string-right('AP', 1, 'Z')` returns `'AP`
- `altova:pad-string-right('AP', 2, 'Z')` returns `'AP`
- `altova:pad-string-right('AP', 3, 'Z')` returns `'APZ`
- `altova:pad-string-right('AP', 4, 'Z')` returns `'APZZ`
- `altova:pad-string-right('AP', -3, 'Z')` returns `'AP`
- `altova:pad-string-right('AP', 3, 'YZ')` returns a pad-character-too-long error

repeat-string [altova:]

```
altova:repeat-string(InputString as xs:string, Repeats as xs:integer) as xs:string
```

Generates a string that is composed of the first InputString argument repeated Repeats number of times.

**Examples**

- `altova:repeat-string("Altova #", 3)` returns "Altova #Altova #Altova #"

substring-after-last [altova:]

```
altova:substring-after-last(MainString as xs:string, CheckString as xs:string) as xs:string
```

If CheckString is found in MainString, then the substring that occurs after CheckString in MainString is returned. If CheckString is not found in MainString, then the empty string is returned. If CheckString is an empty string, then MainString is returned in its entirety. If there is more than one occurrence of CheckString in MainString, then the substring after the last occurrence of CheckString is returned.

**Examples**

- `altova:substring-after-last('ABCDEFGH', 'B')` returns 'CDEFGH'
- `altova:substring-after-last('ABCDEFGH', 'BC')` returns 'DEFGH'
- `altova:substring-after-last('ABCDEFGH', 'BD')` returns ''
- `altova:substring-after-last('ABCDEFGH', 'Z')` returns ''
- `altova:substring-after-last('ABCDEFGH', '')` returns 'ABCDEFGH'
- `altova:substring-after-last('ABCD-ABCD', 'B')` returns 'CD'
- `altova:substring-after-last('ABCD-ABCD-ABCD', 'BCD')` returns ''

substring-before-last [altova:]

```
altova:substring-before-last(MainString as xs:string, CheckString as xs:string) as xs:string
```

If CheckString is found in MainString, then the substring that occurs before CheckString in MainString is returned. If CheckString is not found in MainString, then the empty string is returned. If CheckString is an empty string, then MainString is returned in its entirety. If there is more than one occurrence of CheckString in MainString, then the substring before the last occurrence of CheckString is returned.

**Examples**

- `altova:substring-before-last('ABCDEFGH', 'B')` returns 'ABCDEF'
- `altova:substring-before-last('ABCDEFGH', 'BC')` returns 'ABCD'
- `altova:substring-before-last('ABCDEFGH', '')` returns 'ABCDEFGH'
- `altova:substring-before-last('ABCD-ABCD', 'B')` returns 'CD'
- `altova:substring-before-last('ABCD-ABCD-ABCD', 'BCD')` returns 'ABCD-ABCD-ABCD'

substring-before-first [altova:]

```
altova:substring-before-first(MainString as xs:string, CheckString as xs:string) as xs:string
```

If CheckString is found in MainString, then the substring that occurs before CheckString in MainString is returned. If CheckString is not found in MainString, then the empty string is returned. If CheckString is an empty string, then MainString is returned in its entirety. If there is more than one occurrence of CheckString in MainString, then the substring before the first occurrence of CheckString is returned.

**Examples**

- `altova:substring-before-first('ABCDEFGH', 'B')` returns 'ABC'
- `altova:substring-before-first('ABCDEFGH', 'BC')` returns 'ABCDEFGH'
- `altova:substring-before-first('ABCDEFGH', '')` returns 'ABCDEFGH'
- `altova:substring-before-first('ABCD-ABCD', 'B')` returns 'CD'
- `altova:substring-before-first('ABCD-ABCD-ABCD', 'BCD')` returns 'ABCD-ABCD'
xs:string  XP3.1  XQ3.1
If CheckString is found in MainString, then the substring that occurs before CheckString in MainString is returned. If CheckString is not found in MainString, or if CheckString is an empty string, then the empty string is returned. If there is more than one occurrence of CheckString in MainString, then the substring before the last occurrence of CheckString is returned.

Examples
- `altova:substring-before-last('ABCDEFGH', 'B')` returns 'A'
- `altova:substring-before-last('ABCDEFGH', 'BC')` returns 'A'
- `altova:substring-before-last('ABCDEFGH', 'BD')` returns ''
- `altova:substring-before-last('ABCDEFGH', 'Z')` returns ''
- `altova:substring-before-last('ABCDEFGH', '')` returns ''
- `altova:substring-before-last('ABCD-ABCD', 'B')` returns 'ABCD-A'
- `altova:substring-before-last('ABCD-ABCD-ABCD', 'ABCD')` returns 'ABCD-ABCD-'

substring-pos [altova:]

`altova:substring-pos(StringToCheck as xs:string, StringToFind as xs:string) as xs:integer`  XP3.1  XQ3.1
Returns the character position of the first occurrence of StringToFind in the string StringToCheck. The character position is returned as an integer. The first character of StringToCheck has the position 1. If StringToFind does not occur within StringToCheck, the integer 0 is returned. To check for the second or a later occurrence of StringToCheck, use the next signature of this function.

Examples
- `altova:substring-pos('Altova', 'to')` returns 3
- `altova:substring-pos('Altova', 'tov')` returns 3
- `altova:substring-pos('Altova', 'tv')` returns 0
- `altova:substring-pos('AltovaAltova', 'to')` returns 3
- `altova:substring-pos('Altova-Altova', 'to', 0)` returns 3
- `altova:substring-pos('Altova-Altova', 'to', 4)` returns 10

trim-string [altova:]

`altova:trim-string(InputString as xs:string) as xs:string`  XP3.1  XQ3.1
This function takes an xs:string argument, removes any leading and trailing whitespace, and returns a
"trimmed" xs:string.

Examples
- altova:trim-string("Hello World ") returns "Hello World"
- altova:trim-string("Hello World ") returns "Hello World"
- altova:trim-string("Hello World") returns "Hello World"
- altova:trim-string("Hello World") returns "Hello World"
- altova:trim-string("Hello World") returns "Hello World"

trim-string-left [altova:]

altova:trim-string-left(InputString as xs:string) as xs:string XP3.1 XQ3.1
This function takes an xs:string argument, removes any leading whitespace, and returns a left-trimmed xs:string.

Examples
- altova:trim-string-left(" Hello World ") returns "Hello World 
- altova:trim-string-left("Hello World ") returns "Hello World 
- altova:trim-string-left(" Hello World") returns "Hello World"
- altova:trim-string-left("Hello World") returns "Hello World"
- altova:trim-string-left("Hello World") returns "Hello World"

trim-string-right [altova:]

altova:trim-string-right(InputString as xs:string) as xs:string XP3.1 XQ3.1
This function takes an xs:string argument, removes any trailing whitespace, and returns a right-trimmed xs:string.

Examples
- altova:trim-string-right(" Hello World ") returns " Hello World"
- altova:trim-string-right("Hello World ") returns "Hello World"
- altova:trim-string-right(" Hello World") returns " Hello World"
- altova:trim-string-right("Hello World") returns "Hello World"
- altova:trim-string-right("Hello World") returns "Hello World"

18.2.1.9 XPath/XQuery Functions: Miscellaneous

The following general purpose XPath/XQuery extension functions are supported in the current version of StyleVision and can be used in (i) XPath expressions in an XSLT context, or (ii) XQuery expressions in an XQuery document.

Note about naming of functions and language applicability
Altova extension functions can be used in XPath/XQuery expressions. They provide additional functionality to the functionality that is available in the standard library of XPath, XQuery, and XSLT functions. Altova extension functions are in the Altova extension functions namespace, http://www.altova.com/xslt-
extensions, and are indicated in this section with the prefix altova:, which is assumed to be bound to this namespace. Note that, in future versions of your product, support for a function might be discontinued or the behavior of individual functions might change. Consult the documentation of future releases for information about support for Altova extension functions in that release.

### XPath functions (used in XPath expressions in XSLT):

---

**decode-string [altova:]**

altova:decode-string(Input as xs:base64Binary) as xs:string XP3.1 XQ3.1

altova:decode-string(Input as xs:base64Binary, Encoding as xs:string) as xs:string XP3.1 XQ3.1

Decodes the submitted base64Binary input to a string using the specified encoding. If no encoding is specified, then the UTF-8 encoding is used. The following encodings are supported: US-ASCII, ISO-8859-1, UTF-16, UTF-16LE, UTF-16BE, ISO-10646-UCS2, UTF-32, UTF-32LE, UTF-32BE, ISO-10646-UCS4

**Examples**

- altova:decode-string($XML1/MailData/Meta/b64B) returns the base64Binary input as a UTF-8 encoded string
- altova:decode-string($XML1/MailData/Meta/b64B, "UTF-8") returns the base64Binary input as a UTF-8-encoded string
- altova:decode-string($XML1/MailData/Meta/b64B, "ISO-8859-1") returns the base64Binary input as an ISO-8859-1-encoded string

**encode-string [altova:]**

altova:encode-string(InputString as xs:string) as xs:base64BinaryInteger XP3.1 XQ3.1

altova:encode-string(InputString as xs:string, Encoding as xs:string) as xs:base64BinaryInteger XP3.1 XQ3.1

Encodes the submitted string using, if one is given, the specified encoding. If no encoding is given, then the UTF-8 encoding is used. The encoded string is converted to base64Binary characters, and the converted base64Binary value is returned. Initially, UTF-8 encoding is supported, and support will be extended to the following encodings: US-ASCII, ISO-8859-1, UTF-16, UTF-16LE, UTF-16BE, ISO-10646-UCS2, UTF-32, UTF-32LE, UTF-32BE, ISO-10646-UCS4

**Examples**

- altova:encode-string("Altova") returns the base64Binary equivalent of the UTF-8 encoded string "Altova"
- altova:encode-string("Altova", "UTF-8") returns the base64Binary equivalent of the UTF-8 encoded string "Altova"

**get-temp-folder [altova:]**

altova:get-temp-folder() as xs:string XP2 XQ1 XP3.1 XQ3.1
This function takes no argument. It returns the path to the temporary folder of the current user.

**Examples**

- `altova:get-temp-folder()` would return, on a Windows machine, something like `C:\Users\<UserName>\AppData\Local\Temp\` as an `xs:string`.

### generate-guid [altova:]

`altova:generate-guid()` as `xs:string`  
Generates a unique string GUID string.

**Examples**

- `altova:generate-guid()` returns (for example) `85F971DA-17F3-4E4E-994E-99137873ACCD`

### high-res-timer [altova:]

`altova:high-res-timer()` as `xs:double`  
Returns a system high-resolution timer value in seconds. A high-resolution timer, when present on a system, enables high precision time measurements when these are required (for example, in animations and for determining precise code-execution time). This function provides the resolution of the system's high-res timer.

**Examples**

- `altova:high-res-timer()` returns something like `'1.16766146154566E6'`

### parse-html [altova:]

`altova:parse-html(HTMLText as xs:string)` as `node()`  
The `HTMLText` argument is a string that contains the text of an HTML document. The function creates an HTML tree from the string. The submitted string may or may not contain the HTML element. In either case, the root element of the tree is an element named `HTML`. It is best to make sure that the HTML code in the submitted string is valid HTML.

**Examples**

- `altova:parse-html("<html><head/><body><h1>Header</h1></body></html>")` creates an HTML tree from the submitted string

### sleep[altova:]

`altova:sleep(Millisecs as xs:integer)` as `empty-sequence()`  
Suspends execution of the current operation for the number of milliseconds given by the `Millisecs` argument.

**Examples**

- `altova:sleep(1000)` suspends execution of the current operation for 1000 milliseconds.
18.2.1.10 Barcode Functions

The XSLT Engine uses third-party Java libraries to create barcodes. Given below are the classes and the public methods used. The classes are packaged in AltovaBarcodeExtension.jar, which is located in the folder `<ProgramFilesFolder>\Altova\Common2022\jar`.

The Java libraries used are in sub-folders of the folder `<ProgramFilesFolder>\Altova\Common2022\jar`:

- barcode4j\barcode4j.jar (Website: http://barcode4j.sourceforge.net/)
- zxing\core.jar (Website: http://code.google.com/p/zxing/)

The license files are also located in the respective folders.

Java virtual machine

In order to be able to use the barcode functions, a Java virtual machine must be available on your machine and it must match the bit version of the Altova application (32-bit or 64-bit). The path to the machine is found as noted below.

- If you are using an Altova desktop product, the Altova application attempts to detect the path to the Java virtual machine automatically, by reading (in this order): (i) the Windows registry, and (ii) the `JAVA_HOME` environment variable. You can also add a custom path in the Options dialog of the application; this entry will take priority over any other Java VM path detected automatically.
- If you are running an Altova server product on a Windows machine, the path to the Java virtual machine will be read first from the Windows registry; if this is not successful the `JAVA_HOME` environment variable will be used.
- If you are running an Altova server product on a Linux or macOS machine, then make sure that the `JAVA_HOME` environment variable is properly set and that the Java Virtual Machines library (on Windows, the `jvm.dll` file) can be located in either the `\bin\server` or `\bin\client` directory.

XSLT example to generate barcode

Given below is an XSLT example showing how barcode functions are used in an XSLT stylesheet.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:altova="http://www.altova.com"
    xmlns:altovaext="http://www.altova.com/xslt-extensions"
    xmlns:altovaext-barcode="java:com.altova.extensions.barcode.BarcodeWrapper"
    <xsl:output method="html" encoding="UTF-8" indent="yes"/>
    <html>
        <head><title/></head>
        <body>
            <img alt="barcode" src="data:image/png;base64"/>
        </body>
    </html>
</xsl:stylesheet>
```
XSLT and XPath/XQuery Functions

Appendices

XQuery example to generate QR code

Given below is an XQuery example showing how barcode functions can be used to generate a QR code image.

```xquery
declare variable $lines := unparsed-text-lines('https://info.healthministry.gov.at/data/timeline-cases-provinces.csv', 'utf-8');
declare variable $main := map:merge(tokenize(head($lines), ';')!map{:.:position()});
declare variable $data := map:merge(tail($lines)!array(tokenize(., ';'))!map{?($main?Date), xs:integer(?($main?ConfirmedCasesProvinces)) - xs:integer(?($main?Recovered))});
declare variable $chart_img := altovaext:chart(map{'width': 1900, 'height': 600}, map:for-each($data, function($k, $v){[$k, $v?1!substring-before(., 'T'), $v?2[$k != 'Austria']]})
<img src="data:image/png;base64,{$chart_img}"/>
```

The `com.altova.extensions.barcode` package

The package, `com.altova.extensions.barcode`, is used to generate most of the barcode types.

The following classes are used:

public class BarcodeWrapper

  static BarcodeWrapper newInstance( String name, String msg, int dpi, int orientation, BarcodePropertyWrapper[] arrProperties )
  double getHeightPlusQuiet()
  double getWidthPlusQuiet()
  org.w3c.dom.Document generateBarcodeSVG()
  byte[] generateBarcodePNG()
  String generateBarcodePngAsHexString()

public class BarcodePropertyWrapper

  Used to store the barcode properties that will be dynamically set later

  BarcodePropertyWrapper( String methodName, String propertyValue )
  BarcodePropertyWrapper( String methodName, Integer propertyValue )
  BarcodePropertyWrapper( String methodName, Double propertyValue )
  BarcodePropertyWrapper( String methodName, Boolean propertyValue )
  BarcodePropertyWrapper( String methodName, Character propertyValue )
  String getName()
  Object getProperty()
public class AltovaBarcodeClassResolver Registers the class
com.altova.extensions.barcode.proxy.zxing.QRCodeBean for the qrcode bean, additionally to the classes
registered by the org.krysalis.barcode4j.DefaultBarcodeClassResolver.

The com.altova.extensions.barcode.proxy.zxing package

The package, com.altova.extensions.barcode.proxy.zxing, is used to generate the QRCode barcode
type.

The following classes are used:

class QRCodeBean

- extends org.krysalis.barcode4j.impl.AbstractBarcodeBean
- creates an AbstractBarcodeBean interface for com.google.zxing.qrcode.encoder

void generateBarcode(CanvasProvider canvasImp, String msg)
void setQRErrorCorrectionLevel(QRCodeErrorCorrectionLevel level)
BarcodeDimension calcDimensions(String msg)
double getVerticalQuietZone()
double getBarWidth()

class QRCodeErrorCorrectionLevel Error correction level for the QRCode
static QRCodeErrorCorrectionLevel byName(String name)
"L" = ~7% correction
"M" = ~15% correction
"H" = ~25% correction
"Q" = ~30% correction

18.2.2 Miscellaneous Extension Functions

There are several ready-made functions in programming languages such as Java and C# that are not available
as XQuery/XPath functions or as XSLT functions. A good example would be the math functions available in
Java, such as sin() and cos(). If these functions were available to the designers of XSLT stylesheets and
XQuery queries, it would increase the application area of stylesheets and queries and greatly simplify the tasks
of stylesheet creators. The XSLT and XQuery engines used in a number of Altova products support the use of
extension functions in Java\footnote{Java Extension Functions} and .NET\footnote{.NET Extension Functions}, as well as MSXSL scripts for XSLT\footnote{MSXSL Scripts for XSLT}. This section describes
how to use extension functions and MSXSL scripts in your XSLT stylesheets. The available extension functions
are organized into the following sections:

- Java Extension Functions\footnote{Java Extension Functions}
- .NET Extension Functions\footnote{.NET Extension Functions}
- MSXSL Scripts for XSLT\footnote{MSXSL Scripts for XSLT}

The two main issues considered in the descriptions are: (i) how functions in the respective libraries are called;
and (ii) what rules are followed for converting arguments in a function call to the required input format of the
function, and what rules are followed for the return conversion (function result to XSLT/XQuery data object).
Requirements

For extension functions support, a Java Runtime Environment (for access to Java functions) and .NET Framework 2.0 (minimum, for access to .NET functions) must be installed on the machine running the XSLT transformation or XQuery execution, or must be accessible for the transformations.

18.2.2.1 Java Extension Functions

A Java extension function can be used within an XPath or XQuery expression to invoke a Java constructor or call a Java method (static or instance).

A field in a Java class is considered to be a method without any argument. A field can be static or instance. How to access fields is described in the respective sub-sections, static and instance.

This section is organized into the following sub-sections:

- Java: Constructors
- Java: Static Methods and Static Fields
- Java: Instance Methods and Instance Fields
- Datatypes: XPath/XQuery to Java
- Datatypes: Java to XPath/XQuery

Note the following

- If you are using an Altova desktop product, the Altova application attempts to detect the path to the Java virtual machine automatically, by reading (in this order): (i) the Windows registry, and (ii) the \JAVA_HOME\ environment variable. You can also add a custom path in the Options dialog of the application; this entry will take priority over any other Java VM path detected automatically.
- If you are running an Altova server product on a Windows machine, the path to the Java virtual machine will be read first from the Windows registry; if this is not successful the JAVA_HOME environment variable will be used.
- If you are running an Altova server product on a Linux or macOS machine, then make sure that the JAVA_HOME environment variable is properly set and that the Java Virtual Machines library (on Windows, the jvm.dll file) can be located in either the \bin\server or \bin\client directory.

Form of the extension function

The extension function in the XPath/XQuery expression must have the form prefix:fname().

- The prefix: part identifies the extension function as a Java function. It does so by associating the extension function with an in-scope namespace declaration, the URI of which must begin with java: (see below for examples). The namespace declaration should identify a Java class, for example:
  xmlns:myNs="java:java.lang.Math". However, it could also simply be:
  xmlns:myNs="java" (without a colon), with the identification of the Java class being left to the fname() part of the extension function.
- The fname() part identifies the Java method being called, and supplies the arguments for the method (see below for examples). However, if the namespace URI identified by the prefix: part does not identify a Java class (see preceding point), then the Java class should be identified in the fname() part, before the class and separated from the class by a period (see the second XSLT example below).
Note: The class being called must be on the classpath of the machine.

XSLT example

Here are two examples of how a static method can be called. In the first example, the class name (java.lang.Math) is included in the namespace URI and, therefore, must not be in the fname() part. In the second example, the prefix: part supplies the prefix java: while the fname() part identifies the class as well as the method.

```xml
              select="jMath:cos(3.14)" />

<xsl:value-of xmlns:jmath="java"
              select="jmath:java.lang.Math.cos(3.14)" />
```

The method named in the extension function (cos() in the example above) must match the name of a public static method in the named Java class (java.lang.Math in the example above).

XQuery example

Here is an XQuery example similar to the XSLT example above:

```xml
<cosine xmlns:jMath="java:java.lang.Math">
  {jMath:cos(3.14)}
</cosine>
```

User-defined Java classes

If you have created your own Java classes, methods in these classes are called differently according to: (i) whether the classes are accessed via a JAR file or a class file, and (ii) whether these files (JAR or class) are located in the current directory (the same directory as the XSLT or XQuery document) or not. How to locate these files is described in the sections User-Defined Class Files and User-Defined Jar Files. Note that paths to class files not in the current directory and to all JAR files must be specified.

Note: If you wish to add a namespace to an XSLT stylesheet being generated from an SPS created in StyleVision, the namespace must be added to the top-level schema element of the XML Schema on which the SPS is based. Note that the following namespace declaration xmlns:java="java" is created automatically by default in every SPS created in StyleVision.

18.2.2.1.1 User-Defined Class Files

If access is via a class file, then there are four possibilities:

- The class file is in a package. The XSLT or XQuery file is in the same folder as the Java package. (See example below.)
- The class file is not packaged. The XSLT or XQuery file is in the same folder as the class file. (See example below.)
- The class file is in a package. The XSLT or XQuery file is at some random location. (See example below.)
The class file is not packaged. The XSLT or XQuery file is at some random location. (See example below.)

Consider the case where the class file is not packaged and is in the same folder as the XSLT or XQuery document. In this case, since all classes in the folder are found, the file location does not need to be specified. The syntax to identify a class is:

```
java:classname
```

where

- java: indicates that a user-defined Java function is being called; (Java classes in the current directory will be loaded by default)
- classname is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call.

### Class file packaged, XSLT/XQuery file in same folder as Java package

The example below calls the `getVehicleType()` method of the `Car` class of the `com.altova.extfunc` package. The `com.altova.extfunc` package is in the folder `JavaProject`. The XSLT file is also in the folder `JavaProject`.

```
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:car="java:com.altova.extfunc.Car" >
<xsl:output exclude-result-prefixes="fn car xsl fo xs"/>

<xsl:template match="/"
    <a>
        <xsl:value-of select="car:getVehicleType()"/>
    </a>
</xsl:template>
</xsl:stylesheet>
```

### Class file referenced, XSLT/XQuery file in same folder as class file

The example below calls the `getVehicleType()` method of the `Car` class. Let us say that: (i) the `Car` class file is in the following folder: `JavaProject/com/altova/extfunc`, and (ii) that this folder is the current folder in the example below. The XSLT file is also in the folder `JavaProject/com/altova/extfunc`.

```
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:car="java:Car" >
<xsl:output exclude-result-prefixes="fn car xsl fo xs"/>

<xsl:template match="/"
    <a>
</xsl:template>
</xsl:stylesheet>
```
Class file packaged, XSLT/XQuery file at any location

The example below calls the `getCarColor()` method of the `Car` class of the `com.altova.extfunc` package. The `com.altova.extfunc` package is in the folder `JavaProject`. The XSLT file is at any location. In this case, the location of the package must be specified within the URI as a query string. The syntax is:

```
java:classname[?path=uri-of-package]
```

where

- `java:` indicates that a user-defined Java function is being called
- `uri-of-package` is the URI of the Java package
- `classname` is the name of the required method's class

The class is identified in a namespace URI, and the namespace is used to prefix a method call. The example below shows how to access a class file that is located in another directory than the current directory.

```
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"

    <xsl:output exclude-result-prefixes="fn car xsl xs"/>

    <xsl:template match="/"
        >
        <xsl:variable name="myCar" select="car:new('red')" />
        <a><xsl:value-of select="car:getCarColor($myCar)" /></a>
    </xsl:template>

</xsl:stylesheet>
```

Class file referenced, XSLT/XQuery file at any location

The example below calls the `getCarColor()` method of the `Car` class. Let us say that the `Car` class file is in the folder `C:/JavaProject/com/altova/extfunc`, and the XSLT file is at any location. The location of the class file must then be specified within the namespace URI as a query string. The syntax is:

```
java:classname[?path=uri-of-classfile]
```

where

- `java:` indicates that a user-defined Java function is being called
- `uri-of-classfile` is the URI of the folder containing the class file
- `classname` is the name of the required method's class
The class is identified in a namespace URI, and the namespace is used to prefix a method call. The example below shows how to access a class file that is located in another directory than the current directory.

```xml
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:car="java:Car?path=file:///C:/JavaProject/com/altova/extfunc/" >

    <xsl:output exclude-result-prefixes="fn car xsl xs"/>

    <xsl:template match="/"
        <xsl:variable name="myCar" select="car:new('red')" />
        <a><xsl:value-of select="car:getCarColor($myCar)" /></a>
    </xsl:template>

</xsl:stylesheet>
```

**Note:** When a path is supplied via the extension function, the path is added to the ClassLoader.

### 18.2.2.1.2 User-Defined Jar Files

If access is via a JAR file, the URI of the JAR file must be specified using the following syntax:

```xml
xmlns:classNS="java:classname?path=jar:uri-of-jarfile!/
```

The method is then called by using the prefix of the namespace URI that identifies the class:

`classNS:method()`

**In the above:**

- `java:` indicates that a Java function is being called
- `classname` is the name of the user-defined class
- `?` is the separator between the classname and the path
- `path=jar:` indicates that a path to a JAR file is being given
- `uri-of-jarfile` is the URI of the jar file
- `!/` is the end delimiter of the path
- `classNS:method()` is the call to the method

Alternatively, the classname can be given with the method call. Here are two examples of the syntax:

```xml
xmlns:ns1="java:docx.layout.pages?
path=jar:file:///c:/projects/docs/docx.jar!/
ns1:main()
```

```xml
xmlns:ns2="java?path=jar:file:///c:/projects/docs/docx.jar!/
ns2:docx.layout.pages.main()
```

Here is a complete XSLT example that uses a JAR file to call a Java extension function:
<xsl:stylesheet version="2.0"
   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:fn="http://www.w3.org/2005/xpath-functions"
   xmlns:car="java?path=jar:file:///C:/test/Car1.jar!" >
<xsl:output exclude-result-prefixes="fn car xsl xs"/>
<xsl:template match="/"
   select="car:Car1.new('red')" />
<xsl:value-of select="car:Car1.getCarColor($myCar)"/>
</xsl:template>
</xsl:stylesheet>

Note: When a path is supplied via the extension function, the path is added to the ClassLoader.

18.2.2.1.3 Java: Constructors

An extension function can be used to call a Java constructor. All constructors are called with the pseudo-function new().

If the result of a Java constructor call can be implicitly converted to XPath/XQuery datatypes, then the Java extension function will return a sequence that is an XPath/XQuery datatype. If the result of a Java constructor call cannot be converted to a suitable XPath/XQuery datatype, then the constructor creates a wrapped Java object with a type that is the name of the class returning that Java object. For example, if a constructor for the class java.util.Date is called (java.util.Date.new()), then an object having a type java.util.Date is returned. The lexical format of the returned object may not match the lexical format of an XPath datatype and the value would therefore need to be converted to the lexical format of the required XPath datatype and then to the required XPath datatype.

There are two things that can be done with a Java object created by a constructor:

- It can be assigned to a variable:
  <xsl:variable name="currentdate" select="date:new()"
  xmlns:date="java:java.util.Date" />
- It can be passed to an extension function (see Instance Method and Instance Fields):
  <xsl:value-of select="date:toString(date:new())" xmlns:date="java:java.util.Date" />

18.2.2.1.4 Java: Static Methods and Static Fields

A static method is called directly by its Java name and by supplying the arguments for the method. Static fields (methods that take no arguments), such as the constant-value fields E and PI, are accessed without specifying any argument.
XSLT examples

Here are some examples of how static methods and fields can be called:

```xml
               select="jMath:cos(3.14)" />

               select="jMath:cos( jMath:PI() )" />

               select="jMath:E() * jMath:cos(3.14)" />
```

Notice that the extension functions above have the form prefix:fname(). The prefix in all three cases is jMath:, which is associated with the namespace URI java:java.lang.Math. (The namespace URI must begin with java:. In the examples above it is extended to contain the class name (java.lang.Math).) The fname() part of the extension functions must match the name of a public class (e.g. java.lang.Math) followed by the name of a public static method with its argument/s (such as cos(3.14)) or a public static field (such as PI()).

In the examples above, the class name has been included in the namespace URI. If it were not contained in the namespace URI, then it would have to be included in the fname() part of the extension function. For example:

```xml
<xsl:value-of xmlns:java="java:"
              select="java:java.lang.Math.cos(3.14)" />
```

XQuery example

A similar example in XQuery would be:

```xml
<cosine xmlns:jMath="java:java.lang.Math">
  {jMath:cos(3.14)}
</cosine>
```

18.2.2.1.5 Java: Instance Methods and Instance Fields

An instance method has a Java object passed to it as the first argument of the method call. Such a Java object typically would be created by using an extension function (for example a constructor call) or a stylesheet parameter/variable. An XSLT example of this kind would be:

```xml
<xsl:stylesheet version="1.0" exclude-result-prefixes="date"
                xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:date="java:java.util.Date"
                xmlns:jlang="java:java.lang">
  <xsl:param name="CurrentDate" select="date:new()"/>
  <xsl:template match="/">
    <enrollment institution-id="Altova School"
                 date="{date:toString($CurrentDate)}"
                 type="{jlang:Object.toString(jlang:Object.getClass( date:new() )))"/>
  </xsl:template>
</xsl:stylesheet>
```
In the example above, the value of the node `enrollment/@type` is created as follows:

1. An object is created with a constructor for the class `java.util.Date` (with the `date:new()` constructor).
2. This Java object is passed as the argument of the `jlang.Object.getClass` method.
3. The object obtained by the `getClass` method is passed as the argument to the `jlang.Object.toString` method.

The result (the value of `@type`) will be a string having the value: `java.util.Date`.

An instance field is theoretically different from an instance method in that it is not a Java object per se that is passed as an argument to the instance field. Instead, a parameter or variable is passed as the argument. However, the parameter/variable may itself contain the value returned by a Java object. For example, the parameter `CurrentDate` takes the value returned by a constructor for the class `java.util.Date`. This value is then passed as an argument to the instance method `date:toString` in order to supply the value of `/enrollment/@date`.

18.2.2.1.6 Datatypes: XPath/XQuery to Java

When a Java function is called from within an XPath/XQuery expression, the datatype of the function's arguments is important in determining which of multiple Java classes having the same name is called.

In Java, the following rules are followed:

- If there is more than one Java method with the same name, but each has a different number of arguments than the other/s, then the Java method that best matches the number of arguments in the function call is selected.
- The XPath/XQuery string, number, and boolean datatypes (see list below) are implicitly converted to a corresponding Java datatype. If the supplied XPath/XQuery type can be converted to more than one Java type (for example, `xs:integer`), then that Java type is selected which is declared for the selected method. For example, if the Java method being called is `fx(decimal)` and the supplied XPath/XQuery datatype is `xs:integer`, then `xs:integer` will be converted to Java's `decimal` datatype.

The table below lists the implicit conversions of XPath/XQuery string, number, and boolean types to Java datatypes.

<table>
<thead>
<tr>
<th>XPath/XQuery Type</th>
<th>Java Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xs:string</code></td>
<td><code>java.lang.String</code></td>
</tr>
<tr>
<td><code>xs:boolean</code></td>
<td><code>boolean (primitive), java.lang.Boolean</code></td>
</tr>
<tr>
<td><code>xs:integer</code></td>
<td><code>int, long, short, byte, float, double, and the wrapper classes of these, such as java.lang.Integer</code></td>
</tr>
<tr>
<td><code>xs:float</code></td>
<td><code>float (primitive), java.lang.Float, double (primitive)</code></td>
</tr>
<tr>
<td><code>xs:double</code></td>
<td><code>double (primitive), java.lang.Double</code></td>
</tr>
</tbody>
</table>
Subtypes of the XML Schema datatypes listed above (and which are used in XPath and XQuery) will also be converted to the Java type/s corresponding to that subtype's ancestor type.

In some cases, it might not be possible to select the correct Java method based on the supplied information. For example, consider the following case.

- The supplied argument is an `xs:untypedAtomic` value of 10 and it is intended for the method `mymethod(float)`.  
- However, there is another method in the class which takes an argument of another datatype: `mymethod(double)`.  
- Since the method names are the same and the supplied type (`xs:untypedAtomic`) could be converted correctly to either `float` or `double`, it is possible that `xs:untypedAtomic` is converted to `double` instead of `float`.  
- Consequently the method selected will not be the required method and might not produce the expected result. To work around this, you can create a user-defined method with a different name and use this method.

Types that are not covered in the list above (for example `xs:date`) will not be converted and will generate an error. However, note that in some cases, it might be possible to create the required Java type by using a Java constructor.

### 18.2.2.1.7 Datatypes: Java to XPath/XQuery

When a Java method returns a value, the datatype of the value is a string, numeric or boolean type, then it is converted to the corresponding XPath/XQuery type. For example, Java's `java.lang.Boolean` and `boolean` datatypes are converted to `xsd:boolean`.

One-dimensional arrays returned by functions are expanded to a sequence. Multi-dimensional arrays will not be converted, and should therefore be wrapped.

When a wrapped Java object or a datatype other than string, numeric or boolean is returned, you can ensure conversion to the required XPath/XQuery type by first using a Java method (e.g. `toString`) to convert the Java object to a string. In XPath/XQuery, the string can be modified to fit the lexical representation of the required type and then converted to the required type (for example, by using the `cast as expression`).

### 18.2.2.2 .NET Extension Functions

If you are working on the .NET platform on a Windows machine, you can use extension functions written in any of the .NET languages (for example, C#). A .NET extension function can be used within an XPath or XQuery expression to invoke a constructor, property, or method (static or instance) within a .NET class.

A property of a .NET class is called using the syntax `get_PropertyName()`.

This section is organized into the following sub-sections:
Form of the extension function

The extension function in the XPath/XQuery expression must have the form \texttt{prefix:fname()}. 

- The \texttt{prefix:} part is associated with a URI that identifies the .NET class being addressed.
- The \texttt{fname()} part identifies the constructor, property, or method (static or instance) within the .NET class, and supplies any argument/s, if required.
- The URI must begin with \texttt{clitype:} (which identifies the function as being a .NET extension function).
- The \texttt{prefix:fname()} form of the extension function can be used with system classes and with classes in a loaded assembly. However, if a class needs to be loaded, additional parameters containing the required information will have to be supplied.

Parameters

To load an assembly, the following parameters are used:

- \texttt{asm} The name of the assembly to be loaded.
- \texttt{ver} The version number (maximum of four integers separated by periods).
- \texttt{sn} The key token of the assembly’s strong name (16 hex digits).
- \texttt{from} A URI that gives the location of the assembly (DLL) to be loaded. If the URI is relative, it is relative to the XSLT or XQuery document. If this parameter is present, any other parameter is ignored.
- \texttt{partialname} The partial name of the assembly. It is supplied to \texttt{Assembly.LoadWith.PartialName()}, which will attempt to load the assembly. If \texttt{partialname} is present, any other parameter is ignored.
- \texttt{loc} The locale, for example, \texttt{en-US}. The default is \texttt{neutral}.

If the assembly is to be loaded from a DLL, use the \texttt{from} parameter and omit the \texttt{sn} parameter. If the assembly is to be loaded from the Global Assembly Cache (GAC), use the \texttt{sn} parameter and omit the \texttt{from} parameter.

A question mark must be inserted before the first parameter, and parameters must be separated by a semicolon. The parameter name gives its value with an equals sign (see example below).

Examples of namespace declarations

An example of a namespace declaration in XSLT that identifies the system class \texttt{System.Environment}: 

\texttt{xmlns:myns=“clitype:System.Environment”}

An example of a namespace declaration in XSLT that identifies the class to be loaded as \texttt{Trade.Forward.Scrip}:
xmlns:myns="clitype:Trade.Forward.Scrip\asm=forward;version=10.6.2.1"

An example of a namespace declaration in XQuery that identifies the system class 
MyManagedDLL.testClass:. Two cases are distinguished:

1. When the assembly is loaded from the GAC:
   declare namespace cs="clitype:MyManagedDLL.testClass?asm=MyManagedDLL;
                   ver=1.2.3.4;loc=neutral;sn=b9f091b72dcccba8";

2. When the assembly is loaded from the DLL (complete and partial references below):
   declare namespace cs="clitype:MyManagedDLL.testClass?from=file://C:/Altova
                     Projects/extFunctions/MyManagedDLL.dll;

   declare namespace cs="clitype:MyManagedDLL.testClass?from=MyManagedDLL.dll;

**XSLT example**

Here is a complete XSLT example that calls functions in system class System.Math:

```xml
<xsl:stylesheet version="2.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions">
    <xsl:output method="xml" omit-xml-declaration="yes"/>
    <xsl:template match="/"
        <math xmlns:math="clitype:System.Math"
            <sqrt><xsl:value-of select="math:Sqrt(9)"/></sqrt>
            <pi><xsl:value-of select="math:PI()"/></pi>
            <e><xsl:value-of select="math:E()"/></e>
            <pow><xsl:value-of select="math:Pow(math:PI(), math:E())"/></pow>
        </math>
    </xsl:template>
</xsl:stylesheet>
```

The namespace declaration on the element math associates the prefix math: with the URI 
clitype:System.Math. The clitype: beginning of the URI indicates that what follows identifies either a 
system class or a loaded class. The math: prefix in the XPath expressions associates the extension functions 
with the URI (and, by extension, the class) System.Math. The extension functions identify methods in the class 
System.Math and supply arguments where required.

**XQuery example**

Here is an XQuery example fragment similar to the XSLT example above:

```xml
<math xmlns:math="clitype:System.Math">
    (math:Sqrt(9))
</math>
```

As with the XSLT example above, the namespace declaration identifies the .NET class, in this case a system 
class. The XQuery expression identifies the method to be called and supplies the argument.
18.2.2.2.1 .NET: Constructors

An extension function can be used to call a .NET constructor. All constructors are called with the pseudo-function `new()`. If there is more than one constructor for a class, then the constructor that most closely matches the number of arguments supplied is selected. If no constructor is deemed to match the supplied argument/s, then a 'No constructor found' error is returned.

Constructors that return XPath/XQuery datatypes

If the result of a .NET constructor call can be implicitly converted to XPath/XQuery datatypes, then the .NET extension function will return a sequence that is an XPath/XQuery datatype.

Constructors that return .NET objects

If the result of a .NET constructor call cannot be converted to a suitable XPath/XQuery datatype, then the constructor creates a wrapped .NET object with a type that is the name of the class returning that object. For example, if a constructor for the class `System.DateTime` is called (with `System.DateTime.new()`), then an object having a type `System.DateTime` is returned.

The lexical format of the returned object may not match the lexical format of a required XPath datatype. In such cases, the returned value would need to be: (i) converted to the lexical format of the required XPath datatype; and (ii) cast to the required XPath datatype.

There are three things that can be done with a .NET object created by a constructor:

- It can be used within a variable:
  ```
  <xsl:variable name="currentdate" select="date:new(2008, 4, 29)"
  xmlns:date="clitype:System.DateTime" />
  ```

- It can be passed to an extension function (see Instance Method and Instance Fields):
  ```
  <xsl:value-of select="date:ToString(date:new(2008, 4, 29))"
  xmlns:date="clitype:System.DateTime" />
  ```

- It can be converted to a string, number, or boolean:
  ```
  <xsl:value-of select="xs:integer(date:get_Month(date:new(2008, 4, 29)))"
  xmlns:date="clitype:System.DateTime" />
  ```

18.2.2.2.2 .NET: Static Methods and Static Fields

A static method is called directly by its name and by supplying the arguments for the method. The name used in the call must exactly match a public static method in the class specified. If the method name and the number of arguments that were given in the function call matches more than one method in a class, then the types of the supplied arguments are evaluated for the best match. If a match cannot be found unambiguously, an error is reported.

Note: A field in a .NET class is considered to be a method without any argument. A property is called using the syntax `get_PropertyName()`.

Examples

An XSLT example showing a call to a method with one argument (`System.Math.Sin(arg)`):
An XSLT example showing a call to a field (considered a method with no argument)
(System.Double.MaxValue()):

An XSLT example showing a call to a property (syntax is get_PropertyName())
(System.String()):
<xsl:value-of select="string:get_Length('my string')" xmlns:string="clitype:System.String"/>

An XQuery example showing a call to a method with one argument
(System.Math.Sin(arg)):
<sin xmlns:math="clitype:System.Math">
  { math:Sin(30) }
</sin>

18.2.2.2.3  .NET: Instance Methods and Instance Fields

An instance method has a .NET object passed to it as the first argument of the method call. This .NET object typically would be created by using an extension function (for example a constructor call) or a stylesheet parameter/variable. An XSLT example of this kind would be:

```xml
<xsl:stylesheet version="2.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:fn="http://www.w3.org/2005/xpath-functions">
  <xsl:output method="xml" omit-xml-declaration="yes"/>
  <xsl:template match="/">
    <xsl:variable name="releasedate" select="date:new(2008, 4, 29)"
      xmlns:date="clitype:System.DateTime"/>
    <doc>
      <date>
        <xsl:value-of select="date:ToString(date:new(2008, 4, 29))"
          xmlns:date="clitype:System.DateTime"/>
      </date>
      <date>
        <xsl:value-of select="date:ToString($releasedate)"
          xmlns:date="clitype:System.DateTime"/>
      </date>
    </doc>
  </xsl:template>
</xsl:stylesheet>
```

In the example above, a System.DateTime constructor (new(2008, 4, 29)) is used to create a .NET object of type System.DateTime. This object is created twice, once as the value of the variable releasedate, a second time as the first and only argument of the System.DateTime.ToString() method. The instance method System.DateTime.ToString() is called twice, both times with the System.DateTime constructor (new(2008, 4, 29)).
as its first and only argument. In one of these instances, the variable `releasedate` is used to get the 
.NET object.

**Instance methods and instance fields**

The difference between an instance method and an instance field is theoretical. In an instance method, a .NET object is directly passed as an argument; in an instance field, a parameter or variable is passed instead—though the parameter or variable may itself contain a .NET object. For example, in the example above, the variable `releasedate` contains a .NET object, and it is this variable that is passed as the argument of `ToString()` in the second `date` element constructor. Therefore, the `ToString()` instance in the first `date` element is an instance method while the second is considered to be an instance field. The result produced in both instances, however, is the same.

### 18.2.2.2.4 Datatypes: XPath/XQuery to .NET

When a .NET extension function is used within an XPath/XQuery expression, the datatypes of the function's arguments are important for determining which one of multiple .NET methods having the same name is called.

In .NET, the following rules are followed:

- If there is more than one method with the same name in a class, then the methods available for selection are reduced to those that have the same number of arguments as the function call.
- The XPath/XQuery string, number, and boolean datatypes (see list below) are implicitly converted to a corresponding .NET datatype. If the supplied XPath/XQuery type can be converted to more than one .NET type (for example, `xs:integer`), then that .NET type is selected which is declared for the selected method. For example, if the .NET method being called is `fx(double)` and the supplied XPath/XQuery datatype is `xs:integer`, then `xs:integer` will be converted to .NET's `double` datatype.

The table below lists the implicit conversions of XPath/XQuery string, number, and boolean types to .NET datatypes.

<table>
<thead>
<tr>
<th>XML Schema Datatype</th>
<th>.NET Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xs:string</code></td>
<td><code>StringValue</code>, <code>string</code></td>
</tr>
<tr>
<td><code>xs:boolean</code></td>
<td><code>BooleanValue</code>, <code>bool</code></td>
</tr>
<tr>
<td><code>xs:integer</code></td>
<td><code>IntegerValue</code>, <code>decimal</code>, <code>long</code>, <code>integer</code>, <code>short</code>, <code>byte</code>, <code>double</code>, <code>float</code></td>
</tr>
<tr>
<td><code>xs:float</code></td>
<td><code>FloatValue</code>, <code>float</code>, <code>double</code></td>
</tr>
<tr>
<td><code>xs:double</code></td>
<td><code>DoubleValue</code>, <code>double</code></td>
</tr>
<tr>
<td><code>xs:decimal</code></td>
<td><code>DecimalValue</code>, <code>decimal</code>, <code>double</code>, <code>float</code></td>
</tr>
</tbody>
</table>

Subtypes of the XML Schema datatypes listed above (and which are used in XPath and XQuery) will also be converted to the .NET type/s corresponding to that subtype's ancestor type.

In some cases, it might not be possible to select the correct .NET method based on the supplied information. For example, consider the following case.
The supplied argument is an `xs:untypedAtomic` value of 10 and it is intended for the method `mymethod(float)`.

However, there is another method in the class which takes an argument of another datatype: `mymethod(double)`.

Since the method names are the same and the supplied type (`xs:untypedAtomic`) could be converted correctly to either `float` or `double`, it is possible that `xs:untypedAtomic` is converted to `double` instead of `float`.

Consequently the method selected will not be the required method and might not produce the expected result. To work around this, you can create a user-defined method with a different name and use this method.

Types that are not covered in the list above (for example `xs:date`) will not be converted and will generate an error.

### 18.2.2.2.5 Datatypes: .NET to XPath/XQuery

When a .NET method returns a value and the datatype of the value is a string, numeric or boolean type, then it is converted to the corresponding XPath/XQuery type. For example, .NET's `decimal` datatype is converted to `xsd:decimal`.

When a .NET object or a datatype other than string, numeric or boolean is returned, you can ensure conversion to the required XPath/XQuery type by first using a .NET method (for example `System.DateTime.ToString()`) to convert the .NET object to a string. In XPath/XQuery, the string can be modified to fit the lexical representation of the required type and then converted to the required type (for example, by using the `cast as` expression).

### 18.2.2.3 MSXSL Scripts for XSLT

The `<msxsl:script>` element contains user-defined functions and variables that can be called from within XPath expressions in the XSLT stylesheet. The `<msxsl:script>` is a top-level element, that is, it must be a child element of `<xsl:stylesheet>` or `<xsl:transform>`.

The `<msxsl:script>` element must be in the namespace `urn:schemas-microsoft-com:xslt` (see example below).

**Scripting language and namespace**

The scripting language used within the block is specified in the `<msxsl:script>` element's `language` attribute and the namespace to be used for function calls from XPath expressions is identified with the `implements-prefix` attribute (see below).

```xml
<msxsl:script language="scripting-language" implements-prefix="user-namespace-prefix">
    function-1 or variable-1
    ...
    function-n or variable-n
</msxsl:script>
```
The `<msxsl:script>` element interacts with the Windows Scripting Runtime, so only languages that are installed on your machine may be used within the `<msxsl:script>` element. The .NET Framework 2.0 platform or higher must be installed for MSXSL scripts to be used. Consequently, the .NET scripting languages can be used within the `<msxsl:script>` element.

The `language` attribute accepts the same values as the `language` attribute on the HTML `<script>` element. If the `language` attribute is not specified, then Microsoft JScript is assumed as the default.

The `implements-prefix` attribute takes a value that is a prefix of a declared in-scope namespace. This namespace typically will be a user namespace that has been reserved for a function library. All functions and variables defined within the `<msxsl:script>` element will be in the namespace identified by the prefix specified in the `implements-prefix` attribute. When a function is called from within an XPath expression, the fully qualified function name must be in the same namespace as the function definition.

Example

Here is an example of a complete XSLT stylesheet that uses a function defined within a `<msxsl:script>` element.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="2.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:fn="http://www.w3.org/2005/xpath-functions"
    xmlns:msxsl="urn:schemas-microsoft-com:xslt"
    xmlns:user="http://mycompany.com/mynamespace">

    <msxsl:script language="VBScript" implements-prefix="user">
        <![CDATA[
        ' Input: A currency value: the wholesale price
        ' Returns: The retail price: the input value plus 20% margin,
        ' rounded to the nearest cent
        dim a as integer  = 13
        Function AddMargin(WholesalePrice) as integer
            AddMargin = WholesalePrice * 1.2 + a
        End Function
        ]]>
    </msxsl:script>

    <xsl:template match="/">
        <html>
            <body>
                <p>
                    <b>Total Retail Price =</b> 
                    $<xsl:value-of select="user:AddMargin(50)"/>
                </p>
                <br/>
                <b>Total Wholesale Price =</b> 
                $<xsl:value-of select="50"/>
            </body>
        </html>
    </xsl:template>
</xsl:stylesheet>
```
Datatypes
The values of parameters passed into and out of the script block are limited to XPath datatypes. This restriction does not apply to data passed among functions and variables within the script block.

Assemblies
An assembly can be imported into the script by using the `msxsl:assembly` element. The assembly is identified via a name or a URI. The assembly is imported when the stylesheet is compiled. Here is a simple representation of how the `msxsl:assembly` element is to be used.

```xml
<msxsl:script>
    <msxsl:assembly name="myAssembly.assemblyName" />
    <msxsl:assembly href="pathToAssembly" />

    ...
</msxsl:script>
```

The assembly name can be a full name, such as:

"system.Math, Version=3.1.4500.1 Culture=neutral PublicKeyToken=a46b3f648229c514"

or a short name, such as "myAssembly.Draw".

Namespaces
Namespaces can be declared with the `msxsl:using` element. This enables assembly classes to be written in the script without their namespaces, thus saving you some tedious typing. Here is how the `msxsl:using` element is used so as to declare namespaces.

```xml
<msxsl:script>
    <msxsl:using namespace="myAssemblyNS.NamespaceName" />

    ...
</msxsl:script>
```

The value of the `namespace` attribute is the name of the namespace.
18.3 Datatypes in DB-Generated XML Schemas

When an XML Schema is generated from a database (DB), the datatypes specific to that DB are converted to XML Schema datatypes. The mappings of DB datatypes to XML Schema datatypes for commonly used DBs are given in this Appendix. Select from the list below.

- ADO
- MS Access
- MS SQL Server
- MySQL
- ODBC
- Oracle
- Sybase

18.3.1 ADO

When an XML Schema is generated from an ADO database (DB), the ADO DB datatypes are converted to XML Schema datatypes as listed in the table below.

<table>
<thead>
<tr>
<th>ADO Datatype</th>
<th>XML Schema Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>adGUID</td>
<td>xs:ID</td>
</tr>
<tr>
<td>adChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adWChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adVarChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adWVarChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adVarWChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adLongVarChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adWLongVarChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adVarWChar</td>
<td>xs:string</td>
</tr>
<tr>
<td>adBoolean</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>adSingle</td>
<td>xs:float</td>
</tr>
<tr>
<td>adDouble</td>
<td>xs:double</td>
</tr>
<tr>
<td>adNumeric</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>adCurrency</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>adDBTimeStamp</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>adDate</td>
<td>xs:date</td>
</tr>
<tr>
<td>adBinary</td>
<td>xs:base64Binary</td>
</tr>
<tr>
<td>adVarBinary</td>
<td>xs:base64Binary</td>
</tr>
</tbody>
</table>
### 18.3.2 MS Access

When an XML Schema is generated from an MS Access database (DB), the MS Access DB datatypes are converted to XML Schema datatypes as listed in the table below.

<table>
<thead>
<tr>
<th>MS Access Datatype</th>
<th>XML Schema Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>GUID</td>
<td>xs:ID</td>
</tr>
<tr>
<td>char</td>
<td>xs:string</td>
</tr>
<tr>
<td>varchar</td>
<td>xs:string</td>
</tr>
<tr>
<td>memo</td>
<td>xs:string</td>
</tr>
<tr>
<td>bit</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>Number(single)</td>
<td>xs:float</td>
</tr>
<tr>
<td>Number(double)</td>
<td>xs:double</td>
</tr>
<tr>
<td>Decimal</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>Currency</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>Date/Time</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>Number(Long Integer)</td>
<td>xs:integer</td>
</tr>
<tr>
<td>Number(Integer)</td>
<td>xs:short</td>
</tr>
<tr>
<td>Number(Byte)</td>
<td>xs:byte</td>
</tr>
<tr>
<td>OLE Object</td>
<td>xs:base64Binary</td>
</tr>
</tbody>
</table>
18.3.3 MS SQL Server

When an XML Schema is generated from an MS SQL Server database (DB), the MS SQL Server DB datatypes are converted to XML Schema datatypes as listed in the table below.

<table>
<thead>
<tr>
<th>MS SQL Server Datatype</th>
<th>XML Schema Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>uniqueidentifier</td>
<td>xs:ID</td>
</tr>
<tr>
<td>char</td>
<td>xs:string</td>
</tr>
<tr>
<td>nchar</td>
<td>xs:string</td>
</tr>
<tr>
<td>varchar</td>
<td>xs:string</td>
</tr>
<tr>
<td>nvarchar</td>
<td>xs:string</td>
</tr>
<tr>
<td>text</td>
<td>xs:string</td>
</tr>
<tr>
<td>ntext</td>
<td>xs:string</td>
</tr>
<tr>
<td>sysname</td>
<td>xs:string</td>
</tr>
<tr>
<td>bit</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>real</td>
<td>xs:float</td>
</tr>
<tr>
<td>float</td>
<td>xs:double</td>
</tr>
<tr>
<td>decimal</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>money</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>smallmoney</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>datetime</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>smalldatetime</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>binary</td>
<td>xs:base64Binary</td>
</tr>
<tr>
<td>varbinary</td>
<td>xs:base64Binary</td>
</tr>
<tr>
<td>image</td>
<td>xs:base64Binary</td>
</tr>
<tr>
<td>integer</td>
<td>xs:integer</td>
</tr>
<tr>
<td>smallint</td>
<td>xs:short</td>
</tr>
<tr>
<td>bigint</td>
<td>xs:long</td>
</tr>
<tr>
<td>tinyint</td>
<td>xs:byte</td>
</tr>
</tbody>
</table>

18.3.4 MySQL

When an XML Schema is generated from a MySQL database (DB), the MySQL DB datatypes are converted to XML Schema datatypes as listed in the table below.
### 18.3.5 ODBC

When an XML Schema is generated from an ODBC database (DB), the ODBC DB datatypes are converted to XML Schema datatypes as listed in the table below.

<table>
<thead>
<tr>
<th>ODBC Datatype</th>
<th>XML Schema Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL_GUID</td>
<td>xs:ID</td>
</tr>
<tr>
<td>SQL_CHAR</td>
<td>xs:string</td>
</tr>
<tr>
<td>SQL_VARCHAR</td>
<td>xs:string</td>
</tr>
<tr>
<td>SQL_LONGVARCHAR</td>
<td>xs:string</td>
</tr>
<tr>
<td>SQL_BIT</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>SQL_REAL</td>
<td>xs:float</td>
</tr>
</tbody>
</table>

### Datatypes in DB-Generated XML Schemas

<table>
<thead>
<tr>
<th>MySQL Datatype</th>
<th>XML Schema Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>xs:string</td>
</tr>
<tr>
<td>varchar</td>

</tr>
</tbody>
</table>

18.3.6 Oracle

When an XML Schema is generated from an Oracle database (DB), the Oracle DB datatypes are converted to XML Schema datatypes as listed in the table below.

<table>
<thead>
<tr>
<th>Oracle Datatype</th>
<th>XML Schema Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWID</td>
<td><code>xs:ID</code></td>
</tr>
<tr>
<td>CHAR</td>
<td><code>xs:string</code></td>
</tr>
<tr>
<td>NCHAR</td>
<td><code>xs:string</code></td>
</tr>
<tr>
<td>VARCHAR2</td>
<td><code>xs:string</code></td>
</tr>
<tr>
<td>NVARCHAR2</td>
<td><code>xs:string</code></td>
</tr>
<tr>
<td>CLOB</td>
<td><code>xs:string</code></td>
</tr>
<tr>
<td>NCLOB</td>
<td><code>xs:string</code></td>
</tr>
<tr>
<td>NUMBER (with check constraint applied)*</td>
<td><code>xs:boolean</code></td>
</tr>
<tr>
<td>NUMBER</td>
<td><code>xs:decimal</code></td>
</tr>
<tr>
<td>FLOAT</td>
<td><code>xs:double</code></td>
</tr>
<tr>
<td>DATE</td>
<td><code>xs:dateTime</code></td>
</tr>
<tr>
<td>INTERVAL YEAR TO MONTH</td>
<td><code>xs:gYearMonth</code></td>
</tr>
<tr>
<td>BLOB</td>
<td><code>xs:base64Binary</code></td>
</tr>
</tbody>
</table>

* If a check constraint is applied to a column of datatype NUMBER, and the check constraint checks for
the values 0 or 1, then the NUMBER datatype for this column will be converted to an XML Schema
datatype of xs:boolean. This mechanism is useful for generating an xs:boolean datatype in the
generated XML Schema.

18.3.7 Sybase

When an XML Schema is generated from a Sybase database (DB), the Sybase DB datatypes are converted to
XML Schema datatypes as listed in the table below.

<table>
<thead>
<tr>
<th>Sybase Datatype</th>
<th>XML Schema Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>xs:string</td>
</tr>
<tr>
<td>nchar</td>
<td>xs:string</td>
</tr>
<tr>
<td>varchar</td>
<td>xs:string</td>
</tr>
<tr>
<td>nvarchar</td>
<td>xs:string</td>
</tr>
<tr>
<td>text</td>
<td>xs:string</td>
</tr>
<tr>
<td>sysname-varchar(30)</td>
<td>xs:string</td>
</tr>
<tr>
<td>bit</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>real</td>
<td>xs:float</td>
</tr>
<tr>
<td>float</td>
<td>xs:float</td>
</tr>
<tr>
<td>double</td>
<td>xs:double</td>
</tr>
<tr>
<td>decimal</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>money</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>smallmoney</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>datetime</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>smalldatetime</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>timestamp</td>
<td>xs:dateTime</td>
</tr>
<tr>
<td>binary&lt;=255</td>
<td>xs:base64Binary</td>
</tr>
<tr>
<td>varbinary&lt;=255</td>
<td>xs:base64Binary</td>
</tr>
<tr>
<td>image</td>
<td>xs:base64Binary</td>
</tr>
<tr>
<td>integer</td>
<td>xs:integer</td>
</tr>
<tr>
<td>smallint</td>
<td>xs:short</td>
</tr>
<tr>
<td>tinyint</td>
<td>xs:byte</td>
</tr>
</tbody>
</table>
18.4  Technical Data

This section contains information on some technical aspects of your software. This information is organized into the following sections:

- OS and Memory Requirements
- Altova Engines
- Unicode Support
- Internet Usage

18.4.1   OS and Memory Requirements

Operating System
Altova software applications are available for the following platforms:

- Windows 7 SP1 with Platform Update, Windows 8, Windows 10, Windows 11
- Windows Server 2008 R2 SP1 with Platform Update or newer

Memory
Since the software is written in C++ it does not require the overhead of a Java Runtime Environment and typically requires less memory than comparable Java-based applications. However, each document is loaded fully into memory so as to parse it completely and to improve viewing and editing speed. As a result, the memory requirement increases with the size of the document.

Memory requirements are also influenced by the unlimited Undo history. When repeatedly cutting and pasting large selections in large documents, available memory can rapidly be depleted.

18.4.2   Altova Engines

XML Validator
When opening an XML document, the application uses its built-in XML validator to check for well-formedness, to validate the document against a schema (if specified), and to build trees and infosets. The XML validator is also used to provide intelligent editing help while you edit documents and to dynamically display any validation error that may occur.

The built-in XML validator implements the Final Recommendation of the W3C's XML Schema 1.0 and 1.1 specifications. New developments recommended by the W3C's XML Schema Working Group are continuously being incorporated in the XML validator, so that Altova products give you a state-of-the-art development environment.

XSLT and XQuery Engines
Altova products use the Altova XSLT 1.0, 2.0, and 3.0 Engines and the Altova XQuery 1.0 and 3.1 Engines. If one of these engines is included in the product, then documentation about implementation-specific behavior for each engine is given in the appendices of the documentation.
Note: Altova MapForce generates code using the XSLT 1.0, 2.0 and XQuery 1.0 engines.

18.4.3 Unicode Support

Altova's XML products provide full Unicode support. To edit an XML document, you will also need a font that supports the Unicode characters being used by that document.

Please note that most fonts only contain a very specific subset of the entire Unicode range and are therefore typically targeted at the corresponding writing system. If some text appears garbled, the reason could be that the font you have selected does not contain the required glyphs. So it is useful to have a font that covers the entire Unicode range, especially when editing XML documents in different languages or writing systems. A typical Unicode font found on Windows PCs is Arial Unicode MS.

In the /Examples folder of your application folder you will find an XHTML file called UnicodeUTF-8.html that contains the following sentence in a number of different languages and writing systems:

- When the world wants to talk, it speaks Unicode
- Wenn die Welt miteinander spricht, spricht sie Unicode
- 世界的に話すなら、Unicodeです

Opening this XHTML file will give you a quick impression of Unicode's possibilities and also indicate what writing systems are supported by the fonts available on your PC.

18.4.4 Internet Usage

Altova applications will initiate Internet connections on your behalf in the following situations:

- If you click the "Request evaluation key-code" in the Registration dialog (Help | Software Activation), the three fields in the registration dialog box are transferred to our web server by means of a regular http (port 80) connection and the free evaluation key-code is sent back to the customer via regular SMTP e-mail.
- In some Altova products, you can open a file over the Internet (File | Open | Switch to URL). In this case, the document is retrieved using one of the following protocol methods and connections: HTTP (normally port 80), FTP (normally port 20/21), HTTPS (normally port 443). You could also run an HTTP server on port 8080. (In the URL dialog, specify the port after the server name and a colon.)
- If you open an XML document that refers to an XML Schema or DTD and the document is specified through a URL, the referenced schema document is also retrieved through a HTTP connection (port 80) or another protocol specified in the URL (see Point 2 above). A schema document will also be retrieved when an XML file is validated. Note that validation might happen automatically upon opening a document if you have instructed the application to do this (in the File tab of the Options dialog (Tools | Options)).
- In Altova applications using WSDL and SOAP, web service connections are defined by the WSDL documents.
- If you are using the Send by Mail command (File | Send by Mail) in XMLSpy, the current selection or file is sent by means of any MAPI-compliant mail program installed on the user's PC.
- As part of Software Activation and LiveUpdate as further described in the Altova Software License Agreement.
18.5 License Information

This section contains information about:

- the distribution of this software product
- software activation and license metering
- the license agreement governing the use of this product

Please read this information carefully. It is binding upon you since you agreed to these terms when you installed this software product.

To view the terms of any Altova license, go to the Altova Legal Information page at the Altova website.

18.5.1 Electronic Software Distribution

This product is available through electronic software distribution, a distribution method that provides the following unique benefits:

- You can evaluate the software free-of-charge for 30 days before making a purchasing decision. \(\text{Note: Altova MobileTogether Designer is licensed free of charge.}\)
- Once you decide to buy the software, you can place your order online at the Altova website and get a fully licensed product within minutes.
- When you place an online order, you always get the latest version of our software.
- The product package includes an onscreen help system that can be accessed from within the application interface. The latest version of the user manual is available at www.altova.com in (i) HTML format for online browsing, and (ii) PDF format for download (and to print if you prefer to have the documentation on paper).

30-day evaluation period

After downloading this product, you can evaluate it for a period of up to 30 days free of charge. About 20 days into the evaluation period, the software will start to remind you that it has not yet been licensed. The reminder message will be displayed once each time you start the application. If you would like to continue using the program after the 30-day evaluation period, you must purchase a product license, which is delivered in the form of a license file containing a key code. Unlock the product by uploading the license file in the Software Activation dialog of your product.

You can purchase product licenses at https://shop.altova.com/.

Helping Others within Your Organization to Evaluate the Software

If you wish to distribute the evaluation version within your company network, or if you plan to use it on a PC that is not connected to the Internet, you may distribute only the installer file, provided that this file is not modified in any way. Any person who accesses the software installer that you have provided must request their own 30-day evaluation license key code and after expiration of their evaluation period, must also purchase a license in order to be able to continue using the product.
18.5.2 Software Activation and License Metering

As part of Altova’s Software Activation, the software may use your internal network and Internet connection for the purpose of transmitting license-related data at the time of installation, registration, use, or update to an Altova-operated license server and validating the authenticity of the license-related data in order to protect Altova against unlicensed or illegal use of the software and to improve customer service. Activation is based on the exchange of license related data such as operating system, IP address, date/time, software version, and computer name, along with other information between your computer and an Altova license server.

Your Altova product has a built-in license metering module that further helps you avoid any unintentional violation of the End User License Agreement. Your product is licensed either as a single-user or multi-user installation, and the license-metering module makes sure that no more than the licensed number of users use the application concurrently.

This license-metering technology uses your local area network (LAN) to communicate between instances of the application running on different computers.

Single license
When the application starts up, as part of the license metering process, the software sends a short broadcast datagram to find any other instance of the product running on another computer in the same network segment. If it doesn’t get any response, it will open a port for listening to other instances of the application.

Multi-user license
If more than one instance of the application is used within the same LAN, these instances will briefly communicate with each other on startup. These instances exchange key-codes in order to help you to better determine that the number of concurrent licenses purchased is not accidentally violated. This is the same kind of license metering technology that is common in the Unix world and with a number of database development tools. It allows Altova customers to purchase reasonably-priced concurrent-use multi-user licenses.

We have also designed the applications so that they send few and small network packets so as to not put a burden on your network. The TCP/IP ports (2799) used by your Altova product are officially registered with the IANA (see the IANA Service Name Registry for details) and our license-metering module is tested and proven technology.

If you are using a firewall, you may notice communications on port 2799 between the computers that are running Altova products. You are, of course, free to block such traffic between different groups in your organization, as long as you can ensure by other means, that your license agreement is not violated.

Note about certificates
Your Altova application contacts the Altova licensing server (link.altova.com) via HTTPS. For this communication, Altova uses a registered SSL certificate. If this certificate is replaced (for example, by your IT department or an external agency), then your Altova application will warn you about the connection being insecure. You could use the replacement certificate to start your Altova application, but you would be doing this at your own risk. If you see a Non-secure connection warning message, check the origin of the certificate and consult your IT team (who would be able to decide whether the interception and replacement of the Altova certificate should continue or not).
If your organization needs to use its own certificate (for example, to monitor communication to and from client machines), then we recommend that you install Altova's free license management software, Altova LicenseServer, on your network. Under this setup, client machines can continue to use your organization's certificates, while Altova LicenseServer can be allowed to use the Altova certificate for communication with Altova.

### 18.5.3 Altova End-User License Agreement

- The Altova End-User License Agreement is available here: [https://www.altova.com/legal/eula](https://www.altova.com/legal/eula)
- Altova's Privacy Policy is available here: [https://www.altova.com/privacy](https://www.altova.com/privacy)
